 - How the field's value is posted (i.e., updated on the database). A field's value is posted when an order is completed.

Fastpath:

Refer to [Extract Column References From Miscellaneous Fields](#) for more information about column references.

- If a field's value resides in a **Column** (as opposed to a characteristic value), you must also define whether the question / field is dependent on the order referencing an account or premise. You do this by populating **Question Dependency** with one of the following values:
 - Select **Must Have Account** if this question / field should only appear if the order references an account (new OR existing).
 - Select **Must Have Premise** if this question / field should only appear if the order references a premise (new OR existing).
 - Select **No Dependency** if this question / field should always appear.

Fastpath:

Refer to [Determine Account / Premise Dependencies For Column References](#) for more information.

- **Default Column Value** / **Default Char Value** controls whether the order taker is supplied with a default value when an order is created. Note well: for **Optional** and **Only Applicable on Package** fields, you can specify a different default value on each package.

Campaign - Algorithms

This page defines plug-in algorithms that are executed for orders associated with this campaign. Open this page using **Menu > Sales & Marketing > Campaign > Search** and navigate to the **Algorithms** page.

Description of Page

Campaign is the user-defined code that uniquely identifies the campaign. The campaign's description appears adjacent.

The grid contains **Algorithms** that control campaign-oriented functions. You must define the following for each plug-in algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each **System Event**. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

You can define algorithms for the following **System Events**:

| System Event | Optional / Required | Description |
|----------------------|---------------------|--|
| Campaign Eligibility | Required | <p>A campaign's eligibility algorithms control two things:</p> <ul style="list-style-type: none"> - Whether the campaign appears in the Applicable Campaigns Zone. This content zone suggests possible campaigns for the current customer displayed on control central. You might want to use this zone if you have different campaigns that are offered to different types of customers. Refer to Real-time Marketing of Additional Services to a Customer for an example of how this content zone can be used to "up sell" additional services. - Whether the campaign appears on an order's eligibility tree. Campaigns that appear in this tree are alternate campaigns that may be used on an order. Refer to Real-time Marketing of Services to a Prospect for an example of how an order's eligibility tree can contain alternate campaigns for an order. <p>Refer to The Big Picture Of Campaign Eligibility for information about these algorithms.</p> |
| Order Completion | Optional | <p>When an order is completed for this campaign, algorithms plugged into this spot are called to do additional work (e.g., create a customer contact). You need only specify this type of algorithm if you require additional work to be performed when an order is completed for this campaign.</p> |

Campaign - Package

A package controls the various types of service agreements that will be created if the customer selects the package. This page summarizes all packages that may be selected on orders associated with this campaign. Open this page using **Menu > Sales & Marketing > Campaign > Search** and navigate to the **Package** page.

Description of Page

Campaign is the user-defined code that uniquely identifies the campaign. The campaign's description appears adjacent.

The grid contains an entry for every package associated with this campaign. To view or change a package, press the adjacent go to button (which will transfer you to [Package - Main](#)). To add a new package, use the **Campaign** context menu to transfer to [Package - Main](#) in add mode.

Maintaining Packages

After a user enters basic information about a customer on an [order](#), they are shown the various packages that may be offered to the customer. A package controls the various types of service agreements that will be created if the customer selects the package.

If the customer elects to take a package, the system sets up / updates [the "V"](#) (along with all of the ancillary things that happen when service is initiated, e.g., field activities are created).

The topics in this section describe the package transaction.

Fastpath:

Refer to [The Big Picture of Campaigns, Packages and Orders](#) for general information about packages. Refer to [The Big Picture Of Package Eligibility Rules](#) for a discussion of how to control which packages can be used for different types of customers. Refer to [Designing Campaigns and Packages](#) for guidelines describing how to design your packages.

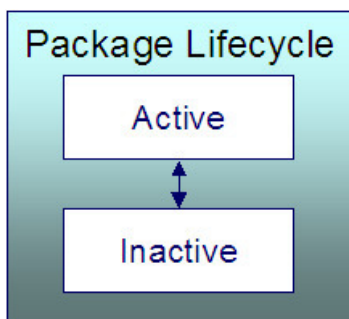

Note:

An order can be completed without selecting a package. It is possible to use the order transaction to simply create / update persons and accounts. Refer to [Campaigns Without Packages](#) for more information.

Lifecycle of a Package

The following diagram illustrates the lifecycle of a package.

Active An Active package may be selected on an order.

Inactive By Inactivating a package, you are preventing it from being selected on future orders.

Package - Main

This page is used to define basic information about a package.

Fastpath:

Refer to [The Big Picture of Campaigns, Packages and Orders](#) and [Designing Campaigns and Packages](#) for more information.

Open this page using **Menu > Sales & Marketing > Package > Search**.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

Use **Campaign** to define the campaign to which this package belongs.

Use **Description** and **Long Description** to describe the package.

Status defines the state of the package. Refer to [Lifecycle of a Package](#) for information about the valid values and the state transition rules.

The tree at the bottom of the page summarizes the information that appears on the remaining tabs. You can click on a hyperlink to transfer you to the appropriate tab with the relevant information displayed.

Package - SAs To Create

This information on this page controls the type of service agreement(s) / service point(s) that are created if this package is selected on an order.

Fastpath:

Refer to [The Big Picture of Campaigns, Packages and Orders](#) and [Designing Campaigns and Packages](#) for more information.

Open this page using **Sales & Marketing, Package** and navigate to the **SAs To Create** tab.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

Warning:

This following information is not intuitive; we strongly recommend that you follow the guidelines under [Designing Campaigns and Packages](#) before attempting to enter this information.

The **SAs To Create** scroll contains one row for every service agreement that will be created if this package is selected on an order. The following fields are used:

- **CIS Division** and **SA Type** define the *type of service agreement* to be created.
- **Start Option** controls how the system will populate the new service agreement with default values. Refer to [start options](#) for more information.
- **SP Type** defines the type of service point that will be created / reused. Refer to [Designing SP Types](#) for more information.
- **Start Method Algorithm** controls how the system creates the new service agreement and service point. Refer to [Determine The Method Used To Create Service Agreements](#) for more information.
- **Create Proposal SA** controls if the new service agreement is a real or a proposal SA. This switch only appears if the quotation Contract Management module is not **turned off**. Refer to [Proposal Service Agreements Must Exist](#) for more information.

Package - Questions & Misc Fields

It is possible to design a campaign so that the user is prompted for additional information when a package is selected on an order. This page is used to define how the package overrides the questions and miscellaneous fields defined on the [campaign](#).

Fastpath:

Refer to [The Big Picture of Campaigns, Packages and Orders](#) and [Designing Campaigns and Packages](#) for more information.

Open this page using **Menu > Sales & Marketing > Package > Search** and navigate to the **Questions & Misc Fields** page.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

Campaign contains a concatenation of basic information about the campaign.

Warning:

The following information is not intuitive; we strongly recommend that you follow the guidelines under [Designing Campaigns and Packages](#) before attempting to enter this information.

The grid contains one row for every [Questions & Misc Field](#) defined on the **Campaign**. You need only modify this information if this package behaves differently than the campaign (e.g., a field is required on the package, but optional on the campaign). To override a field on this package, turn on the **Override** switch and change the appropriate fields. There are several restrictions in respect of what can be overridden as described below:

- If a question / miscellaneous field is Required on the campaign, no fields may be overridden on the package.
- If a question / miscellaneous field is Optional on the campaign, you may override all field values. However, if the package has been used on a Completed order, you may not change its **Applicability** to be Required.
- If a question / miscellaneous field is designated as only applicable on package on the campaign, you should designate its applicability as Required, Optional or Not Used On This Package. If the field is either Required or Optional on this package, you may also override the other field values. Please note that if the package has been used on a Completed order, you may not change its **Applicability** to be Required.

Fastpath:

Please refer to the Description of Page that appears under [Campaign - Questions & Misc Fields](#) for a description of the fields on the page.

Package - Eligibility

This page is used to define the conditions under which a package can be selected on an order.

Fastpath:

Refer to [The Big Picture Of Package Eligibility](#) and [Determine Package Eligibility Rules](#) for more information.

Open this page using **Menu > Sales & Marketing > Package > Search** and navigate to the **Eligibility** page.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

Warning:

The following information is not intuitive; we strongly recommend that you follow the guidelines under [The Big Picture Of Package Eligibility](#) and [Determine Package Eligibility Rules](#) before attempting to enter this information.

The **Eligibility Criteria Group** scroll contains one entry for each group of eligibility criteria. The following fields may be defined for each group:

- Use **Sequence** to control the relative order in which the group is executed when the system determines if the package can be selected on an order (smaller numbers are executed before larger numbers).
- Use **Description** and **Long Description** to describe the criteria group.
- Use **If Group is True** to define what should happen if the eligibility criteria (defined in the following grid) return a value of True.
 - Choose Eligible if this package can be selected on the order.
 - Choose Ineligible if this package cannot be selected on the order.
 - Choose Check Next Group if the next criteria group should be checked.
- Use **If Group is False** to define what should happen if the eligibility criteria (defined in the following grid) return a value of False.
 - Choose Eligible if this package can be selected on the order.
 - Choose Ineligible if this package cannot be selected on the order.
 - Choose Check Next Group if the next criteria group should be checked.

The grid that follows contains the package's eligibility criteria. Think of each row as an "if statement" that can result in the related eligibility group being True or False. For example, you might have a row that indicates the customer is eligible for the package if their customer class is residential. The following bullets provide a brief description of each field on an eligibility criterion. Please refer to [Defining Logical Criteria](#) for several examples of how this information can be used.

- Use **Sequence** to control the order in which the criteria are checked.
- Use **Criteria Field** to define the field to compare:
 - Choose Field if you want to compare a response to a question / miscellaneous field to a given value. Push the adjacent search button to select the field.
 - Choose Algorithm if you want to compare anything other than a response to a question / miscellaneous field. Push the adjacent search button to select the algorithm that is responsible for retrieving the comparison value.
- Use **Criteria Comparison** to define the method of comparison:
 - Choose Algorithm if you want an algorithm to perform the comparison and return a value of True, False or Insufficient Data.
 - Choose any other option if you want to compare the **Criteria Field Type** using a logical operator. The following options are available:
- Use **>**, **<**, **=**, **>=**, **<=**, **<>** (not equal) to compare the **Criteria Field Type** using standard logical operators. Enter the comparison value in the adjacent field.
- Use **In** to compare the **Criteria Field Type** to a list of values. Each value is separated by a comma. For example, if a field value must equal 1, 3 or 9, you would enter a comparison value of 1,3,9.
- Use **Between** to compare the **Criteria Field Type** to a range of values. For example, if a field value must be between 1 and 9, you would enter a comparison value of 1,9. Note, the comparison is inclusive of the low and high values.
 - The next three fields control whether the related logical criteria cause the eligibility group to be considered True or False:
 - Use **If True** to control what happens if the related logical criterion returns a value of True. You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false, then the package will be judged Ineligible or Eligible based on the values defined above in **If Group is False** and **If Group is True**.
 - Use **If False** to control what happens if the related logical criterion returns a value of False. You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is

false, then the package will be judged Ineligible or Eligible based on the values defined above in **If Group is False** and **If Group is True**.

- Use **If Insufficient Data** to control what happens if the related logical criterion returns a value of "Insufficient Data". You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false, then the package will be judged Ineligible or Eligible based on the values defined above in **If Group is False** and **If Group is True**.

Package - Instructions

This page is used to define special instructions that should be presented to the user when they select this package. This information appears on the [Order - Package Confirmation](#) page.

Fastpath:

Refer to [Determine If Additional Instructions Are Needed](#) for more information.

Open this page using **Menu > Sales & Marketing > Package > Search** and navigate to the **Instructions** page.

Description of Page

Package contains a concatenation of basic information about the package. **Package ID** is the system-assigned unique identifier of the package. These values only appear after the order is added to the database.

The grid contains a row for each instruction to be presented to the user when they select a package. The following fields are used:

- Use **Sort Sequence** to control the relative order of the instruction.
- Use **Display Icon** to control the icon that prefixes the instruction. Refer to [Display Icons](#) for more information.
- Use **Description** to define the text of the instruction.

The Big Picture of Program Management

The program management functionality satisfies many diverse requirements. For example, you can use this functionality to:

- Market your products and/or services to customers and measure the success of your efforts.
- Encourage customers to enroll in various sales and marketing initiatives. For example, you can use program management to organize a campaign to encourage customers to participate in a conservation program, or to sign up for special contract options.
- Set up marketing surveys and record your customer's responses.
- Assign representatives to accounts.
- And more...

The topics in this section provide more information about the program management functionality.

The Big Picture of Initiatives, Leads, and Representatives

Three objects are at the heart of the program management functionality: **Initiatives**, **Leads**, and **Representatives**.

- An **initiative** defines a structured campaign that outlines the efforts to encourage customers to participate in a program targeted at a specific market segment.
- A **lead** is an instance of an initiative for targeted customers.
- There are two types of Representatives:
 - A **Sales Representative** is a user or group of users who can be assigned to follow up or manage leads. This representative is also responsible to sell or encourage the customer to participate in a program.
 - A **Third Party Representative** is a third party (typically external) who can receive assignments to perform specific tasks within a lead; such as, undertaking a visit to a property to perform an inspection, and installation work)

The topics in this section provide background information about these objects.

The Big Picture of Initiatives

An initiative defines a structured campaign designed to encourage customers to participate in a program. An initiative can:

- Target a market segment by specifying criteria that must be satisfied before leads are generated for customers.
- Ensure that customers are still eligible to participate in a program at sign up or enrollment time.
- Define a structured marketing effort for the events or actions that should take place during the life of a lead to encourage a customer to participate in the program.
- Define whether the lead is related to other objects (such as, the premise) in addition to the account.
- Contain sub-initiatives. Together, an initiative and its subsidiary initiatives form an initiative hierarchy. This supports reporting purposes and the analysis of the success of different market segments and marketing efforts.

Refer to [Maintaining Initiatives](#) on page 725 for more information.

About Initiative Hierarchies

Initiatives form an initiative hierarchy when one initiative is configured as a sub-initiative to a parent initiative. An initiative hierarchy can be used when a program is targeted at several market segments, or when different market segments each require a unique marketing effort to be executed. Initiative hierarchies can be up to five levels deep.

The following is a general example of a multi-level initiative hierarchy:

- Level 1 could be a “strategy” initiative.
- Level 2 could contain multiple campaigns. Each campaign can have a different way of marketing the strategy.
- Level 3 could define multiple marketing efforts. Each effort can have a different method for marketing the campaign.
- Level 4 could contain market segments that are the targets of a marketing effort.

Note: The terms used above are just for the example. Your implementation would define the actual terms used for the levels in an initiative hierarchy.

A **parent initiative** may be set up for reporting purposes, in which case you could choose to configure the initiative so that no leads are generated for it. For example, a “strategy” may not have eligibility criteria or lead event type profile defined against it. It may simply have sub-initiatives to define segments, and those segments could be the initiatives for which leads are generated. Reporting is able to be performed at the multiple levels in order to summarize the effectiveness of the sub-initiatives.

The Components of an Initiative

The topics in this section provide information about the components of an initiative.

About Initiative Eligibility Criteria

Each initiative can define its target market by specifying the criteria that must be satisfied before a customer is invited to participate in a program. It can also confirm that the customer is still eligible to participate in a program at sign up or enrollment time. An initiative may have zero, one, or many eligibility criteria. Each customer is subjected to these criteria to determine whether they will have a lead generated for them for the initiative and/or whether they are still eligible to sign up or enroll into a program.

Designing these criteria can be easy or time-consuming; it all depends on the complexity of your business rules. The base product provides a number of initiative eligibility criteria types. Most of them perform comparisons based on a specific field; for example, one of the criteria types checks whether an account has submitted a rebate claim for a specific conservation program. Some types of eligibility criteria could simply check whether or not a specific condition is true. For instance, a base-supplied eligibility criteria business object checks that there is no active credit and collection process for the account.

Other types of eligibility criteria perform comparisons with scalar values (such as, a number of days, number of kwh) or with derived values (such as, attributes of an account). The base product provides a Freeform Criteria business object that can be used for these purposes. This business object provides flexibility in that the value to supply in the comparison field is driven by a Derive Value Algorithm Type. A number of these algorithm types are delivered with this business object. Your implementations can add to these algorithm types as needed.

Your implementation can decide to use specific criteria business objects (base-supplied and/or implementation-specific), extend the base-supplied Freeform Criteria business object, or a mixture of both. Refer to [Designing Initiative Eligibility Criteria](#) for more details.

To set up an eligibility criterion, you must define the following:

- When the eligibility criterion should be executed - also called criteria execution point
- The field to be compared
- The comparison method

For the **criteria execution point**, the options include:

- Prior to a lead being generated for a customer
- Prior to the customer being signed up or enrolled into a program
- Both of the above

For the **field to be compared**, you can execute an algorithm to:

- Retrieve a field value or values from someplace else in the system (such as, the customer class or types of services associated with the customer)
- Derive a value based on some data from someplace else in the system (such as, the number of days since the last lead was created for the customer)

For the **comparison method**, you select the operator to perform the comparison on the field to be compared. The result from the algorithm will be TRUE, FALSE, or INSUFFICIENT DATA. Each of these results should specify the next action. The valid actions include:

- Indicate that the customer is eligible
- Indicate that the customer is not eligible
- Check the next condition
- Issue an error (this option is only available for Insufficient Data)

Refer to [Defining Eligibility Criteria for an Initiative](#) on page 726 for more information about setting up eligibility criteria on an initiative.

About Related Object Criteria

Each initiative can define its target market by specifying the criteria that must be satisfied before a customer is invited to participate in a program (see [About Initiative Eligibility Criteria](#) on page 712 for more information). An initiative may also be targeted at a specific entity (or related object) for that customer; for example, assume a customer has two properties in two different states - one in State A and one in State B. The customer may only be invited to participate, or be eligible, for a program for their specific property located in State A. In this situation, each eligible customer may then be subjected to Related Object Criteria following the execution of Initiative Eligibility Criteria to determine which of their properties are eligible to participate in a program (meaning, have one lead generated just for the account if one of their properties meets the criteria or a lead generated for each of the customer's eligible properties).

An initiative defines the related object(s) to associate with leads via the Object Nomination algorithm on the initiative business object. The lead generation process executes the object nomination algorithm after executing initiative eligibility criteria. The base-supplied Initiative parent business object (C1-Initiative) is configured with an object nomination algorithm that retrieves the premises that are associated with the account's active and pending start service agreement's service points. The algorithm applies the related object criteria (configured on the initiative) to each premise and if the premise is deemed eligible, it is returned as a related object for the lead.

Designing related object criteria can be easy or time-consuming. It all depends on the complexity of your business rules. The base product provides examples of related object criteria that looks for one or more premises to associate with a lead. One example checks for premises with a specific service point type. Another looks for a premise using its geographic value. For additional ways to find premises to link to a lead, implementations can either add specific related object criteria business objects (similar to the base samples) or extend the base-supplied Freeform Premise Criteria business object. The Freeform Premise Criteria business object provides flexibility in that the value to supply in the comparison field is driven by a Derive Value Algorithm Type. A number of these algorithm types are delivered

with this business object. Your implementation can add to these algorithm types as needed. Refer to [Designing Related Object Criteria](#) for more details.

When you set up a related object criterion, you must define two things:

- The field to be compared.
- The comparison method.

For the **field to be compared**, you can execute an algorithm to retrieve a field value or values from someplace else in the system; for example, retrieve a premise's service point types for which the customer has service.

For the **comparison method**, select the operator to perform the comparison on the field to be compared. The result from the comparison will be TRUE, FALSE, or INSUFFICIENT DATA. Each of these results should specify the next action. The valid actions include:

- Indicate that the related object is eligible
- Indicate that the related object is not eligible
- Check the next condition
- Issue an error

Refer to [Defining Related Object Criteria for an Initiative](#) on page 727 for more information.

Examples of Initiative Criteria

The following is an example of how to set up initiative criteria.

Initiative: Smart Rate Program For Residential Customers

The program targets summertime pricing for residential customers. Customers are required to reduce energy use between 2 PM and 7 PM for no more than 15 summer days, which are referred to as smart days. A higher rate is charged during this time period. A discounted rate is applied for all other times during the season.

Initiative Eligibility Criteria

To be eligible for this initiative, the account must be a residential account with an average daily usage that is more than 10 kWh, not currently on a smart rate program, and is on either the ERES1 or ERES2 rate schedule. The account must also not have any active credit and collection process.

| Sequence | Description | Criteria Field Algorithm | Operator | Comparison Value | If True | If False | If Insufficient Data | Criteria Execution Point |
|----------|------------------------------|---|----------|--|----------------------|--------------|----------------------|---------------------------------------|
| 10 | Residential customers | Retrieve Customer Class (Define an algorithm instance for base algorithm type C1-ICGETACEL, Retrieve account attribute) | = | R | Check next condition | Not Eligible | Not Eligible | Both (lead generation and enrollment) |
| 20 | Average daily usage > 10 kWh | Retrieve average daily kWh usage (Define an algorithm for base algorithm type C1-ICGETAVSQ, Retrieve average service quantity) | > | 10 | Check next condition | Not Eligible | Not Eligible | Both (lead generation and enrollment) |
| 30 | Not on a smart rate program | Retrieve all contract options (Use base algorithm C1-ICGETCOPT) | = | 295076574650 (Contract option for smart day events) | Check next condition | Not Eligible | Not Eligible | Both (lead generation and enrollment) |

| Sequence | Description | Criteria Field Algorithm | Operator | Comparison Value | If True | If False | If Insufficient Data | Criteria Execution Point |
|----------|---------------------------------|--|----------|------------------|----------------------|--------------|----------------------|---------------------------------------|
| 40 | Account is current | Check if Account Is Current (Use base algorithm C1-ICCHKACCU) | = | true | Check next condition | Not Eligible | Not Eligible | Both (lead generation and enrollment) |
| 50 | Active service on eligible rate | Retrieve all active rates (Use base algorithm C1-GETACTVRT) | IN | ERES1, ERES2 | Eligible | Not Eligible | Not Eligible | Both (lead generation and enrollment) |

Related Object Criteria

If the account is eligible, the premise(s) associated with the account's active and pending start service agreement's service points of type E-RES will be linked to the lead as related object(s).

| Sequence | Description | Criteria Field Algorithm | Operator | Comparison Value | If True | If False | If Insufficient Data |
|----------|---|--|----------|------------------|----------|--------------|----------------------|
| 10 | Premises with E-RES (electric residential) service points | Retrieve Premise SP Types (Base algorithm C1-ICPRMSPTY) | = | E-RES | Eligible | Not Eligible | Not Eligible |

About the Lead Event Type Profile

Each initiative can define a structured marketing effort for the events or actions that should take place during the life of a lead to encourage a customer to participate in a program. Each event or action is defined by a Lead Event Type. For example, one event could be that a letter or an email is sent to a customer. The collection and sequencing of lead event types defined on an initiative is referred to as the Lead Event Type Profile.

Refer to [Creating Initiatives](#) on page 725 and [Maintaining Initiatives](#) on page 725 for more information on setting up and maintaining the Lead Event Type Profile on an initiative.

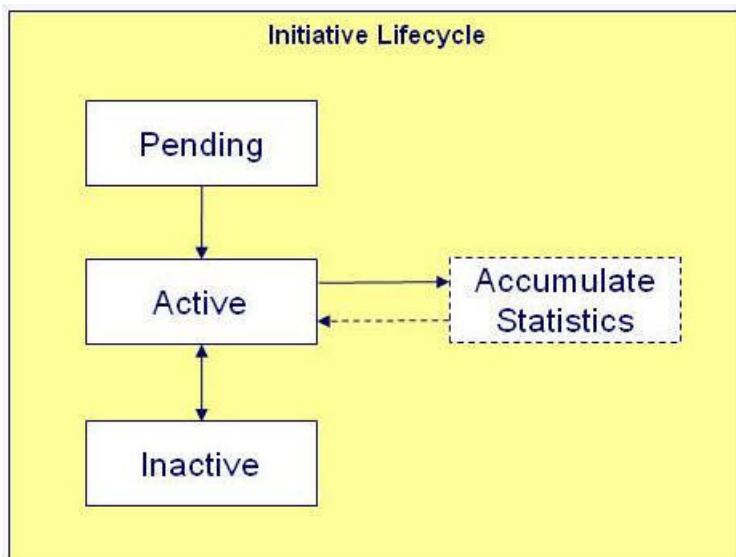

About the Initiative Log

Every initiative has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When an initiative is created.
- When an initiative's status changes (e.g. transitions to the active, accumulate statistics, inactive states).
- When lead related background processes are submitted for execution.
- When users want to manually add log entries as desired.

The Lifecycle of an Initiative

The following diagram shows the possible lifecycle of an Initiative:

Pending state: An initiative starts out in a pending state.

Active state: An initiative is transitioned manually by a user to the active state. Leads can only be generated for an initiative in an active state.

Accumulate Statistics state: A user or the system may transition an active initiative to a periodically transitioning accumulate statistics state. During this state, statistics for the initiative are accumulated prior to returning back to the active state.

Inactive state: An initiative may be transitioned manually by a user to the inactive state when they want to deactivate the initiative either temporarily or permanently. A user can manually place the initiative back to the active state from the inactive state.

Refer to [Maintaining Initiatives](#) on page 725 for more information.

Initiative Information Can Be Overridden

“Initiative info” is the concatenated string of information that summarizes an initiative throughout the system. The base-package logic constructs this string by concatenating the following information:

- Initiative description
- Status of the initiative
- Start date and end date (if available) of the initiative

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on the Initiative's maintenance object.

The Big Picture of Leads

A lead is an instance of an initiative for a targeted customer. A lead may contain events or actions that are there to encourage a customer to participate in a program.

Refer to [Maintaining Leads](#) on page 731 for more information about working with Leads.

How Leads Are Created

Leads are created as follows:

- The system can generate a lead, or leads, for each customer that satisfies the initiative eligibility criteria and/or related object criteria that is defined on an initiative.
- Users can manually create a lead at their discretion.

Refer to section [Creating Leads from an Initiative](#) on page 727 and [Manually Creating a Lead](#) on page 731 for more information.

The Components of a Lead

A lead has two components: A **Lead Event** and a **Lead Log**.

Lead Event

A lead has one or more lead events. These events are the actions designed to encourage a customer to participate in a program. For example, one event could be that a letter or an email is sent to a customer.

Refer to [The Big Picture of Lead Events](#) on page 720 for more information.

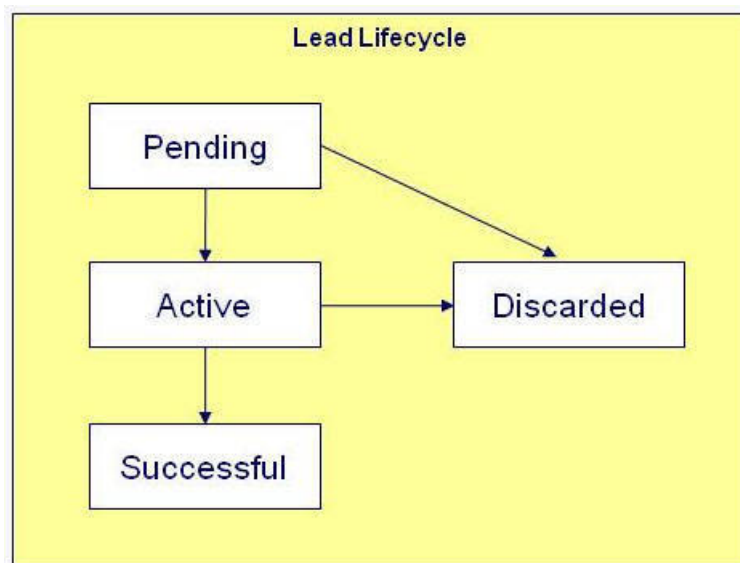

Lead Log

Every lead has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a lead is created
- When a lead's status changes (e.g. transitions to the active, successful or discarded state)
- When a lead event executes
- Users can manually add log entries as desired.

The Lifecycle of a Lead

The following diagram shows the possible lifecycle of a Lead:

Pending state: Leads can be created in either the **Pending** or **Active** state. By generating them in the **Pending** state, you can verify the targeted customers before actively marketing the initiative.

Active state: Leads can be created in either the **Pending** or **Active** state. When a lead is created or transitioned to the **Active** state, lead events are created to encourage the customers to participate in the initiative. For example, one event could be that a letter or an email is sent to a customer. The lead events and the sequence in which they occur are defined on the initiative's lead event type profile. The lead remains in the active state while it is being actively marketed to the customer.

Successful state: The system infers that a lead has succeeded by the creation of other data in the system, at which time the lead transitions to the **Successful** state. For example:

- If an active lead for a customer is related to a rebate claim conservation program, the lead is determined to be successful when that rebate claim is filed for the customer.
- If an active lead for a customer is related to a contract option, the lead is determined to be successful when the customer's service agreement is linked to that contract option.
- If an active lead for a customer is related to a campaign, the lead is determined to be successful if a completed order exists for the customer for the campaign.

- If an active lead is assigned to a third party representative (to perform one or more tasks), the lead is determined to be successful if the Notify Third Party lead event is completed.

Discarded state: An unsuccessful lead transitions to the **Discarded** state after a certain amount of time has passed, as defined on the initiative. If the initiative does not specify a time period, the lead remains in the active state until a user manually discards it.

Refer to [Maintaining Leads](#) on page 731 for more information.

Advanced Analysis of Leads

Leads can be sent to an external system (such as Oracle DataRaker) for advanced analysis prior to activating the lead.

The base product provides Advanced Analysis System Lead (C1–AdvancedAnalysisLead) business object for this purpose. Its lifecycle includes steps to send the lead to the external system and activate/discard the lead based on the result of analysis..

Additional configuration is needed in Program Management master configuration to enable external analysis/validation. See master configuration embedded help for more details.

The Lifecycle of a Lead with Advanced Analysis

The following describes the states of a Lead that is sent to an external system for advanced analysis prior to activation..

(Refer to the C1–AdvancedAnalysisLead business object to view the lifecycle diagram.)

Pending state: Leads can be created in either the **Pending** or **Ready for Extract** state. By generating them in the **Pending** state, you can verify the targeted customers before actively marketing the initiative.

Ready for Extract state: At this state, leads are ready to be sent to the external system for analysis. A monitor batch process is defined on this state, to ensure that leads in this state are transitioned only when the batch process runs.

Waiting for Analysis state: When a lead is transitioned to this state, an outbound message containing lead information is sent to the external system.

Error state: The lead is transitioned to this state if the system is unable to send the outbound message. Retry logic on this state will attempt to resend the lead to the external system. Leads in this state can also be **Discarded** if needed.

Active state: When a lead completes external analysis, the External Validation and External Activation Priority flags on the lead are updated. An inbound web service sends back the lead and transitions the lead into the **Active** state. An enter algorithm evaluates the External Activation Priority flag. If the lead is marked as being a priority for activation (based on settings in master configuration), the lead stays in the **Active** state. Otherwise, the lead is **Discarded**.

When a lead is in the **Active** state, lead events are created to encourage the customers to participate in the initiative. For example, one event could be that a letter or an email is sent to a customer. The lead events and the sequence in which they occur are defined on the initiative's lead event type profile. The lead remains in the active state while it is being actively marketed to the customer.

Successful state: The system infers that a lead has succeeded by the creation of other data in the system, at which time the lead transitions to the **Successful** state. For example:

- If an active lead for a customer is related to a rebate claim conservation program, the lead is determined to be successful when that rebate claim is filed for the customer.
- If an active lead for a customer is related to a contract option, the lead is determined to be successful when the customer's service agreement is linked to that contract option.
- If an active lead for a customer is related to a campaign, the lead is determined to be successful if a completed order exists for the customer for the campaign.
- If an active lead is assigned to a third party representative (to perform one or more tasks), the lead is determined to be successful if the Notify Third Party lead event is completed.

An enter algorithm on this state sends an outbound message, to notify the external system about lead success.

Discarded state: Leads that are evaluated as non-priority for activation are transitioned to this state. Unsuccessful leads also transition to this state after a certain amount of time has passed, as defined on the initiative. If the initiative does not specify a time period, unsuccessful leads remain in the **Active** state until a user manually discards it.

Refer to [Maintaining Leads](#) on page 731 for more information.

Lead Information Can Be Overridden

“Lead info” is the concatenated string of information that summarizes a lead throughout the system. The base-package logic constructs this string by concatenating the following information:

- Initiative description
- Status of the lead
- Creation date/time of the lead.

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on the Lead's maintenance object.

Leads Are Highlighted As Alerts

If you plug-in the appropriate alert algorithm (C1-OPENLDALR) on the Installation record, alert(s) will be shown for open leads associated with the person, account and premise in context. A separate alert is shown for each unique Lead that is in a non-final state. Each alert message shows the Lead's info string.

How and When Are Leads Activated

Leads are activated as follows:

- The system can generate a lead for each customer that satisfies the initiative eligibility criteria and/or related object criteria that is defined on an initiative. The leads can be created in either a Pending or Active state. These leads can then be activated by a background process when required by the user.
- Users can manually activate a lead at their discretion.

Refer to section [Creating Leads from an Initiative](#) on page 727 and [Maintaining a Lead](#) on page 732 for more information.

How are Leads Completed

The system infers that a lead has succeeded by the creation of other data in the system, at which time the lead transitions to the **Successful** state. For example:

- If an active lead is related to a rebate claim conservation program, the lead is determined to be successful when that rebate claim is filed for the customer.
- If an active lead is related to a contract option, the lead is determined to be successful when the customer's service agreement is linked to that contract option.
- If an active lead for is related to a campaign, the lead is determined to be successful if a completed order exists for the customer for the campaign.
- If an active lead is assigned to a third party representative, to perform one or more tasks, the lead is determined to be successful if the Notify Third Party lead event is completed.

Users can also manually transition a lead to the Successful state at their discretion. Refer to [Maintaining a Lead](#) on page 732 for more information about working with Leads.

How Are Leads Discarded

When leads are sent to an external system for analysis prior to lead activation, a possible result of the analysis is that the lead is flagged as non-priority for activation. When this occurs, the lead is discarded.

Unsuccessful leads transition to the Discarded state after a certain amount of time has passed, as defined on the initiative. The initiative's lead event type profile can include an event that automatically discards a lead after a designated number of days. If the initiative does not specify this auto-discard event, the lead remains in the active state until a user manually discards it.

Some types of lead events can also trigger a lead to be discarded when specific conditions are met; for example, a lead that is assigned to a third party representative can be automatically discarded when the third party representative finds

that the account is ineligible for the initiative. Refer to [The Lifecycle of a Third Party Representative](#) on page 724 for more details.

In addition, automatic lead discards capture a lead discard reason. Lead event types that support auto-discard define their respective default lead discard reasons. Refer to [Setting Up Lead Event Types](#) and [Maintaining a Lead](#) on page 732 for more information

Sign Up Options Can Be Overridden

The lead's Sign Up special action button performs the following:

- Displays a Sign Up UI map (if one exists) to capture additional inputs for sign up processing.
- Executes a Sign Up service script to process the sign up.
- Displays a confirmation map if the sign up is successful.

The Sign Up UI map and Sign Up service script can be overridden via options on the initiative's business object. Refer to [Overriding Initiative Sign Up Options](#) for more details.

The Big Picture of Lead Events

A lead has one or more lead events. These events are the actions designed to encourage a customer to participate in a program. For example, one event could be that a letter or an email is sent to a customer.

You define the number and type of events to be initially inherited by a lead by configuring the Lead Event Type Profile on an initiative. Refer to [About the Lead Event Type Profile](#) on page 715 for more information.

A lead event can include one or more steps. The lead event type defines a list of step types, if applicable.

The topics in this section provide additional information about lead events.

How are Lead Events Created

If a lead is created in a Pending state, there are no lead events associated with the lead. It is only when leads are created in or transitioned to the Active state, that lead events are created for the lead. The initial number of events and when the events shall occur are inherited from the lead's initiative.

Some types of events can also get created as a result of special actions on the lead. For instance, when a lead process requires a third party representative to perform one or more tasks after signup, the Sign Up action on the Lead portal automatically creates the Notify Third Party lead event.

The Components of a Lead Event

A lead event can have one or more steps. The lead event's business object defines whether or not steps are applicable to that type of event. The corresponding lead event type defines the valid step types. For an example, refer to the Third Party Lead Event (C1-ThirdPartyLeadEvt) and Send Notification to Third Party Lead Event Type (C1-LETypeNotifyThirdParty) business objects provided in base.

Lead Event Log

Every lead event has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a lead event is created.
- When a lead event's status changes (e.g. transitions to the completed or cancelled state).
- Details of the content sent (if applicable).
- Users can manually add log entries as desired.

The Lifecycle of a Lead Event

The following diagram shows the possible lifecycle of a Lead Event business object:

Pending state: Lead events are initially created in the Pending state. A lead event can take a number of paths after it is created; it all depends on how you've configured the system.

Complete state: A lead event contains a date when it should be activated. This is referred to as its trigger date. On this date, the system invokes the algorithm associated with the lead event to execute the event or action. A user may complete a pending event at their discretion.

Cancelled state: A pending event will be cancelled automatically by the system when a lead is canceled. A user may cancel a pending event at their discretion.

Refer to [Maintaining Lead Events](#) on page 733 for more information.

The Lifecycle of a Third Party Lead Event

The following diagram shows the possible lifecycle of a Third Party Lead Event business object:

Pending state: Third party lead events are initially created in the Pending state. A third party lead event can take a number of paths after it is created; it all depends on how you've configured the system.

In Progress state: A third party lead event contains a date when it should be activated. This is referred to as its trigger date. On this date, the system invokes the algorithm associated with the lead event to execute the event or action. The lead event is set to In Progress and the lead event is sent to the third party representative.

Complete state: A third party lead event may be completed based on updates received from the third party. In most cases, the third party lead event is completed when all the event steps are complete. In addition, a user may complete an In Progress event at their discretion.

Cancelled state: A Pending or In Progress third party lead event will be cancelled automatically by the system when the lead is canceled. A user may cancel a Pending or In Progress event at their discretion.

Refer to [Maintaining Third Party Lead Events](#) on page 733 for more information.

Lead Event Information Can Be Overridden

“Lead Event info” is the concatenated string of information that summarizes a lead event throughout the system. The base-package logic constructs this string by concatenating the following information:

- Lead event type description
- Status of the lead event
- Trigger date of the lead event

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on the Lead Event's maintenance object.

Third Party Lead Event Step Information Can Be Overridden

The **Initiative Leads** zone on the **Third Party Representative** portal shows an event step information string for **Last Complete Step** and **Next Pending Step**. A base-package service script constructs this string by concatenating the following information:

- Step type description
- Intended Work Date/Time
- Completion Date/Time

You can override this by specifying an **Override Step Information Script** on the Program Management Master Configuration.

See [Program Management Master Configuration](#) for more details.

How and When Lead Events Are Activated

A lead event contains the date it should be activated; this is referred to as its trigger date. On this date, the Lead Event Periodic Monitor Process (a background process (C1-LDEVT)) invokes the algorithm associated with a lead event's event type. The algorithm, in turn, will decide on the state in which to leave the lead event.

If a user can't wait for the Lead Event Periodic Monitor Process real-time, they can click a button on Lead Event – Main to activate / trigger an event online in real-time. Refer to [Maintaining Lead Events](#) on page 733 for more information.

You control how a lead event's trigger date is populated by configuring the Lead Event Type profile in an initiative. You indicate the number of days the lead event should be activated after the creation of the lead. Refer to [Maintaining Initiatives](#) on page 725 for more information.

Activating Events Should Add a Log Entry

As described previously, a lead and lead event have a log holding a history of meaningful events in their lives. Most algorithms associated with a lead event's event type will add an entry to both the lead and lead event logs.

These log entries are more than just an audit trail as they also reference the objects that are created during execution. For example, if an algorithm creates a customer contact, the ID of the customer contact will be referenced on the log (and end-users will be able to drill down on the log entry to see the customer contact).

How Lead Events Are Cancelled

A pending lead event will be cancelled automatically by the system when the lead is canceled.

A user may cancel a pending lead event at their discretion. Refer to [Maintaining Lead Events](#) on page 733 for more information.

A third party representative can also initiate the cancellation of a lead event. Refer to [The Lifecycle of a Third Party Lead Event](#) on page 721 for more details.

The Big Picture of Sales Representatives

A sales representative is a group or individual who can be assigned to follow up and manage leads.

Individual sales representatives can be members of one or more groups, and they can be an internal user or an external party.

Groups can be used to control which sales representatives are allocated to the leads for an initiative. For example, you can set up a group whose sales representatives are responsible for industrial customers. Initiatives that target industrial customers can then be configured so that this group is specified as the only one whose sales representatives can be assigned the initiative's leads.

Because many reports will aggregate information for all sales representatives in a group, you may choose to set up a sales representative group just for reporting purposes.

The topics in this section provide additional information about Sales Representatives.

The Lifecycle of a Sales Representative

The following diagram shows the possible lifecycle of a Sales Representative:

Active state: A Sales Representative starts out in an active state.

Inactive state: A Sales Representative may be transitioned manually by a user to the inactive state when they want to deactivate the Sales Representative either temporarily or permanently. A user can manually place the Sales Representative back to the active state from the inactive state.

Refer to [Maintaining Sales Representatives](#) on page 734 for more information.

Sales Representative Log

Every Sales Representative has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a Sales Representative is created

- When a Sales Representative's status changes (e.g. transitions to the inactive state)
- Users can manually add log entries (you might want to think of these as "diary" entries) as desired.

The Big Picture of Third Party Representatives

A third party representative is similar to a sales representative except that they are typically not internal employees and they have a different set of responsibilities.

Lead-related tasks may be outsourced to a third party representative who is better equipped to perform the work. These tasks may include pre-installation visits, energy audits, equipment installation, and equipment recycling. An initiative's lead event type profile defines whether or not lead-related work is sent to a third party representative.

Work is typically sent to a third party representative when a customer signs up for an initiative. The base product provides an online Sign Up action on active leads. This action creates a Third Party Lead Event that triggers the third party notification.

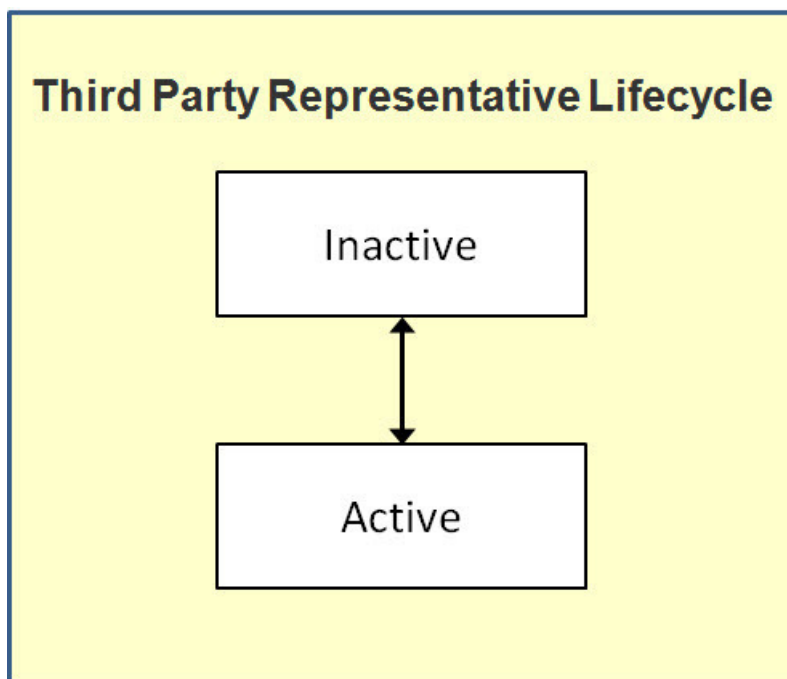

The third party representative is also responsible for providing updates to the system about the assigned leads. These updates can include event status updates, updates to important date/time information (e.g., completion date/time) and comments. This feedback enables users of the system to monitor the progress of leads and provide any necessary customer service.

Refer to the [The Lifecycle of a Third Party Lead Event](#) on page 721 for more details on third party lead events.

The topics in this section provide additional information about Third Party Representatives.

The Lifecycle of a Third Party Representative

The following diagram shows the possible lifecycle of a Third Party Representative:

Active state: A Third Party Representative starts out in an active state.

Inactive state: A Third Party Representative may be transitioned manually by a user to the inactive state when they want to deactivate the Third Party Representative either temporarily or permanently. A user can manually place the Third Party Representative back to the active state from the inactive state.

Refer to [Maintaining Third Party Representatives](#) for more information.

Third Party Representative Log

Every Third Party Representative has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When a Third Party Representative is created.
- When a Third Party Representative's status changes (e.g. transitions to the inactive state).
- Users can manually add log entries as desired.

Maintaining Initiatives

An initiative defines a structured campaign that outlines the efforts to encourage customers to participate in a program targeted at a specific market segment.

Refer to [The Big Picture of Initiatives](#) for more information about initiatives.

Initiative Portal

You use the Initiative portal to maintain initiatives.

The **Main** page contains the following zones:

- **Initiative:** Displays the basic information about the initiative.
- **Initiative Eligibility Criteria Overview:** Displays initiative eligibility criteria associated with the initiative.
- **Related Object Criteria Overview:** Displays criteria for finding one or more related objects (such as, a premise) to link to a lead.
- **Initiative Hierarchy:** Displays the entire hierarchy of initiatives that the selected initiative is a part of.
- **Initiative Leads:** Displays the leads that are associated with the initiative.
- **Lead Processing:** Allows you to submit the lead generation or lead disposition batch process.

The **Statistics** page contains the following

- **Lead Summary by Representative:** Displays the summary of leads for the initiative hierarchy, grouped by representatives.
- **Initiative Leads:** Displays the leads that are associated with the initiative.
- **Lead Outcome Graph:** Displays the number of leads linked to the initiative hierarchy that entered the final state within the last 24 months.
- **Lead Statistics:** Displays statistics for the leads associated with the initiative.
- **Lead Monthly Statistics:** Displays statistics for the leads associated with the initiative on a monthly basis.
- **Unassigned Leads:** Displays leads that are not yet assigned to a sales representative and are not in a final state. (**Note:** Leads can be assigned to a sales representative in bulk.)

How To Perform Common Initiative Functions

The topics in this section describe how to perform common initiative functions from the Initiative portal.

Creating Initiatives

Use this procedure to create a new Initiative.

1. Select **Menu > Sales & Marketing > Initiative > Add**.
2. Select the business object that will define the initiative and click **OK**.
3. Enter the initiative's name, (short) description, detailed description, start date, and end date.
4. Specify if the initiative is a master or a subsidiary initiative.
 - a) If the initiative is a **Subsidiary Initiative**, search for and select the initiative that is the parent to this initiative.
5. Specify whether the master initiative will participate in demand-side analytics processing through Contract Option Participation Analysis.
6. Specify whether or not leads can be generated for the initiative.
 - a) If leads can be generated, complete the options regarding communication channel and related object creation.
7. In the Third Party Notification section, specify the Lead Event Type to use to notify a third party. This lead event type is used when creating a third party notification lead event, if applicable, when a customer signs up or enrolls into a program.

8. In the Lead Reassignment Notification section, indicate how the system should respond if a lead is reassigned to another sales representative.
9. In the Statistics Notification section, specify how often, in hours, the statistics for the initiative should be updated. A background process accumulates the statistics for an initiative when enough time has elapsed since the statistics were last updated. A user may also manually initiate the process to update the statistics for an initiative.
10. If this initiative will have leads, add lead event types in the Lead Event Type Profile section to define the events or actions that will occur during the lifetime of the lead to encourage the customer to participate in the initiative. To add lead event types in the Lead Event Type Profile section:
 - a) Assign an **Event Sequence** to each list entry.
 - b) Search for and select a **Lead Event Type** to indicate the type of lead event to generate for each list entry (for example send customer an email or create a customer contact).
 - c) Specify the number of **Days After Lead Creation** that the related lead event will be triggered.
11. Click **Save**.

Maintaining an Initiative

The topics in this section describe procedures for maintaining an initiative:

Allowable Record Actions on an Initiative

Use this procedure to maintain an initiative using standard record actions.

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. Click the appropriate record action button:
 - **Edit** – Click the **Edit** button to edit the main attributes of an initiative. When you click **Save**, the system updates the record.
 - **Duplicate** – Click the **Duplicate** button to create a duplicate of the initiative being displayed. Before the new object is added to the database, a window appears asking you to enter the unique identifier of the new object. When you click **OK**, the system creates the record by copying the original record.
 - **Activate** – Click the **Activate** button to transition a pending or inactive initiative to the active state.
 - **Deactivate** – Click to **Deactivate** button to transition an active initiative to an inactive state.
 - **Refresh Statistics** - Click the **Refresh Statistics** button to manually initiate the accumulation of the statistics for the initiative.
 - **Delete** – Click the **Delete** button and click **OK** to delete the initiative from the database. Before you delete an initiative, the system verifies that the initiative is not referenced anywhere in the system. If it is, you cannot delete it. For example, if you attempt to delete an initiative, the system ensures the initiative has not been referenced on a lead, etc.

Defining Eligibility Criteria for an Initiative

Use this procedure to define eligibility criteria for an initiative. The following steps apply to each criterion.

Prerequisites: You must create an initiative that can have leads before you can define eligibility criteria for the initiative.

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative that you want to maintain. *(The selected initiative opens in the Initiative portal.)*

5. To define eligibility criteria for the initiative, click the **Add** link in the Initiative Eligibility Criteria Overview zone title bar. *(This zone is displayed for initiatives that can have leads.)*
6. Select the business object that will define the initiative criteria and click **OK**.
The base package provides a number of initiative eligibility criteria business objects. Each business object defines its valid comparison algorithm(s), operator(s), and value(s). Refer to the maintenance maps of these business objects for details. For more information about eligibility criteria types, refer to [About Initiative Eligibility Criteria](#) on page 712.
7. Enter a sequence number, description, detailed description, and criteria execution point for the criterion.
8. Complete the Criteria Comparison section. Each business object defines the valid selections for: **Algorithm, Comparison Operator** and **Comparison Value**.
Refer to the embedded help on the maintenance map for more details on these fields.
9. Complete the Comparison Results section. Specify the action for each possible comparison outcome - meaning, **If True, If False, and If Insufficient Data**.
Refer to the embedded help on the maintenance map for more details on these fields.
10. Click **Save**.

Repeat steps 5 to 10 to add additional criterion for the initiative.

Defining Related Object Criteria for an Initiative

Use this procedure to define related object criteria for an initiative. The following steps apply to each criterion.

Prerequisites: You must create an initiative that can have leads before you can define related object criteria for the initiative.

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. To define related object criteria for the initiative, click the **Add** link in the Related Object Criteria Overview zone title bar. *(This zone is displayed for initiatives that can have leads.)*
6. Select the business object that will define the initiative criteria and click **OK**.
The base package provides a number of related object criteria types that attempt to link an account's premise(s) to the lead. Each initiative criteria business object defines its valid comparison algorithm(s), operators and value(s). Refer to the maintenance maps of these business objects for details. For more information on eligibility criteria types, refer to [About Related Object Criteria](#) on page 713.
7. Enter a sequence number, description, and detailed description for the criterion.
8. Complete the Criteria Comparison section. Each business object defines the valid selections for: **Algorithm, Comparison Operator, and Comparison Value**.
Refer to the embedded help on the maintenance map for more details on these fields.
9. Complete the Comparison Results section. Specify the action to take for each possible outcome of the comparison - meaning, **If True, If False, and If Insufficient Data**.
Refer to the embedded help on the maintenance map for more details on these fields.
10. Click **Save**.

Repeat steps 5 to 10 to add additional criterion for the initiative.

Viewing Initiative Hierarchy

The Initiative Hierarchy zone on the Initiatives portal displays the hierarchy the selected initiative is a part of. By clicking on any initiative in the hierarchy, you will be navigated to the selected initiative.

Creating Leads from an Initiative

The topics in this section describe how to create leads from an Initiative.

Bulk Creation of Leads

Use this procedure to create leads in bulk.

1. Select **Menu > Sales & Marketing > Initiative > Search**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain.
The selected initiative opens in the Initiative portal.
5. To create leads for the initiative, click **Lead Generation** on the Lead Generation and Disposition zone. This zone is displayed for initiatives in the active state, can have leads and allows a batch job to be submitted for the creation of leads.
 - Select the **Lead Status** to leave the created leads in. Valid values are Pending or Active. Creating leads in a pending state allows a user to confirm the lead population prior to activating these leads
 - Specify the **Number of Leads to Generate**. This may be used to create a sample set of leads to test the initiative's eligibility criteria.
 - Specify the **Email Address**. You may optionally specify an email address if you want to be informed when the batch job completes
6. Click **OK**.

Uploading Leads

Note: This functionality is to be used on small volume uploads.

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. To upload Leads for an initiative, click the **Lead Upload** link in the Initiative Leads zone title bar. This displays the Lead Upload page, which you can use to upload a CSV file containing account IDs for which leads will be generated.
6. Click **Submit**.

Managing Leads from an Initiative

The procedures in this section describe how to manage leads from an initiative.

Viewing Initiative Leads

The Initiative Leads zone is displayed on both the Main page and the Statistics page.

By default, the Initiative Leads zone is populated with all leads for the initiative (or initiative hierarchy group) for all sales representatives.

On the Statistics page, you can limit the set of leads using the Lead Summary by Representative zone. See [Viewing Lead Summary by Representative](#) on page 729 for details.

The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Last Complete Event**. You can navigate to the lead event by clicking on the last complete event for a lead.
- For open leads, the **Next Pending Event**. You can navigate to the lead event by clicking on the next pending event for a lead.
- The **Sales Representative** shows the representative assigned to the lead.

Activating, Deleting, and Discarding Leads for an Initiative in Bulk

Use the following procedure to activate, delete or discard leads for an initiative.

1. Select **Menu > Sales & Marketing > Initiative > Search**
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain.
The selected initiative opens in the Initiative portal.
5. Scroll, as needed, to the Lead Processing zone.
6. To activate, delete or discard leads for the initiative, click **Lead Disposition**. This allows a batch job to be submitted for the activation, deletion or discarding of leads.
 - Select the **Pending Lead Disposition** to indicate the action to take on pending leads. The possible actions are: Activate (pending leads), Delete (in case of erroneous generation), Ignore.
 - Select the **Active Lead Disposition** to indicate to action to take on active leads. The possible actions Ignore and Discard.
 - Select the **Discard Reason** to be used for any active leads that get discarded. The values are maintained on the Status Reason control table.
 - Specify the **Email Address**. You may optionally specify an email address if you want to be informed when the batch job completes
7. Click **OK**.

Viewing Initiative Statistics

The Statistics page displays statistical information about the leads of the current initiative in context. It shows the following:

- Lead counts by sales representative and status
- List of leads
- Graph of completed and discarded leads over a period of time
- Graph of leads by status
- Graph of active leads per sales representative
- Graph of open, completed and discarded leads over a period of time
- Graph of the top discard reasons over a period of time

The following sections describe these zones. You can also refer to each zone's embedded help for more details.

Viewing Lead Summary by Representative

The Lead Summary by Representative zone displays a summary of leads for the initiative (or initiative hierarchy group) by individual representative. If the Initiative is configured not have a sales representative, the zone will group those leads under 'Leads without Representative'.

To limit the summary of leads by sales representative:

1. Select **Menu > Sales & Marketing > Initiative > Search**.
2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain.
The selected initiative opens in the Initiative portal.
5. Go to the **Statistics** page and scroll, as necessary, to view the Lead Summary by Representative zone.
6. Specify **Start Date** and/or **End Date** to limit the summary to leads created within this date range. If specified, start date must be on or before the current date and end date must be on or after the start date. If left blank, end date is defaulted to the current date.

7. If **Include Inactive Leads** is set to No, leads for the initiative (or initiative hierarchy group) regardless of status are included.

The following is displayed in the result set:

- A summary line for the individual sales representative shows the total Lead Count.
- A breakdown is included beneath each sales representative summary line that shows a subtotal Lead Count by lead state.
- An icon is displayed that allows broadcasting of the representative, initiative, date range and lead state (if available) to other zones on the portal. Lead state broadcast is only available on the subtotal lines.

Graphs and Statistics for an Initiative

The following zones display statistics for the initiative's leads.

Note: The system periodically refreshes the statistics for an initiative when the time specified on an initiative has lapsed. A user may also manually initiate the refreshing of statistics if required.

Lead Outcome Graph

This Lead Outcome Graph zone shows the number of Leads linked to the initiative (or initiative group hierarchy) that entered the final state in the last 24 months starting from the most recent completed Lead.

The date shown on the X-axis will be the first day of the month. Note that the information displayed here is based on the most recent completed Lead as of the time the Initiative Statistics is accumulated.

Lead Statistics

The Lead Statistics zone has two charts to provide statistics for leads for the initiative:

- **Leads by State:** The chart shows the number of leads for each state in the lead's lifecycle as of the initiative's Statistics Date/Time. Each state can be represented by a unique color. These colors are defined on the Program Management master configuration. Refer to [Program Management Master Configuration](#) for setting up program management options for more information.
- **Active Leads by Representative:** The chart shows the top five individual sales representatives for the initiative (i.e. sales representatives with the largest number of active leads assigned to them as of the Statistics Date/Time). The top five sales representative can be represented by a unique color. These colors are defined on the Program Management master configuration. Refer to [Program Management Master Configuration](#) for setting up program management options for more information.

Lead Monthly Statistics

The Lead Monthly Statistics zone has two charts to provide statistics for leads for the initiative:

- **Leads by State:** The chronological graph highlights the number of open, completed and discarded leads over time for the initiative in context. The date displayed on the x-axis represents the start date of the statistics period. For example, 01-01-2013 shows statistics for the period 01-01-2013 through 01-31-2013. Each State can be represented by a unique color. These colors, along with the number of months to display are defined on the Program Management master configuration. Refer to [Program Management Master Configuration](#) for setting up program management options for more information.
- **Active Leads by Representative:** The chronological graph highlights the top 4 discard reasons over time for the initiative in context. Statistics for all other discard reasons are accumulated in a catch-all bucket. The date displayed on the x-axis represents the start date of the statistics period. For example, 01-01-2013 shows statistics for the period 01-01-2013 through 01-31-2013. Each Discard Reason can be represented by a unique color. These colors, along with the number of months to display are defined on the Program Management master configuration. Refer to [Program Management Master Configuration](#) for setting up program management options for more information.

Displaying and Assigning Unassigned Leads

Use the following procedure to review and assign, as appropriate, non-final and unassigned leads that are associated to the initiative in context.

1. Select **Menu > Sales & Marketing > Initiative > Search.**

2. Enter your search criteria in the Initiative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the initiative you want to maintain. The selected initiative opens in the Initiative portal.
5. Go to the **Statistics** page and scroll, as necessary, to view the Unassigned Leads Zone.
6. Enter a Start Date and End Date range that encompasses the desired period.
7. Click **Refresh** to view unassigned leads that were created within the period specified.
8. (optional) Assign one or more leads from the result set:
 - a) Select the unassigned leads from the results set.
 - b) Enter the sales representative that will be assigned the leads.
 - c) Press **Assign to Sales Rep.**
 - d) Select the Sales Representative from the dropdown menu and click **OK**.

Maintaining Leads

A lead is an instance of an initiative for a targeted customer. A lead may contain events or actions that are there to encourage a customer to participate in a program

The topics in this section describe the common functions associated with leads.

My Leads

You can use the My Lead menu item to maintain leads.

- If your User ID is linked to a Sales Representative, you are navigated to the Sales Representative portal with the user in context.
- If your User ID is not linked to a Sales Representative, you are navigated to the Leads Query portal.

Lead Portal

You use the Leads portal to maintain leads. This portal contains the following zones:

- **Lead:** Displays the basic information about the lead.
- **Lead Events:** Displays the events associated with the lead in chronological order.
- **Related Leads:** Displays the leads that are related to the current lead's related objects (e.g. account).
- **Attachments:** Displays uploaded documents that are related to the lead.
- **Notes:** Displays all notes for the lead and its lead events.
- **Third Party Event:** if a third party lead event exists, this zone displays the lead event's information, including the event steps

How To Perform Common Lead Functions

The topics in this section describe how to perform common lead maintenance functions from the Lead portal.

Manually Creating a Lead

Use this procedure to manually create a new lead.

1. Select **Menu > Sales & Marketing > Lead > Add**.
2. Select the lead's Initiative and click **OK**.
The Account Lead page displays so that you can complete the lead.
Enter the following information as required by the Initiative:
 3. Search for and select the **sales representative** for the lead.
 4. Indicate how the customer requested information about the initiative in the **response channel**.
 5. Indicate if the customer has **signed up** for the initiative.
 6. Search for and select the **account** that will be associated to the lead.
 7. Search for and select the **premise** that will be associated to the lead.

8. Click **Save**.

Note: Leads can also be created through the Initiative context menus and Account context menus.

Maintaining a Lead

1. Select **Menu > Sales & Marketing > Lead > Search**.
2. Enter your search criteria in the Lead Query zone.
3. Click **Refresh**.
4. In the search results list (not applicable if Lead ID is specified in the search criteria), click the link for the lead you want to view maintain. The selected lead opens in the Lead portal.

Note: You may also navigate to the Lead portal by clicking on the appropriate lead from various portals and zones. Examples include:

- Sidebar Portal: Alerts zone
- Initiative Portal: Initiative Leads zone
- Sales Representative Portal: Initiative Leads zone or Initiative Lead Events

5. Click the appropriate record action button:

Buttons that appear when the lead is Pending:

- **Edit** – Click the **Edit** button to allow you to edit the main attributes of the lead. When you click **Save**, the system updates the record.
- **Delete** – Click the **Delete** button and click **OK** to delete a pending lead from the database. Before you delete a lead, the system verifies that the lead is not referenced anywhere in the system. If it is, you cannot delete it.
- **Activate** – Click the **Activate** button to transition a pending lead to the active state. When a lead is activated, lead events for the lead are created to encourage the customers to participate in the initiative.

Buttons that appear when the lead is Active:

- **Edit** – *see the description above.*
- **Discard** – Select the **Discard** button to inactivate an active lead. Select a **Status Reason** indicating why the lead is being inactivated and click **Save**. The values are maintained on the Status Reason control table
- **Complete** – Click the **Complete** button to indicate that an active lead has been successful.
- **Sign Up** – Click the **Sign Up** button to initiate a script that is defined on the Initiative's business object. The base package script **C1-IntvSignU** reevaluates the customer to determine if they are still eligible to participate in a program, indicates the customer has signed up or enrolled on the lead and creates a third party lead event (if applicable) to notify the relevant third party of the actions to be performed. The Response Channel on the lead is also updated for analytical purposes

6. Click the **Add Notes** button, in the Notes zone, to capture additional information for the lead.
7. The **Third Party Event Zone** displays third party lead event (if any) details along with the steps involved in the lead event

Adding New Lead Events to a Lead

1. Select **Menu > Sales & Marketing > Lead > Search**.
2. Enter your search criteria in the Lead Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the lead you want to view maintain. The selected lead opens in the Lead portal.
5. To add a lead event to the lead, click the **Add Lead Event** link in the Lead Events zone title bar.
6. Search for and select the appropriate lead event type.
7. Specify the Trigger Date of when the lead event is to be executed.
8. Specify the Communication Channel to indicate what form the event will be sent.

9. Click **Save**.

Repeat steps 5 to 9 for add additional lead events.

Adding Lead Notes

1. Select **Menu > Sales & Marketing > Lead > Search**.

2. Enter your search criteria in the Lead Query zone.

The C1-owned base package search options include:

- Name and address
- Related object
- Representative and initiative
- Lead ID

3. Click **Refresh**.

4. In the search results list, click the link for the lead you want to view maintain. The selected lead opens in the Lead portal.

5. Scroll, as necessary, to view the Notes zone.

6. Click the **Add Notes** link in the zone's title bar.

7. Enter the desired information in the **Add Notes for Lead** pop-up window and click **Save**.

Maintaining Lead Events

A lead event is an event or action in a lead to take place to encourage a customer to participate in a program. A lead may contain many lead events.

The Lead Event portal is used to maintain lead events. This portal contains the following zones:

- **Lead Event:** Displays the basic information about the lead event.
- **Notes:** Displays user-defined comments about this lead event

To maintain a lead event:

1. Select **Menu > Sales & Marketing > Lead Event > Search**.

2. Enter your search criteria in the Lead Event Query zone.

3. Click **Refresh**.

4. In the search results list, click the link for the lead event you want to maintain. The selected lead opens in the Lead Event portal.

Note: You may also navigate to the Lead Event portal by clicking on the appropriate lead event from various portals and zones. Examples include:

- Initiative Portal: Initiative Leads zone
- Sales Representative Portal: Initiative Leads zone or Initiative Lead Events

5. Click the appropriate record action button:

- **Edit** – Click the **Edit** button to allow you to edit the main attributes of the lead event. When you click Save, the system updates the record.
- **Complete** – Click the **Complete** button to indicate a pending lead event is completed.
- **Cancel** - Select the **Cancel** button to cancel a pending lead event.

6. Click the **Add Notes** icon, in the Notes zone, to capture additional information for the lead.

Maintaining Third Party Lead Events

A third party lead event represents an action within a lead to either encourage a customer to participate in a program, or perform an on-site service. A lead may contain one or more third party lead events.

The Lead Event portal is used to maintain third party lead events. This portal contains the following zones:

- **Lead Event:** Displays the basic information about the lead event.
- **Notes:** Displays user-defined comments about this lead event

To maintain a third party lead event:

1. Select **Menu > Sales & Marketing > Lead Event.**

2. Enter your search criteria in the Lead Event Query zone.

The C1-owned base package search options include:

- Name and address
- Related object
- Initiative and representative
- Lead and lead event

3. Click **Refresh.**

4. In the search results list, click the link for the lead event you want to maintain. The selected lead opens in the Lead Event portal.

Note: You may also navigate to the Lead Event portal by clicking on the appropriate lead event from various portals and zones. Examples include:

- Initiative Portal: Initiative Leads zone
- Sales Representative Portal: Initiative Leads zone or Initiative Lead Events

5. Click the appropriate record action button:

- **Edit** – Click the **Edit** button to allow you to edit the main attributes of the lead event. When you click Save, the system updates the record.
- **In Progress** – Click the **In Progress** button to initiate the notification process and have the third party lead event sent to the representative.
- **Cancel** - Select the **Cancel** button to cancel a pending lead event.

6. Click the **Add Notes** icon, in the Notes zone, to capture additional information for the lead.

Maintaining Sales Representatives

A Sales Representative is a user or group of users who can be assigned to follow up on leads and responsible for selling the initiatives product or service to the customer.

The topics in this section describe the common functions associated with Sales Representatives.

Sales Representatives Portal

You use the Sales Representative portal to maintain sales representatives. This portal contains the following zones:

- **Sales Representative:** Defines the basic information about the representative.
- **Initiative Lead Summary:** Lists initiatives and information about leads for each initiative for the representative. Clicking the broadcast icon from the summary table in this zone displays the following additional zones:
 - **Initiative Leads:** Displays leads for the initiative and representative.
 - **Initiative Lead Event Summary:** Displays lead event statistics for the initiative lead and representative.
 - **Initiative Lead Events:** Displays lead events for the initiative lead and representative.
- **Group's Representatives:** This zone is displayed for a representative group and lists the individual representatives who are members of the group.
- **Representative's Groups:** This zone is displayed for an individual representative and lists the representative groups of which this representative is a member.

How To Perform Common Sales Representative Functions

The topics in this section describe how to perform common sales representative functions from the Sales Representative portal.

Creating Sales Representatives

Use this procedure to create a new sales representative.

1. Select **Menu > Sales & Marketing > Sales Representative > Add.**
2. Select the sales representative type that will define the representative and click **OK.**
3. Enter the appropriate information for the representative:
 - For a Group Sales Representative:
 - Specify the Sales Representative name and description.
 - Search for and select Individual Sales Representative who will be a member of the group.
 - For an Individual Sales Representative:
 - Specify the Sales Representative name and description.
 - Search for and select User for the individual sales representative.
 - Search for and select Group Sales Representative that the individual sales representative will be a member of.
4. Click **Save.**

Maintaining Sales Representatives

1. Select **Menu > Sales & Marketing > Sales Representative > Search.**
2. Enter your search criteria in the Sales Representative Query zone.
3. Click **Refresh.**
4. In the search results list, click the link for the sales representative you want to maintain. The selected sales representative opens in the Sales Representative portal.

Note: You may also navigate to the Sales Representative portal by clicking on the appropriate Sales Representative from various portals and zones. Examples include:

- Initiative Portal: The Initiative Zone or the Lead Summary By Representative.
 - Lead Portal: Lead zone
5. Click the appropriate record action button:
 - **Edit** – Click the **Edit** button to allow you to edit the main attributes of a sales representative. When you click **Save**, the system updates the record
 - **Duplicate** – Click the **Duplicate** button to create a duplicate of the sales representative being displayed. Before the new object is added to the database, a window appears asking you to enter the unique identifier of the new object. When you click **OK**, the system creates the record by copying the original record
 - **Deactivate** – Click the **Deactivate** button to transition an active sales representative to an inactive state
 - **Delete** – Click the **Delete** button and click **OK** to delete the sales representative from the database. Before you delete a sales representative, the system verifies that the sales representative is not referenced anywhere in the system. If this is the case, you cannot delete the representative. For example, if you attempt to delete a sales representative, the system ensures the sales representative is not referenced on a lead, etc.
 6. For an individual sales representative, you can add the sales representative to another group by clicking the **Add Rep to Another Group** link in the Representative's Group zones title bar. Select a group sales representative and click **Save**. You can remove the representative from a group (or groups) by selecting the group(s) and clicking the **Remove Rep from Group(s)** button.
 7. For a representative group, you can add a representative to the group by clicking the **Add Rep To This Group** link in the Group's Representatives zone's title bar. Search for and select the individual sales representative to add to the group and click **Save**. You can remove representatives from a group by selecting the representatives and clicking the **Remove Rep(s) from Group** button.

Displaying Leads and Lead Event Information for a Sales Representative

From the Initiative Lead Summary zone on the Sales Representative portal, you can broadcast a representative, initiative, date range and lead state (if available) to other zones on the portal.

Displaying Leads Associated Information for a Sales Representative

The Initiative Lead Summary zone on the Sales Representative portal displays the leads that have been assigned to the sales representative. If the representative is a group, leads are summarized for all individuals in the group.

To limit the summary of leads for the sales representative:

1. Select **Menu > Sales & Marketing > Sales Representative > Search**.
2. Enter your search criteria in the Sales Representative Query zone.
3. Click Refresh.
4. In the search results list, click the link for the sales representative you want to view or manage. The selected sales representative opens in the Sales Representative portal.
5. Specify **Start Date** and/or **End Date** to limit the summary to leads created within this date range. If specified, start date must be on or before the current date and end date must be on or after the start date. If left blank, end date is defaulted to the current date.
6. If **Only Show Active Initiatives** is set to **Yes**, only leads linked to initiatives in the active state are summarized. Otherwise, leads for all initiatives regardless of status are included.
7. Click **Refresh**.

The following is displayed in the result set:

- A summary line for each initiative shows the total **Lead Count** for the individual or group rep.
- A breakdown is included beneath each initiative summary line that shows a subtotal **Lead Count** by lead state.
- An icon is displayed that allows broadcasting of the representative, initiative, date range and lead state (if available) to other zones on the portal. Lead state broadcast is only available on the subtotal lines.

Sales Representative Initiatives Leads Zone

By clicking on one of the broadcast items in the Initiative Lead Summary zone, the Initiative Leads zone on the Sales Representative portal is populated with relevant lead information for the selected item. If the sales representative is a group, leads for all individuals in the group are shown.

The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Last Complete Event**. You can navigate to the lead event by clicking on the last complete event for a lead.
- For open leads, the **Next Pending Event**. You can navigate to the lead event by clicking on the next pending event for a lead.
- The **Sales Representative** shows the rep assigned to each lead.

For information about using this zone to reassign leads to another representative, see [Reassigning Leads for a Sales Representative](#) on page 737.

Initiatives Lead Event Type Summary

By clicking on one of the broadcast items in the Initiative Lead Summary zone, the Initiative Lead Event Type Summary zone is displayed. If the representative is a group, lead events are accumulated for all individuals in the group. The summary spans the 14 day period on/after the Start Date which defaults to current date if blank. If you want to specify the start date, click Refresh to update the zone.

The following is displayed in the result set:

- The **Event Count** shows the total number of events for a specific Event Type on each day within the 14 day period. You can click on the broadcast icon to see a list of events for the **Event Date** and **Event Type** on the Initiative Lead Events zone.
- The **Event Status** bar provides a breakdown of the total event count by status. Each color segment shown represents a different event status for pending, completed and canceled events. Colors used are defined on the program management master configuration.

- Hover the mouse pointer over a segment of the bar to see the respective count and status represented by the segment.
- Click on a segment of the bar to broadcast the event date, event type and event status. Broadcasting from the event status bar instead of the broadcast icon will limit the Initiative Lead Events zone to a particular status.

Initiatives Lead Events Summary

By clicking on one of the broadcast items in the Initiative Lead Event Type Summary zone, the Initiative Lead Events zone is populated. This zone displays lead events for the initiative, representative, lead event type (if available) and status (if available). If the representative is a group, events for all individuals in the group are shown. Only lead events with a trigger date on or after the **Start Date** are displayed.

The following is displayed in the result set:

- **Event Date** and **Lead Event** information is shown for each event. You can navigate to a specific lead event by clicking on a lead event.
- **Lead** shows the lead information for the initiative's lead. You can navigate to the lead by clicking on a lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking customer information for a lead.
- The **Sales Representative** shows the representative assigned to the lead.

Reassigning Leads for a Sales Representative

To reassign leads from one sales representative to another sales representative:

1. On the Initiatives Leads zone, select the leads that you want to reassign and click **Reassign Rep.**
2. Select the Sales Representative to reassign the selected lead to and click **Save.**

Maintaining Third Party Representatives

A Third Party Representative is someone who can receive assignments to perform specific tasks within a lead; such as, undertaking a visit to a property to perform an inspection or an installation. Refer to [The Big Picture of Third Party Representatives](#) for more information

The topics in this section describe the common functions associated with Third Party Representatives.

Third Party Representatives Portal

The Third Party Representative portal is used to maintain third party representatives. This portal contains the following zones:

- **Third Party Representative:** Defines the basic information about the third party representative.
- **Initiative Lead Summary:** Displays a summary of initiatives that have leads assigned for the third party representative. Clicking the broadcast icon from the summary table in this zone displays the following additional zones:
 - **Initiative Leads:** Displays leads for the broadcasted initiative and third party representative.
 - **Unassigned Leads:** Displays unassigned leads for the broadcasted initiative that are not yet assigned to a third party representative.

How To Perform Common Third Party Representative Functions

The topics in this section describe how to perform common representative functions from the Third Party Representative portal.

Creating Third Party Representatives

Use this procedure to create a new third party representative.

Note: Before adding the third party representative, they must be added as a Person without an account in the system. For more information about this process, see [How To Add A New Customer From Control Central](#).

1. Select **Menu > Sales & Marketing > Third Party Representative > Add.**
2. Enter the appropriate information for the representative:

- Specify the Third Party Representative name and description.
- Search for and select the Person record for the third party representative.
- Select the External System that will be used to communicate to the third party representative.

3. Click **Save**.

Maintaining Third Party Representatives

1. Select **Menu > Sales & Marketing > Third Party Representative**.
2. Enter your search criteria in the Third Party Representative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the third party representative you want to maintain. The selected third party representative opens in the Third Party Representative portal.
5. Click the appropriate record action button:
 - **Edit** – Click the **Edit** button to allow you to edit the main attributes of a third party representative. When you click **Save**, the system updates the record
 - **Duplicate** – Click the **Duplicate** button to create a duplicate of the third party representative being displayed. Before the new object is added to the database, a window appears asking you to enter the unique identifier of the new object. When you click **OK**, the system creates the record by copying the original record
 - **Deactivate** – Click the **Deactivate** button to transition an active third party representative to an inactive state
 - **Delete** – Click the **Delete** button and click **OK** to delete the third party representative from the database. Before you delete a third party representative, the system verifies that the third party representative is not referenced anywhere in the system. If it is, you cannot delete it. For example, if you attempt to delete a third party representative, the system ensures the third party representative is not referenced on a lead, etc.

Displaying Leads Associated Information for a Third Party Representative

The Initiative Lead Summary zone on the Third Party Representative portal displays the leads that have been assigned to the Third Party representative.

To limit the summary of leads for the sales representative:

1. Select **Menu > Sales & Marketing > Third Party Representative > Search**.
2. Enter your search criteria in the Third Party Representative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the sales representative you want to view or manage. The selected sales representative opens in the Sales Representative portal.
5. Specify **Start Date** and/or **End Date** to limit the summary to leads created within this date range. If specified, start date must be on or before the current date and end date must be on or after the start date. If left blank, end date is defaulted to the current date.
6. If **Only Show Active Initiatives** is set to **Yes**, only leads linked to initiatives in the active state are summarized; otherwise, leads for all initiatives regardless of status are included.
7. Click **Refresh**.

The following is displayed in the result set:

- A summary line for each initiative shows the total **Lead Count** for the third party representative.
- A breakdown is included beneath each initiative summary line that shows a subtotal **Lead Count** by lead state.
- An icon is displayed that allows broadcasting of the third party representative, initiative, date range and lead state (if available) to other zones on the portal. Lead state broadcast is only available on the subtotal lines.

The Initiative Leads zone on the Third Party Representative portal displays the leads that have been assigned to the third party representative. The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.

- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Last Completed Step**. You can navigate to the lead event by clicking on the event/step information.
- For active third party lead events, the **Next Pending Step**. You can navigate to the lead event by clicking on the event/step information.
- The **Sales Representative** shows the representative assigned to the lead.

The Unassigned Leads zone on the Third Party Representative portal displays active leads that are not yet assigned to a third party representative. The following is displayed in the result set for each lead:

- Basic **Lead** information for the initiative's lead. You can navigate to the lead by clicking on the lead.
- **Customer Information** related to the lead. You can navigate to the account related to the lead by clicking on the customer information.
- The **Sales Representative** shows the representative assigned to the lead.
- You can assign leads to the third party representative using the **Assign to Third Party** button.

See [Displaying and Assigning Leads to a Third Party Representative](#) on page 739 for more information.

Displaying and Assigning Leads to a Third Party Representative

Use the following procedure to view leads that are not assigned to a third party representative, and assign one or more of those leads to the third party representative in context.

1. Select **Menu > Sales & Marketing > Third Party Representative > Search**.
2. Enter your search criteria in the Third Party Representative Query zone.
3. Click **Refresh**.
4. In the search results list, click the link for the third party representative you want to view. The selected third party representative opens in the Third Party Representative portal.
5. The **Initiative Lead Summary** zone shows the initiatives that have leads assigned to the third party representative in context. Click the broadcast button on an initiative to view its unassigned leads.
6. Scroll down to view the **Unassigned Leads** zone. This zone will display if there are active leads (for the broadcast initiative) that are not yet assigned to a third party representative.
7. To assign one or more leads to the third party representative in context:
 - a) Select the unassigned lead(s) from the results set.
 - b) Press **Assign to Third Party**.
 - c) Click **OK**.

Rates

When you set up a customer in the system, you create a service agreement for every service that the customer uses. The most important information specified on a service agreement is the rate. The rate controls:

- How the service's charges are calculated.
- How the charges are described on the customer's bills.
- How the general ledger is affected by the charges.

It's important to understand that while *most* service agreements are associated to a rate, you may have service agreements that don't use a rate to calculate their charges; for example, you may have [billable charge](#) service agreements to bill a customer for charges that have been calculated in an external system. Whether or not a service agreement uses a rate and the list of rates that can be specified on a service agreement are controlled by the service agreement's [SA Type](#).

In addition to calculating charges for service, your implementation can also use rates to calculate [adjustments](#).

**Fastpath:**

Refer to [How Rates Affect The Information On A Bill](#) for how billing uses the information in a rate to calculate a bill segment. Refer to [Calculated Adjustments](#) for how to use a rate to calculate an adjustment.

**Note:**

Do not equate a rate in your legacy system with a rate in this system. You may find that the system's flexibility will result in fewer rates than you have today. For example, your current rate structure may have three rates for service because there are different prices based on the customer's geographic area. In this system, however, you can set up a single rate and vary the price based on where the customer lives.

This chapter describes the structure and process to configure rates.

Rate schedules created using the new rate engine are referred to as **Calculation Rule-Based Rates** or, simply, **Rates**; and those created using the original rate engine are referred to as **Component-Based Rates**. This chapter focuses on Calculation Rule-Based Rates, unless stated otherwise.

**CAUTION:**

Component-Based Rates, or classic rates, is not the recommended approach for new implementations. Component-Based Rates is intended for upgrading customers who currently use this rate structure and have not converted to Calculation Rule-Based Rates.

Calculation Rule-Based Rates

Calculation Rule-Based Rates (Rates) offer a flexible and reusable structure to calculate charges, centralize configuration, and reduce your development effort and time.

This chapter describes the structure and process to configure Rates.

All Calculation Rule-Based Rates Share a Common Structure

The basic components used to calculate charges are **Calculation Rules**. Each calculation rule is configured to perform a specific type of calculation, such as calculating tax charges, the number of days in a billing period, or the amount of consumption used by a customer in a billing period.

Calculation rules are organized into **Calculation Groups**, which are logical collections of calculation rules that can be referenced by rate schedules. Calculation rules and groups are commonly "generic" and can be applied to multiple rates.

Furthermore, calculation groups can be nested within other calculation rules. When the parent rule is processed, it executes all the rules that are nested in its referenced group. This strategy allows a single rule to execute any number of nested rules. Nesting also allows common calculations to be encapsulated into a set of calculation rules that can be included in multiple rates.

Calculation groups are defined for a rate schedule in one of three ways:

- **Pre-Processing Calculation Groups** perform initial calculations in preparation for the rate version calculation group.
- **Rate Version Calculation Groups** are effective-dated calculation groups that perform the main calculations of the rate schedule.
- **Post-Processing Calculation Groups** perform calculations after rate version calculation groups are executed.

See [About Calculation Groups](#) for more information.

At the highest level, every rate has a single rate schedule that contains basic information that shouldn't change over time; such as, the billing frequency, currency, and the rate's proration strategy. This information combined with the calculations groups, and other high-level configuration, comprise the Rate Schedule

Control Tables That Must Be Set Up Before Creating a Rate Schedule

This section describes tables that must be set up before you can add a rate schedule.

Master Configuration

The **Rate Engine Configuration** master configuration can be used to define the behavior of the Rate Schedule portals used when creating rate schedules.

To edit this master configuration, select **Admin > Master Configuration**, and click the edit icon for the **Rate Engine Configuration**.

The **Rate Engine Implementation** dropdown list defines which rate engine(s) will be used by your organization.

- **Calculation-Rule Based** indicates that your implementation uses calculation rule-based rates, which require the configuration of rate schedules with calculation groups and calculation rules.
- **Component-Based** indicates that your implementation uses component-based rates, which require the configuration of rate versions with rate components, and rate schedules with SQ and register rules.
- **Both** indicates that your implementation uses both rate engines. If this applies to you, then the system will use this option to ease navigation as follows:
 - Select **Menu > Rates > Rate Schedule > Add** to launch the page to add a new rate schedule. *(A hyperlink is included to take the user to the component-based rate schedule maintenance page, if necessary.)*
 - Select **Menu > Rates > Rate Schedule > Search** to launch the **Rate Schedule Query** portal.
 - The query results attempt to highlight component-based rates by appending “**(Component-Based)**” to the rate schedule's description.
 - Once a rate schedule is selected from the result set, the system navigates the user to either the calculation rule-based **Rate Schedule portal** or the component-based **Rate Schedule page**.

The **External Communication** section is used when the rate engine needs to communicate with an external system. For example, service quantities are needed to test a rate on the **Rate Check** portal. These service quantities may be entered on the portal, retrieved from an existing bill segment, or (in the case of a service agreement that requires bill determinants) request service quantities from Oracle Utilities Meter Data Management.

- **Request Type** identifies the various data requests that can be made to an external system. Request types are defined in the RATE_EXT_REQ_TYPE_FLG lookup field. To introduce additional request types, add appropriate lookup values to this lookup field for each request type you wish to support.

The base package includes the following business objects to be defined on the outbound message types created for such requests:

- **Rate Check Usage:** C1-UsageRequestOutMsg (used to request bill determinants from MDM on the rate check portal)
- **External System** and **Outbound Message Type** are used when creating the outbound message for the data request.

Defining Frequency Codes

When you create a rate schedule, you must enter a code defining the frequency in which the prices are expressed, e.g., monthly, quarterly, biannual, etc. To set up frequency codes, open **Admin > Rates > Frequency**.

Description of Page

Enter a unique **Frequency ID** and **Description** for each frequency.

Before entering the remaining fields, you must analyze the "proration provisions" in your rates. For example, consider a rate used to calculate charges for a "month's worth of service". Assume this rate's charges will not be prorated when the customer's service period is anywhere between 27 and 33 days. This rate requires a frequency that indicates:

- **12 Periods / Year** (because it's a monthly rate).
- **Minimum Days Offset** equal to 3.

- **Maximum Days Offset** equal to 3.

When the system creates a bill using a rate with this frequency, it compares the number of days of consumption on the bill to the minimum and maximum number of days inferred by the rate's frequency. In the example above, the minimum number of days would be 27 (365 days / 12 period per year - 3 offset for minimum days). The maximum number of days would be 33 (365 days / 12 periods per year + 3 offset for maximum days). Therefore, if a bill's consumption period is less than 27 days or more than 33 days, the bill's charges are prorated.

Note:

Overriding the system's standard proration logic. If the standard proration logic does not satisfy your requirements, you may plug in an override proration algorithm to calculate the proration factors as required by your implementation. For example, we have encountered companies who treat a year as having 360 days rather than 365 days. Such a company would need to develop an override proration algorithm and plug it on the [Installation](#) record.

Where Used

Every Rate Schedule must have a frequency. Refer to [Defining Rate Schedules](#) for more information.

UOM versus TOU versus SQI

Almost all rates contain prices in respect of some number of something. This something could be anything from a therm of gas to a kilowatt-hour of electricity. We use three distinct codes to identify the "thing" being priced in a rate. These codes are **UOM** (unit of measure), **TOU** (time of use), and **SQI** (service quantity identifier). These codes must be set up before you can create a rate schedule.

You don't have to use all three codes when you specify a price in a rate. Rather, you use the codes that are needed to clearly identify the thing being priced. We'll use a few examples to clarify this concept.

Let's consider a rate that simply has a price per therm. For this rate, you'd only use a UOM code to identify the thing being priced (and this code should be something simple like THRM).

Next, let's consider a rate that has a different price for kilowatts consumed during peak hours as compared to those used during off-peak hours. You would use a combination of UOM and TOU to define the thing being priced. In this example, we'd recommend using a single UOM for kilowatt-hours (labeled kWh) and two TOU codes - one for the peak period (labeled PEAK) and the other for the off-peak period (labeled OFFPEAK).

Note:

Rule. If the thing being priced is measured by a meter, you must use the same UOM/TOU code(s) in the rate as are specified on the meter's register(s). Refer to [Setting Up Unit Of Measure Codes](#) for more information.

And finally, let's consider a rate that has a charge for "annual highest kW (demand) during peak hours". This is a very complicated thing to price. You have several options in respect of the combination of UOM, TOU, SQI to use to express this unit. The following table contains every conceivable combination to express this single thing:

| Option | UOM | TOU | SQI |
|--------|-------------------------------|------|-----------------------------------|
| 1 | KW | PEAK | ANNHIGH - Annual Highest |
| 2 | KW | | PEAKANHI - Peak Annual Highest |
| 3 | | | ANHIPPKW - Annual Highest Peak KW |
| 4 | KWAP - KW Annual Highest Peak | | |

5

KW

AHPEAK - Annual Highest
Peak**Note:**

Rule Of Thumb. We strongly recommend using an SQI to identify things not measured by your meters. This means that you shouldn't use the last two options in the above table. Of the first three options, the choice is yours. It's really a question of how you prefer to record your billed consumption.

**Fastpath:**

For more information about UOM and TOU refer to:

- [Setting Up Unit Of Measure Codes](#)
- [Setting Up Time Of Use Codes](#)
- [Defining Service Quantity Identifiers](#)

Setting Up Bill Factors

This section describes bill factors and how they are used to levy the many charges referenced in a rate.

**Warning:**

Most bill factors exist to support calculations performed by calculation rules. This means that you must design your calculation rules before you can design your bill factors. We strongly recommend that you design "on paper" how each rate's calculation rules look before attempting to set up bill factors.

An Overview of Bill Factors

The primary reason that calculation rules exist is to define how much to charge for the services sold by your company. When you create calculation rules, you have four ways to indicate how much to charge:

- Specify the value directly in the calculation rule.
- Define that the value is defined in a *bill factor*.
- Define that the value is calculated by a *for calculation purposes only* calculation rule.
- Tell the calculation rule to call an algorithm to get the price.

The remainder of this section describes the bill factor approach. The other methods are discussed in [Case Study: Three Simple Rates](#) and in [Designing Rate Components](#).

Bill factors are used to pass a value to a calculation rule; such as specifying a tax rate. To further illustrate this, you could specify the current tax rate, say 6%, directly in every rate's calculation rules OR you could indicate every rate should levy the current state tax rate and have the system look up the applicable rate when it calculates bills. The latter approach involves using a bill factor to indicate that the amount to charge should be retrieved from someplace other than the calculation rule when a bill is calculated.

You can use bill factors to define any of the following types of charges:

- A flat amount. This would typically be used to define service charges, minimum charges, and asset charges.
- An amount for a given unit of measure. This would typically be used to define the price for measured consumption (such as, the price per therm).
- A percentage. This would typically be used for tax rates and discount percents.

As a rule of thumb, you would use a bill factor (rather than specify the value in the calculation rule) when any of the following situations exist:

- The same charge exists in many rates. For example, if there are three rates that all contain the same service charge, it would make sense to use a bill factor to levy this charge rather than specify the same value on three calculation rules.

- The amount being charged is dependent upon some physical characteristic of the customer's equipment. For example, if the price differs depending on whether the customer owns the transformer, you would use a bill factor to specify the price.
- The amount being charged is dictated by some external organization and therefore can change independently from the rate. For example, tax percentages and use fees are set by taxing authorities and can be changed at any time (and you don't want to change the rate when these charges change).
- The amount being charged varies depending on WHERE the customer lives. If you have a rate where the price per gallon differs depending on where the customer lives, you should use a bill factor to levy this type of charge.
- A charge (or discount) is only levied for a subset of customers for defined periods of time. For example, if you have a discount that is only given to customers who have had service for more than two years, you would use a bill factor to specify the discount percent.
- The price differs per customer. For example, you may have a rate for large gas customers where the price per therm is different for every customer. In this situation, you would use a bill factor to specify the price.
- The price differs based on the number of weeks of consumption. This typically occurs in a deregulated environment when the price charge is based on the weighted average spot market price in effect during the bill period.

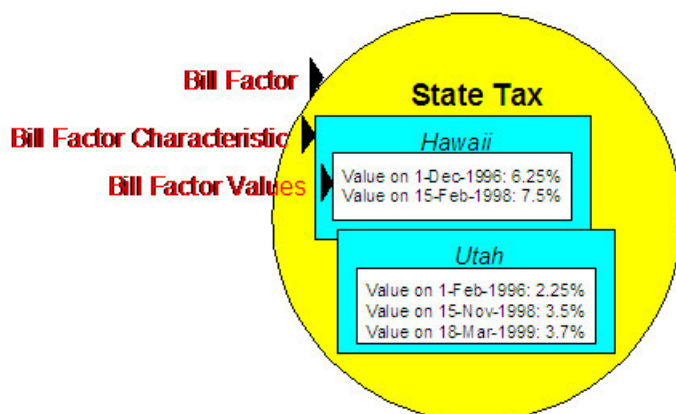

Warning:

As you can deduce, bill factors are extremely flexible. While the flexibility makes for a very powerful rate engine, it also presents you a dizzying array of options. We have discovered that to take advantage of the flexibility, you need to gain an overall understanding of the pricing and taxation provisions in ALL of your rates. Only then can you make logical and pragmatic decisions in respect of the number and type of bill factors.

The Structure of a Bill Factor

All bill factors share a common structure as illustrated below:

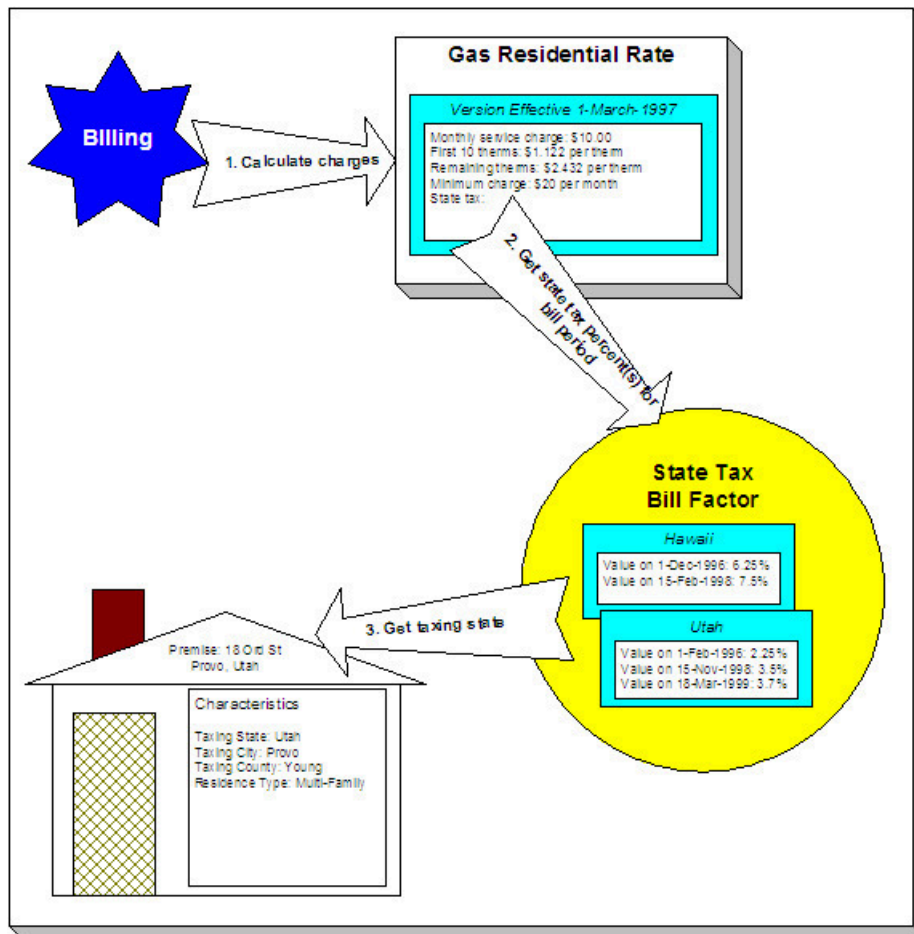

The above example shows a standard bill factor, which is made up of the following tables:

- **Bill Factor.** A **bill factor** contains descriptive information and attributes that control how the bill factor may be used in the system.
- **Bill Factor Characteristic.** All bill factors have the capability of having different values depending on some characteristic of the premise or service point. For example, a bill factor used to levy a state tax would have a different tax rate depending on the state in which the customer resides. A **bill factor characteristic** must exist for every state with a tax (states without a tax will not be linked to the state tax bill factor). At billing time, if the system cannot find a bill factor characteristic that corresponds with the customer's state of residence, the charge will be skipped.
- **Bill Factor Value.** Each bill factor characteristic may have many **bill factor values** over time. To continue with our state tax example, each state with a tax can have different tax rates over time. There are different ways in which a bill factor's values may be defined:

- For bill factors whose values are applicable to many customers where only one value is effective on a given date (such as, a city tax) the values are defined using bill factor values. Refer to [Defining Bill Factor Values](#) for more information.
- For bill factors whose value differs per customer, the value is defined in the customer's service agreement. Refer to [Service Agreement - Contract Value](#) for more information about bill factors in contract terms.
- For bill factors whose values are applicable to many customers where more than one value is effective on a given date (such as, an interval price or a weighted average price) the values are defined on an interval value set. Refer to [Defining Interval Values](#) for more information about interval value sets.

An Illustration of a Bill Factor and Its Characteristics

The following picture illustrates how a bill factor and its characteristics are used to retrieve the relevant state tax at billing time:

The following points describe the illustration:

- At billing time, the billing engine sends a request to a rate to calculate the charges for a customer's consumption.
- The rate calculates charges without bill factors until it encounters the calculation rule that levies state tax. This calculation rule references a bill factor. This means the rate must get the tax rate(s) in effect during the billing period from this bill factor.
- The state tax bill factor contains an attribute defining that the premise's taxing state characteristic controls the bill factor value. The bill factor therefore extracts the taxing state from the premise.

Note:

Deriving characteristic values. Rather than have the system extract the characteristic value from an entity, you can setup the system to derive the characteristic value when the rate is calculated. For example, if all of your customers are located in a single state, you may not want to maintain the taxing state on every premise. To do this, you could setup the rate to "hard code" a taxing state of say Hawaii. This is an advanced topic, but it may prove useful for your implementation. Refer to [Deriving / Passing In Characteristic Values](#) for the details.

- The premise returns the taxing state and the bill factor extracts the tax rate(s) in effect during the bill period and returns them to the rate.
- The rate applies the tax percents and returns the charges to billing.

Note:

Some bill factors don't need a characteristic. There are bill factors whose value does not differ based on a characteristic. For example, if your organization offers employee discounts, the discount percent is probably the same for all employees and therefore this bill factor doesn't need a characteristic to select the bill factor value at billing time. However, because of the relational design of the system, every bill factor value must reference both a bill factor and a characteristic value. Therefore, if you have bill factors whose value is not related to a characteristic, you must specify a characteristic type on the bill factor with a characteristic value that is exactly the same as the characteristic type. Refer to [Employee Discounts](#) for an example.

Fastpath:

For more information about setting up characteristics, see [Setting Up Characteristic Types and Their Values](#) .

Deriving/Passing In Characteristic Values

In [An Illustration of a Bill Factor and Its Characteristics](#), we described how the system retrieves a characteristic value from a premise when a bill factor is encountered that uses a premise characteristic. This is a very common technique and is easy to understand. However, there are situations when an entity in Oracle Utilities Customer Care and Billing doesn't contain the appropriate characteristic value and therefore other techniques must be used. These techniques may not apply to your implementation, but they're worth understanding to help you form an intuitive understanding of rate application:

- There are implementations that only use the Oracle Utilities Customer Care and Billing rate engine. These implementations do not setup accounts, premises, etc. Rather, they simply setup their rate schedules, calculation rules, and bill factors. The rate engine is called from another application. This means the rate engine can't retrieve characteristic values from within Oracle Utilities Customer Care and Billing (because there are no objects where the characteristic values are defined). In this situation, the application that calls the rate engine must supply the characteristic types and values to be used when a bill factor requires this type of information.
- Assume you have a charge that is based on the account's customer class and the service agreement's revenue class. The characteristic value for this type of charge is not extractable through a single entity. Rather, the system must construct the characteristic value in real-time by concatenating information from the account and service agreement that is being billed. In this situation, you can use pre-processing calculation group to derive this characteristic type and value. This calculation group would create a characteristic type and value in real time by concatenating the account's customer class and the service agreement's revenue class. This characteristic type and value only exists in memory while the rate application executes.

When you setup a bill factor to use a characteristic whose value is derived or passed in, you need to define its characteristic source as Characteristics Collection. This source tells the system to extract the characteristic value from memory rather than extracting it from an object within the system.

Note:

The plug-in spots on a calculation rule have access to the Characteristics Collection. You might find this useful if you have a calculation rule that needs to calculate characteristic values for subsequent calculation rules.

Defining Bill Factors

You create a bill factor for every type of charge whose value is not specified directly in a calculation rule.

It is recommended to use two windows to set up a bill factor. On the first, you define general information describing how the bill factor is used in the system. On the second, you define all the characteristic values for the bill factor.

Defining General Bill Factor Information

Begin to define a bill factor by selecting **Menu > Rates > Bill Factor > Add.**

Description of Page

Enter a unique **Bill Factor** code and a **Description** for the bill factor.

Use **Bill Factor Type** to indicate if this bill factor uses Regular, Interval (i.e., real-time), or Time of Use values.

- **Regular.** Indicates that this bill factor's values are specified on [Bill Factor Value - Main](#) or on [Service Agreement - Contract Values](#).
- **Interval.** Indicates that this bill factor's values are specified on [Defining Interval Values](#)
- **Time of Use.** Indicates that this bill factor's values are specified on [Bill Factor TOU Values](#) or on [SA Interval Billing Info - TOU Contract Values](#) (**Note:** This option is only applicable to Component-Based Rates).

Enter a **Currency Code** to define the bill factor's denomination, or currency. This field is disabled if the bill factor is referenced on a calculation rule.

Note:

Bill factors referenced on a calculation rules must be denominated in the same currency as is the rate.

Select the **Value Type** to define the kind of value maintained by this bill factor. The Value Type options are:

- **Charge.** The value maintained in this bill factor is a fixed amount (e.g., a flat charge).
- **Percentage.** The value maintained in this bill factor is a percentage.
- **Unit Rate.** The value maintained in the bill factor is a price per service quantity.

This field is disabled if the bill factor is already referenced on a calculation rule or if the bill factor already has values

Turn on **Error If No Value** if the system should create a billing error when a bill factor value doesn't exist for the characteristic value linked to the customer. To clarify, understand that there are different types of bill factors:

- Those that should have a value for every customer whose rate references the bill factor. A bill factor used to levy the relevant state tax is a good example (assuming every state has a tax). For this type of bill factor, if the system cannot find a bill factor value for the taxing state, it must generate a billing error because data is missing from the system. You would turn on **Error if No Value** for this type of bill factor.
- Those that only have a value when the customer has a characteristic value that levies a charge. A bill factor used to levy the relevant city tax is a good example (because not all cities levy taxes). For this type of bill factor, if the system cannot find a bill factor value for the city in which the customer lives, the calculation rule will be skipped and no billing error will be generated. You would turn off **Error if No Value** for this type of bill factor

Bill factors used to levy taxes may or may not be eligible for tax exemptions; it's up to the respective taxing authority. Customers who are eligible for the tax exemption will have their tax obligation reduced (or nullified) at billing time. For bill factors that are eligible for tax exemptions, turn on **Tax Exemption**. If a service agreement is fully or partially exempt for the taxes defined by a given bill factor, the bill factor and the exemption information for the customer must be indicated on the Service Agreement page. This field will be disabled if the bill factor is referenced as being tax exempt in a service agreement.

Note:

Tax Exemptions limited to Apply To Calculation Rules. Although bill factors marked as eligible for tax exemptions may be referenced on several different types of calculation rules, only [Apply To](#) calculation rules include the logic to check for tax exemption eligibility.

Fastpath:

For more information about how to make a customer tax exempt, refer to [Service Agreement - Tax Exemptions](#).

Some types of bill factors do not have the same value for all customers. Rather, their value may be unique for every customer or it may be unique for some customers and common for others. For example, you may have rates where the price per kilowatt-hour is defined for every customer using the rate. You may have other rates where certain customers have their own price per kilowatt-hour defined and other customers who use the value defined on the bill factor. For any type of bill factor where a customer may have their own unique price, turn on **Value In Contract Term**. For any service agreement that has a unique value for a given bill factor, the bill factor and the service agreement's value must be indicated on the [Service Agreement](#) page. When applying the rate for a bill factor of this type, the system will first check for the existence of a contract value for the service agreement and if one is not found, it will use the value on the bill factor. This field will be disabled if a contract term referencing this bill factor exists.

Note:

The **Error if No Value** switch also affects what happens if there is no contract term for the bill factor. If the error switch is on, a billing error will be generated. If the error switch is off, no billing error will be generated and the calculation rule will be skipped.

Fastpath:

For an example of a bill factor whose value is specified in a contract term, refer to [Customer Specific Prices](#). For more information about how to specify a bill factor value in a customer's contract, refer to [Service Agreement - Rate Info](#).

Contract riders are used when the charge associated with the bill factor is only applicable to some customers for some period of time. For example, if a bill factor is used to provide a discount during the first 3 months of service, then a contract rider would be used. Turn on **Contract Rider Applicability** if the bill factor's applicability is contingent on the existence of a contract rider. This field will be gray if a contract rider referencing this bill factor exists on a service agreement.

Fastpath:

For an example of a bill factor whose value is dependent on a contract rider, refer to [Employee Discounts](#). For more information about how to establish a contract rider for a customer, refer to [Service Agreement - Contract Riders](#).

The proration information tells the system how to handle changes to bill factor values and their optional contract riders that may occur during a customer's bill period. Turn on **Allow Proration** if changes to the bill factor's value and/or contract riders should be prorated. If the **Bill Factor Type** is not specified as Interval and if changes should **not** be prorated, indicate the **Rate Selection Date Algorithm** to use when the system retrieves bill factor values or determines if contract riders are applicable.

If you have sub service agreements, turn on **Use Sub SA Contract** terms if billing should access contract riders, values, tax exemptions from the sub SA rather than the master. If this switch is off, the system will use the master SA's riders, contract value, and tax exemptions when it creates bills for a sub service agreement. Refer to [Sub Service Agreements](#) for more information.

If the Contract Management module is not **turned off**, which includes [umbrella agreement management](#), and you have checked either Tax Exemption, Value in Contract Term or Contract Rider Availability, indicate the **Terms of Service Usage**. Valid values are Check SA Only, Check TOS Only and Check TOS First, then SA. Refer to [Overriding Rate Terms](#) for details about how to set this value based on your business needs.

Bill Factor Tree

The right half of this page is dedicated to a tree that shows the bill factors characteristics and their respective values (for Regular bill factors) or interval value Sets (for Interval bill factors). You can use this tree to both view high level information about these objects and to transfer to the respective page in which an object is maintained by using the available Go To buttons.

Where Used

Many types of Rate Components may use a Bill Factor to define the price being charged. Refer to [Designing Calculation Groups and Rules](#) for more information.

The BILPC-TOTAL algorithm type that is used to levy late payment charges references the bill factor that defines the late payment charge percent. Refer to [SA Type - Main](#) for more information about this algorithm.

A Service Agreement references Bill Factors as follows:

- When a service agreement's Apply To calculation rule references tax exemptable bill factors AND the customer is tax exempt, the service agreement will define the bill factors from which the customer is exempt. Refer to [Service Agreement - Tax Exemptions](#) for more information.
- When a service agreement's rate references bill factors whose prices are customer-specific (i.e., specified on a contract term), the service agreement will contain prices for these bill factors. Refer to [Service Agreement - Contract Values](#) for more information.
- When a service agreement's rate references bill factors that are contingent on contract riders, the service agreement will define the rider period (if any) for these bill factors. Refer to [Service Agreement - Contract Riders](#) for more information.

Setting Up Bill Factor Characteristics

After defining general information about a bill factor, open **Menu > Rates > Bill Factor > Search** and navigate to the **Bill Factor Characteristics** page to define characteristic values where applicable. For example, a bill factor used to levy the applicable city tax would require the definition of every city that levies a tax.

Note:

If all values for a bill factor are specified in contract terms, you do not need to set up Bill Factor Characteristics.

Description of Page

Enter a **Characteristic Type** to indicate the type of characteristic that controls how the bill factor's value is defined. This field will be disabled if Bill Factor Characteristics are specified in the following grid.

The **Characteristic Source** defines where the system retrieves the characteristic value at billing time. The Characteristic Source options are:

| | |
|---------------------------|---|
| Account | The characteristic type's value will be retrieved from the service agreement's account. |
| Characteristic Collection | Refer to Deriving / Passing In Characteristic Values for an explanation of this value. |
| Main Person | The characteristic type's value will be retrieved from the main person linked to the service agreement's account. |
| N/A | The characteristic type's value is the same for all customers using the rate. If this option is used, you must still choose a Characteristic Type. This Characteristic Type should have a single Characteristic Value. The ID of the characteristic value must be identical to the ID of the characteristic type. |
| Premise | The characteristic type's value will be retrieved from the service agreement's characteristic premise. |
| SA | The characteristic type's value will be retrieved from the service agreement. |

SP

The characteristic type's value will be retrieved from the customer's service point. If multiple service points are linked to the service agreement, one will be chosen at random.

**Fastpath:**

For more information about characteristics, see [Setting Up Characteristic Types and Their Values](#) and [An Illustration Of A Bill Factor And Its Characteristics](#).

Use the add and remove buttons to define the **Characteristic Values** that are relevant for the bill factor's Characteristic Type. For example, if the bill factor is used to levy a city tax, you would define the city's that have a city tax in the above collection.

Use the **Minutes Per Interval** if your Bill Factor is of type Interval. This defines, for each characteristic value, the number of minutes expected between each record of interval data.

Use the **External ID** if the values for this characteristic are interfaced to the system from an external source and you want to record an identifier for the source.

If your Bill Factor is of type Interval and the [installation record](#) indicates that [seasonal time shift](#) is required, then you must enter the appropriate **Seasonal Time Shift** record applicable for the interval data. Please take special note of the issue described in the [Evenly Sized Intervals](#) section.

**Fastpath:**

For more information, refer to [Seasonal Time Shifts](#).

**Note:**

If the bill factor's value is the same for all customers, you still must link a "dummy" characteristic value to the bill factor. In other words, you'll have to create a characteristic type called "n/a" and define for it a characteristic value of "n/a". Then, on the bill factor, you reference the "n/a" characteristic type and on the above window, you indicate a characteristic value of "n/a".

Defining Bill Factor Values

After the bill factor and its characteristic values are defined, you define the price / percent and GL distribution associated with each bill factor characteristic. The topics in this section describe the pages used to set up this information.

Bill Factor Value - Main

After the bill factor and its characteristic values are defined, select **Menu > Rates > Bill Factor Value** to define the price / percent applicable to each bill factor characteristic.

**Important:**

You do not set up Bill Factor Values for bill factors whose values are specified in an interval value data set or if all the values are customer specific and are defined as contract terms. Refer to [Defining Interval Values](#) for more information about interval value sets. Refer to [Service Agreement - Contract Value](#) for more information about bill factors in contract terms.

Description of Page

Enter the **Effective Date** and respective **Value** for the bill factor and characteristic value. The first date should be the earliest date on which the bill factor's charges are effective. Subsequent effective dates and values are required whenever the value changes.

**Note:**

Default note. A **Value** of 0, zero, will be defaulted.

Bill Factor Value - GL Distribution

Select **Menu > Rates > Bill Factor Value** and navigate to the **GL Distribution** page to define the GL account affected by the bill factor characteristic.

Description of Page

If the bill factor characteristic's charges are booked to a different GL account depending on the characteristic value, specify the appropriate **Distribution Code** for each **Revenue Class**.

Important:

Specifying distribution codes on a bill factor is optional. You would only do this if the GL distribution code differs based on the characteristic value (such as, the city tax payable GL account differs depending on the city). If you do not enter the above information, the distribution code will be used.

The GL distribution code on the bill factor's value will not be used in the following cases:

- Value derived solely on contract value or contract value in combination with contract rider and/or tax exemption, where characteristic value is no longer used to determine the bill factor value.
- Value derived in calculate service quantity and math calculation rules where multiple bill factors may be configured in the rule resulting to multiple values contributing to the calculation of the line amount.

Rate Schedule Execution

When a rate schedule is executed, the system executes the calculation rules contained in the calculation groups defined for the rate schedule as follows:

1. First, the system executes the calculation rules defined within Pre-Processing Calculation Groups.
 - The rate engine may a bill segment calculation header for pre-processing calculations, if bill calculation lines are to be created.
 - Calculation groups are executed in order according to the Sequence defined on the rate schedule.
 - Calculation rules within each group are executed according to the Sequence configured within the group.
2. Next, the system executes the calculation rules within the Rate Version Calculation Groups. The system uses the Effective Date on each calculation group to determine which group(s) to execute. If more than one version of a calculation group is in effect during the billing period, the system may prorate the calculations, based on the configuration of the rate schedule.
 - The rate engine creates a separate bill segment calculation header for each rate version calculation group.
 - Calculation rules within each group are executed according to the Sequence configured within the group.
3. Finally, the system executes the calculation rules defined within Post-Processing Calculation Groups.
 - The rate engine creates a separate bill segment calculation header for post-processing calculations.
 - Calculation groups are executed in order according to the Sequence defined on the rate schedule.
 - Calculation rules within each group are executed according to the Sequence configured within the group.

Additional Information.

- After every rate version calculation group is processed, the rate application returns the calculation details to the process that called it. This point is important as it means that rate application executes in memory (i.e., it does NOT insert the calculation details on the database, rather, it returns them to whatever process called rate application). Because rate application executes in memory, it can be used to perform billing calculations in many parts of the system. For example:
 - Both online and batch billing use rate application to calculate the charges that are eventually saved on the bill's bill segments.
 - The [Rate Check](#) transaction calls rate application when you want to check a rate real-time. When you use this transaction, you enter the consumption that's passed into rate application and then rate application shows you the calculation details that result.

- Plug-ins exist that call rate application to estimate bill segments when adequate billing history doesn't exist. For example, the BUDCALC-PH budget recommendation algorithm calls rate application to calculate a budget amount for a customer without adequate history. Another example is the DEPRECOM-MBT deposit recommendation algorithm. This plug-in calls rate application to calculate a recommended deposit amount for a customer without adequate history.

Understanding Calculation Groups and Rules

This section provides descriptions of calculation groups and calculation rules, and describes how to identify components of rates that can be defined using calculation rules and groups.

About Calculation Groups and Rules

This section includes descriptions of calculation groups and calculation rules.

About Calculation Groups

Calculation groups are collections of calculation rules that are applied to calculate quantities for billing and billing charges for service agreements.

As noted previously, calculation groups are associated with specific rate schedules in one of three ways:

- **Pre-Processing Calculation Groups:** These are generally used to derive service quantities or measure measured quantities. The following illustrate some use cases of when a pre-processing calculation group might be needed:
 - When a rate contains prices for things that aren't measured directly by the customers' meters. For example, if the rate calculates a charge based on a service agreement's contracted quantity.
 - When a meter measures something in a unit of measure that has to be converted into a different unit of measure before it can be rated. For example, a meter measures gas in cubic feet, but the rate contains prices in therms.

During billing, a separate bill segment calculation header is produced for each Rate Version Calculation Group used to calculate charges. An additional calculation header is added if Pre-Processing Calculation Groups create bill calculation lines and by default, all these calculation lines are linked to a single calculation header. Before invoking the rate's Pre-Processing Calculation Groups, the rate engine processor builds the initial service quantity (SQ) collection based on the item collection and final values in the read collection.

- **Rate Version Calculation Groups:** These are the calculation groups used create a bill segment for the service agreement. Calculation rules that support rate version proration such as Service Quantity, Stepped Service Quantity, Item Type, Flat Charge, Maximum and Minimum Charge, must be executed only in a rate version calculation group.

When the system creates a bill segment for a service agreement, it checks if multiple Rate Version Calculation Groups are in effect during the bill period. If so, it uses the rate's **Allow RV Proration** and **RV Selection Date** values to determine if it should prorate the various Rate Version Calculation Groups, or if it should pick one of the Rate Version Calculation Groups effective during the bill period. Rate Version Calculation Groups are executed after the rate's pre-processing calculation groups.

- **Effective Date:** defines the date on which each rate version calculation group becomes effective.
- **Description on Bill:** Specifies the description of the rate version calculation group on the bill. This description is saved on bill calculation details created using this rate version calculation group. Substitution characters may be used to substitute variables into the description during billing. Refer to [How To Use Description on Bill](#) in the [Defining Calculation Rules](#) chapter for a discussion of the various substitution variables.
- **Post-Processing Calculation Groups:** These are similar to Pre-Processing Calculation Groups, except that these are executed after the Rate Version Calculation Groups. The intended types of functionality include applying taxes on calculated charges, or deriving more complex GL distribution.

Calculation rules that support rate version proration such as Service Quantity, Stepped Service Quantity, Item Type, Flat Charge, Maximum and Minimum Charge, are not designed to be executed in post and pre-processing calculation groups.

During billing, a separate bill segment calculation header is produced for each Rate Version Calculation Group used to calculate charges. An additional calculation header is added if Post-Processing Calculation Groups create bill calculation lines and by default, all these calculation lines are linked to a single calculation header.

Calculation groups can also be referenced by "Execute Calculation Group" calculation rules. See "Execute Calculation Group Rules - Nesting Calculation Rules" in [About Calculation Rules](#) for more information.

About Calculation Rules

Calculation rules are standard and custom rules that perform calculations used when calculating quantities for billing and billing charges for a customer's service agreements.

Calculation rules are created for a specific calculation group. For example, if you were configuring two calculation groups and both included a specific calculation rule, you would need to create two instances of the calculation rule, one for each group.

Attributes used to define calculation rules typically include the following:

- **Basic Information:** Basic information about the calculation rule, including its name and description, the calculation group to which the rule belongs, the sequence of the rule within the group, the description that appears on the bill, and other information. This information is standard for most calculation rules.
- **Parameters:** The parameters used by the rule. Parameters are specific to each rule. See [Base Package Calculation Rule Descriptions](#) for details about the calculation rules included with the base package.

Execute Calculation Group Rules - Nesting Calculation Rules

Execute Calculation Group rules are used to define business logic to allow reference to a separated specified calculation group. This allows rules that are used frequently to be bunched under a single calculation group, which can be referenced / called by other rules as needed. For example, if a set of standard rules should be applied to all rate schedules, this set of rules can be configured as part of a calculation group, which is referenced by a single calculation rule of this type. Execute Calculation Group rules use the following options:

- **Referred Calculation Group:** defines the calculation group referenced by the rule.
- **Characteristics:** defines additional calculation rule attributes that may be used in rate processing or for reporting purposes. A calculation rule's characteristics are copied onto the resultant bill lines for those characteristic types that are allowed on bill segment calculation lines.

Note: There is a limit of 99 calculation groups that can be called from a calculation group defined directly on a rate schedule or via related child calculation groups when using Execute Calculation Group calculation rules.

Eligibility Criteria

Calculation rule eligibility criteria are user-definable conditions that could cause a given calculation rule to be applied or skipped. This can involve the evaluation of some attribute of the service agreement, or service point, or something else entirely.

A calculation rule can have multiple eligibility criteria for determining if the rule should be applied or skipped, based on a user-defined sequence. Each eligibility criteria uses the following settings:

- **Criteria Comparison:** defines the specific comparison for the criteria, based on the following:
 - **Criteria Field Type:** the means used to retrieve the value of the criteria field (algorithm, bill factor, calculation line, characteristic, contract quantity, service quantity, or historic service quantity)
 - **Comparison Operator:** the operator used in the comparison
 - **Comparison Value:** a user-specified value to which the retrieved value is compared (using the comparison operator)
- **Comparison Results:** defines how the rule should behave, based on the results of the comparison defined under Criteria Comparison:
 - **If True:** the action to take if the comparison is true

- **If False:** the action to take if the comparison is false
- **If Insufficient Data:** the action to take if there is insufficient data to perform the comparison

Calculation Line Category Types

Calculation line category types are used to establish connections between calculation rules. Calculation rules can specify a member category and value to which they belong. When this same category and value are referenced as a "Target Category" by other rules (the rule is applied to the results of rate version calculation rules (defined in the same rate schedule) that belong to the category and value.

For example, calculation rules whose results are subject to taxes might belong to the "Subject to Tax" (TAXABLE) category and "County Tax" value. Apply To calculation rules defined for the same rate schedule with a target category of "Subject to Tax" and "County Tax" values are applied to "Subject to Tax" member rules.

Calculation Line Category Types are defined by the following:

- **Calculation Line Category Type:** The unique identifier of a calculation line category type definition
- **Description:** The description of the calculation line category type.
- **Category Values:** The valid category values for the calculation line category type.

Base Package Calculation Rules

Oracle Utilities Customer Care and Billing includes the following base package calculation rule types that can be used when creating calculation rules:

- **Apply To:** Used to create bill lines that levy charges based on amounts calculated on other bill lines.
- **Calculate Final Reading Values:** Used to determine the final values for readings based on user-defined UOM/TOU/SQI.
- **Calculate Service Quantity:** Used to derive or calculate a service quantity that is eventually inserted into the bill segment SQ collection.
- **Copy Service Quantity From Master Bill Segment:** Used to copy all the entries from the master bill segment SQ collection to the sub bill segment SQ collection.
- **Execute Calculation Group:** Used to call and pass parameters to another calculation group.
- **Flat Charge:** Used to create bill lines that levy service charges and fees that aren't based on how much the customer uses.
- **Item Type:** Used to create bill lines that levy charges based on the number and type of items used by a customer. The system keeps track of items on the service point(s) linked to the customer's service agreement.
- **Math:** Used to derive interval data based on a formula, and apply TOU mappings and/or other operations to the derived data to calculate service quantities
- **Maximum Charge:** Used to create bill lines that levy charges only when the sum of previously calculated lines is more than the maximum charge amount.
- **Minimum Charge:** Used to create bill lines that levy charges only when the sum of previously calculated lines is less than the minimum charge amount.
- **Service Quantity:** Used to create bill lines that levy charges based on some type of consumption.
- **Simple Summary:** Used to create a "subtotal" on the bill, by summarizing bill lines produced by other calculation rules in the same calculation group.
- **Stepped Service Quantity:** Used to create bill lines that levy charges based on some type of consumption when different prices are applied to different ranges of consumption (for example, the first 50 kWh are \$0.43 per kWh, anything in excess of 50 kWh is charged at \$0.71 per kWh)
- **Summary:** Used to create a "subtotal" on the bill. It exists purely for reporting and informational purposes.

See [Base Package Calculation Rule Descriptions](#) for details about each of these calculation rules.

Designing Calculation Groups and Rules

Before starting to design calculation groups and rules for your rates, please review the concepts outlines in the **Designing Rate Components** section in the [Rates](#) chapter. That section provides a good background for understanding how to break down rates into component pieces that can be modeled by calculation groups and rules.

This section provides guidelines for how to design and plan the calculation groups and rules you will need for your rates, and provides a simple case study of how to define the calculation rules and groups you might use for a set of rates for a small municipal electric company.

Analyzing Your Rates and Identifying Calculation Rules and Groups

One of the steps you will go through when implementing your rates is to look at the bill lines for your rates and ask yourself what are the variables that cause each line's charges to be calculated the way they are. After you've determined all of the potential bill lines you can start designing your calculation groups and rules. Typically, you create one calculation rule for every line that can appear on the customer's bill. These rules can be grouped in different configurations based on how you want your bills to appear and the needs of your implementation. Recall that bill segment calculation headers are created for Pre-Processing, Rate Version, and Post-Processing calculation groups. In addition, most rules can be configured generate a bill line.

Best Practices

When designing calculation groups and rules, the following general rules apply:

- **Pre-Processing Calculation Groups.** Perform any initial processing or conversions that should occur before the rate version calculation group. This can include:
 - Calculating the number of days in a billing period (Calculate Service Quantity)
 - Calculating service quantities that are not measured (demand, kVa, etc.) (Calculate Final Reading Values, Calculate Service Quantity, Math)
 - Validating that consumption is within tolerances set by the rate (residential limits, etc.) (Calculate Service Quantity, with eligibility criteria)
- Calculations processed by calculation rules should be performed by **Rate Version Calculation Groups.** This includes most charge calculations, including:
 - Charges based on service quantities (Service Quantity, Stepped Service Quantity)
 - Customer charges (Flat Charge)
 - Minimum/maximum charges (Minimum Charge, Maximum Charge)
 - Discounts (Apply To)
 - Taxes (Apply To)
 - Summaries (Summary, Simple Summary)
- Additional processing should be performed by **Post-Processing Calculation Groups.** This can include:
 - Allocating consumption/revenue (energy revenue vs. demand revenue) (Service Quantity)

Example Configurations

Let's look at a couple of different possible configurations for a simple electric rate that includes the following:

- Customer Charge
- Service Charge (price per kWh)
- Minimum Charge
- Discount

This rate could be set up in the following ways:

- A single Rate Version calculation group that contains a calculation rule for each of the above
- A set of Rate Version calculation groups as follows:
 - A calculation group for "flat" charges, such as the Customer Charge
 - A calculation group for consumption-based charges (including the Service Charge and Minimum Charge).
 - A calculation group for discounts or other charges applied to the total of other charges (which would include the Discount)

There are no hard and fast rules concerning how calculation rules should be grouped. How this is done should be based on the specific needs of the implementation but it's a good idea to look for ways to keep your configuration

simple for maintenance and upkeep purposes. This includes changes to existing rates as well as adding/removing rates over time.

Reusing Calculation Rules

One of the steps you will go through when implementing your rates is to look at the bill lines for your rates and ask yourself what are the variables that cause each line's charges to be calculated the way they are. After you've determined all of the potential bill lines you can start designing your calculation groups and rules. Typically, you create one calculation rule for every line that can appear on the customer's bill. These rules can be grouped in different configurations based on how you want your bills to appear and the needs of your implementation. Recall that bill segment calculation headers are created for Pre-Processing, Rate Version, and Post-Processing calculation groups. In addition, most rules can be configured generate a bill line.

Identifying Calculation Rules that can be Shared/Reused

As you analyze the bill lines used by your rates, you should look for bill lines that utilize similar or identical variables or calculations. These calculations are candidates for reuse. For example, if all of your residential rates offer a discount for early payment, you would want to create a single rule to calculate that discount, and then use it each of the rates to which it applies.

How to Reuse Calculation Rules

There are two approaches that can be used to reuse calculation rules.

- **Encapsulating Rules in a Calculation Group**

This approach involves grouping rules that can be applied to more than one rate into a single calculation group. You would use this approach when you identify charges and other components in your rates that apply to multiple rates, but that can be grouped together. Taxes for multiple types of jurisdictions (for example, State, County, and City) would be suitable for this approach.

To use this approach, you simply create a calculation group that contains the rules to be applied to more than one rate. For the tax example, you might create the following group and rules:

Calculation Group: Taxes, which includes:

Calculation Rule: State Tax (Apply To)

Calculation Rule: County Tax (Apply To)

Calculation Rule: City Tax (Apply To)

This "Taxes" calculation group can be included as a Rate Version Calculation Group in each of the rates to which the taxes apply. This calculation group could also be referenced by an "Execute Calculation Group" rule, as outlined below.

- **Using "Execute Calculation Group" Rules**

This approach involves creating a calculation group that contains one or more rules, which is then referenced by another "Execute Calculation Group" rule. This approach can be used when you identify a charge or calculation that could be applicable within one or more calculation groups. For example, if multiple rates involve calculating peak demand (or some other quantity that is not measured by your customers' meters), you could create a "Calculate Demand" rule and include it in a group that is then referenced by an "Execute Calculation Group" rule.

To use this approach, you create a calculation group that contains the calculation rules to be used within multiple calculation groups. You then create an "Execute Calculation Group" rule that references the group. Last, you include this "Execute Calculation Group" rule in the calculation groups to which it applies. For the calculate demand example, you might create the following:

Calculation Rule: Calculate Demand (Execute Calculation Group), which references:

Calculation Group: Calculate Demand, which includes:

Calculation Rule: Calculate Demand (Calculate Service Quantity)

The "Calculate Demand" Execute Calculation Group rule can be included in any calculation group used to calculate service quantities that includes calculating peak demand.

"Execute Calculation Group" rules can be used with any calculation group. To return the taxes example from above, if you wanted to include your "Taxes" calculation group within other groups, you could use the following:

Calculation Rule: Taxes (Execute Calculation Group), which references:

Calculation Group: Taxes, which includes:

Calculation Rule: State Tax (Apply To)

Calculation Rule: County Tax (Apply To)

Calculation Rule: City Tax (Apply To)

See "Execute Calculation Group Rules - Nesting Calculation Rules" in [About Calculation Rules](#) for more information about Execute Calculation Group rules.

Leveraging Eligibility Criteria to Dynamically Apply Calculation Rules

Another tool to consider when creating your calculation groups and rules is Eligibility Criteria. Eligibility criteria allow you to define rules that determine the conditions under which a calculation rule is applied or not.

For example, if you need to calculate demand for one or more of your rates, you might create separate calculation rules to calculate demand based on interval values of different units of measure (kWh vs kVarh for instance). You could create rules for each and include them in a single "Calculate Demand" calculation group, but assign eligibility criteria to each such that they are only executed when processing for the specified unit of measure.

See Eligibility Criteria in [About Calculation Rules](#) for more information about eligibility criteria and how they can be used with calculation rules. In addition, refer to **The Big Picture of Rate Component Eligibility Rules** in the [Rates](#) chapter for additional background on eligibility criteria.

Case Study: Three Sample Rates

Let's look at a sample set of rates, and how they might be implemented. We'll also look at which components of these rates can be shared.

Rates

The following rates are electric rates offered by a small municipal electric company.

| Rate | Domestic Rate A | Commercial Rate B | Power Rate C |
|-------------------------------------|--|---|--|
| Cost of Service | <p>Stepped charges, as follows:</p> <p>\$3.08 for the first 10 kWh or less, plus</p> <p>19.23 cents per kWh for the next 40 kWh, plus</p> <p>15.44 cents per kWh for the next 150 kWh, plus</p> <p>14.93 cents per kWh for the next 300 kWh, plus</p> <p>14.71 cents per kWh for all kWh in excess of 500 kWh</p> | <p>Stepped charges, as follows:</p> <p>\$2.95 for the first 10 kWh or less, plus</p> <p>19.23 cents per kWh for the next 40 kWh, plus</p> <p>18.85 cents per kWh for the next 50 kWh, plus</p> <p>16.86 cents per kWh for the next 400 kWh, plus</p> <p>15.45 cents per kWh for the next 3,000 kWh, plus</p> <p>14.87 cents per kWh for all kWh in excess of 3,500 kWh.</p> | <p>1. Customer Charge:\$52.00</p> <p>2. Demand: \$11.44 per KW</p> <p>3. Energy: \$11.28 cents per KWH</p> <p>Billing Demand</p> <p>The Billing Demand for any month shall be the greater of the following:</p> <p>1. The maximum 15 minute measured demand during the month as measured in kilowatts, or</p> <p>2. 70% of the maximum 15 minute measured demand as so determined during the preceding 11 months.</p> |
| Discount | <p>Discount of ½ cent per kilowatt-hour after the first 10 kilowatt-hours, if paid on or before the discount expiration date.</p> <p>For qualifying elderly residents, an additional 10% discount is allowed on the basic rate if paid on or before the discount expiration date and no arrears exist on their accounts.</p> | <p>Discount of ½ cent per kilowatt-hour after the first 10 kilowatt-hours, if paid on or before the discount expiration date.</p> | <p>Discount of 10% exclusive of purchased power and fuel adjustment charge paid on or before the discount expiration date.</p> |
| Purchased Power and Fuel Adjustment | <p>An upward or downward adjustment applied to all kWh sold, based on the total cost of purchased power and fuel compared to the portion of that cost contained in the base rate (11.615 cents/kWh).</p> <p>The purchase power and fuel adjustment shall be rounded to the sixth decimal place and shall be applied to all kilowatt-hours sold in the following month.</p> | See Domestic Rate A | See Domestic Rate A |

| Rate | Domestic Rate A | Commercial Rate B | Power Rate C |
|-------|-------------------------------|-------------------------------|--|
| Misc. | N/A | N/A | Minimum Bill The Customer Charge |
| Taxes | State, County, and City Taxes | State, County, and City Taxes | State, County, and City Taxes |

Calculation Rules

Now let's look at these same rates in terms of how we might implement them using calculation rules. The table below lists the type of calculation rule used for each item on the rate.

| Rate | Domestic Rate A | Commercial Rate B | Power Rate C |
|-------------------------------------|---|--|--|
| Cost of Service | Stepped Charges: <ul style="list-style-type: none"> • Stepped Service Quantity calculation rule • Minimum Charge calculation rule (note that the first tier is a fixed price for the first 10 kWh or less) | Stepped Charges: <ul style="list-style-type: none"> • Stepped Service Quantity calculation rule • Minimum Charge calculation rule (note that the first tier is a fixed price for the first 10 kWh or less) | Customer Charge: <ul style="list-style-type: none"> • Flat Charge calculation rule Demand: <ul style="list-style-type: none"> • Service Quantity calculation rule • Math calculation rule (to calculate demand from interval values)* Energy: <ul style="list-style-type: none"> • Service Quantity calculation rule *Could be included in either a Pre-Processing or Rate Version Calculation Group |
| Discount | Discount: <ul style="list-style-type: none"> • Apply To calculation rule Elderly Discount: <ul style="list-style-type: none"> • Apply To calculation rule | Discount: <ul style="list-style-type: none"> • Apply To calculation rule | Discount: <ul style="list-style-type: none"> • Apply To calculation rule |
| Purchased Power and Fuel Adjustment | PPF Adjustment: <ul style="list-style-type: none"> • Service Quantity calculation rule <p>Note: The PPF adjustment rate would be defined as a Bill Factor, updated monthly based on the prior month's total cost.</p> | PPF Adjustment: <ul style="list-style-type: none"> • Service Quantity calculation rule | PPF Adjustment: <ul style="list-style-type: none"> • Service Quantity calculation rule |
| Misc. | N/A | N/A | Minimum Bill: <ul style="list-style-type: none"> • Minimum Charge calculation rule |

| Rate | Domestic Rate A | Commercial Rate B | Power Rate C |
|-------|--|--|--|
| Taxes | State, County, and City Taxes: <ul style="list-style-type: none"> Apply To calculation rule (one for each type of tax) | State, County, and City Taxes: <ul style="list-style-type: none"> Apply To calculation rule (one for each type of tax) | State, County, and City Taxes: <ul style="list-style-type: none"> Apply To calculation rule (one for each type of tax) |

Shared Components

Now, let's look at the components of these rates that can be shared.

Discounts: Rates A and B both use the same discount, so we could create a single "AB Discount" calculation rule that could be used with both rates. Note: Either this could be in its own calculation group that is listed among the Rate Version Calculation Groups for each rate, or the group could be referenced by an "Execute Calculation Group" rule which in turn would be included in one of the other Rate Version Calculation Groups used in each rate.

Purchased Power and Fuel Adjustment: Rates A, B, and C all use the same adjustment for purchased power and fuel, so we could create a single "PPF Adjustment" calculation rule that could be used with all three rates. Again, this calculation rule could be in its own calculation group listed on the rate, or in a group referenced by an "Execute Calculation Group" rule included in another group.

Taxes: Rates A, B, and C are all subject to the same taxes, so we could create calculation rules for each type of tax (State, County, and City) in a single group that could be used with all three rates. Again, these calculation rules could be in their own calculation group listed on the rate, or in a group referenced by an "Execute Calculation Group" rule included in another group.

The Big Picture of Calculation Rule Eligibility Rules

You can use eligibility rules to define the criteria when a calculation rule should be applied (or skipped); for example,

- You may have a calculation rule that generates an employee discount. This calculation rule may have eligibility criteria that requires the person to have a given characteristic type and value (this assumes you use a person characteristic to identify employees) before the calculation rule is applied.
- You may have a calculation rule that applies a surcharge if the customer uses 25% more than they used in the same period in prior year.

Note:

Eligibility rules are optional. If you add eligibility rules to a calculation rule, the calculation rule will be skipped or applied per the instructions in the rules. If you don't add eligibility rules to a calculation rule, however, the calculation rule will be executed – this is because calculation rules are eligible by default

The topics in this section describe eligibility rules.

A Rate Component is Eligible by Default

If you don't want to setup eligibility rules, you don't have to. If you don't specify eligibility rules on a calculation rule, it's eligible and will be processed by rate application.

Defining Logical Eligibility Criteria

When you setup an eligibility criterion, you must define three things:

- The field to be compared
- The comparison method
- The comparison results

Criteria Comparison

You have the following choices in respect of identifying the **Criteria Field Type**:

- **Algorithm.** You can execute an algorithm to retrieve a field value from someplace else in the system. This is a very powerful feature, but it's not terribly intuitive. We'll present an example later in this section to illustrate the power of this approach.
- **Bill Factor.** You can retrieve a bill factor value to use as a field value in the comparison.
- **Calc Line.** You can retrieve a calculation line amount to use as a field value. The value is derived by summing calculation lines defined as members of a target category.
- **Characteristic.** You can retrieve a characteristic value linked to any of the following:
 - The service agreement being billed
 - The service agreement's account
 - The main person linked to the service agreement's account
 - The characteristic premise linked to the service agreement
 - One of the service points linked to the service agreement
 - In addition, you can retrieve a characteristic value from the Characteristic Collection where values are derived while the rate is being calculated (characteristic values can be created by calculation rules)
- **Contract Quantity.** You can retrieve a contract quantity for the service agreement.
- **Service Quantity.** You can retrieve the value of a given service quantity from the SQ collection based on a specified UOM / TOU / SQL.
- **Historical Quantity.** You can derive a value based on the service agreement's historical bill segment service quantities for the specified UOM / TOU / SQL.

You have the following choices in respect of identifying the **Comparison Method**:

- You can choose an operator (e.g., >, <, =, BETWEEN, IN, etc.) and a comparison value

Comparison Results

Once you have this information and have applied your comparison, you must define what action should be taken. You must specify what to do if the results are True, False, or Insufficient Data.

- **If True or False.** You have the option to apply the rule or not, or check the next condition.
- **If Insufficient Data.** You have the option apply the rule or not, check the next condition, or generate an error.

See [Examples of Calculation Rule Eligibility Rules](#) for illustrations of these rules.

Examples of Calculation Rule Eligibility Rules

The topics in this section provide examples about how to setup calculation rule eligibility rules.

A Calculation Rule with a Service Quantity Comparison

Imagine a calculation rule that is only eligible if the customer is a low-income customer and has used more than 1,000 kWh. This calculation rule would need the following eligibility rules:

- Customer is a low income customer
- The customer has used more than 1,000 kWh during the bill period

These rules will look as follows:

| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
|-----|------------------|-------------------|---------|----------|----------------------|
|-----|------------------|-------------------|---------|----------|----------------------|

| | | | | | |
|----|---|----------|----------------------|-------------------|-------------------|
| 10 | Main person characteristic: Characteristic type = Low income indicator | = YES | Check next condition | Do Not Apply Rule | Do Not Apply Rule |
| 20 | SQ value: UOM = KWH | >= 1,000 | Apply Rule | Do Not Apply Rule | Error |

The criteria are similar - they retrieve a value and compare it to something:

The first criterion is fairly simple:

- **Field to Compare.** We indicate that the value of the Low Income Indicator characteristic is kept on the main person linked to the account should be retrieved. We assumed that this characteristic type has values of YES and NO.
- **Comparison Method and Results.** We indicate that if the person has a characteristic value of YES, then we should check the next condition; otherwise, we indicate if the eligibility rule is false or there is insufficient data, the calculation rule is skipped.

The second criterion works similarly:

- **Field to Compare.** We indicate the service quantity (SQ) that holds the total amount of KWH that should be retrieved.
- **Comparison Method and Results.** We simply compare the value to 1,000. If the SQ is greater than or equal to 1000, the eligibility rule is True and the calculation rule is applied. If the SQ is less than 1000, the eligibility rule is false and the calculation rule is skipped. If there is insufficient data, there is an error generated.

A Calculation Rule with a Characteristic Lookup and Consumption Comparison

Imagine a calculation rule that is eligible for customers who have signed up for a consumption reduction program and have low consumption. This would require the following criteria:

- Check that the customer has signed up for the reduction program.
- Check to see that the customer's consumption is lower than the threshold.

These rules will look as follows:

| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
|-----|---|-------------------|----------------------|-------------------|----------------------|
| 10 | Check if the customer has signed up for the reduction program | = Y | Check next condition | Do Not Apply Rule | Do Not Apply Rule |
| 20 | Check if consumption is less than the threshold | <= 100 Kilowatt | Apply Rule | Do Not Apply Rule | Do Not Apply Rule |

The criteria are similar - they retrieve a value and compare it to something:

The first criterion works as follows:

- **Field to Compare.** We indicate the value of the reduction program characteristic type (CI_CLMSM) is found on the service agreement. We assumed that this characteristic type has values of Y and N.
- **Comparison Method and Results.** Comparison Method and Results. We indicate that if the service agreement has a characteristic value of Y, then we should check the next condition. If the condition is false or insufficient data, the calculation rule is skipped.

The second criterion works as follows:

- **Field to Compare.** We indicate the service quantity (SQ) that holds the total amount of KW that should be retrieved.
- **Comparison Method and Results.** We indicate that we want to compare the service quantity to the threshold (100 kW). If the service agreement's bill segment has a service quantity that is less than or equal to 100 kW, it is True and the calculation rule is applied. If the condition is false or insufficient data, the calculation rule is skipped.

A Calculation Rule with a Discount for Being on Autopay

Imagine a calculation rule that is only eligible if the current customer has signed up for Autopay. This calculation rule would need the following eligibility rule:

- Customer has Autopay

This rule will look as follows:

| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
|-----|--|-------------------|------------|-------------------|----------------------|
| 10 | Algorithm: check if customer has Autopay | = Y | Apply Rule | Do Not Apply Rule | Do Not Apply Rule |

The criterion calls an algorithm that performs a logical comparison.

The criterion works as follows:

- **Field to Compare.** We chose a "field to compare" algorithm that checks if the account associated with the bill segment is on Autopay. If an autopay setup exists, then it returns a value of Y. If not, however, it returns N
- **Comparison Method and Results.** We simply compare the value returned by the algorithm to Y and indicate the appropriate response. If the condition is true, the calculation rule is applied. If the condition is false or insufficient data, the calculation rule is skipped.

Note:

Refer to CI_CHK_APAY for more information about this algorithm.

Working with Calculation Groups and Rules

This section outlines how users work with calculation groups and calculation rules.

Defining Calculation Groups

Use this procedure to define calculation groups.

- Select **Menu > Rates > Calculation Group > Add.**
- Enter a **Name** for the calculation group.
- Enter a short **Description** and **Detailed Description** for the group.
- Click **Save.**

Note: You can also add a calculation group directly from the Rate Schedule portal. The **Add Calculation Group** action on the Pre-Processing Calculation Groups, Rate Version Calculation Groups and Post-Processing Calculation Groups sections allows you to create the calculation group and link the new group to the Rate Schedule.

To add a calculation rule to the calculation group, click the **Add Rule** link in the **Calculation Rules List** zone title bar. See [Defining Calculation Rules](#) for more information about creating calculation rules.

You can now create calculation rules for this group.

See [About Calculation Groups](#) for more information about calculation groups.

Searching and Maintaining Calculation Groups

Use this procedure to search for and view a calculation group.

- Select **Menu > Rates > Calculation Group > Search**.
- Enter your search criteria.

You can search by **Calculation Group** name or **Description**.

- Click **Refresh**.
- In the search results list, click the **Description** link for the calculation group you want to view or edit.

The selected calculation group is displayed in the **Calculation Group** portal. You use this portal to maintain calculation groups. This portal includes the following zones:

- **Calculation Group:** Defines basic information about calculation group
- **Calculation Rules List:** lists the calculation rules belonging to the group. Eligibility criteria referenced by a calculation rule are listed indented beneath each rule. If a calculation rule in turn references a calculation group, the calculation group executed by the rule is displayed.
- **Referencing Rates Schedules List:** lists the rates schedules that reference the group
- **Referencing Calculation Rules List:** lists the calculation rules that reference the group

Use this procedure to maintain a calculation group:

- Select **Menu > Rates > Calculation Group > Search** to navigate to the Calculation Group Query portal.
- Search for and select the appropriate calculation group.
- Click **Edit**, **Delete**, or **Duplicate** as appropriate.
- To add a calculation rule to the calculation group, click the **Add Rule** link in the **Calculation Rules List** zone title bar. See [Defining Calculation Rules](#) for more information about creating calculation rules.
- To update the sequence values for all calculation rules in the group, click the **Resequence All Rules** link in the **Calculation Rules List** zone title bar.
 - Edit the sequence values for all rules by specifying new **Start Sequence** and **Increment By** values.
 - Click **OK** to update the calculation rules with new sequence numbers.
- To Edit or Delete a specific calculation rule in the group, select the **Edit** or **Delete** icon in the Calculation Rules List zone as appropriate.
- To Delete one or more of the calculation rules in the group:
 - Select one or more of the calculation rules you want to delete.
 - Click **Delete Calc Rules**.
 - Click **OK** to delete the selected calculation rules
- To update the bill print details for one or more of the calculation rules in the group:
 - Select one or more of the calculation rules for which you want to change the bill print details.
 - Click **Update Bill Print**.
 - Edit the bill print details for the selected calculation rules.
 - Click **Save** to update the selected calculation rules with the new bill print details.
- To change the sequence values for one or more of the calculation rules in the group:
 - Select one or more of the calculation rules for which you want to change the sequence values.
 - Click **Resequence Rules**.
 - Edit the sequence values for all the selected calculation rules.
 - Click **Save** to update the selected calculation rules with the new sequence values.

See [About Calculation Groups](#) for more information about calculation groups.

Defining Calculation Line Category Types

Use this procedure to define calculation line category types.

- Select **Menu > Rates > Calculation Line Category Type > Add.**
- Enter a **Category Type** name for the category type.
- Enter a short **Description** and **Detailed Description** for the category type.
- Define the **Category Value** and **Description** for each value for the category type.
- Click **Save.**

You can now reference this category and its values as either the Member Category or Target Category on calculation rules.

See "Calculation Line Category Types" in [About Calculation Rules](#) for more information about calculation line category types.

Maintaining Calculation Line Category Types

Use this procedure to search for and maintain calculation line category types.

- Select **Menu > Rates > Calculation Line Category Type > Search.**
The **Calculation Line Category Type List** zone displays the calculation line category types defined in the system.
- Click the broadcast icon for the calculation line category type you wish to view and/or edit.
The selected calculation line category type is displayed in the **Calculation Line Category Type** zone.
- Click **Edit**, **Delete**, or **Duplicate** as appropriate.

See "Calculation Line Category Types" in [About Calculation Rules](#) for more information about calculation line category types.

Defining Calculation Rules

Use this procedure to define calculation rules.

- Select **Menu > Rates > Calculation Rule > Add.**
- Select the **Calculation Group** to which the rule will belong.
- Select the **Calculation Rule BO** for the calculation rule.

Refer to [Base Package Calculation Rule Descriptions](#) for detailed descriptions of the available calculation rules and their associated business objects.

- Enter name for the **Calculation Rule.**
- Enter the **Sequence** for the rule. This designates the order in which the rule will be executed within its parent calculation group.
- Enter a short **Description** and **Detailed Description** for the rule.
- Enter or select other parameters for the rule as appropriate.

Refer to [Base Package Calculation Rule Descriptions](#) for detailed descriptions of the available calculation rules and the parameters used by each.

- Click **Save.**

See [About Calculation Rules](#) for more information about calculation rules.

How to Use Description on Bill

Enter the verbiage to appear on the bill segment in the **Description On Bill**. Turn on **Print** if the verbiage should appear on the printed bill.

Note:

Suppressing calculation details on the printed bill. Only calculation rules that are used to calculate intermediate values are typically suppressed on a bill. For these types of calculation rules, we recommend using **Description on Bill** to show users how the line was calculated, but select No from the **Print** dropdown menu. This way, users will see the calculation details on the [Bill Segment - Calc Lines](#) window, but the customer won't see it on their bill.

Many lines that appear on a bill do not contain static verbiage. Rather, the printed lines contain information from the calculation process. For example, the bill line for state tax would typically contain the tax percent.

You control exactly what is substituted in the bill line by entering one or more of the following substitution variables in the **Description on Bill** field:

Note: If none of the following substitution characters satisfy your need, there is a plug-in option on the calculation rule business object that allows customer modified variables. Algorithms can be attached to the business object as a Build Line Description system event.

| Substitution Character | What It Does |
|------------------------|--|
| %A | <p>Replaces the substitution character with the amount of the bill line. Please be aware of the following:</p> <ul style="list-style-type: none"> • If the calculation rule isn't designated as being "for calculation purposes only" (FCPO), all trailing zeroes up to the decimal position of the rate's currency will be removed. If the calculation rule is designated as being "for calculation purposes only" (FCPO), the number of decimal places as defined in the calculation rule's precision will be shown. • All leading zeroes will be removed unless the value is between 1 and -1 in which case a leading 0 will appear before the decimal place. • The Symbol on the Currency control table will prefix the value. • The position of the negative sign and currency symbol is dependent on the display profile of the user who generate the bill (or who submitted the batch billing process). |
| %B | <p>Replaces the substitution character with the begin/start date covered by the bill calculation line.</p> <p>If the charge is proratable, %B may be used in conjunction with %E to display the period covered by the bill calculation line.</p> |
| %C | <p>Replaces the substitution character with the number of items being billed. Leading zeroes are suppressed.</p> |

%D

Replaces the substitution character with message 10101 from message category 11109. This message is maintained in the standard message table.

We recommend this message be set to "(prorated for %1 of %2 days)" where %1 will be substituted with the number of days of prorated consumption charged on the bill line and %2 will be the "normal" days associated with the rate's prices. This message will only be substituted when the calculation rule is prorated. Note, neither %1 nor %2 are required.

Either this character OR %F should be used when you desire to substitute the price / percent into the bill line.

If the charge is prorable, %D should be used in conjunction with %R to print an appropriate message when the charges are prorated.

%E

Replaces the substitution character with the end date covered by the bill calculation line.

If the charge is prorable, %E may be used in conjunction with %B to display the period covered by the bill calculation line.

%F

Replaces the substitution character with message 10102 from message category 11109. This message is maintained in the standard message table.

We recommend this message be set to "(prorated by %1)" where %1 will be substituted with the factor used to prorate the charge. This message will only be substituted when the calculation rule is prorated. Note, %1 is not required.

If the charge is prorable, %F should be used in conjunction with %I to print an appropriate message when the charges are prorated.

%H

Replaces the substitution character with the high value defined on the calculation rule used to calculate the specific stepped charge on the bill line.

| | |
|----|--|
| %I | <p>Replaces the substitution character with the value specified in the calculation rule / bill factor.</p> <p>If the value is a percent,</p> <ul style="list-style-type: none"> • all leading and trailing zeroes will be suppressed, • and a "%" will be suffixed to the resultant value. <p>If the value is not a percent,</p> <ul style="list-style-type: none"> • all trailing zeroes up to the decimal position of the rate's currency will be removed, • and all leading zeroes will be removed unless the value is between 1 and -1 in which case a leading 0 will appear before the decimal place, • and note that the position of the negative sign and currency symbol is dependent on the display profile of the user who generate the bill (or who submitted the batch billing process). <p>Either this character OR %R should be used when you desire to substitute the price / percent into the bill line. Using %I will cause the value as specified in the calculation rule to be substituted regardless of whether the charges are prorated.</p> <p>If the charge is prorable, %I should be used in conjunction with %F to print an appropriate message when the charges are prorated.</p> |
| %L | <p>Replaces the substitution character with the low value defined on the calculation rule used to calculate the specific stepped charge on the bill line.</p> |
| %M | <p>Replaces the substitution character with the item type defined on the calculation rule used to calculate the specific item type charge on the bill line.</p> <p>This is only applicable to calculation rule-based rates.</p> |
| %O | <p>Replaces the substitution character with the description of the time-of-use (TOU) code being billed on this line</p> |
| %Q | <p>Replaces the substitution character with the service quantity being billed. Leading zeroes are suppressed. The decimal places shown are specified in a field on the Unit Of Measure control table.</p> <p>If you wish to suppress trailing zeroes after the decimal, you must set up the Allow Consumption Zero Suppression In Bill Description option type on the Financial Transaction Options Feature Configuration.</p> |

| | |
|------------------------|---|
| %R | <p>Replaces the substitution character with the value specified in the calculation rule / bill factor. Either this character OR %I should be used when you desire to substitute the price / percent into the bill line. Using %R causes the prorated price / percent to be printed in the bill line (%I causes the price / percent as specified in the rate to be printed during proration situations).</p> <p>If the charge is proratable, %R should be used in conjunction with %D to print an appropriate message when the charges are prorated.</p> |
| %S | <p>Replaces the substitution character with the summed amount. All trailing zeroes up to the decimal position of the rate's currency will be removed. All leading zeroes will be removed unless the value is between 1 and -1 in which case a leading 0 will appear before the decimal place. The Symbol on the Currency control table will prefix the value. If the value is negative, a "-" will prefix the value.</p> <p>This character should only be used with Minimum, Apply To, and Summary calculation rules.</p> |
| %T | <p>Replaces the substitution character with message 10103 from message category 11109. This message is maintained in the standard message table.</p> <p>We recommend this message be set to "(%1% exempt)" where %1 will be substituted with the tax exemption percent as specified in the service agreement. This message will only be substituted when the calculation rule's bill factor is eligible for tax exemptions AND the customer is exempt from the tax. Note, %1 is not required.</p> |
| %V | <p>Replaces the substitution character with the "C1-ADDSC" characteristic ad hoc value retrieved by the calculation rule used to calculate the charge on the bill line.</p> |
| Lines that don't print | <p>If the bill line is not printed (as defined by the Print option), message 10104 from message category 4 will be appended to the bill line. This message is maintained in the standard message table.</p> <p>We recommend this message be "NOT SEEN BY CUSTOMER!" This message appears in the bill line that appears in the billing windows but does not appear on the customer's bill.</p> |

The following are examples of the content of common **Description on Bills** along with how the line would look on the customer's bill:

| Description on Bill On Calculation Rule | How It Looks On A Bill |
|---|------------------------|
|---|------------------------|

| | |
|------------------------------------|--|
| %C lamp pole(s) at %I per pole %F | 1,234 lamp pole(s) at \$5.00 per pole (prorated by .3333) |
| %C lamp pole(s) at %R per pole %D | 1,234 lamp pole(s) at \$1.50 per pole (prorated for 10 of 30 days) |
| First %Q kWh at %I per kWh %F | First 100.32 kWh at \$0.12349 per kWh (prorated by .3333) |
| First %Q kWh at %R per kWh %D | First 100.32 kWh at \$0.12349 per kWh (prorated for 10 of 30 days) |
| %Q kWh at %I per kWh | 100.32 kWh at \$0.12349 per kWh |
| State sales tax %R %T | State sales tax 6.25% (50% exempt) |
| Minimum charge of %I %F | Minimum charge of \$10.00 (prorated by .3333) |
| Subtotal of %S | Subtotal of \$1,123.23 |
| Charges for %O: %Q kW at %I per kW | Charges for Off Peak Winter: 234.43 kW at \$0.05 per kW |

The prorated references will only appear if the calculation rule's charges are prorated due to a short or long bill period.

Searching and Maintaining Calculation Rules

Use this procedure to search for and maintain calculation rules.

- Select **Menu > Rates > Calculation Rule > Search**.
- Enter your search criteria.

Available query options include **Calculation Rule** and **Calculation Rule BO**.

- When searching by **Calculation Rule**, you can search by **Calculation Group**, **Calculation Rule** name, or **Description**.
- When searching by **Calculation Rule BO**, you can search by **Business Object**, or **Description**.
- Click **Refresh**.
- In the search results list, click the **Description** link for the calculation rule you want to view or edit. To navigate to the rule's calculation group, click the **Calculation Group** link.

The selected calculation rule is displayed in the **Calculation Rule** portal. You use this portal to maintain calculation rules. This portal includes the following zones:

- **Calculation Rule**: Defines basic information about calculation rule
- **Eligibility Criteria List**: Lists optional eligibility criteria for the current calculation rule. Eligibility criteria are used to determine whether a calculation rule should be applied (or skipped) during rate processing.

Use this procedure to maintain a calculation rule:

- Select **Menu > Rates > Calculation Rule > Search** to navigate to the Calculation Rule Query portal.
- Search for and select the appropriate calculation rule.
- Click **Edit**, **Delete**, or **Duplicate** as appropriate.
- To define eligibility criteria for the rule, click the **Add** link in the **Eligibility Criteria List** zone title bar. See "Eligibility Criteria" in [About Calculation Rules](#) for more information.

See [About Calculation Rules](#) for more information about calculation rules.

Defining Calculation Rule Eligibility Criteria

Use this procedure to define eligibility criteria for a calculation rule.

Prerequisites: You must create a calculation rule before you can define eligibility criteria.

- Click the **Add** link in the **Eligibility Criteria List** zone title bar.
- Enter a **Sequence** number, **Description**, and **Detailed Description** for the criteria.
- Complete the **Criteria Comparison** section as follows:
 - **Criteria Field:** the means used to retrieve the value of the criteria field (algorithm, bill factor, calculation line, characteristic, contract quantity, service quantity, or historic service quantity)
 - **Comparison Operator:** the operator used in the comparison
 - **Value:** a user-specified value to which the retrieved value is compared (using the comparison operator)
- Complete the **Comparison Results** section as follows:
 - **If True:** the action to take if the comparison is true
 - **If False:** the action to take if the comparison is false
 - **If Insufficient Data:** the action to take if there is insufficient data to perform the comparison
- Click **Save**.

See [The Big Picture of Calculation Rule Eligibility Rules](#) for more information.

Creating Rate Schedules

This section outlines how users work with rate schedules.

Defining Rate Schedules

Use this procedure to define rate schedules.

Prerequisites: You must configure an instance of the **Rate Engine Configuration** master configuration in order to create and/or maintain rate schedules.

- Select **Menu > Rates > Rate Schedule > Add**.

The Rate Schedule maintenance screen opens. To navigate to the Component-Based Rate Schedule page, click **Switch to Component-Based**.

- Enter a code for the **Rate Schedule**.
- Enter a short **Description** for the rate schedule.
- Select the **Service Type** (Electric Service, Gas Service, etc.) for the rate schedule.
- Select the **Frequency** (monthly, quarterly, etc.) for the rate schedule
- Select the **Currency Code** used with the rate schedule.
- Select whether or not the rate schedule will **Allow Estimates** when performing calculations.
- Select whether or not the rate schedule will **Allow RV Proration** when performing calculations.
- Select the **RV Proration Date**, used if the rate schedule does NOT allow RV proration. Valid options include Accounting Date, Bill End Date, and Bill Start Date.
- Define the **Pre-Processing Calculation Groups** used by the rate schedule. If the calculation groups do not exist yet, use the **Add Calculation Group** action to add each new calculation group and link it to the rate schedule. Refer to the embedded help for more information.

For each pre-processing calculation group, specify:

- **Sequence:** The sequence in which the group is executed when the pre-processing groups are processed.
- **Description:** A description of the calculation group
- **Calculation Group:** The calculation group.

Use the **Add/Remove Links** action on each calculation group to maintain the cross-references between the rules in the group. This action includes an ability to maintain a rule's target categories.

- Define the **Rate Version Calculation Groups** used by the rate schedule. If the calculation groups do not exist yet, use the **Add Calculation Group** action to add each new calculation group and link it to the rate schedule. Refer to the embedded help for more information.

For each rate version calculation group, specify:

- **Effective Date:** The date on which each rate version calculation group becomes effective
- **Description on Bill:** Specifies the description of the rate version calculation group on the bill. This description is saved on bill calculation details created using this rate version calculation group. Substitution characters may be used to substitute variables into the description during billing. Refer to [How To Use Description on Bill](#) for a discussion of the various substitution variables.
- **Calculation Group:** The calculation group.

Use the **Add/Remove Links** action on each calculation group to maintain the cross-references between the rules in the group. This action includes an ability to maintain a rule's target categories.

- Define the **Post-Processing Calculation Groups** used by the rate schedule. If the calculation groups do not exist yet, use the **Add Calculation Group** action to add each new calculation group and link it to the rate schedule. Refer to the embedded help for more information.

For each post-processing calculation group, specify:

- **Sequence:** The sequence in which the group is executed when the post-processing groups are processed.
- **Description:** A description of the calculation group
- **Calculation Group:** The calculation group.

Use the **Add/Remove Links** action on each calculation group to maintain the cross-references between the rules in the group. This action includes an ability to maintain a rule's target categories.

- Define one more recommended **Meter Configuration Types** for meters linked to service agreements (by way of their service points) for the rate schedule.
- Define one or more **Bill Messages** that should appear on bills that use the rate schedule. For each message, specify
 - **Bill Message:** The message that should appear on the bill.
 - The **Start Date** and **End Date** when the bill message should appear on the bill. Leave **End Date** blank if the message should appear indefinitely,
- Click **Save**.

This rate schedule can now be referenced on service agreements.

Searching and Maintaining Rate Schedules

Use this procedure to search for and view a rate schedule.

Prerequisites: You must configure an instance of the **Rate Engine Configuration** master configuration in order to create and/or maintain rate schedules.

- Select **Menu > Rates > Rate Schedule > Search**.
- Enter your search criteria.

You can search by **Rate Schedule**, **Description**, or **Rate Engine** (Calculation Rule-Based or Component-Based).

- Click **Search**.
- In the search results list, click the **Description** link for the rate schedule you want to view or edit.

Note: Component-based rate schedules will be highlighted by having “(Component-Based)” appended to their listing in the search results.

- The selected rate schedule is displayed in the (Calculation Rule-Based) **Rate Schedule** portal. You use this portal to maintain rate schedule. This portal includes the following zones:
 - **Rate Schedule:** Defines basic information about the rate schedule.
 - **Rate Schedule Tree:** Displays the hierarchy of Calculation Groups and Calculation Rules for the Rate Schedule. Only the most recent rate version calculation group is initially displayed. In this zone you can:

- Click a calculation group or calculation rule link to go to the Calculation Group or Calculation Rule portal for the associated calculation group or calculation rule.
- Click the Broadcast icon for a calculation rule to open the Cross Reference Rule zone. This zone displays the rate schedule's calculation rules that are members of the broadcast calculation rule's target category.
- Click the **Show All Rate Versions** button to display all rate versions for the rate schedule. This will also display the **Show Effective Rate Version** button, which you can use to display the information for the most recent rate version.

Use this procedure to maintain a rate schedule:

- Select **Menu > Rates > Rate Schedule > Search** to navigate to the Rate Schedule Query portal.
- Search for and select the appropriate rate schedule.
 - The selected rate schedule is displayed in the (new) **Rate Schedule** portal.
 - Click **Edit**, **Delete**, or **Duplicate** as appropriate.

Note:

If you select a component-based rate schedule, the selected rate schedule is displayed in the (component-based) **Rate Schedule** page.

Base Package Calculation Rule Descriptions

This section provides detailed descriptions of each of the base package calculation rules provided with Oracle Utilities Customer Care and Billing. The descriptions of the calculation rules below contain the following information

- **Rule Name:** The name of the rule
- **Base Package Calculation Rule Business Object:** The base package business object used by the rule
- **Apply Calculation Rule Algorithm Type / Algorithm:** The base package algorithm type and algorithm specified in the "Apply Calc Rule" system event for the rule
- **Rule Parameters:** Parameters used to define the rule (if applicable). Does not include common parameters used by all rules (see Common Parameters).
- **Example:** One or more example configurations of the rule. Note that all examples use default values for all Apply Calculation Rule Algorithm Parameters.

Common Parameters

All calculation rules use the following common parameters:

- **Calculation Group:** The calculation group to which the rule belongs
- **Calculation Rule:** The user-defined name given to the calculation rule
- **Sequence:** The relative position of the calculation rule in respect of the other rules in the calculation group. This controls the order in which the system performs the calculation.
- **Description:** A short description of the rule. This is used as the Information String for the rule in the user interface.
- **Detailed Description:** A detailed description of the rule.

In addition, several of the base package calculation rules also use the following parameters:

- **Description On Bill:** The text that appears on the bill line generated for this calculation rule. Variables can be used to dynamically generate text (such as, price and quantity) when billing calculates the charges. Refer to [How To Use Description on Bill](#) for more information about available substitution variables.
- **Print (Yes or No):** A flag that specifies if the bill line created by this calculation rule should appear on the customer's bill. All bill lines are shown on Bill Segment - Calculation Details. However, only those lines marked as Print are presented to the customer.
- **Print If Zero (Yes or No):** A flag that specifies if a bill line should be printed if the bill line's value is zero.
- **Rounding Type:** This flag specifies if the calculated value should be rounded Down, Up, or Nearest. Used with Precision to control how the system rounds the rule's calculated value.

- **Precision:** This field defaults to a value consistent with the decimal positions defined on the rate schedule's currency code. Used with Rounding Type to control how the system rounds the rule's calculated value.
- **FCPO (For Calculation Purposes Only):** A flag that indicates if this calculation rule exists purely to calculate a value used by another calculation rule. When set to Yes, the system does not include the calculated amount in the bill total. The following are required when FCPO is set to Yes:
 - **Create Bill Line:** Determines if a bill line should be created for the rule (if there is no need to show the results to the customer or a user, there is no need to create a bill line).
 - **FCPO Retention Rule:** If a bill line created, this defines if the FCPO amount should be set to zero on the bill line or whether the bill line's amount should be set equal to the FCPO amount.
- **Override Proration:** A flag that specifies if an override proration algorithm should be used. This is used in situations when the standard proration logic does not satisfy your requirements. In this case, you may plug in an override proration algorithm to calculate the proration factors required by your implementation. This algorithm can be specified on the calculation rule business object or on the parent calculation rule business object if the override proration applies to all rates.
- **Seasonal (Yes or No):** A flag that specifies if charges associated with the calculation rule are only levied during a specific season. If set to "Yes", the following must be specified:
 - **Season Start:** Defines the start of the season for the calculation rule.
 - **Season End:** Defines the end of the season for the calculation rule.
 - **Seasonal Prorate Method:** Defines how the system should prorate a seasonal charge when a bill segment's period is not entirely within the seasonal period. The following options are available:
 - **Accounting Date, Consumption End Date and Consumption Start Date** options will not prorate the charge calculated by the calculation rule. Rather, it will only calculate the charge if the accounting date associated with the bill segment is within the seasonal period, or if the consumption period's end date is within the seasonal period, or if the consumption period's start date is within the seasonal period respectively.
 - **Prorate** will prorate the calculation rule charge based on number of days in the season that is included in the bill period.
 - The **Prorate Seasonal SQ** option is only pertinent if you have:
 - Seasonal service quantity (SQ) charges, AND
 - Meters that measure seasonal consumption on separate registers, AND
 - You have a bill that crosses seasonal boundaries, AND
 - You have multiple rate version calculation groups effective across the bill period.

If the Prorate Seasonal SQ option is used, the system will prorate the charge calculated by a SQ calculation rule based on the number of days in the season that is included in the rate version calculation group's period.
- **GL Distribution:** If the charge calculated by the calculation rule impacts the general ledger, you must define the distribution code used to construct the GL account.
 - **Distribution Code Source:** Specifies the type of GL distribution to use for this calculation rule.

If the calculation rule's charges should be booked to a single GL account regardless of the service agreement's SA Type's revenue class, select the **Specific Distribution Code** source and enter a **Distribution Code**.

If the calculation rule's charges are booked to a different GL account depending on the service agreement's revenue class, select the **Revenue Class** source and insert the appropriate **Revenue Class** and **Distribution Code** for each that uses the rate.
- **Cross Reference:** Defines the calculation line categories that the resultant calculation details belong to. For example, for a rate that calculates city and state taxes on consumption and demand based charges, the following categories could be used to calculate these taxes:
 - A calculation line category type called "Taxable" with a category value for City Tax and another for State Tax.
 - Each of the rate's calculation rules used for consumption and demand based charges should define the Member Category(s) that it belongs to ("Taxable - City Tax" and "Taxable - State Tax"). In other words, these rules would be defined as a member of the city tax and state tax categories.

- The Apply To rules used to calculate city tax and state tax should define the respective Target Category(s) ("Taxable - City Tax" and "Taxable - State Tax") that they are applied to.

There are two types of cross-reference categories:

- **Target Category:** Specifies the category that the calculation rule targets. Used with Apply To, Maximum Charge, and Minimum Charge calculation rules.
- **Member Category:** Specifies the category to which the calculation rule belongs.
- **Characteristics:** Defines additional calculation rule attributes that may be used in rate processing or for reporting purposes. A calculation rule's characteristics are copied onto the resultant bill lines for those characteristic types that are allowed on bill segment calc lines. You can indicate that "C1-ADDSC" characteristic ad hoc value of a bill line should be substituted into the bill line's description by using the %V substitution variable in the calculation rule's **Description On Bill** field.

Calculation Rule Validation

All calculation rules are validated when created to ensure they contain proper data needed to perform their calculations. The algorithms used to perform these validations are performed by the algorithms specified in the "Validation" system event on the calculation rule's business object.

Calculation Rules

This section provides descriptions for the base package calculation rules.

Apply To

Apply To calculation rules create bill lines that levy charges based on amounts calculated on other bill lines. Apply To calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges to which "Apply To" rules will be applied must be defined as members of the target category. See **Cross-Reference** under [Common Parameters](#) for more information about Member and Target categories.

- **Rule Name:** Apply To
- **Base Package Calculation Rule Business Object:** C1-ApplyTo
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-APPLYTO
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Error If No Value:** Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
 - **Seasonal:** See [Common Parameters](#).
 - **Value Type:** Defines if the price is a Charge, Percentage or Unit Rate.
 - **Value Source:** specifies the source of the price. Depending on the value source selected, either a Bill Factor, Value, or Value Algorithm is required.
- **Example:** The following calculation rule applies a county tax other calculation rules that belong the "Taxable - County Tax" category.

Calculation Group: Taxes

Calculation Rule: CNTYTAX

Sequence: 530

Description: County Tax

Description On Bill: County sales tax %R %T

Print: Yes

Print if Zero: No

Rounding Type: Nearest

Precision: 0.01

FCPO: No

Override Proration: No

Calculation Details:

- **Error If No Value:** No
- **Seasonal:** No
- **Value Type:** Percentage
- **Value Source:** Bill Factor
- **Bill Factor:** County Tax

GL Distribution:

- **Distribution Source Code:** Specific Distribution Code
- **Distribution Code:** Payable - County Tax

Cross Reference:

- **Target Category (Category Type / Value):** Taxable / County Tax
- **Member Category (Category Type/Value):** Summary Item / Summary Line

Calculate Final Reading Values

Calculate Final Reading Values calculation rules determine the final values for readings based on user-defined UOM/TOU/SQI.

- **Rule Name:** Calculate Final Reading Values
- **Base Package Calculation Rule Business Object:** C1-CalculateFinalValue
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-CALCFNVL
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Unit of Measure:** The unit of measure for the measured quantity.
 - **Time of Use:** The time of use for the measured quantity.
 - **Service Quantity Identifier:** The service quantity identifier for the measured quantity.
 - **Retain Measured SQ:** indicates whether to save the accumulated measured quantity entry in the SQ collection. If this value is set to No, it means the value will be removed from the SQ collection. Before any pre-processing rule is executed, the rate engine will place the sum / max value of the read details into the SQ collection. For example, if the read details contain entries for measured CCF, there will be an entry in the SQ collection for the total CCF from all read details. This might be what is needed, but it may be extraneous if a rule converts the measured quantity into therms. In this situation, the SQ collection only needs therms and the CCF entry can be removed.
 - **Formula:** Defines the formula used to calculate the final read quantity. Bill Factors (or scalar variables) to be used in the calculation are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Bill Factor 1, V2 = Bill Factor 2, etc.). Measured Quantity is referenced as MQ in the formula. Mathematical operations supported include addition, subtraction, multiplication and division. For example: (MQ * V1) would be the formula to convert CCF to THERM.
 - **Scalar Variables:** Defines the scalar variables or Bill Factors to be used in the calculation. When referenced in the formula, scalar variables are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Bill Factor 1, V2 = Bill Factor 2, etc.). Note that only regular bill factors may be used in the formula. Interval and Time of Use bill factors are not supported.
 - **Sequence:** Designates the number of the variable (V1, V2, etc.)
 - **Bill Factor:** The Bill Factor used for the variable.
 - **Result:** Defines the type of data (**Unit of Measure**, **Time of Use**, and/or **Service Quantity Identifier**) to be used for the final quantity calculated by the rule.
 - **Processing:** The following processing takes place:
 - The rule will process each read detail whose initial UOM matches the measured quantity UOM.
 - It substitutes the reference to MQ in the formula with each read's measured quantity and then calls the formula service passing the defined bill factors as variables 1 to n. The read's end date is passed as the effective date.

- It then populates each read's final value with the results of the formula and it populates the final UOM / TOU / SQI with the values defined on the rule.
- It populates the SQ collection with the results (this will either add a new value if the Final UOM / TOU / SQI is not present in the SQ collection, OR it will update the existing SQ quantity with the sum or max of the calculated value depending on the Final UOM's measure's peak value). Note, the initial and final values of such an SQ will be the calculated value.
- It then removes the measured UOM / TOU / SQI from the SQ collection if the rule has been configured as such.
- **Example:** This calculation rule converts CCF (as recorded on the meter) to therms for billing purposes.

Calculation Group: CCF to Therm Conversion (Calculate SQ - SQ and BF)

Calculation Rule: CCF2TH

Sequence: 10

Description: Convert CCF to TH

Calculation Details:

- **Unit of Measure:** 100 cubic feet of gas
- **Retain Measured SQ:** Yes
- **Formula:** MQ*V1*V2

Scalar Variables (Sequence / Bill Factor):

- 1 / Pressure adjustment zone
- 2 /Take point for therm conv.fac

Result:

- **Unit of Measure:** Thermal units

Calculate Service Quantity

Calculate Service Quantity calculation rules derive or calculate a service quantity that is eventually inserted into the bill segment SQ collection. Calculate Service Quantity calculation rules are generally used to either manipulate measured consumption, or to derive quantities that are not measured by a meter.

- **Rule Name:** Calculate Service Quantity
- **Base Package Calculation Rule Business Object:** C1-CalculateServiceQuantity
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-CALC-SQ
- **Rule Parameters:**
 - **Scalar Variable 1 (Scalar Variable 2, Scalar Variable 3, ... Scalar Variable 5):** Defines one of the scalar variables to be used in the calculation. When used in formulas, scalar variables are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Scalar Variable 1, V2 = Scalar Variable 2, etc.).
 - **Type:** Defines the type of variable and can be one of the following:
 - **Algorithm:** an algorithm is responsible for retrieving the scalar variable value, e.g. calculate number of days in the bill period.
 - **Bill Factor:** the value for a specified bill factor that is in effect for the period.
 - **Calculated Line:** the value is derived by summing previously calculated lines defined as members of a target category.
 - **Characteristic Value:** the value is derived by summing characteristic values of a given characteristic type.
 - **Contract Quantity:** the value for a given contract quantity type specified on a service agreement.
 - **Historical Service Quantity:** the value is derived based on the SA's historical bill segment service quantities for the specified UOM / TOU / SQI. The Aggregate Function defines the calculation to perform on the set of historical service quantities retrieved to derive a single value. Average, Maximum, Minimum and Sum are supported.

- **Service Quantity:** service quantities from the bill period's SQ collection, based on a specified UOM / TOU / SQI. This type of variable allows this rule to make use of values calculated by other rules.
- **Previous Quantity:** the value is derived from the SA's most recent frozen bill segment service quantities for the specified UOM / TOU / SQI.
- **Missing Value Action:** Defines what should take place if the system is unable to retrieve or derive a value for a particular scalar variable. Valid options are as follows:
 - Select **Error** to create an exception
 - Select **Skip** to exit the rule and process the next rule
 - Select **Use Default Value** if the scalar variable should be set to the default value specified
- **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Calculation Rule Processing:** Indicates if the rule is **Always** executed by rate application, even if the consumption details on the original bill segment are to be used when the system recalculates a bill segment. If the rule should not be executed when the consumption details on the original bill segment are used, indicate that the calculation rule should only be executed on the **Initial SQ Calculation**.
 - **Fail Action:** Indicates the action to take if an error is encountered when applying the rule's formula. Available options are to either create a bill segment **Error**, or to **Skip** the calculation rule.
 - **Calculation Rule Output:** Specifies whether calculation rule should add or update a **Service Quantity** entry in the bill period's SQ collection, or create a bill **Calculation Line**, or **Both**.
 - **Retain SQ:** Indicates whether to save the calculated value on the bill segment. If this value is set to **No**, it means the value will only exist in the SQ collection while the rate engine is calculating. A value of **No** should be used for SQ entries that do not have to be retained for audit or analytic purposes.
 - **Formula Source:** Specifies the type of formula to use for the rule. Valid options include "Simple Formula" and "Conditional Formula".
 - **Formula:** Specify the **Simple Formula** to apply. Scalar variables to be used in the calculation are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Scalar Variable 1, V2 = Scalar Variable 2, etc.). Mathematical operations supported include addition, subtraction, multiplication and division. For example: $(V1*V2)/2$.
 - **Conditional Formula:** this allows comparison between one or more pairs of operands to determine the specific formula to execute. A conditional formula can utilize one or more conditions. Each condition comprises the following:
 - **Operand 1:** the first operand in the condition. Can reference an expression with one or more scalar variables (designated as Vn), e.g. $[V1+V2]$ or $[(V1/V2)*V3]$.
 - **Operator:** the operator used to compare Operand 1 with Operand 2.
 - **Operand 2:** the second operand in the condition. Can reference an expression with one or more scalar variables, or a constant (similar to Operand 1).
 - **True Action:** indicates how to proceed if the comparison between the operands is true. Can be one of the following:
 - Apply True Formula:** indicates that the True Formula be executed.
 - Check Next Condition:** indicates that the next condition should be checked.
 - **True Formula:** the formula to apply if True Action is set to Apply True Formula. Can reference an expression with one or more scalar variables (designated as Vn), or a constant.
 - **False Action:** indicates how to proceed if the comparison between the operands is false. Can be one of the following:
 - Apply False Formula:** indicates that the False Formula be executed.
 - Check Next Condition:** indicates that the next condition should be checked.
 - False Formula:** the formula to apply if the False Action is set to Apply False Formula. Can reference a vector (designated as IVn, where n is the number of the vector) or an expression referencing one or more vectors or a scalar variable (designated as Vn).
- **Result:** Define the **Unit of Measure**, **Time of Use** and/or **Service Quantity Identifier** to be used if this calculation rule inserts or updates a service quantity in the bill period's SQ collection.

- **Example:** This calculation rule calculates total kWh from On Peak and Off Peak service quantities.

Calculation Group: Calculate KWH

Calculation Rule: TOTKWH

Sequence: 10

Description: Total amount of KWH (On Peak + Off Peak)

Scalar Variable 1:

- **Type:** Service Quantity
- **Missing Value Action:** Error
- **Unit of Measure:** Kilowatt hour
- **Time of Use:** On Peak
- **SQ To Use:** Billable

Scalar Variable 2:

- **Type:** Service Quantity
- **Missing Value Action:** Error
- **Unit of Measure:** Kilowatt hour
- **Time of Use:** Off Peak
- **SQ To Use:** Billable

Calculation Details:

- **Calculation Rule Processing:** Always
- **Fail Action:** Error
- **Calculation Rule Output:** Service Quantity
- **Retain SQ:** No
- **Formula Source:** Simple Formula
- **Formula:** V1 + V2

Result:

- **Unit of Measure:** Kilowatt hour

Copy Service Quantity from Master Bill Segment

Calculate Final Reading Values calculation rules determine the final values for readings based on user-defined UOM/TOU/SQI.

- **Rule Name:** Copy Service Quantity From Master Bill Segment
- **Base Package Calculation Rule Business Object:** C1-CopySQFromMasterBillSegment
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-CPY-MB-SQ
- **Rule Parameters:**
 - **Characteristics:** Defines characteristic(s) and corresponding value(s) that are to be passed to the referenced calculation group.
 - **Characteristic Type:** Defines the characteristic type that is to be associated to the calculation rule.

Note:

Characteristic Types for rates must be configured to be used on a calculation rule and/or in the characteristic collection. Refer to [Defining Characteristic Types](#) for information on how to set up characteristic types.

- **Characteristic Value:** Defines the parameter value that will be associated to the characteristic type.

Execute Calc Group

Execute Calc Group calculation rules call another calculation group, and pass characteristics and their values to the referenced calculation group.

- **Rule Name:** Execute Calculation Group
- **Base Package Calculation Rule Business Object:** C1-CalcRuleReferredCalcGroup
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-ACALR-RFG
- **Rule Parameters:**
 - **Referenced Calculation Group:** Defines the calculation group that's being called.
 - **Calculation Group:** Defines the calculation group that's being called.
 - **Characteristics:** Defines characteristic(s) and corresponding value(s) that are to be passed to the referenced calculation group.
 - **Characteristic Type:** Defines the characteristic type that is to be passed to the referenced calculation group.

Note:

Characteristic Types for rates must be configured to be used on a calculation rule and/or in the characteristic collection. Refer to [Defining Characteristic Types](#) for information on how to set up characteristic types.

Characteristic Value: Defines the parameter value that will be associated to the characteristic type.

Flat Charge

Flat Charge calculation rules create bill lines that levy service charges and fees that aren't based on how much the customer uses. For example a flat charge calculation rule may be used to apply a monthly service charge of \$10 to a customer's bill.

- **Rule Name:** Flat Charge
- **Base Package Calculation Rule Business Object:** C1-FlatCharge
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-FLAT-CHRG
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Seasonal:** See [Common Parameters](#).
 - **Value Type:** Defines the type of value to use for the rule. For Flat Charge rules, this should be set to **Charge**.
 - **Value Source:** Specifies the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
 - **Example:** This calculation rule levies a customer charge.

Calculation Group: Customer Charge

Calculation Rule: CSTCHG

Sequence: 20

Description: Customer Charge

Description On Bill: Customer Charge

Print: Yes

Print if Zero: No

Rounding Type: Nearest

Precision: 0.01

FCPO: No

Override Proration: No

Calculation Details:

- **Seasonal:** No

- **Value Type:** Charge
- **Value Source:** Value
- **Value:** 5

GL Distribution:

- **Distribution Source Code:** Specific Distribution Code
- **Distribution Code:** Revenue - Energy

Cross Reference:

- **Member Category (Category Type / Value):** Subject to tax / City taxable

Item Type

Item Type calculation rules create bill lines that levy charges based on the number and type of items used by a customer. The system keeps track of items on the service point(s) linked to the customer's service agreement.

- **Rule Name:** Item Type
- **Base Package Calculation Rule Business Object:** C1-ItemType
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-ITEMTYPE
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Seasonal:** See [Common Parameters](#).
 - **Item Type:** Defines the types of items to which charges are applied. When defining more than one item type on a single calculation rule, you can indicate that the item type of a bill line should be substituted into the bill line's description by using the %M substitution variable in the calculation rule's **Description On Bill** field.
 - **Error If No Value:** A flag that indicates (Yes or No) if a bill error should be generated if the item type specified on the calculation rule was not supplied at billing time.
 - **Value Type:** Defines the type of charge. Valid options include Charge, Percentage, or Unit Rate.
 - **Value Source:** Defines the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
 - **Value/Bill Factor/Algorithm:** The specific Value, Bill Factor, or Algorithm that serves as the source of the price used to calculate the charge.
 - **Example:** This calculation rule calculates charges for light poles.

Calculation Group: Lamp Charges

Calculation Rule: POLE CHARGE

Sequence: 10

Description: Pole Charge

Description On Bill: %C lamp poles at %R per pole %D %I

Print: Yes

Print if Zero: No

Rounding Type: Nearest

Precision: 0.01

FCPO: No

Override Proration: No

Calculation Details:

- **Seasonal:** No
- **Items:**

- **Item Type:** Pole(s)
- **Error If No Value:** No
- **Value Type:** Unit Rate
- **Value Source:** Value
- **Value / Bill Factor /Algorithm:** 3

GL Distribution:

- **Distribution Source Code:** Specific Distribution Code
- **Distribution Code:** Revenue - Area Lighting

Cross Reference:

- **Member Category (Category Type / Value):** Charges / Total Charges
- **Member Category (Category Type / Value):** Charges / Lamp Charges

Math

Math calculation rules derive interval data based on a formula, and apply TOU mappings and/or other operations to the derived data to calculate service quantities.

- **Rule Name:** Math
- **Base Package Calculation Rule Business Object:** C1-Math
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-MATH
- **Rule Parameters:**
 - **Vector 1 (Vector 2, Vector 3, ..., Vector 5):** Defines one of the vectors (Vector 1, 2, 3, ..., 5) to be used in the calculation. When used in formulas, interval values for vectors are designated as IV1, IV2, IV3, ..., IV5.
 - **Vector Type:** Defines the type of vector. Valid options include **Interval Bill Factor** and **Interval Service Quantity**.
 - **Bill Factor:** Defines the Interval Bill Factor from which interval values are derived for the vector.
 - **Unit of Measure/Time of Use/Service Quantity Identifier:** The UOM/TOU/SQI used to retrieve interval values from either the usage request service quantity entries given a usage request ID and usage period, or from the rate engine buffer populated prior to calling rate application.
 - **Missing Interval Data Action:** Defines the action to take (**Error** or **Skip**) if interval data is missing for the expected period
 - **Scalars:** Defines scalar variables to be used in the calculation. When used in formulas, scalar variables are designated as Vn, where n is the number of the variable (based on the sequence in which they are defined in the list).
 - **Scalar Type:** Defines the type of variable. Can be one of the following:
 - **Bill Factor:** The value for a specified bill factor that is in effect for the billing period.
 - **Set Function:** The result of applying a function to a set of interval measurement values (defined as a vector).
 - **Service Quantity:** Service quantities from the current SQ list, based on a specified UOM, TOU, or SQI. This type of variable allows this rule to make use of values calculated by other rules.
 - **Bill Factor:** Defines the bill factor used to retrieve the variable value (applicable only if Scalar Type is Bill Factor)
 - **Unit of Measure:** Defines the UOM for service quantities to retrieve from the SQ list (applicable only if Scalar Type is Service Quantity).
 - **Time of Use:** Defines the TOU for service quantities to retrieve from the SQ list (applicable only if Scalar Type is Service Quantity).
 - **Service Quantity Identifier:** Defines the SQI for service quantities to retrieve from the SQ list (applicable only if Scalar Type is Service Quantity).
 - **SQ to Use:** Every service quantity supplied to a rate has two quantities; the quantity initially measured, and the quantity that should be priced by the rate. Most of the time these two amounts will be the same, unless

another rule has executed and caused the billable quantity to change. Each rule needs to know if it should use the **Initial** or **Billable** quantity.

- **Set Function:** Defines the function used to calculate a scalar value from a set of interval values (defined as a vector). This is applicable only if Scalar Type is Set Function). Can be one of the following:
 - **Average:** calculates the average of the vector's interval measurement values.
 - **Count:** returns the number of interval measurements.
 - **Max:** returns the maximum value from the vector's interval measurement values.
 - **Min:** returns the minimum value from the vector's interval measurement values.
 - **Total:** calculates the total of the vector's interval measurement values.
- **Vector:** the vector to be used for this variable (applicable only if Scalar Type is Set Function). Can be one of the following:
 - **FV** (Final Vector Interval Value): the vector containing the results of the formula defined in the Calculation Details section.
 - **IV1** (Vector 1 Interval Value): the vector defined as Vector 1.
 - **IV2** (Vector 2 Interval Value): the vector defined as Vector 2.
 - **IV3** (Vector 3 Interval Value): the vector defined as Vector 3.
 - **IV4** (Vector 4 Interval Value): the vector defined as Vector 4.
 - **IV5** (Vector 5 Interval Value): the vector defined as Vector 5.
- **Missing Value Action:** Defines the action to take (**Error**, **Skip**, or **Use Default Value**) if data is missing for the scalar variable for the expected period
- **Default Value:** The default value to use if data is missing for the scalar variable. Applicable only if Missing Value Action is Use Default Value.
- **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Calculation Rule Processing:** Indicates if the rule is **Always** executed by rate application, even if the consumption details on the original bill segment are to be used when the system recalculates a bill segment. If the rule should not be executed when the consumption details on the original bill segment are used, indicate that the calculation rule should only be executed on the **Initial SQ Calculation**.
 - **Fail Action:** Indicates the action to take if an error is encountered when applying the rule's formula. Available options are to either create a bill segment **Error**, or to **Skip** the calculation rule.
 - **Calculation Rule Output:** Specifies whether calculation rule should add or update a **Service Quantity** entry in the bill period's SQ collection, or create a bill **Calculation Line**, or **Both**.
 - **Retain SQ:** Indicates whether to save the calculated value on the bill segment. If this value is set to **No**, it means the value will only exist in the SQ collection while the rate engine is calculating. A value of **No** should be used for SQ entries that do not have to be retained for audit or analytic purposes.
 - **Formula Source:** Specifies the type of formula to use for the rule. Valid options include "Simple Formula" and "Conditional Formula".
 - **Formula:** Specify the **Simple Formula** to apply. Scalar variables to be used in the calculation are designated as Vn, where n matches the number assigned to the variable (i.e. V1 = Scalar Variable 1, V2 = Scalar Variable 2, etc.). Mathematical operations supported include addition, subtraction, multiplication and division. For example: $(V1*V2)/2$.
 - **Conditional Formula:** this allows comparison between one or more pairs of operands to determine the specific formula to execute. A conditional formula can utilize one or more conditions. Each condition comprises the following:
 - **Operand 1:** the first operand in the condition. Can reference an expression with one or more scalar variables (designated as Vn), e.g. $[V1+V2]$ or $[(V1/V2)*V3]$.
 - **Operator:** the operator used to compare Operand 1 with Operand 2.
 - **Operand 2:** the second operand in the condition. Can reference an expression with one or more scalar variables, or a constant (similar to Operand 1).
 - **True Action:** indicates how to proceed if the comparison between the operands is true. Can be one of the following:

Apply True Formula: indicates that the True Formula be executed.

Check Next Condition: indicates that the next condition should be checked.

- **True Formula:** the formula to apply if True Action is set to Apply True Formula. Can reference an expression with one or more scalar variables (designated as Vn), or a constant.
- **False Action:** indicates how to proceed if the comparison between the operands is false. Can be one of the following:

Apply False Formula: indicates that the False Formula be executed.

- **Check Next Condition:** indicates that the next condition should be checked.
- **False Formula:** the formula to apply if the False Action is set to Apply False Formula. Can reference a vector (designated as IVn, where n is the number of the vector) or an expression referencing one or more vectors or a scalar variable (designated as Vn).
- **Result:** Defines how service quantities are inserted into the SQ list. Math calculation rules can insert one or more entries into the SQ list.
 - **Result Source:** Defines the method to use to calculate for the service quantity. Can be one of the following:
 - **Set Function Against Derived Vector:** Applies a function to the derived interval values. The function to be applied is specified in the Set Function field.
 - **Scalar Formula Result:** Applies a user-defined formula. The formula is specified in the Scalar Formula field.
 - **Set Function:** the function to apply to the derived interval values (applicable only if Result Source is set to Set Function Against Derived Vector). Can be one of the following:
 - **Average:** Calculates the average of the derived interval measurement values.
 - **Count:** Returns the number of derived interval measurements.
 - **Max:** Returns the maximum value from the derived interval measurement values.
 - **Min:** Returns the minimum value from the derived interval measurement values.
 - **Total:** Calculates the total of the derived interval measurement values.
 - **Scalar Formula:** the formula to apply (applicable only if Result Source is set to Scalar Formula). Variables used in this formula must be defined in the Scalars section. When referenced in formulas, scalar variables are designated as Vn (where n is the number of the variable).
 - **Unit of Measure:** the UOM to be used when inserting service quantity entries
 - **Time of Use:** the TOU to be used when inserting service quantity entries
 - **Service Quantity Identifier:** the SQI to be used when inserting service quantity entries
 - **Apply TOU Map:** Indicates if a TOU map should be applied to the derived interval values. If TOU periods and values are returned as a result of TOU mapping, then service quantity entries are inserted.
 - **TOU Map:** Defines the TOU Map to apply to the derived interval values (applicable only if Apply TOU Map is set to Yes).
 - **TOU Mapping Function:** Defines the function to apply to the derived interval values when calculating for the time of use values (applicable only of Apply TOU Map is set to Yes). Can be one of the following:
 - **Max:** Returns the maximum value from the derived interval values for each TOU period.
 - **Sum:** Returns the sum of the derived interval values for each TOU period.
- **Processing:**

Math rules derive interval values based on a formula, and apply TOU mappings and/or other operations to the derived data to calculate billing quantities. Examples include the following:

- Derive an interval data curve (vector) given a formula. For example, derive a power factor curve given a formula using kWh and kVarh curves.
- Apply TOU mapping to a derived interval data curve. For example, after deriving the power factor curve, perform TOU mapping on the result.
- Perform mathematical operations on SQ entries. For example, get total kWh consumption by adding "kWh On Peak", "kWh Off Peak", and "kWh Shoulder Peak" where "kWh On Peak", "kWh Off Peak", and "kWh Shoulder Peak" were calculated by a previous calculation rule.

Each interval data curve is defined as a vector parameter (the rule can define up to 5 vectors). Mathematical operations defined by the "Vector Processing" parameters can be performed between vectors (e.g. IV1 * IV2) and between vectors and scalar variables (e.g. IV1 * V1).

- **Example:** This calculation rule calculates prices for interval usage by multiplying an interval service quantity times an interval price bill factor.

Calculation Group: Electric Commercial - Interval Pricing

Maximum Charge

Maximum Charge calculation rules are used to create bill lines that levy charges only when the sum of previously calculated lines is more than the maximum charge amount. Maximum charge calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges that the maximum is levied on must be defined as members of the target category. See **Cross-Reference** under [Common Parameters](#) for more information about Member and Target categories.

Note that if the values being compared are negative values, the comparison is NOT done on the absolute values, but rather on the actual values. For example, imagine you have a maximum discount of \$ -2.00 and previous calculation rules have calculated a discount of \$ -3.00. You want a calculation rule to create a bill line for \$1.00 to reduce the

discount. A maximum charge calculation rule will not work in this case because -3 is considered less than -2. For this business scenario you should use a Minimum Charge calculation rule.

Note: Maximum Charge calculation rules are rare. You tend to only see them in deregulated markets where customers have agreed to pay the market rate but want a cap on the maximum they'll pay each bill period.

- **Rule Name:** Maximum Charge
- **Base Package Calculation Rule Business Object:** C1-Maximum
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-MAXIMUM
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Error If No Value:** Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
 - **Seasonal:** See [Common Parameters](#).
 - **Value Type:** Defines the type of value to use for the maximum value for the rule. For Maximum Charge rules, this should be set to **Charge**.
 - **Value Source:** Specifies the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
 - **Example:** This calculation rule sets a maximum charge for area lighting.

Cross Reference:

- **Target Category (Category Type / Value):** Revenue / Maximum Consumption Charge

Minimum Charge

Minimum Charge calculation rules create bill lines that levy charges only when the sum of previously calculated lines is less than the minimum charge amount. Minimum charge calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges that the minimum is levied on must be defined

as members of the target category. See **Cross-Reference** under [Common Parameters](#) for more information about Member and Target categories.

Note that if the values being compared are negative values, the comparison is NOT done on the absolute values, but rather on the actual values. For example, imagine you have a minimum discount of \$ -2.00 and previous calculation rules have calculated a discount of \$ -1.00. You want a calculation rule to create a bill line for \$ -1.00 to apply a further discount. A minimum charge calculation rule will not work in this case because -1 is considered more than -2. For this business scenario you should use a maximum charge calculation rule.

- **Rule Name:** Minimum Charge
- **Base Package Calculation Rule Business Object:** C1-Minimum
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-MINIMUM
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Error If No Value:** Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
 - **Seasonal:** See [Common Parameters](#).
 - **Value Type:** Defines the type of value to use for the minimum value for the rule. For Minimum Charge rules, this should be set to **Charge**.
 - **Value Source:** Specifies the source of the price used to calculate the charge. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
 - **Example:** This calculation rule defines a minimum charge for use with residential electric rates.

Service Quantity

Service Quantity calculation rules create bill lines that levy charges based on some type of consumption.

Frequently the amount consumed is measured by a meter's registers and sometimes it's calculated using Pre-Processing calculation and sometimes it's derived based on the type of item (such as, lamps). Regardless of how the amount consumed is calculated, the charge for the consumption amount is levied using this type of calculation rule.

- **Rule Name:** Service Quantity
- **Base Package Calculation Rule Business Object:** C1-ServiceQuantity
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-SQ
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Unit of Measure:** The UOM used as the service quantity that the price is applied to.
 - **Time of Use:** The TOU used as the service quantity that the price is applied to.
 - **Service Quantity Identifier:** The SQI used as the service quantity that the price is applied to.
 - **Error If No Value:** A flag that indicates (Yes or No) if a bill error should be generated if the UOM/TOU/SQI specified on the rule was not supplied at billing time.
 - **Measures Peak:** Indicates (Yes or No) if the UOM/TOU/SQI specified for the rule is used to measure peak (demand) values.
 - **GL Statistical Qty:** A flag that specifies (Yes or No) if GL journal lines generated for this calculation rule should also contain the service quantity amount as a statistical quantity. You would use this option if you keep track of both dollar amounts and consumption units in your general ledger.
 - **Seasonal:** See [Common Parameters](#).
 - **Value Type:** Defines the type of price to be used in the rule's calculations. Valid options include Charge, Percentage, or Unit Rate.
 - **Value Source:** Defines the source of the price used in the rule's calculations. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
- **Example:** This calculation rule calculates charges based a customer's KWH consumption.

Stepped Service Quantity

Stepped Service Quantity calculation rules create bill lines that levy charges based on some type of consumption when different prices are applied to different ranges of consumption (for example, the first 50 kWh are \$0.43 per kWh, anything in excess of 50 kWh is charged at \$0.71 per kWh)

- **Rule Name:** Stepped Service Quantity

- **Base Package Calculation Rule Business Object:** C1-SteppedSQ
- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-STPD-SQ
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Unit of Measure:** The UOM used as the service quantity that the price is applied to.
 - **Time of Use:** The TOU used as the service quantity that the price is applied to.
 - **Service Quantity Identifier:** The SQI used as the service quantity that the price is applied to.
 - **Error If No Value:** A flag that indicates (Yes or No) if a bill error should be generated if the UOM/TOU/SQI specified on the rule was not supplied at billing time.
 - **Measures Peak:** Indicates (Yes or No) if the UOM/TOU/SQI specified for the rule is used to measure peak (demand) values.
 - **GL Statistical Qty:** A flag that specifies (Yes or No) if GL journal lines generated for this calculation rule should also contain the service quantity amount as a statistical quantity. You would use this option if you keep track of both dollar amounts and consumption units in your general ledger.
 - **Create Step Summary:** Stepped service quantity calculation rules may be configured with either a single step or multiple steps. The Create Step Summary flag is used to produce a summary bill segment calculation line if the calculation rule has multiple steps. Valid options include:
 - **Summarize Step Lines, Print:** Creates a stepped charge summary bill line that will appear on the customer's bill.
 - **Summarize Step Lines, Do Not Print:** Creates a stepped charge summary bill line that will be shown on Bill Segment - Calculation Details, but not appear on the customer's bill.
 - **Step Calculation Details:**
 - **Seasonal:** See [Common Parameters](#).
 - **Step Multiplier Algorithm:** Specifies the algorithm that will be used calculate the step boundaries. Used only if step boundaries are dynamic and are calculated based on something that's only known at billing time.
 - **Values:** Defines the values associated with each of the ranges (steps) of consumption used by the rule. For example, if the charge is applicable to the first 300 kilowatt-hours, you would enter Low Value 0 and High Value 300. When multiple tiers exist, the high value of the first tier is the low value of the second tier (and so on). To extend our example, the second tier would have a low value of 300; the high value may be left blank (the system assumes a blank high value means "to infinity").
 - **Low Value:** Defines the low value for the consumption range. This field supports values of up to 14 digits and 4 decimal places (e.g. a maximum value of 99,999,999,999.9999).
You can indicate that the low value of a bill line should be substituted into the bill line's description by using the %L substitution variable in the calculation rule's **Description On Bill** field.
 - **High Value:** Defines the high value for the consumption range. This field supports values of up to 14 digits and 4 decimal places (e.g. a maximum value of 99,999,999,999.9999).
You can indicate that the high value of a bill line should be substituted into the bill line's description by using the %H substitution variable in the calculation rule's **Description On Bill** field.
 - **Value Type:** Defines the type of price to be applied to the consumption range in the rule's calculations. Valid options include Charge, or Unit Rate.
 - **Value Source:** Defines the source of the price to be applied to the consumption range in the rule's calculations. Depending on the source selected, this will be a Bill Factor, Value, or Algorithm.
 - **Value/Bill Factor/Algorithm:** Specifies the Bill Factor, Value, or Algorithm used when calculating charges for the consumption range.
 - **Example:** This calculation rule calculates charges for electric service based on stepped charges for kWh consumption during the Fall

Calculation Group: Electric Residential - Stepped

Calculation Rule: KWHSTFL

Sequence: 10

Description: Fall kWh Stepped Charges

Description On Bill: Usage %Q kWh at %I per kWh %F

Print: Yes

Print if Zero: No

Rounding Type: Nearest

Precision: 0.01000

FCPO: No

Override Proration: No

Calculation Details:

- **Unit of Measure:** Kilowatt hour
- **Error If No Value:** No
- **Measures Peak:** No
- **GL Statistical Qty:** Yes
- **Create Step Summary:** Create Summary, Do Not Print

Step Calculation Details:

- **Seasonal:** Yes
- **Seasonal Prorate Method:** Accounting Date
- **Season Start:** 09-01
- **Season End:** 11-30
- **Value 1:**
 - **Low Value:** 0
 - **High Value:** 300
 - **Value Type:** Unit Rate
 - **Value Source:** Value
 - **Value / Bill Factor / Algorithm:** 0.0485
- **Value 2:**
 - **Low Value:** 300
 - **High Value:** [blank]
 - **Value Type:** Unit Rate
 - **Value Source:** Value
 - **Value / Bill Factor / Algorithm:** 0.0564

GL Distribution:

- **Distribution Source Code:** Specific Distribution Code
- **Distribution Code:** Revenue - Electric - Residential

Cross Reference:

- **Member Category (Category Type / Value):** Revenue / Consumption Charge

Summary

Summary calculation rules create a "subtotal" on the bill. It exists purely for reporting and informational purposes. Summary calculation rules must define the respective target category that they are applied to. The calculation rule(s) that compute charges should be included in the summary must be defined as members of the target category. See **Cross-Reference** under [Common Parameters](#) for more information about Member and Target categories.

- **Rule Name:** Summary
- **Base Package Calculation Rule Business Object:** C1-Summary

- **Apply Calculation Rule Algorithm Type / Algorithm:** C1-SUMMARY
- **Rule Parameters:**
 - **Calculation Details:** Details regarding how the calculation rule performs its calculations:
 - **Error If No Value:** Indicates what should happen if the system cannot find any calculation rules that are members of the target category at billing time.
- **Example:** This calculation rule creates a consumption summary on the bill based on other calculation rules included in the rate that belong to the "Revenue / Consumption Charge" category.

Calculation Group: Electric Residential Charges

Calculation Rule: USGSUM

Sequence: 30

Description: Usage Summary

Description On Bill: Summary

Print: Yes

Print if Zero: No

Rounding Type: Nearest

Precision: 0.01000

FCPO: No

Calculation Details:

- **Error If No Value:** No

- **Target Category (Category Type / Value):** Revenue / Consumption Charge
- **Member Category (Category Type / Value):** Summary / Summary of Consumption Charge

Rate Check

This section describes the features and functionality of Rate Check.

About Rate Check

The **Rate Check** feature allows you to test your rate schedules under different scenarios. For example, you can test your rates for an existing account using previous bill segments, or by providing user-specified bill period and service quantities.

Performing a Rate Check

Note: The Rate Check portal works with both calculation rule-based and component-based rate schedules.

Use this procedure to perform a rate check.

- Select **Menu > Rates > Rate Check**.
- Select the **Rate Schedule** for the rate check.
- Select the **Service Agreement** for the rate check.
- Select the **Bill Segment** for the rate check (if you wish to base the rate check on an existing bill segment).
- Enter the **Start Date**, **End Date**, and **Accounting Date** for the rate check.
- Select the **Revenue Class** for the rate check.
- If you are basing the rate check on user-specified **Service Quantities**, enter the following for each as applicable:
 - **UOM:** The unit of measure applicable for the rate check (based on the specified rate schedule)
 - **TOU:** The time of use applicable for the rate check (based on the specified rate schedule)
 - **SQI:** The service quantity identifier applicable for the rate check (based on the specified rate schedule)
- **Measured Quantity:** The amount of the service quantity specified.

- **Service Point ID:** The service point which recorded the service quantities, if applicable

Note: If you specified a Service Agreement and Bill Segment, this section is populated based on the selected data, but can be manually overwritten.

- Specify characteristic types and values for any **Characteristics** are applicable to the rate check. Characteristic types and values are used to apply appropriate bill factor values during rate processing.
- If you are using a calculation rule-based rate schedule, specify if the system **Should Trace** the process. This produces logs that outline the calculation groups and rules used by the rate schedule.
- Execute the rate check:
 - If you wish to execute the rate check using a specified bill segment or service quantities, click **Check Rate**.
 - If you wish to execute the rate check using billing determinants retrieved from an external system (such as Oracle Utilities Meter Data Management), select the appropriate function from the **Select Function** dropdown list.

Viewing the Results of a Rate Check

The outcome of the rate check process is displayed on the **Results** tab. This tab contains the following zones:

- **Main:** Displays results of the rate check, including:
 - **Rate Schedule:** The rate schedule used in the rate check
 - **Revenue Class:** The revenue class used for the rate check.
 - **Bill Period:** The start and end dates for the bill period used by the rate check.
 - **Consumption Period:** The start and dates for the consumption period used by the rate check.
 - **Accounting Date:** The Accounting Date used by the rate check.
 - **Calculated Amount:** The calculated total for the rate check
- **Calculation Lines:** Displays the bill calculation headers and lines for the rate schedule.
- **Read Details:** Displays meter read details for the consumption used in the rate calculation.
- **SQ Details:** Displays a list of service quantities used in the rate calculation.
- **Characteristics:** Displays characteristics referenced by the rate calculation (if applicable).
- **Trace Log:** Displays logs that outline the calculation groups and rules used by the rate schedule. This zone is populated only if using a calculation rule-based rate schedule, and if the Should Trace dropdown list is set to "No".

Effective Dates and Price Proration

This section describes how proration applies to different types of calculation rules. Proration implies assessing charges proportionately.

The term "proration" describes two different issues:

- Prorating a charge whose value changes during a bill period. For example, if a tax rate changes during a bill period and you've indicated that such changes should be prorated, the system prorates the tax change (e.g., 20 days at 5% and 10 days at 6%).
- Prorating charges when the time period being billed is not in sync with the time period in which the charges were defined in the rate. For example, if a rate contains a flat monthly charge and the bill period spans two months, the flat charge must be prorated.

This is a complicated topic as it's possible for many proration issues to exist on a single bill. For example, on a single bill:

- The rate structure can change several times during the bill period (i.e., multiple rate versions are effective).
- The taxing authority changes the tax rate.
- The customer's tax exemption changes.
- The customer-specific price can change.
- etc.

Types of Proration

The following section describes the types of proration performed by applying a rate.

Fastpath:

For more information on how prorated charges are presented on the printed bill, refer to [How To Use Description On Bill](#).

Consumption Period Proration

A rate schedule specifies its frequency. Bill segments generated using a rate are expected to have a consumption period that corresponds to this frequency. When a bill segment's consumption period falls outside of the rate frequency's normal period, proratable service quantities may be adjusted to match the normal period for calculation. The service quantities are then re-adjusted based on calculation period proration.

Fastpath:

Refer to [Service Quantity Proration](#) for more information about these calculations.

Calculation Period Proration

There can be multiple versions of a given rate over time. Each version has an effective date. When the system detects that a rate schedule has multiple versions of a rate in effect during a bill period, it may or may not prorate the charges. You control exactly how the system handles this situation using the rate schedule's proration parameters.

If multiple rate versions are effective during the consumption period and the rate schedule is configured to prorate the rate versions, a given bill segment will contain a set of bill calculation lines for each rate version. You should consider quite carefully how to handle this situation on your printed bills as rate version proration can confuse a customer.

Fastpath:

Refer to [Defining Calculation Rules](#) for more information.

Bill Factor Proration

A rate contains calculation rules. The primary reason a calculation rule exists is to define how much to charge for the services sold by your company. When you create calculation rules, you have two ways to indicate how much to charge:

- You can specify the value directly in a calculation rule.
- You can have the calculation rule use a bill factor that contains the value.

Bill factors are effective-dated (meaning, their values may change over time). When the system detects that a calculation rule's bill factor has multiple values in effect during a bill period, it may or may not prorate the charges. You control exactly how the system handles this situation using the bill factor's proration parameters.

Fastpath:

Refer to [Defining Bill Factors](#) and [Bill Factor Value Proration](#) for more information.

Tax Exemption Proration

Bill factors that levy taxes may or may not be eligible for tax exemptions; it's up to the respective taxing authority. Customers who are eligible for tax exemptions will have their tax obligation reduced (or nullified) at billing time.

Whether or not a customer is tax exempt (and the percent exempt) is defined on the service agreement's tax exemption page. A customer's tax exemptability is effective-dated (it may change over time). If a customer's tax exemptability

changes during a bill period, the system may or may not prorate the charges. You control exactly how the system handles this situation using the bill factor's proration parameters.

Contract Value Proration

Some types of bill factors do not have the same value for all customers. For example, you may have rates where the price per kilowatt-hour can be different for every customer using the rate.

For bill factors whose value is customer-specific, the value is defined on the service agreement's contract value page. The contract value is effective-dated (it may change over time). If a customer's contract value changes during a bill period, the system may or may not prorate the changes. You control exactly how the system handles this situation using the bill factor's proration parameters.

Contract Rider Proration

Contract riders are used when the charge associated with a bill factor is only applicable to some customers for some period of time. For example, if a bill factor is used to provide a discount during the first three months of service, then a contract rider would be used.

A customer's contract rider applicability period is defined on the service agreement's contract rider page. A rider's applicability may change during a customer's bill period. You control exactly what the system does when a rider's applicability changes during a bill period using the bill factor's proration parameters.

A Service Agreement's Rate Changes Are Not Prorated

A service agreement's rate is effective-dated (it may change over time). When the system calculates a service agreement's bill segment when multiple rates are effective during the bill period, it will use a single rate from the service agreement's rate history. The system chooses the rate as per the service agreement's SA type's rate selection date.

Fastpath:

Refer to [SA Type - Rate](#) for more information.

Proration Factors

The purpose of calculation rules is to generate bill calculation lines. When rate application builds bill calculation lines, it may also prorate the charges.

There are multiple types of proration performed by rate application. Service quantities, step boundaries, rate values, and bill factor values may all be prorated as part of applying a rate.

We need to establish some terms in order to understand the calculations.

Normal Days

As mentioned previously, the rate schedule references a frequency that specifies the number of times per year that service agreements referencing the rate are expected to bill. The following formula dictates a rate frequency's normal days: $365 \text{ days} / \text{number of periods per year}$.

Example:

- For a monthly frequency (12 periods per year), $365 / 12 = 30$ days.
- For a quarterly frequency (4 periods per year), $365 / 4 = 91$ days.

Fastpath:

Refer to [Defining Frequency Codes](#) for more information.

Consumption Period Factor

Before applying a rate, the bill segment's consumption period is determined. The ratio of normal days to consumption period days is the consumption period factor.

The system uses the Minimum and Maximum Days Offset on the rate's *Frequency* to determine whether or not the calculation rule should be prorated due to a short or long consumption period.

If the number of days in the consumption period is within the tolerance of days determined by the specified on the rate's frequency, the consumption period factor is 1 (not applicable).

Example:

If the consumption period spans 60 days and the rate's normal days equals 30 days then the consumption period factor is:

- $30 \text{ days} / 60 \text{ days} = 0.5$

If the consumption period spans 31 days and the rate's normal days equals 30 days and the maximum offset is 3 days, the consumption period factor is 1 (not applicable) because the consumption period days falls within the tolerance specified on the frequency.

Fastpath:

For more information on how a bill segment's consumption period is determined, refer to [How The System Determines How Much Was Consumed](#) . For more information on specifying minimum and maximum offset days on frequency, refer to [Defining Frequency Codes](#).

Calculation Period Factor

The calculation period is the date range where a rate version is effective during the consumption period. For each rate version that is effective during the consumption period, a bill segment calculation period is created. A set of bill calculation lines is created for each calculation period.

A calculation period factor is determined for each calculation period. The calculation period factor is the ratio of calculation period days to normal days. If the consumption period factor is 1 (not applicable), then the calculation period factor is the ratio of calculation period days to consumption period days.

Example:

If the consumption period covers April 1 to April 30 and there was a new effective rate version as of April 21, there are two calculation periods.

- Calculation period April 1 to April 20, calculation period factor = $20 \text{ days} / 30 \text{ days} = 0.6666667$.
- Calculation period April 21 to April 30, calculation period factor = $10 \text{ days} / 30 \text{ days} = 0.3333333$.

BF Value Period Factor

The bill factor value period is the date range where a prorable bill factor value is effective during the calculation period.

When a bill factor value changes during the calculation period, the results is that multiple bill calculation lines are generated for the same calculation rule.

The ratio of the number of days within the calculation period that a distinct value is effective to the number of days in the calculation period determines the BF value period factor. When the bill factor is set up not to prorate, the BF value period factor is 1 (not applicable).

Example:

If the state tax rate changes from 6% to 6.5% on April 16 and the calculation period is April 1 to April 30, there are two bill factor value periods.

- Bill factor value period April 1 to April 15, BF value period factor = 15 days / 30 days = 0.5.
- Bill factor value period April 16 to April 30, BF value period factor = 15 days / 30 days = 0.5.

Fastpath:

Refer to [Defining Bill Factors](#) for more information on specifying whether the bill factor allows proration.

Overriding Proration Factors

If the system logic for determining proration factors does not satisfy your requirements, you may plug in an override proration algorithm to calculate the proration factors as required by your implementation.

- For Calculation Rule-Based Rates, the override proration algorithm is specified in the calculation rule's business object.
- For Component-Based Rates, the overriding proration algorithm is specified in the [Installation](#) record.

The system is delivered with an algorithm type that sets the proration factors to 1 (not applicable) when a predefined characteristic is specified on a calculation rule. Refer to OVPF-NOPROR for more information.

Service Quantity Proration

When a bill calculation line is generated for a service quantity type calculation rule, the applicable service quantity is multiplied by the consumption period factor. That product is then multiplied by the calculation period factor to determine the prorated service quantity for the bill calculation line.

Example:

Customer's electricity bill segment's consumption period is from April 1 through May 15. A new rate version for the rate schedule is effective as of April 16. 100 kWh is consumed.

Assuming a monthly frequency, if the consumption period spans 45 days and the first calculation period spans 15 days, and the applicable service quantity is 100 kWh; then:

- Consumption period factor = 30 normal days / 45 days = 0.6666667.
- Calculation period factor = 15 days / 30 normal days = 0.5.
- Prorated service quantity = 100 kWh x 0.6666667 x 0.5 = 33 kWh.

The next calculation period extends to the end of the consumption period (30 days):

- Consumption period factor does not change = 0.6666667.
- Calculation period factor = 30 days / 30 days = 1.0.
- Prorated service quantity = 100 kWh x 0.6666667 x 1.0 = 67 kWh.

Measures Peak

If the calculation rule specifies that the service quantity measures peak, then service quantity proration is not performed. Although service quantities are not prorated if a calculation rule measures peak, calculation rule values (like price per kW) are prorated.

Fastpath:

Refer to [Calculation Rule Value Proration](#) for more information.

Step Proration

If a calculation rule's charges are based on stepped pricing then the step boundaries are also prorated (as long as the calculation rule is not marked as measures peak). Step boundaries are multiplied by the calculation period factor to determine the adjusted steps boundaries.

Example:

Assuming a monthly frequency, if the calculation rule's step boundaries are 100 kWh to 300 kWh, and the calculation period is 45 days; the step boundaries are prorated as:

- $45 \text{ days} / 30 \text{ days} \times 100 \text{ kWh} = 150 \text{ kWh}$.
- $45 \text{ days} / 30 \text{ days} \times 300 \text{ kWh} = 450 \text{ kWh}$.

Step Multipliers

If the calculation rule specifies that the steps be multiplied by the result value of another calculation rule, step proration is not performed. It is assumed that the result value from the referenced calculation rule has already been prorated, as the referenced step calculation rule is subject to [Calculation Rule Value Proration](#).

Calculation Rule Value Proration

Except for summary type calculation rules (which are not prorated at all), a value is specified on the calculation rule. The value may be a unit rate, percentage or charge. The value may be specified directly on the calculation rule, derived from a bill factor, derived from another calculation rule, or calculated by an algorithm.

Regardless of where the calculation rule value comes from, it will be multiplied by the calculation period factor when determining the charge on a bill calculation line. Exceptions to this rule are:

- Unit rate values where the calculation rule's measures peak attribute is not checked.
- Percentage values.
- Calculation rule values derived from another calculation rule.

Even though the calculation rule values are not prorated for unit rate and percentage value types, if these rate values change during the calculation period due to a bill factor value change, bill factor value proration still applies.

Values derived from another calculation rule are not subject to rate value proration, as calculation rule value proration was already performed on the referenced calculation rule. Again, if the bill factor value changed on the referenced calculation rule, bill factor value proration still applies.

Example:

A calculation rule charges \$2.00 per kW. The rate schedule's normal days equals 30, and the calculation period spans 15 days. The peak kW service quantity is 50 kW.

- The calculation period factor is 0.5 (15 days / 30 days).
- Calculation rule value proration yields $\$2.00 \times 0.5 = \1.00 per kW.

Fastpath:

For more information on bill factor value proration, refer to [Bill Factor Value Proration](#).

Bill Factor Value Proration

Bill factor value proration behaves the same way any time a bill factor value changes within a calculation period. This could be due to a change in a tax rate, a contract rider becoming effective, a tax exemption expiring, etc.

Multiple bill calculation lines are generated for a given calculation rule when a prorable bill factor value changes during the calculation period.

Example:

If the state tax rate changes from 6% to 6.5% on April 16, and the calculation period is April 1 to April 30.

- The first BF value factor period April 1 to April 15, so BF value period factor is 0.5.
- The value used in the first bill calculation line for state tax is $6\% \times 0.5 = 3\%$.
- The second bill factor value period is April 16 to April 30, so the BF value period factor is 0.5.
- The value used in the second bill calculation line for state tax is $6.5\% \times 0.5 = 3.25\%$.

Example of Generating Prorated Bill Calculation Lines

Let's say that 1200 kWh was consumed from March 17 to April 30. The peak kW for the consumption period is 20 kW.

A monthly rate schedule E-COM1 exists with two rate versions.

Rate version effective prior to April 1 has the following components:

- \$0.05 per kWh.
- \$1.00 per kW.

Rate version effective as of April 1 has the following calculation rules:

- \$0.04 per kWh; as of April 16, \$0.07 per kWh (new effective bill factor value).
- \$1.50 per kW; as of April 16, \$1.25 per kW (new effective bill factor value).

Calculation Period March 17 to March 31

The consumption period spans 45 days, so the consumption period factor is $30 \text{ normal days} / 45 \text{ days} = 0.6666667$.

This calculation period spans 15 days, so the calculation period factor is 0.5.

Service quantity proration for the first calculation period yields:

- $1200 \text{ kWh} \times 0.6666667 \text{ (consumption period factor)} \times 0.5 \text{ (calculation period factor)} = 400 \text{ kWh}$.
- $20 \text{ kW} \times 1 \text{ (not applicable)} = 20 \text{ kW}$.

Calculation rule value proration for the first calculation period yields:

- $\$0.05 \times 1 \text{ (not applicable)} = \0.05 per kWh .
- $\$1.00 \times 0.5 \text{ (calculation period factor)} = \0.50 per kW .

First Set of Bill Calculation Lines

Bill calculation line 1: $400 \text{ kWh} \times \$0.05 = \20.00 .

Bill calculation line 2: $20 \text{ kW} \times \$0.50 = \10.00 .

Calculation Period April 1 to April 30

This calculation period spans 30 days, so the calculation period factor is 1.

Service quantity proration for the calculation period yields:

- $1200 \text{ kWh} \times 0.6666667 \text{ (consumption period factor)} \times 1 \text{ (calculation period factor)} = 800 \text{ kWh}$.
- $20 \text{ kW} \times 1 \text{ (not applicable)} = 20 \text{ kW}$.

Calculation rule value proration for the first calculation period yields:

- $\$0.04 \times 1 \text{ (not applicable)} \times 0.5 \text{ (BF value period factor)} = \0.02 per kWh .
- $\$0.07 \times 1 \text{ (not applicable)} \times 0.5 \text{ (BF value period factor)} = \0.035 per kWh .
- $\$1.50 \times 1 \text{ (calculation period factor)} \times 0.5 \text{ (BF value period factor)} = \0.75 per kW .
- $\$1.25 \times 1 \text{ (calculation period factor)} \times 0.5 \text{ (BF value period factor)} = \0.625 per kW .

Second Set of Bill Calculation Lines

Bill calculation line 1: $800 \text{ kWh} \times \$0.02 \text{ per kWh} = \16.00 .

Bill calculation line 2: $800 \text{ kWh} \times \$0.035 \text{ per kWh} = \26.00 .

Bill calculation line 3: $20 \text{ kW} \times \$0.75 \text{ per kW} = \15.00 .

Bill calculation line 4: $20 \text{ kW} \times \$0.625 \text{ per kW} = \12.50 .

Seasonal Proration

Seasonal proration adds another layer of complexity. If calculation rules are specified to prorate seasonally, the seasonal period specified on a given seasonal calculation rule dictates how a calculation rule's value or associated service quantity is prorated.

There are two proration methods, Prorate and Prorate Seasonal SQ, which may be specified on seasonal calculation rules. Both of these proration methods behave the same way with respect to calculation rule value proration. If a given seasonal calculation rule is eligible for [Calculation Rule Value Proration](#), the ratio of days in the season that are applicable during the calculation period to the days in the calculation period determines the seasonal factor. When it comes to service quantity proration, the two proration methods are different. If a given seasonal calculation rule is eligible for [Service Quantity Proration](#), it prorates the service quantities as follows:

- Prorate. A seasonal factor is calculated as the ratio of days in the season that are applicable during the calculation period to the days in the calculation period. This ratio is applied along with the consumption period factor and calculation period factor to determine the prorated service quantity.
- Prorate seasonal SQ. In this case, it is assumed that either the meter measures seasonal consumption on separate registers or the consumption has been split into separate service quantities by other means (like an SQ rule). To determine a prorated seasonal service quantity, the seasonal proration factor is calculated as for a Prorate seasonal calculation rule. The seasonal factor is then multiplied by another ratio of total consumption period days to days in the season that are applicable for the total consumption period. This modified seasonal factor is applied along with the consumption period factor and calculation period factor to determine the prorated service quantity.

Note:

Prorate seasonal SQ. Specify this option only if you can determine the seasonal consumption as an independent service quantity for use by rate application. Because the service quantities themselves dictate the applicability of the calculation rule, a given service quantity need not appear in rate versions effective outside the season (i.e. a rate version effective on October 1 may not include calculation rules that charge for kWh/summer).

Override Seasonal Proration. If the seasonal functionality provided with the system does not work for your organization, you may override the logic using the Override Seasonal Proration plug-in spot on the [installation](#) record. For example, perhaps the seasonal period is determined dynamically based on the scheduled meter read date of the bill cycle.

Example (Prorate):

Let's say that 600 kWh and 50 kW are the billable service quantities for a consumption period from April 1 to April 30. Prorate seasonal calculation rules are defined on a monthly rate that charge \$0.05 per kWh and \$0.75 per kW from January 1 to April 15. Prorate seasonal calculation rules are defined on the same rate version that charge \$0.06 per kWh and \$0.80 per kW between April 16 and December 31. Assume only one rate version is effective for the consumption period.

- The consumption period factor is 1 (not applicable).
- The calculation period factor is 1.0.
- The seasonal factor for the kWh calculation rule whose season is effective from January 1 to April 15 is 0.5 (15 season days in calculation period / 30 days in the calculation period).
- The resulting bill calculation line uses service quantity proration:
- $600 \text{ kWh} \times 0.5 \text{ (seasonal factor)} \times \$0.05 = \$15.00$.
- The seasonal factor for the kW calculation rule whose season is effective from January 1 to April 15 is also 0.5.
- The resulting bill calculation line uses calculation rule value proration:
- $50 \text{ kW} \times \$0.75 \times 0.5 \text{ (seasonal factor)} = \18.75 .
- The seasonal factor for the kWh calculation rule whose season is effective from April 16 to December 31 is 0.5.
- The resulting bill calculation line uses service quantity proration:
- $600 \text{ kWh} \times 0.5 \text{ (seasonal factor)} \times \$0.06 = \$18.00$.
- The seasonal factor for the kW calculation rule whose season is effective from April 16 to December 31 is also 0.5.
- The resulting bill calculation line uses calculation rule value proration:
- $50 \text{ kW} \times \$0.80 \times 0.5 \text{ (seasonal factor)} = \20.00 .

Example (Prorate seasonal SQ):

Let's say that a given meter measures winter consumption separate from summer consumption. The meter itself measures kWh/summer on a register between June 21 and September 18, and measure kWh/winter on another register at other times of the year.

We are generating a bill segment with a consumption period from September 2 to October 30. A monthly rate schedule has two rate versions effective during the consumption period. The latest rate version is effective on October 1.

Each of the rate version calculation groups have Prorate seasonal SQ seasonal calculation rules defined. The first rate version's calculation rules charge \$0.06 per kWh/summer and \$0.05 per kWh/winter. The second rate version calculation group has a single calculation rule that charges \$0.05 per kWh/winter.

Assume that the billable service quantities are 800 kWh/summer and 1600 kWh/winter.

First set of bill calculation lines (September 2 to September 30):

- The consumption period factor is $30 \text{ normal days} / 60 \text{ consumption days} = 0.5$.
- The calculation period factor is $30 \text{ calculation days} / 30 \text{ normal days} = 1.0$.
- calculation rule 1 (\$0.06 per kWh/summer):
- The seasonal factor $17 \text{ seasonal days} / 30 \text{ calculation days} = 0.5666667$.
- The modified seasonal factor is $0.5666667 \times 60 \text{ consumption days} / 17 \text{ seasonal days} = 2.0$.
- The resulting bill calculation line:
- $800 \text{ kWh/summer} \times 0.5 \text{ (consumption period factor)} \times 2.0 \text{ (modified seasonal factor)} \times \$0.06 = \$48.00$.
- calculation rule 2 (\$0.05 per kWh/winter):
- The seasonal factor is $12 \text{ seasonal days} / 30 \text{ calculation days} = 0.4$.
- The modified seasonal factor is $0.4 \times 60 \text{ consumption days} / 42 \text{ seasonal days} = 0.571428$.
- The resulting bill calculation line:
- $1600 \text{ kWh/winter} \times 0.5 \text{ (consumption period factor)} \times 0.571428 \text{ (modified seasonal factor)} \times \$0.05 = \$22.86$.

Second set of bill calculation lines (October 1 to October 30):

- The consumption period factor is $30 \text{ normal days} / 60 \text{ consumption days} = 0.5$.
- The calculation period factor is $30 \text{ calculation days} / 30 \text{ normal days} = 1.0$.
- Calculation rule 1 (\$0.05 per kWh/winter):
- The seasonal factor $30 \text{ seasonal days} / 30 \text{ calculation days} = 1.0$.
- The modified seasonal factor is $1.0 \times 60 \text{ consumption days} / 42 \text{ seasonal days} = 1.428571$.
- The resulting bill calculation line:
- $1600 \text{ kWh/winter} \times 0.5 \text{ (consumption period factor)} \times 1.428571 \text{ (modified seasonal factor)} \times \$0.05 = \$57.14$.

Fastpath:

For more information on specifying seasonal proration options, refer to [Defining Calculation Rules](#).

Price Changes and Interval Quantities

All of the above sections described situations where the service quantities will be prorated due to changes in the price during the billing period. The above sections assume that the bill contains a simple metering scenario, where reads will not exist on the date of the price break.

However, consider an interval billing example. There are two basic pricing scenarios for interval quantities:

- Interval prices are applied to interval quantities. In this case, proration is not applicable because the prices are changing at small intervals and the appropriate calculation rule understands how to apply the prices to the interval quantities.
- Time of use prices. In this case, interval quantities are being mapped to time of use codes. The standard calculation rule algorithm will compare interval quantities to a time of use map resulting in new entries in the bill segment's SQ collection. Subsequent calculation rules will then apply the appropriate price for each SQ. In

the time of use pricing scenario, it is possible for the prices to change during the bill period. When this happens, proration should not be necessary because readings will exist for the date of the price break.

Setting Up Estimated Consumption for Items

Some types of physical devices (such as, items) use power but a meter does NOT measure the power consumed. The most common example is a street light. If this situation exists for your company AND if the amount charged for the lamp varies based on the amount of estimated power used, then you will have to maintain estimated DAILY consumption for each type of item. The system uses this information at billing time to estimate how much power was used by the customer's items and then prices the estimated consumption as per the terms in the service quantity calculation rule.

Select **Admin > Rates > Item Type SQ Estimate** to define estimated consumption.

Description of Page

Select the **Item Type** using the search.

Enter the estimated daily consumption in the **Daily Service Quantity**. Each Service Quantity has an **Effective Date** so that changes in the estimated quantities may be recorded over time.

Note:

The unit of measure of the daily service quantity is displayed adjacent to the item type description. This value is defined on the item type table. Refer to [Setting Up Item Types](#) for more information.

Where Used

This information is used when the system calculates a bill segment for a service agreement that references service points with items. If the items reference item types for which the system should estimate consumption, the system extracts the daily consumption amount from this table.

Setting Up Degree Days (and Average Temperatures)

Many organizations print degree-day and/or average temperature information on their customers' bills. Select **Admin > Billing > Degree Days > Search** to define these values for a given trend area.

Description of Page

The easiest way to define degree days is to select a **Trend Area** and **Month In Year** and tab out of the field. The system generates one row in the **Degree Days** collection for each day of the month. After the days exist in the collection, you should define the following for each day:

Degree Day This is a unit of measure used to express the extent to which temperatures vary from a specific reference temperature on a given date.

Maximum Temperature This is the maximum temperature on a given date.

Minimum Temperature This is the minimum temperature on a given date.

Average Temperature This is the average temperature on a given date.

Where Used

This information may be used by your bill print routines.

Component-Based Rates

CAUTION:

Component-Based Rates, or classic rates, is not the recommended approach for new implementations. Component-Based Rates is intended for upgrading customers who currently use this rate structure and have not converted to Calculation Rule-Based Rates.

Combining Rating Strategies

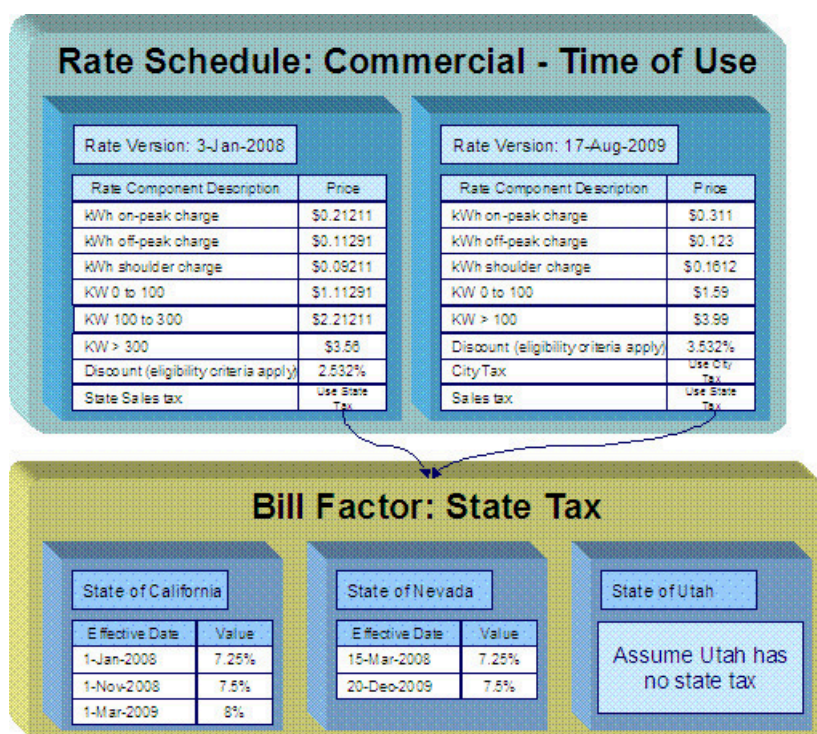

A customer's service agreements can reference both component-based and calculation rule-based rate schedules. For example, a customer could have an existing service agreement for their gas service which references a component-based rate schedule, and add a new service agreement for electric service that references a calculation rule-based rate schedule. When the system calculates the customer's bill, it processes the rate based on the type of rate associated with each service agreement. In this example, when creating the bill segment for the customer's gas service, the system will use the component-based rate engine, but when creating the bill segment for the customer's electric service; it would use the calculation rule-based rate engine.

When you set up a customer in the system, you create a service agreement for every service that the customer uses. The most important information specified on a service agreement is the rate. The rate controls:

This section describes Component-Based Rates.

All Component-Based Rates Share a Common Structure

All rates share a common structure as illustrated in the following sample rate:

This rate is constructed using the following components:

- Every rate has a single **rate schedule** that contains information about the rate that doesn't change over time. For example, the rate's description.
- A rate's effective-dated calculation algorithms are stored in a **rate version**. Every rate schedule has at least one rate version. Multiple rate versions exist when something about the algorithms changes and it's important to keep the prior version in order to recalculate historical bills. The rate shown above has 2 rate versions; one effective on 3-January-2008, the other effective on 17-August-2009.
- A rate version's calculation algorithms are stored in **rate components**. Every rate version will have at least one rate component. The number of rate components linked to a rate version is dependent on the complexity of the calculation rules. We have seen very simple calculation rules that need only a single rate component; we have seen

others that require over 150 rate components. You will find the construction of rate components to be the most challenging task of the setup process.

- **Bill factors** are used to specify the amount to charge when the amount is the same for many rates. Notice that both of the above rate versions reference the prevailing "state tax" bill factor rather than specifying the specific tax percent. This allows the tax rate to be maintained in one place.

Note:

Bill factors have many uses. Bill factors have many uses in addition to specifying tax rates. Refer to [An Overview Of Bill Factors](#) for more information

How to Create a New Component-Based Rate

The following describes the major steps to set up a component-based rate.

- Create a rate schedule for the rate. Refer to [Setting Up A Rate Schedule](#) for more information.
- Set up a rate version to establish the earliest effective date of the rate. Refer to [Defining Rate Versions](#) for more information. We recommend that you set the status of the rate version to In Progress while you're working on the rate.
- Set up rate components to define the rate version's calculation rules. Refer to [Defining Rate Components](#) and [Rate Version Merge](#) for more information.
- After all rate components have been setup, return to [Rate Version - Main](#) and change the rate version's status to Validated. At this point, you can use [Rate Check](#) to test the rate version.
- After you have checked the rate, return to the [Rate Version - Main](#) and change the status to Finished. This allows the rate to be used by billing.
- Define the various SA types that can use the rate. You do this by referencing the rate on [SA Type - Rate](#) . Note that only primary rate schedules may be referenced on SA Types.

Control Tables That Must Be Set Up Before Creating a Component-Based Rate Schedule

See [Control Tables That Must Be Set Up Before Creating a Rate Schedule](#) for information about the main tables that must be configured.

Including:

- [Master Configuration](#)
- [Defining Frequency Codes](#)
- [UOM versus TOU versus SQI](#)

This section describes *additional* tables that must be set up before you can add a component-based rate schedule.

Defining Measured Quantity Manipulation Rules

This section describes when and how you have the system manipulate measured consumption before it is applied to the charges in a rate.

Warning:

Quantity manipulation rules exist to support calculations performed by rate components. This means that you must design your rate components before you can design your quantity manipulation rules. We strongly recommend that you design "on paper" how every rate's rate components looks before you attempt to set up these rules.

When and How to Manipulate Measured Consumption

Many rates calculate charges based on measured consumption. For example, a simple electric rate has a price expressed as an amount per kilowatt-hour (kWh) and the customer's meter measures kWh. However, other rates contain charges for things that aren't measured directly by the customer's meters. Examples include the following:

- Most gas meters measure consumption in cubic feet, but the charges in gas rates are expressed in therms.
- A customer's service agreement may indicate that the number of kilowatts billed per month will be the greater of the measured kilowatts OR the minimum number of kilowatts as defined in the service agreement.
- A customer's meter may only contain two registers: one that measures kWh consumed during peak hours, and another that measures kWh consumed during off peak hours. However, there are charges in the rate based on the total kWh consumed regardless of when the power was used.

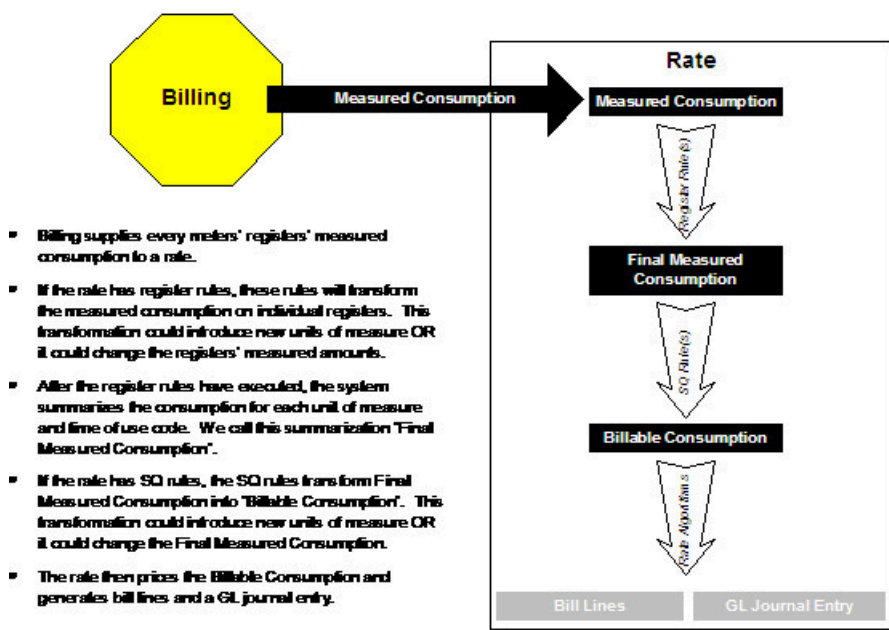

All of these examples share the same trait: the unit of measure being priced is not the same as the unit of measure being measured. If any of your rates possess this trait, then you have to tell the system about it so that it knows to perform extra manipulations before it calculates charges.

So, how do you tell the system to manipulate measured consumption? You have two options:

- Create a Service Quantity (SQ) Rule and link it to the rate schedule
- Create a Register Rule and link it to the rate schedule

When a rate schedule has either type of rule, the system executes the rule's algorithm immediately before it calculates charges. The rule's algorithms manipulate measured consumption so that the rate is supplied with consumption in the manner that it expects.

You must understand the difference between these two types of rules before you can set them up. The following diagram describes how the two types of rules are used and this should help you understand the differences between them:

Note:

Bottom line. Register rules are used when your rates require the manipulation of measured consumption and this manipulation requires attributes directly related to the service point, the meter, or the premise. SQ rules also manipulate measured consumption. However, this manipulation is done without regard to the individual service points or meters.

The following table defines which type of rule would be used for each of the earlier manipulation examples:

| Situation | Type of Rule | Explanation |
|-----------|--------------|-------------|
|-----------|--------------|-------------|

| | | |
|--|---------------|---|
| Cubic Feet (CCF) to Therm conversion | Register rule | A register rule is used because a given bill could contain many registers that measure CCF and each register could have a different therm conversion factor. If an SQ rule was used, a single conversion factor would be applied to the total CCF from all registers. |
| Minimum contract quantity | SQ rule | An SQ rule is used because we want to add together the total amount of consumption from all registers and then compare it to a contract quantity. |
| Add together peak and off peak consumption | SQ rule | An SQ rule is used because we want to add together the total amount of consumption from all registers. |

Setting Up Register Rules

Warning:

Do NOT attempt to set up register rules until you have a very good understanding of what your meters measure and how your rates charge for this consumption. In addition, you should completely understand the concepts described in [When and How to Manipulate Measured Consumption](#) before creating these rules.

To set up register rules, choose **Admin > Rates > Register Rule > Search**.

Description of Page

Enter a unique **Register Rule ID** and a **Description** for the register rule.

Enter **Comments** that describe, in detail, what the rule does.

Select the **Algorithm** that controls how the system manipulates the consumption supplied to the rate. Define the **Parameters** to be used by the register algorithm.

The following table indicates the algorithms that are supplied with the system, its Algorithm Type and how each register algorithm uses its parameters.

Base Package Register Rules

Note:

If the register rule algorithms that are supplied with the base package are not sufficient for your rating requirements, you will have to write a new register rule algorithm. Refer to [How to Add a New Register Rule](#) for how to do this.

| Register Algorithm | Algorithm Type | What It Does | Parameters Used |
|--------------------|----------------|--------------|-----------------|
|--------------------|----------------|--------------|-----------------|

| | | | |
|----------------------------------|----|--|--|
| Bill Factor Based UOM Conversion | BU | <p>Converts a measured quantity into a final quantity using the value specified on a bill factor.</p> <p>Final Quantity (expressed in the UOM in param 2) =</p> <p>Quantity for UOM (in param 1) *</p> <p>Value for Bill Factor (in param 3)</p> <p>This algorithm would be useful when you need to convert cubic feet (CCF) into therms based on the takepoint from which the premise gets its gas.</p> | <p>Param 1 = Measured UOM</p> <p>Param 2 = Final UOM</p> <p>Param 3 = Bill Factor containing conversion factor</p> |
| Real Time Pricing | RT | <p>Converts a measured quantity (UOM) into a final quantity (Result SQI) by multiplying the measured quantity by the price (Bill Factor) effective on the read's start date/time.</p> <p>Final Quantity (expressed in the SQI in param 3) =</p> <p>Quantity for UOM (in param 1) *</p> <p>Value for Real Time Bill Factor (in param 2)</p> <p>Note, this option is useful if you have simple real time pricing algorithms and do not use the interval billing subsystem. Refer to Pricing Interval Consumption Using Interval Prices for more information.</p> | <p>Param 1 = UOM</p> <p>Param 2 = Bill Factor</p> <p>Param 3 = Resultant SQI</p> |

| | | | |
|----------------------------------|----|---|------------------------------------|
| Seasonal Register TOU Conversion | ST | Converts time-of-use codes of "current season" and "prior season" to "winter" and "summer" based on the billing period. | Param 1 = Summer Begin Date (MMDD) |
| | | | Param 2 = Winter Begin Date (MMDD) |
| | | Summer Begin Date contains the MMDD when summer starts. | Param 3 = Current Season TOU |
| | | Winter Begin Date contains the MMDD when winter starts. | Param 4 = Prior Season TOU |
| | | Current Season TOU contains the TOU code of the register that measures the current season's consumption. | Param 5 = Winter TOU |
| | | Prior Season TOU contains the TOU code of the register that measures the prior season's consumption. | Param 6 = Summer TOU |
| | | Winter TOU contains the TOU code to be used for winter consumption (the register read's TOU code is changed to this for winter consumption). | |
| | | Summer TOU contains the TOU code to be used for summer consumption (the register read's TOU code is changed to this for summer consumption). | |

For more information about defining algorithm types, refer to [Setting Up Algorithm Types](#).

Where Used

A primary Rate Schedule may have zero or more register rules. Refer to [Rate Schedule - Register Rules](#) for more information.

How To Setup A Register Rule To Adjust A Cubic Foot Of Gas Based On Pressure

Refer to [Gas Pressure Factor Adjustments](#) for an example.

How to Set Up a Register Rule to Convert Cubic Feet to Therms

Let's assume a gas rate contains therm-oriented charges, but the customer's meters only measure in cubic feet. This means that you will need a register rule to convert the measured consumption into therm-oriented consumption.

The following table shows the array that will be supplied to the rate assuming the customer's meter measures CCF:

| Unit Of Measure | Time Of Use | Measured Quantity | Final Quantity |
|-----------------|-------------|-------------------|----------------|
| CCF | | 1000 | 1000 |

Now, let's assume the rate contains charges based on therms. This means that the rate needs to have the array changed as follow:

| Unit Of Measure | Time Of Use | Measured Quantity | Final Quantity |
|-----------------|-------------|-------------------|----------------|
| CCF | | 1000 | 1000 |
| TH | | | 1010 |

As you can see, a new entry was added to the array. This new entry contains the amount of therms associated with the measured CCF. To do this you would need to create a register rule with the following attributes (and link it to the appropriate rates):

| Field | Value |
|--------------------|----------------------------------|
| Register Algorithm | Bill factor based UOM conversion |
| UOM (Source) | CCF |
| UOM (Result) | TH |
| Bill Factor | CCFCNV |

In addition, you will also have to set up the following bill factor and characteristic information:

- Add a characteristic type to define your various take points (call it, TAKEPT). Indicate this characteristic is specified on premises.
- Define characteristic values for the take point characteristic. These will be the take points in your service area.
- Add the bill factor you identified in the register rule (i.e., CCFCNV). Indicate that the type of characteristic to use is the take point characteristic type (i.e., TAKEPT). Add bill factor characteristics for each take point.
- Add a bill factor value for each bill factor characteristic. This value will contain the CCF to term conversion factor to be used for the specific take point.
- Update the relevant postal defaults so that the appropriate take point will default onto your premises.
- Update existing premises with their respective take point (by specifying the appropriate characteristic value for the take point characteristic).

Fastpath:

For more information about bill factors and characteristics, refer to [Setting Up Bill Factors](#) and [Setting Up Characteristic Types & Their Values](#).

How to Set Up a Register Rule to Price Interval Consumption Using Interval Prices

Refer to [Pricing Interval Consumption Using Interval Prices](#) for an example.

Setting Up Service Quantity (SQ) Rules

Warning:

Do NOT attempt to set up SQ rules until you have a very good understanding of what your meters measure and how your rates charge for this consumption. In addition, you should completely understand the concepts described in [UOM versus TOU versus SQI](#) before creating these rules. In addition, you should completely understand the concepts described in [When and How to Manipulate Measured Consumption](#) before creating these rules.

To set up Service Quantity (SQ) rules, choose **Admin > Rates > Service Quantity Rule > Search**.

Description of Page

Enter a unique **SQ Rule ID** and a **Description** for the SQ rule.

Enter a **Long Description** that describes, in detail, what the rule does.

Indicate the **UOM**, **TOU** and **SQI** to be output by the rule.

Every service quantity supplied to a rate has two quantities - the amount of service as it was initially measured, and the amount of service that should be priced by the rate. Generally, an SQ Rule does not change the initially measured quantities. There are two exceptions to this, which are the Mathematical Functions rule (MA) and the Sum rule (SM). (Refer to the algorithm type descriptions of each rule for more information.)

Indicate whether the system should **Create Billing Error** if the SQ Rule is not able to execute successfully. For most SQ Rules you would turn this option on. However, if the rule is linked to a rate where the rule is only applicable to a subset of the customer base using the rate, you may not want a billing error to be issued if the rule cannot execute. For example, consider a rule used to derive total kWh by adding together peak kWh and off-peak kWh. You would only use such a rule if you measured peak and off-peak consumption, but you had prices in respect of total consumption. In the situation where this SQ Rule was linked to a rate used by customers with and without time-of-use meters, you would not want the system to issue a billing error for those customers without time-of-use meters (because their meter already measures total consumption).

Use **SQ Rule Processing** to indicate if the SQ rule is Always executed by rate application, even if the consumption details on the original bill segment are to be used when the system recalculates a bill segment (refer to [Rebill \(Bill Segment\)](#)). If the SQ rule should not be executed when the consumption details on the original bill segment are used, indicate that the SQ rule should only be executed on the Initial SQ Calculation . SQ rules that create a characteristic type / value (in the characteristic collection) used by one or more bill factors referenced in a rate component should typically be always executed. Refer to [Base Package SQ Rules](#) for examples of SQ rules that create a characteristic type / value.

Select the **SQ Algorithm Type** that controls how the system manipulates the consumption supplied to the rate. Define the **Parameters** to be used by the SQ algorithm.

Base Package SQ Rules

The following table describes the SQ rule algorithms that are supplied with the system.

Note:

If the algorithms described below are not sufficient for your rating requirements, you must write a new SQ rule algorithm. Refer to [How to Add a New SQ Rule](#) for how to do this.

| SQ Algorithm | Algorithm Type | What It Does | Parameters Used |
|--------------|----------------|--------------|-----------------|
|--------------|----------------|--------------|-----------------|

Bill Credits for Electric Consolidated Billing BC

This SQ rule creates a Characteristic Type / Value to handle consolidated billing credits. These values are used by one or more bill factors referenced in the rate components to vary the amount associated with a given bill line.

The characteristic type and value are generated if a service provider (SPr) provides consolidated billing for its customer. These credits are applied irrespective of whether the SPr provides full or partial consolidated billing and whether or not the customer takes both gas and electric services.

SA Relationship Type

tells the system the type of SA relationship (e.g., energy service provider versus meter agent) that is interrogated.

Service Type tells the system the service type associated with electricity (as the characteristic value returned differs for electric-only service providers).

The Characteristic collection will be updated with the **Characteristic Type** and an appropriate Value as follows:

- **BR Dual Commodity Value** if the SPr provides bill ready consolidation for more than one service
- **BR Electric Only Value** if the SPr provides bill ready consolidation for electric only
- **RR Dual Commodity Value** if the SPr provides rate ready consolidation for more than one service
- **RR Electric Only Value** if the SPr provides rate ready consolidation for electric only

Param 1 = SA Relationship Type

Param 2 = Service Type for Electric

Param 3 = Characteristic Type - Billing Credit

Param 4 = Characteristic Value - BR Dual Commodity Value

Param 5 = Characteristic Value - BR Electric Only Value

Param 6 = Characteristic Value = RR Dual Commodity Value

Param 7 = Characteristic Value = RR Electric Only Value

Bill Credits for Gas
Consolidated Billing

CT

This SQ rule creates a characteristic type / value if a service provider provides consolidated billing for the customer being billed. These values are used by one or more bill factors in the rate components to vary the amount associated with a given bill line.

The characteristic type and value are generated if a customer's gas service provider (SP) provides consolidated billing (i.e., the service provider has a billing relationship of "they bill for us").

The **Service Type** tells the system how to identify gas service.

The **SA Relationship Type** tells the system the type of SA relationship (e.g., energy service provider versus meter agent) that is interrogated.

If the above conditions are true, the Characteristic collection will be updated with the **Characteristic Type** and an appropriate Value as follows:

- **CTA Credit Residential** if the customer class matches the **Customer Class for Residential**
- **CTA Credit Non-Residential** if the customer class does not match the **Customer Class for Residential**

Param 1 = Service Type

Param 2 = SA Relationship Type

Param 3 = Customer Class for Residential

Param 4 = Characteristic Type - CTA Credit

Param 5 = Characteristic Value - CTA Credit Residential

Param 6 = Characteristic Value - CTA Credit Non-Residential

Bill days (Days)

DY

This SQ rule calculates the total number of days in the bill period. This algorithm is necessary if you have charges that are based on the number of days of service (e.g., a minimum charge that varies based on the days of service). Refer to [Calculated Minimum Charges and Step Boundaries Based On The Number Of Days Of Usage And The Region In Which The Customer Resides](#) for good examples of when to use such an SQ rule.

No parameters are used.

Characteristic Value

CV

This SQ rule creates an entry in the SQ array containing the sum of the characteristic values of a given Characteristic Type. The values are accumulated from the entity defined in the parameter list.

Param 1 = Characteristic Type

Param 2 = Characteristic Source

Param 3 = Minimum Value

Resulting Quantity (expressed in the Output UOM / TOU / SQI) = the sum of the characteristic values of a given

Characteristic Type.

Characteristic Source

determines the entity that holds the characteristic values:

- If **Characteristic Source** is "SA", the characteristic value effective on the bill start date for the Characteristic Type (P1) and SA Id is returned.
- If **Characteristic Source** is "ACCOUNT", the characteristic value effective on the bill start date for the Characteristic Type (P1) and Account Id is returned.
- If **Characteristic Source** is "PREMISE", the characteristic values are accumulated from all premises linked to the SA ID.
- If **Characteristic Source** is "SP", the characteristic values are accumulated from all service points linked to the SA ID.

If **Minimum Value** is greater than zero and the resultant characteristic value is less than the specified **Minimum Value**, an error is generated.

Check Load Factor

LF

This SQ rule generates a To Do entry if a customer's actual demand exceeds a fixed demand amount (and actual kWh exceeds a calculated kWh).

The actual algorithm is as follows:

Retrieve maximum demand from SQ collection as the greatest of **kW/Peak**, **kW/Part Peak** and **kW/Off-Peak**. If this maximum demand \leq **Threshold Maximum Demand**, escape the routine. If this maximum demand $>$ **Threshold Maximum Demand**:

- Compute 'Calculated kWh' = **Threshold Maximum Demand** * total days in bill period, times 24.
- If **Actual kWh/Calculated kWh** $>$ 1, create a To Do Entry (using the **To Do Type** and **To Do Role** (if specified)). The base package includes the **To Do Type LF** to use for this parameter value, unless you've set up your own.

Param 1 = UOM of demand (e.g., KW)

Param 2 = TOU of peak period

Param 3 = TOU of off-peak period

Param 4 = TOU of part peak period

Param 5 = UOM of actual KWH (e.g., KWH)

Param 6 = Threshold maximum demand

Param 7 = **To Do** Type

Param 8 = **To Do** Role (optional)

Consumption History

CH

This SQ rule adds an entry in the SQ array that contains a given amount of historical consumption.

This algorithm can return MAX (maximum), MIN (minimum), SUM (total) or AVG (daily average) consumption as defined by the **Operator**. It retrieves this consumption from the SA's historical bill segments (from the service quantities that are stored on the bill segments).

UOM / TOU / SQI define the type of historical consumption that is retrieved.

The historical period whose consumption is accessed is defined by EITHER:

- **Number of Historical Periods** (a period is defined by the rate schedule's frequency) or
- The previous historical season (defined by **Start Month/Day** and **End Month/Day**).

PLEASE SPECIFY EITHER OF THE ABOVE PARAMETERS.

Note. If the system finds historical bills with a period outside the normal period for the rate's frequency, proration takes place if the input UOM does not Measure Peak. The algorithm accesses consumption data starting from the most recent bill going backwards. As soon as an irregular bill period is encountered, the system attempts to determine appropriate consumption for a "normal" period by prorating the irregular bill based on actual data from previous bills.

For example, if historic

Param 1 = Season Start Month / Day (MM/DD)

Param 2 = Season End Month / Day (MM/DD)

Param 3 = Number of Historical Billing Periods

Param 4 = UOM

Param 5 = TOU

Param 6 = SQI

Param 7 = Operator

Contract Quantity

CQ

This SQ rule is used to create an entry in the SQ array for a given Contract Quantity Type specified in a SA. If multiple values are effective during a bill period, the Proration Rule determines what happens. (See below).

Param 1 = Contract Quantity Type

Param 2 = Proration Rule: CQBD, CQED, CQMA, CQMI, CQPR

Resulting Quantity (expressed in the Output UOM / TOU / SQI) = the value of a given **Contract Quantity Type** in a SA. If multiple values are effective during a bill period the **Proration Rule** determines what happens:

- If **Proration Rule** is 'Use Contract Quantity effective at Beginning of Bill Period' (i.e., CQBD), SQ Amount = Contract Quantity effective at the start of the bill period.
- If **Proration Rule** is 'Use Contract Quantity effective at End of Bill Period' (i.e., CQED), SQ Amount = Contract Quantity effective at the end of the bill period.
- If **Proration Rule** is 'Maximum' (i.e., CQMA), SQ Amount = largest Contract Quantity effective in the bill period.
- If **Proration Rule** is 'Minimum' (i.e., CQMI), SQ Amount = smallest Contract Quantity effective in the bill period.
- If **Proration Rule** is 'Prorate' (i.e., CQPR), SQ Amount = Sum of all prorated contract quantities (calculate the number of days in the bill period (X); calculate the number of days in the bill period that each contract quantity is effective (Y(i)); prorate each contract quantity (i) = (Contract Quantity(i) * Y(i) / X)

Direct Access Credits

CD

This SQ rule creates a characteristic type / value to handle credits issued to the customer for participating in direct access. These values are used by one or more bill factors in the rate components to vary the amount associated with a given bill line.

This rule always creates a characteristic type equal to **Characteristic Type DA Credit**. The characteristic value will be set as follows:

- If the service agreement being billed has a service agreement relationship with either the **ESP Relationship Type** or the **CTA Relationship Type**, a characteristic value of **Characteristic Value - DA Customer** will be created.
- If not, a characteristic value of **Characteristic Value - Non DA Customer** will be created.

Param 1 = ESP Relationship Type

Param 2 = CTA Relationship Type

Param 3 = Characteristic Type - DA Credit

Param 4 = Characteristic Value - DA Customer

Param 5 = Characteristic Value - Non DA

Early Pay

EP

This SQ rule is only used if you provide customers with early payment discounts via a discount on their next bill segment. This rule works as follows:

Param 1 = Char Type - Number of Days Early

Param 2 = Char Type - Eligible For Early Pay Disc

Param 3 = Char Value - Eligible For Early Pay Disc

- First, it determines if the prior bill segment's bill was paid before its due date. It does this by retrieving the customer's balance as of the prior bill's due date - 1 day. If this amount is \leq zero, it checks if a payment exists with a payment date on or after the bill's bill date and before the bill's due date. If yes, processing continues.
- A characteristic type / value is created where the value holds the number of days early (and the characteristic type is equal to **Char Type - Number of Days Early**).
- In addition, this routine accumulates the sum of the bill lines on the prior bill segment for which the early payment discount is eligible. It does this by accumulating all bill lines that reference a given characteristic type and value (where characteristic type is equal to **Char Type - Eligible For Early Pay Disc**, and **Char Value - Eligible For Early Pay Disc**). It populates the total amount in the service quantity defined on the SQ rule. This means that you must define this characteristic type / value on each rate component whose resultant value is eligible to receive an early payment discount.

This rules anticipates the early pay discount being levied using two rate components:

Mathematical Functions MA

This SQ rule performs mathematical functions on service quantities prior to rate application.

There are three major groups of parameters:

1) **Quantity 1** (identified by a service quantity's UOM/TOU/SQI).

2) **Mathematical operand**

3) **Quantity 2** (identified by a service quantity's UOM/TOU/SQI or a Bill Factor)

For example, if you want to add together two SQ entries, these values would contain:

1) the unique identifier of one of the SQ's (in parameters 1 through 3)

2) the "+" symbol (in parameter 4)

3) the unique identifier of the other SQ (in parameters 5 through 7)

It should be stressed that **Quantity 2** can either reference a **bill factor** (param 8) or an SQ entry (parameters 5 through 7). If both are specified, the bill factor is used.

The two **default values** (param 9 and param 10) are only used if Quantity 1 and/or Quantity 2 reference SQ's / bill factor that are not present at billing time. There are three ways to use these **default values**:

- If you want to multiply a SQ by a constant value, define the SQ in Quantity 1 and the constant value in Param 10, i.e., you don't have to specify anything in Param's 5 through 8.

- If you want a default value used if the system cannot find a SQ that matches the UOM/TOU/SQI, define this value in Param 9 and/or Param 10.

Quantity 1:

Param 1 = UOM of service quantity entry

Param 2 = TOU of service quantity entry

Param 3 = SQI of service quantity entry

Or

Param 9 = Decimal number

Mathematical Operand:

Param 4 = operand symbol (i.e., +, -, *, /)

Quantity 2:

Param 5 = UOM of service quantity entry

Param 6 = TOU of service quantity entry

Param 7 = SQI of service quantity entry

Or

Param 8 = Bill factor ID

Or

Param 10 = Decimal number

Maximum Service Quantity MQ

This SQ rule compares a quantity (either measured or created via a previous SQ rule) against a contract quantity and returns whichever is larger.

Param 1 = UOM

Param 2 = TOU

Param 3 = SQI

Param 4 = Contract Quantity Type

Resulting Quantity (expressed in the Output UOM / TOU / SQI) =

greater of quantity for **UOM / TOU / SQI**

OR

service agreement quantity for **Contract Quantity Type**

Meter Ownership

MO

This SQ rule returns SQI = number of meters that are not owned by the company per day.

Param 1 = Meter Ownership/Services Relationship Type

It applies if a service provider owns a direct access customer's meter or a customer owns its own meter.

The system expects an SA Relationship to exist with the **Meter Ownership/ Services Relationship Type**. If a Relationship exists where the service provider is a third party, the number of meters linked to this SA is counted and returned.

Meter Service Credits

MD

This SQ rule creates a characteristic type / value to handle credits issued to the customer because a customer's meter is read by a 3rd party service provider. These values are used by one or more bill factors in the rate components to vary the amount associated with a given bill line.

It applies if a service provider (SPr) provides meter reading services for its customer. These credits are applied irrespective of whether or not the customer takes both gas and electric service and the method the SPr uses to read the meter.

Meter Reading

Relationship Type tells the system the type of SA relationship (e.g., energy service provider versus meter agent) that is interrogated.

Service Type tells the system the service type associated with electricity (as the characteristic value returned differs for electric-only service providers).

The Characteristic collection will be updated with the **Characteristic Type** and an appropriate Value as follows:

- **MDMA Dual Commodity Value** if the ESP provides meter reading for more than one service
- **MDMA Electric Only Value** if the ESP provides bill ready consolidation for electric only

Param 1 = Meter Reading Relationship Type

Param 2 = Service Type for Electric

Param 3 = Characteristic Type - MDMA Credit

Param 4 = Characteristic Value - MDMA Dual Commodity Value

Param 5 = Characteristic Value - MDMA Electric Only Value

| | | | |
|----------------|----|---|---|
| Season Days | SD | <p>This SQ rule is used to create an entry in the SQ array that contains the number of days in the current bill period that fall in a defined season.</p> <p>Resulting Quantity (expressed in the Output UOM / TOU / SQI) = number of days in the current bill period that fall in Season Start and Season End. For example, if bill period = 03/15/99 to 04/15/99 and Season Start date = 04/01 and Season End date = 10/31, then resulting quantity = 15.</p> | <p>Param 1 = Season Start (MMDD)</p> <p>Param 2 = Season End (MMDD)</p> |
| Seasonal Usage | SU | <p>This SQ rule is responsible for taking a non-seasonal UOM/TOU/SQI and producing a seasonal UOM/TOU/SQI, depending on the bill period. For example, if you have a meter which only measures on and off peak consumption, but a rate that bills for summer on peak and summer off peak consumption, then this rule will be used.</p> <p>Resulting value = value of UOM1/ TOU1/ SQI1 * (value of UOM2/ TOU2/ SQI2 / value of UOM3/ TOU3/ SQI3)</p> | <p>Normal consumption</p> <p>Param 1 = UOM1</p> <p>Param 2 = TOU1</p> <p>Param 3 = SQI1</p> <p>Number of days in the season</p> <p>Param 4 = UOM2</p> <p>Param 5 = TOU2</p> <p>Param 6 = SQI2</p> <p>Number of days in the billing period</p> <p>Param 7 = UOM3</p> <p>Param 8 = TOU3</p> <p>Param 9 = SQI3</p> |

| | | | |
|-----|----|---|---|
| Sum | SM | <p>This SQ rule adds up several quantities (either measured or created via a previous SQ rule). This algorithm would be useful when you need to add together "time-of-use" registers because there are charges in the rate that are for the total amount of consumption regardless of when it was used.</p> <p>Resulting Quantity (expressed in the Output UOM / TOU / SQI) =</p> <p>Quantity for UOM (in param 1) TOU (in param 2) SQI (in param 3) +</p> <p>Quantity for UOM (in param 4) TOU (in param 5) SQI (in param 6) +</p> <p>Quantity for UOM (in param 7) TOU (in param 8) SQI (in param 9)</p> | <p>Quantity 1</p> <p>Param 1 = First UOM</p> <p>Param 2 = First TOU</p> <p>Param 3 = First SQI</p> <p>Quantity 2</p> <p>Param 4 = Second UOM</p> <p>Param 5 = Second TOU</p> <p>Param 6 = Second SQI</p> <p>Quantity 3</p> <p>Param 7 = Third UOM</p> <p>Param 8 = Third TOU</p> <p>Param 9 = Third SQI</p> |
|-----|----|---|---|

For more information about defining algorithm types, refer to [Setting Up Algorithm Types](#).

Where Used

A Rate Schedule may have zero or more SQ Rules. Refer to [Rate Schedule - SQ Rules](#) for more information.

How to Set Up an SQ Rule to Add Together Two Service Quantities

Let's assume the rate contains charges based on the TOTAL amount of s (a variable representing the price per kWh with no TOU or SQI). However, some customers who use this rate have time-of-use meters that measure kWh in respect of peak and off-peak hours (i.e., the meters have two registers where one measures kWh peak and the other measures kWh off-peak). This means that you will need an SQ Rule to add together the two measured service quantities to derive total kWh.

The following table shows the array that will be supplied to the rate assuming the customer's meter measures kWh peak usage and kWh off peak usage:

| Unit Of Measure | Time Of Use | SQ Identifier | Initial Quantity | Billable Quantity |
|-----------------|-------------|---------------|------------------|-------------------|
| KWH | PEAK | | 1000 | 1000 |
| KWH | OFFPEAK | | 800 | 800 |

Now, let's assume the rate contains charges based on the TOTAL amount of s (with the variable s representing the sum of KWH PEAK and KWH OFFPEAK). This means that the rate needs to have the array changed as follow:

| Unit Of Measure | Time Of Use | SQ Identifier | Initial Quantity | Billable Quantity |
|-----------------|-------------|---------------|------------------|-------------------|
|-----------------|-------------|---------------|------------------|-------------------|

| | | | |
|-----|---------|------|------|
| KWH | PEAK | 1000 | 1000 |
| KWH | OFFPEAK | 800 | 800 |
| KWH | | | 1800 |

As you can see, a new entry was added to the array. This new entry contains the sum of two existing service quantities. Notice that the new entry doesn't have an initial quantity. This is because an SQ Rule will create it and SQ Rules never populate initial quantity (only metered consumption can exist in initial quantity). To add this new entry, create an SQ Rule with the following attributes (and link it to the appropriate rates):

| | |
|------------------------|---|
| Field | Value |
| SQ Algorithm | Sum |
| UOM 1 | KWH |
| TOU 1 | PEAK |
| SQI 1 | |
| UOM 2 | KWH |
| TOU 2 | OFFPEAK |
| SQI 2 | |
| UOM 3 | |
| TOU 3 | |
| SQI 3 | |
| Quantity to Use | Billable Quantity (actually, it doesn't matter because both the Billable and Initial Quantities will contain the same value in this scenario). |
| Create a Billing Error | It depends on your situation. If all customers using this rate have time-of-use meters that need to be summed together to come up with the total kWh, then you'd want to create a billing error if the system is not supplied with the appropriate service quantities. If some customers using this rate have time-of-use meters and others just have summary meters that don't differentiate based on time-of-use, you would NOT select this option because you wouldn't want a billing error generated for customers without a time-of-use meter. |

Defining Service Quantity Identifiers (SQI)

Consider a rate that contains a charge per "meter day" where the total number of meter days equals the number of days in the billing period multiplied by the number of customer-owned meters at the premise. At billing time, you'd need an SQ Rule to count the number of customer-owned meters and multiply this value by the number of days in the billing period. You could instruct the SQ Rule to place the resultant number of meter days in some unit of measure

(meaning you'd have to create a UOM called "meter day"). Alternatively, you could instruct the SQ Rule to place the resultant number in a service quantity identifier (SQI) (meaning you'd have to create an SQI called "meter day"). The choice is yours. As a rule of thumb, we'd recommend creating an SQI for those things that are not measured by a meter.

Warning:

SQIs exist to support calculations performed by rate components. This means that you must design your rate components before you can design your service quantity identifiers. We strongly recommend that you design "on paper" how every rate's rate component looks before you attempt to set up your SQIs.

Note:

If you create an SQI, you must also have a corresponding SQ Rule to calculate the amount of the SQI to be priced by the rate. If not, it is impossible for the system to generate a bill line for the SQI because there will be no quantity associated with the SQI.

To define service quantity identifiers, open **Admin > Service Quantity Identifier**.

Description of Page

Enter a unique **Service Qty. Identifier** and **Description** for every SQI.

Enter the appropriate number of **Decimal Positions** for each SQI. The rate application process uses this information to round the calculated service quantity prior to applying appropriate rate components.

Where Used

An SQ Rule may use an SQ Identifier to describe what it generates. Refer to [Setting Up Service Quantity \(SQ\) Rules](#) for more information.

A Service Quantity Rate Component may use an SQ Identifier to describe what it is pricing. In this situation, the rate must contain an SQ Rule that generates a quantity for this SQI; otherwise there will be a price without a service quantity. Refer to [Rate Component - Main Information](#) for more information.

Setting Up a Component-Based Rate Schedule

A primary rate schedule is setup for every rate that you offer to your customers. A subsidiary rate schedule is setup to encapsulate common rate components shared by multiple primary rate schedules. Rate schedules are defined using the pages described in this section.

Note:

A rate schedule isn't complete without rate versions and rate components. Refer to [All Component-Based Rates Share A Common Structure](#) for information about how you must also create rate versions and rate components for every rate schedule.

Rate Schedule - Main

You start the rate definition process by selecting **Menu > Rates > Rate Schedule > Search**. On this page you enter general information about the rate.

Description of Page

Enter a unique **Rate Schedule ID** to identify the rate. The value that you supply will typically correspond with the identity of the rate in your rate book.

Enter a **Description** for the rate schedule.

Select the **Rate Schedule Type** that applies to the rate schedule. Rate schedules can be either **Primary** or **Subsidiary**. Primary rate schedules are the main type of rate schedule used to calculate charges and bills for customers. Subsidiary rate schedules can be used to define rate components that are shared by more than one primary rate. For example, if an organization has multiple rate schedules that reference the same tax rate components, these tax rate components

could be placed into a subsidiary rate which the primary rates would reference. Note that subsidiary rate schedules may not be referenced on service agreements, or defined as default rate schedules on SA Types. See [Use Sub Rate Schedules to Encapsulate Common Rate Components](#) for more information about subsidiary rate schedules.

Note:

Service Type, Frequency, Currency Code and **Allow Estimates** defined for the primary rate schedule are used to drive the calculations at billing time and may not be specified on subsidiary rates

Select the **Service Type** that describes the service associated with this rate. When you maintain an existing rate schedule, this field will be disabled if the rate is referenced on at least one SA Type. See [Setting Up Service Types](#) for more information.

Select a **Frequency** to define the time period in which the rate's charges are expressed. See [Defining Frequency Codes](#) for more information.

Note:

Frequency may also affect the read used to bill a customer. If you use the base package's get consumption algorithm to amalgamate reads during billing, the rates frequency also affects whether a bill segment is created AND the period of time during which the system will look for an "end read". Refer to [Meter Read Snapshot](#) for more information.

Select a **Currency Code** to define the currency in which the rate's prices are expressed. See [Defining Currency Codes](#) for more information.

Note:

Currency note. All bill factors that are referenced on the rate's rate components must be denominated in the same currency as defined on the rate schedule. This is because bill factors are used when the price is "soft" and all prices in a rate, be they hard or soft, must be in the same currency. Also note - all rates referenced on an account's service agreements must be denominated in the same currency as defined on the account.

Turn on **Allow Estimates** if the bill process is allowed to estimate consumption for service agreements that use this rate. Consumption is estimated if all of the following points are true:

- A real read cannot be found.
- The service agreement allows estimation.
- The bill cycle schedule allows estimation (if the bill is produced by the billing background process).
- The rate schedule allows estimation.

Turn on **Allow RVs Proration** if a change in the Rate Version during a bill period should be prorated. If changes should not be prorated, indicate the **RV Selection Date** to use when the system determines which rate version to use; available options are:

| | |
|-----------------|--|
| Accounting Date | The rate version effective on the bill's accounting date will be used. |
| Bill End Date | The rate version effective on the bill's end date will be used. |
| Bill Start Date | The rate version effective on the bill's start date will be used. |

Rate Schedule Tree

The right half of this page is dedicated to a tree that shows the rate schedule's SQ Rules, Register Rules, Rate Versions, and Primary/Sub Rates (primary rate schedules list any linked sub rates including the sub rates SQ Rules, Rate Versions, etc.; subsidiary rate schedules list any linked primary rates). You can use this tree to view high-level information about these objects. You may also transfer to a given rate version by selecting that rate version.

**Note:**

The Duplicate button enables you to copy another rate schedule and optionally, its rate versions. Refer to [Duplicate Button](#) in the system wide standards document for more information.

Where Used

Most SA Types contain a collection of valid Rate Schedules. Refer to [SA Type - Rate](#) for more information.

Most Service Agreements reference a Rate Schedule. Refer to [Service Agreement - Rate Info](#) for more information.

Rate Schedule - SQ Rules

When a rate contains prices for things that aren't measured directly by the customers' meters, you must link SQ Rules to the rate. When a rate schedule has SQ Rules, the system executes each rule's algorithm before it calculates the charges embodied in the rate's rate components. These SQ Rules manipulate measured consumption so that the rate is supplied with consumption in the manner that it expects. Open **Menu** > **Rates** > **Rate Schedule** > **Search** and navigate to the **SQ Rule** page to link SQ Rules to a rate.

**Fastpath:**

For more information, refer to [Setting Up Service Quantity \(SQ\) Rules](#).

**Note:**

The [Rate Schedule Merge](#) page enables you to build the SQ rule collection for your rate schedule by copying collections from existing rate schedules.

Description of Page

Enter a **Service Quantity Rule** for every type of service quantity manipulation required by the rate. The **Sequence** number is important when you have multiple rules linked to the rate, as it defines the order in which the rules will be executed.

Where Used

Billing uses this information to create additional service quantities at billing time.

Rate Schedule - Register Rules

When a meter measures something in a unit of measure that has to be converted into a different unit of measure before it can be rated, you must link register rules to the rate. A good example is when a meter measures gas in cubic feet, but the rate contains prices in therms.

When a rate schedule has register rules, the system executes each rule's algorithm before it calculates charges. These register rules convert measured consumption so that the rate is supplied with consumption in the manner that it expects.

**Fastpath:**

For more information about register rules, refer to [Setting Up Register Rules](#).

**Note:**

The [Rate Schedule Merge](#) page enables you to build the register rule collection for your rate schedule by copying collections from existing rate schedules.

Select **Menu** > **Rates** > **Rate Schedule** > **Search** and navigate to the **Register Rule** page to link register rules to a rate.

Description of Page

Enter a **Register Rule** for every type of register rule to be executed before consumption is rated. The **Sequence number** is important when you have multiple rules linked to the rate, as it defines the order in which the rules will be executed.

**Note:**

Register Rules are not allowed on subsidiary rate schedules.

Where Used

Billing uses this information to create or adjust service quantities at billing time.

Rate Schedule - Bill Messages

When a rate schedule has bill messages, the system will sweep these messages onto bills that use the rate.

**Fastpath:**

For more information about bill messages, refer to [The Source Of Bill Messages](#).

**Note:**

The [Rate Schedule Merge](#) page enables you to build the bill message collection for your rate schedule by copying collections from existing rate schedules.

Select **Menu > Rates > Rate Schedule > Search** and navigate to the **Bill Messages** to link bill messages to a rate.

Description of Page

Use the **Bill Messages** collection to define **Bill Message** codes that should appear on bills that use a given rate schedule. For each message, also specify the **Start Date** and **End Date** when such a message should appear on the bill (leave **End Date** blank if the message should appear indefinitely).

Where Used

The system snaps bill messages on a bill during bill completion. Refer to [The Source Of Bill Messages](#) for more information.

Rate Schedule - Meter Configuration Type**Note:**

The [Rate Schedule Merge](#) page enables you to build the meter configurations collection for your rate schedule by copying collections from existing rate schedules.

Select **Menu > Rates > Rate Schedule > Search** and navigate to the **Meter Configuration Type** page to define the types of meters that may be linked to service agreements that use this rate.

Description of Page

Use the **Meter Configuration Type** collection to define the recommended meter configuration types for meters linked to service agreements (by way of their service points) for a given rate schedule.

**Note:**

Meter Configuration Types are not allowed on subsidiary rate schedules.

Where Used

This information is used by the system to verify that meter configuration types for any meters linked to the SA's service points are valid for the SA's rate. This check exists when you change the rate for a service agreement or when you change the meter configuration type of a meter configuration that is currently linked to an active SA (via the meter and the SP). Note that if a meter configuration for the SA's service point's meter does not match one of the types in the list, a warning is issued, not an error.

Rate Schedule - Sub Rates

Select **Menu > Rates > Rate Schedule > Search** and navigate to the **Sub Rates** page to define any subsidiary rate schedules associated with the current (primary) rate schedule.

**Note:**

Sub Rates are only allowed on Primary rate schedules. See [Use Sub Rate Schedules to Encapsulate Common Rate Components](#) for more information about subsidiary rate schedules.

Description of Page

Use the **Sub Rate Schedule** collection to define the subsidiary rate schedules linked to the current rate schedule.

The **Sequence** is important when you have multiple sub rates linked to the primary rate, as it defines the order in which the sub rates will be calculated.

Where Used

At billing time, if there are sub rate schedules linked to the service agreement's primary rate schedule, rate components defined in the sub rate schedules are used to calculate charges. Bill segments contain separate bill calculation details for each primary rate schedule and sub rate schedule used in its calculation.

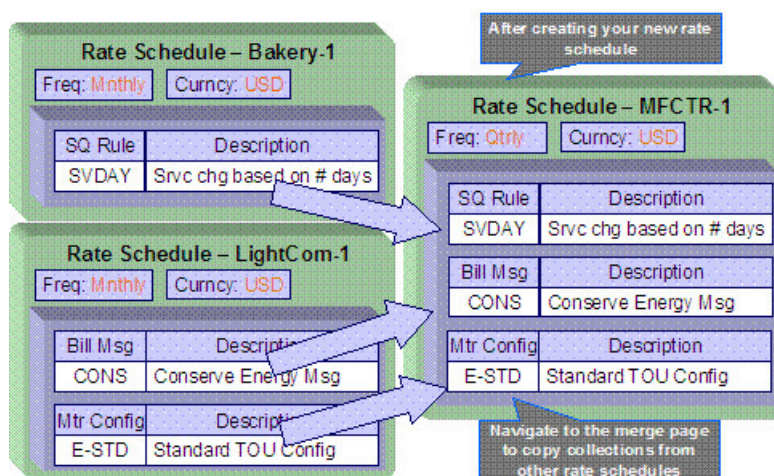

Rate Schedule Merge for Component-Based Rates

Use this page to modify an existing rate schedule by copying information from other rate schedules. This page may be used to copy records from the SQ rule, register rule, bill message and meter configuration type collections from one or more existing rate schedules to another. Some examples of when this page may be used are as follows:

- You wish to create a new rate schedule, which is similar to an existing rate schedule. Rather than copying all the information from the existing rate schedule and then removing the inapplicable components, this page may be used to selectively copy only the information applicable to the new rate schedule.
- Perhaps you offer a rate to your customer, which contains many optional components. Rather than building a generic rate schedule used by many customers, and using other logic to determine which options are applicable to which customer, you may choose to build a custom rate schedule for each customer, using only the components applicable to that customer. In this scenario, you may choose to create special 'mini' rate schedules, one for each of the various options. Then, you could use the rate schedule merge page to select the components applicable for the new custom rate schedule.
- Perhaps you are adding several new bill messages, which are applicable to multiple existing rate schedules. Once you have added the new messages to one rate schedule, you may find it easier to update the subsequent rate schedules by using the rate merge page to copy the messages across.

**Note:**

The target rate schedule must exist prior to using this page. If you are creating a new rate, you must first go to the [Rate Schedule](#) page to add the new rate schedule and then navigate to the merge page to copy collection information.

**Note:**

Duplicate versus Merge. The [Rate Schedule](#) page has [Duplication](#) capability. You would duplicate a rate schedule if you want to a) create a new rate schedule AND b) populate it with all the information from an existing rate schedule. You would use the rate schedule merge page if you want to build a rate schedule using pieces of one or more rate schedules.

Open **Menu > Rates > Rate Schedule Merge Classic** to open this page.

Description of Page

Select the **Original Rate Schedule** that is the target for merging the rate schedule collection information.

Select the **Merge From Rate Schedule** that is your template rate schedule to copy the collections from.

**Note:**

You may only copy information from one Merge From rate schedule at a time. If you wish to copy information from more than one rate schedule, select the first Merge From rate schedule, copy the desired records, Save, then select the next Merge From rate schedule.

The left portion of the page will display any existing records in the collections for the original rate schedule. The right portion of the page will display the existing records in the collections for the Merge From rate schedule.

You may use the **Copy All** button to copy all the records in all the collections from the Merge From rate to the Original rate. If you do not choose to copy all, you may copy records individually as described below.

The left portion of the **SQ Rule** collection initially displays existing SQ rule records linked to the original rate schedule. In the **Merge Type**, you will see the word Original, for any of these records. The **Sequence** number and **SQ Rule** description are displayed. In the right portion of the collection, the existing records in the merge from rate are displayed initially.

The left portion of the **Register Rule** collection initially displays existing register rule records linked to the original rate schedule. In the **Merge Type**, you will see the word Original, for any of these records. The **Sequence** number and **Register Rule** description are displayed. In the right portion of the collection, the existing records in the merge from rate are displayed initially.

The left portion of the **Bill Messages** collection initially displays existing bill messages linked to the original rate schedule. In the **Merge Type**, you will see the word Original, for any of these records. The description of each **Bill Message** is displayed. In the right portion of the collection, the existing records in the merge from rate are displayed initially.

The left portion of the **Meter Configuration** collection initially displays existing meter configuration records linked to the original rate schedule. In the **Merge Type**, you will see the word Original, for any of these records. The description of each **Meter Configuration** is displayed. In the right portion of the collection, the existing records in the merge from rate are displayed initially.

The topics in this section describe how to perform common maintenance tasks.

Removing a Row

If you wish to remove a record linked to the Original rate schedule, press the delete button to the left of the record.

Adding a New Row

You may move any of the records from the Merge From rate to the original rate by selecting the left arrow adjacent to the desired row. Once a record is moved it will disappear from the Merge From information and appear in the Original information with the word Merge in the Merge Type column.

Removing an Uncommitted Row

If you have copied a row across by mistake, you may remove it by clicking on the right arrow adjacent to the appropriate record.

Moving Rows Up and Down

The **SQ Rule** and **Register Rule** grids contain sequence numbers that indicate the order in which the rules should be executed. You may modify the execution order using the up and down arrows.

You may also need to renumber the sequences so that your rules are executed in the proper order. The fields **Start from sequence number** and **Increment By** are used to define the sequence number to assign to the first rule and the subsequent values to assign to subsequent rules.

Note:

Once the record is saved, both register rules are marked as Original.

Setting Up Bill Factors for Interval and TOU Values

This section describes bill factors for interval and TOU values, and how they are used to levy the many charges referenced in a rate. See [Setting Up Bill Factors](#) for information about bill factors in other situations.

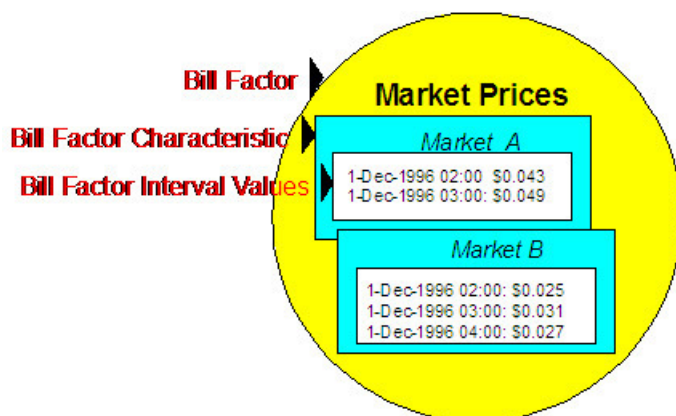

Warning:

Most bill factors exist to support calculations performed by rate components. This means that you must design your rate components before you can design your bill factors. We strongly recommend that you design "on paper" how every rate's rate components looks before you attempt to set up bill factors.

Bill Factor Interval Values

A bill factor may also contain interval values.

Interval values are typically used to record interval prices (such as, prices that are applicable to short time intervals of say 15 minutes). Just as with simple bill factors, they may have characteristics defined. In the above example, the characteristic is the "Market" where the prices are defined. This bill factor probably indicates that the Service Agreement has a characteristic indicating the market from which it gets its prices. This enables you to use a common rate for customers who get their prices from different markets.

The application of these interval values requires the use of an algorithm. Depending on your business needs, there are many ways that this can be implemented.

- If your business uses the interval billing subsystem, then functionality is available for applying these interval values to interval quantities. Refer to [The Big Picture of Interval Billing](#) for more information.

- If your business does not use the interval billing subsystem, then there is still functionality available in rates for using interval values. See [Interval Values Can Be Used For More Than Just Interval Prices](#) for one example. Refer to [Pricing Interval Consumption Using Interval Prices](#) for another example.

Interval Values Can Be Used For More Than Just Interval Prices

The interval value transaction can be used for more than recording interval prices. One such purpose is to record rolling average prices. Let's use an example to make the point. Assume the following:

- You operate in a deregulated environment and part of the price charged to your customers is based on the spot-market price.
- Your customers don't have interval meters. Rather, they simply have meters that are read once a month. When you calculate a customer's bill, you must determine the single price to be applied to the total amount of consumption for the month.
- The price applied to a customer's bill is based on the number of weeks of consumption and the end date of the bill period. For example, a customer whose bill ends on 12-Sept-2001 with 3 weeks of consumption would probably have a different price than a customer whose bill ends on the same date but has 6 weeks of consumption. Why? Because the spot market price varies during the different billing periods.
- Different prices may be calculated based on the customer's load profile. This would mean that a residential customer whose bill ends on 12-Sept-2001 with 3 weeks of consumption would have a different price than a commercial customer whose 3 week bill ends on the same date. Why? Because residential customers tend to consume in different time periods than do commercial customers (and therefore different spot market prices were in effect).

If you assume the above, then you'd need the ability to record different prices based on:

- The bill end date
- The number of weeks / days in the billing period
- The customer's load profile

You can use the interval pricing objects to record this information. You do this as follows:

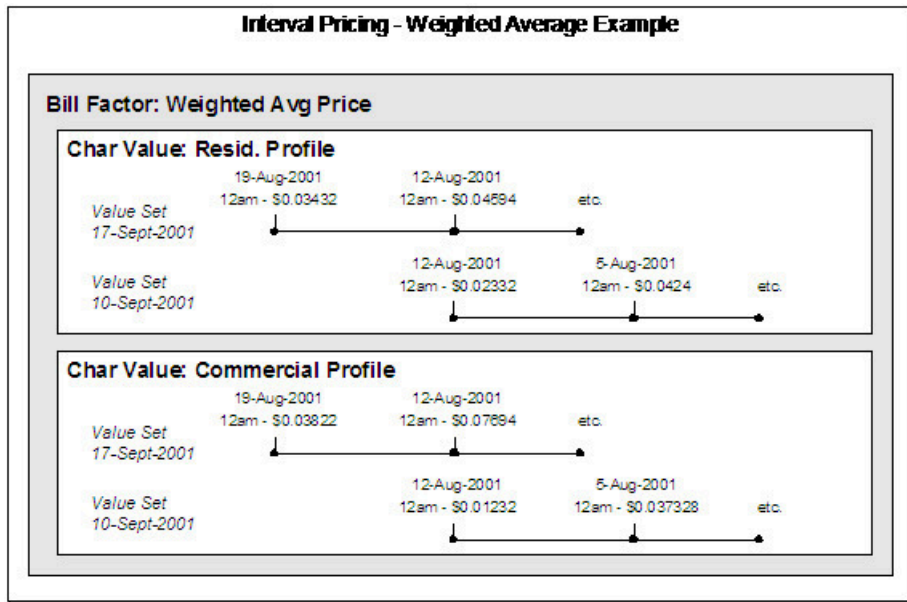

- Create a characteristic type called LOADPROF. Associate with it characteristic values of RESID and COMMERCIAL.
- Create a bill factor called WAP and have it reference the LOADPROF characteristic type.
- Enter an interval pricing value set for each bill end week cutoff date. And for each interval pricing value set, add an interval value for each bill start week cutoff date.

The following table will help visualize an interval pricing value set for the bills ending the week of 17-Sept-2001:

| Bill Period | Bill Start Date | Weight Avg Price |
|----------------------------------|-----------------|------------------|
| 4 Week Weighted Average PX Price | 19-Aug-2001 | 0.03432 |
| 5 Week Weighted Average PX Price | 12-Aug-2001 | 0.04594 |
| 6 Week Weighted Average PX Price | 5-Aug-2001 | 0.02302 |
| 7 Week Weighted Average PX Price | 29-July-2001 | 0.06039 |
| 8 Week Weighted Average PX Price | 22-July-2001 | 0.02981 |

| | | |
|-----------------------------------|--------------|----------|
| 9 Week Weighted Average PX Price | 15-July-2001 | 0.01921 |
| 10 Week Weighted Average PX Price | 8-July-2001 | 0.05010 |
| 11 Week Weighted Average PX Price | 1-July-2001 | 0.060929 |
| 12 Week Weighted Average PX Price | 24-June-2001 | 0.03939 |

Below, we've illustrated how interval pricing information might look for a bill factor that holds the weighted average prices.

Fastpath:

Refer to [Pricing Non-Interval Consumption Using a Weighted Average Price](#) for how a rate component value algorithm makes use of the above information when a bill is calculated for a customer.

Interval Data is Stored in Data Sets

Interval data in the system will have many different origins.

- It may be contract-related data, which is setup at the beginning of the contract or contract year
- It may be data, which is interfaced from an external source periodically

Regardless of the origin of the data, all data will have similar characteristics

- Data will be received by the system, or created by the system periodically. The system will store whatever new data needs to be stored.
- The period represented by the batch of new data is variable.
- New data may be an update to previously received data

Refer to [Interval Quantities are Stored in Data Sets](#) for information about how interval data is stored. This same model is used for bill factor interval data. There is no difference.

Bill Factor TOU Values

A bill factor may also contain values, which differ by a TOU code. This enables you to set up prices that differ by TOU or to set up contract values, which differ by TOU.

Bill Factor TOU values are typically used to record prices, which vary by time of use code. TOU prices are used in conjunction with time of use mapping. The customer would typically have interval quantities, which are mapped, using a TOU Map, into a collection of time of use quantities. Defining a bill factor with prices per TOU allows you to set up a single rate component to apply charges to these quantities, resulting in multiple bill calculation lines.

Similar to simple bill factors, TOU bill factors may have characteristics defined. In the above example, the characteristic is the "Market" where the prices are defined. This bill factor probably indicates that the Service Agreement has a characteristic indicating the market from which it gets its prices. This enables you to use a common rate for customers who get their prices from different markets.

In addition to defining the characteristics, TOU bill factors must also indicate the TOU Group. The TOU group is a collection of time period definitions, which make up a TOU map. This enables you to define different prices for On Peak, when it is part of a two-part TOU map versus when it is part of a three-part TOU map.

Fastpath:

Refer to [Grouping of TOU Codes](#) for more information.

The TOU prices are defined for the combination of characteristic and TOU Group. In the examples below, a bill factor's characteristic is State. Also note that the effective date of the prices are the same for all time of use codes. If the price of any TOU value changes, then a new set of prices for all TOU codes must be entered.

| TOUs in Group 2 | | California |
|-----------------|--|-----------------------------|
| | | Effective 1 Jul 1999 |
| On Peak/Summer | | \$0.98 |
| Off Peak/Summer | | \$0.74 |
| On Peak/Winter | | \$0.84 |
| Off Peak/Winter | | \$0.63 |

| TOUs in Group 3 | | California |
|-----------------|--|-----------------------------|
| | | Effective 1 Jul 2000 |
| On Peak/Spring | | \$1.03 |
| Off Peak/Spring | | \$0.74 |
| On Peak/Autumn | | \$0.92 |
| Off Peak/Autumn | | \$0.63 |

| TOUs in Group 2 | | Oregon |
|-----------------|--|-----------------------------|
| | | Effective 1 Jul 1999 |
| On Peak/Summer | | \$0.98 |
| Off Peak/Summer | | \$0.74 |
| On Peak/Winter | | \$0.84 |
| Off Peak/Winter | | \$0.63 |

The application of these time of use values requires the use of an algorithm. If your business uses the interval billing subsystem and uses time of use mapping and pricing, then functionality is available for applying these values to

interval quantities, which have been mapped into time of use quantities. Refer to [The Big Picture of Interval Billing](#) for more information.

TOU Values Can Be Used For More Than Just Prices

TOU values can be used for more than recording prices. Many contract-based values may also be recorded per TOU. For example, a contract for an interval billing customer may designate a hedge cover or a minimum demand value or a contract demand value. Although you may have interval quantity curves to define these values, that would be difficult to define and maintain. A more common scenario would be to define a TOU Map and to define these values for each TOU. A TOU Bill Factor could be used to define these values.

TOU Values May Differ By Customer

In the same way that simple bill factors may be used to define customer specific prices and values, TOU bill factors may also be used to define customer specific prices and values. Refer to [Customer Specific TOU Values](#) for more information.

Defining Interval Values

Open **Menu** > **Rates** > **BF Interval Values** > **Search** to maintain interval values.

Note:

Interval values must reference a bill factor. You must set up a bill factor before you can define interval prices. Refer to [Setting Up Bill Factors](#) for more information.

Description of Page

Interval Value Set is a concatenation of important information about the data set. The **Interval Value Set ID** is a system-assigned random number that stays with an interval value set for the life of the system. This value is assigned when the set is first added.

All interval pricing information must reference a predefined **Bill Factor**, **Characteristic Type**, and **Characteristic Value**. Use the **Bill Factor Characteristic** search button to select all three values. Refer to [Setting Up Bill Factors](#) for more information.

Use **Set Date / Time** to define the effective date of the set of prices or values defined in the following grid. This is considered a server date and will follow the seasonal time shifting as defined on the base time zone. Refer to [Seasonal Time Shifts](#) for more information.

Use the **Start Date / Time** to indicate the starting point for the display of the interval data.

At least one interval data record must exist in the collection of interval data. For each interval data record, the **Interval Value Date / Time** and the **Interval Value** are captured. This date is considered a logical date and will follow the seasonal time shifting as defined on the bill factor / characteristic. Refer to [Seasonal Time Shifts](#) for more information.

If seasonal time shift records are linked to both the base time zone and the bill factor/characteristic, the **Seasonal Time Shift** associated with your bill factor/characteristic is displayed. Refer to [Setting Up Bill Factor Characteristics](#) for more information.

If seasonal time shift records are linked to both the base time zone and the bill factor/characteristic, the **Seasonal Time Shift Remark** indicates whether the data is displayed and should be entered in legal time or standard time. Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time. If either the bill factor/characteristic or the base time zone do not indicate a seasonal time shift record, then the toggle button will not be visible and data is displayed and expected in standard time.

Where Used

Various rate component algorithms make use of interval pricing information.

Bill Factor Interval Values Query

This query shows the most recent interval values for an interval value bill factor/characteristic and a time period as of a given time.

Open **Menu > Rates > BF Interval Values Query** to display interval bill factor values.

Description of Page

Information describing the **Bill Factor**, **Characteristic Type**, and **Characteristic Value** whose data you wish to query is displayed.

Use the **Start Date / Time** and **End Date / Time** if you want to limit the query to a specific time period.

Use the **Set Date / Time** to indicate the "as of what date" to use for retrieving interval data. Only data sets with a set date/time prior to this date/time will be accessed.

The **Selection Type** is used to determine what data to show

History. This option displays all bill factor interval data for the Bill Factor/Characteristic and time period, if specified. It will include data in data sets of any status value.

Most Recent Complete Data. This finds the most recent bill factor interval value data for each interval from completed data sets only.

Once you have selected your criteria, use the search button to display the data. The interval value data collection will contain the following information:

- The **Interval Value Date/Time** and **Interval Value** for each interval is displayed. Adjacent, information about the data set to which this interval is linked is displayed, including the **Set Date / Time** and **Interval Value Set ID**.
- If seasonal time shift records are linked to both the base time zone and the bill factor/characteristic, the **Seasonal Time Shift** associated with your bill factor/characteristic is displayed.
- The **Seasonal Time Shift Remark** indicates whether the data is displayed and should be entered in legal time or standard time. Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time.

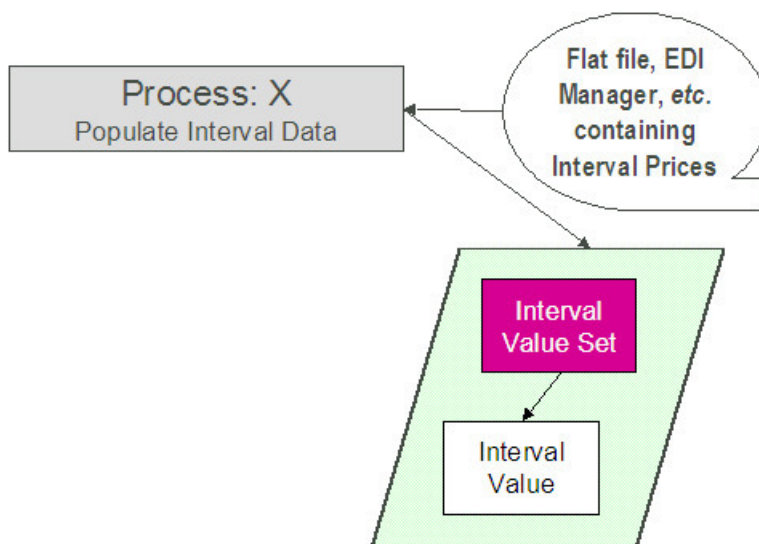

Note:

If seasonal time shift information is missing for the bill factor/characteristic or for the base time zone, then data is always displayed and expected in standard time.

Upload Interval Values

The following diagram illustrates the processes involved in the uploading of interval values into the system.

The topics in this section describe how these processes work.

Process X - Populate Interval Data

Process X refers to the mechanism used by your organization to populate the Interval Value tables. Process X will have the following responsibilities:

- It determines the appropriate Bill Factor and Characteristic to which this data belongs. Recall that the bill factor / characteristic may reference an external ID.
- It creates a new Interval Value Set for this bill factor characteristic with the current date and time
- If the interval data is from a different time zone, or is not in standard time for the base time zone, the time of each interval must be converted to the base time. Refer to [Time Zone and Time Changes](#) for more information.
- All prices being uploaded for the same bill factor and characteristic should be inserted into the Interval Value table and should reference the same Interval Value Set
- Inserts a record in the interval value set key table.

The topics in this section describe the tables to populate.

Interval Value Set

You must create a data set for each batch of records being uploaded in the system for the same bill factor / characteristic. The name of this table is CI_INTV_VAL_SET. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|----------|
|-------------|--------|-------|-----------|----------|

| | | | | |
|-----------------|----|---|-----|--|
| INTV_VAL_SET_ID | 12 | Y | A/N | <p>This is a random unique key. This key is referenced on the interval value record.</p> <p>It's suggested that this is a random number. If your process that inserts records on this table is capable of calling a routine, call ProgramCIPZKEYG and it will supply a 12 digit random number for you.</p> |
| BF_CD | 8 | Y | A/N | <p>This along with CHAR_TYPE_CD and CHAR_VAL indicate the bill factor / characteristic to which this interval value set belongs.</p> <p>Refer to Setting Up Bill Factors for more information.</p> |
| CHAR_TYPE_CD | 8 | Y | A/N | <p>This along with BF_CD and CHAR_VAL indicate the bill factor / characteristic to which this interval value set belongs.</p> <p>Refer to Setting Up Bill Factors for more information.</p> |
| CHAR_VAL | 16 | Y | A/N | <p>This along with BF_CD and CHAR_TYPE_CD indicate the bill factor / characteristic to which this interval value set belongs.</p> <p>Refer to Setting Up Bill Factors for more information.</p> |

| | | | | |
|----------|----|---|----------|--|
| SET_DTTM | 26 | Y | DateTime | <p>This is the data/time that the data set was received. This must be populated with the current date / time. This is considered a server date and will follow the seasonal time shifting as defined on the base time zone. Refer to Seasonal Time Shifts for more information.</p> <p>Refer to Algorithms Find the Most Up To Data for information about why this date/time is important.</p> |
|----------|----|---|----------|--|

Interval Value

Each piece of interval data for the same bill factor/characteristic will be stored as an Interval Value record linked to the newly created data set. The name of this table is CI_INTV_VAL. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-----------------|--------|-------|-----------|--|
| INTV_VAL_SET_ID | 12 | Y | A/N | This is a foreign key reference to the Interval Value Set that groups the interval values together. This should be your newly created id from above. |
| INTV_VAL_DTTM | 26 | Y | DateTime | This is the date and time of the interval value. This must be stored relative to the base time zone. Refer to Time Zone and Time Changes for more information. |
| INTV_VAL | 18.7 | Y | N | This is the value (price) for the interval. |

Interval Value Set Key

When a system-generated key value is assigned to a record, you need to also store the key value in a key table that corresponds to the record's database table. The name of this table is CI_INTV_VAL_SET_K. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-----------------|--------|-------|-----------|---|
| INTV_VAL_SET_ID | 12 | Y | A/N | This should be your newly created Interval Value Set ID from above. |
| ENV_ID | 6 | Y | N | This is the environment id defined on the installation options . |

Defining Bill Factor TOU Values

Open **Menu** > **Rates** > **BF TOU Values** > **Search** to maintain time of use bill factor values.

Note:

TOU Bill Factor values must reference a bill factor and characteristic. You must set up a bill factor and its characteristics before you can define TOU values. Refer to [Setting Up Bill Factors](#) for more information.

Description of Page

The **BF Characteristic TOU Group** search button gives you the ability to search for existing TOU BF values for a Bill Factor, Characteristic and TOU Group combination.

The **BF Characteristic** search button gives you the ability to search for a Bill Factor, Characteristic combination to which the TOU values will be linked.

Once a bill factor and characteristic combination are chosen, the system displays the values of the **Bill Factor**, **Characteristic Type**, **Characteristic Value** and **Value Type**.

Choose the **TOU Group** to determine the collection of time of use codes to which prices will be defined.

Indicate the **Effective Date** of the collection of **Time of Use** codes and their **Values**.

Where Used

Various rate component algorithms make use of TOU value information. This information is also available for any type of algorithm that may need to use the information, for example interval data derivation algorithms.

Defining Rate Versions

After defining general information about a rate on [Rate Schedule Maintenance](#), you must link to it a rate version. The rate version defines the effective date of the calculation rules defined in its rate components. A rate schedule will have multiple rate versions if its calculation rules (i.e., its rate components) change over time.

Note:

A switch on the rate schedules controls what happens if multiple rate versions are effective during a bill period. When the system creates a bill segment for a service agreement, it checks if multiple rate versions are in effect during the bill period. If so, it uses the [rate schedule's Allow RVs Proration](#) switch and **RV Selection Date** flag to determine if it should prorate the various rate versions or if it should pick one of the rate versions effective during the bill period.

After a rate version exists, you add rate components to it using [Rate Component Maintenance](#) and/or [Rate Version Merge](#). After you have added all necessary rate components, don't forget to return to [Rate Version - Main](#) and change the state of the rate version to Finished (otherwise, it cannot be used by billing).

The topics in this section describe how to setup a rate version.

Lifecycle of a Rate Version

The following diagram shows the possible lifecycle of a rate version (you'll notice that you can change a rate version from any state to any state).

A rate version is in the In Progress state while you build its rate components. While a rate version is in this state, the system does not cross validate among rate components because they are added, changed, or deleted using [Rate Component Maintenance](#) and/or [Rate Version Merge](#). However, the system will perform inter-field validation applicable to each type of rate component. Rate versions in this state may not be used by [Rate Check](#), nor will they be used up by the billing process.

You transition a rate version to the Validated state when you're ready to check it using [Rate Check](#), but you don't want billing to use it to calculate charges. When a rate version is transitioned to this state, the system performs cross validation among its rate components. If any validation errors are found, an error message is displayed and the status remains In Progress. If all validation checks are passed, the rate version status will become Validated. We'd like to stress that rate versions in this state may be used by [Rate Check](#), but will not be used by billing.

You transition a rate version to the Finished state when it can be used by billing to calculate charges. All of the cross validation between rate components will be performed when transitioning to this state.

Note:

Finished and Validated states also affect rate component maintenance. If a rate version is Finished or Validated, the system performs internal consistency checks every time a rate component is added, changed or deleted using [Rate Component Maintenance](#) and/or [Rate Version Merge](#). If you don't want these checks to be performed while you're working on a rate version's rate components, change its state to In Progress.

Rate Version - Main

Use **Menu > Rates > Rate Version Classic > Search** to maintain a rate version.

Description of Page

Rate Version contains basic information about the rate version. This information only appears after the rate version has been added to the database.

Rate Schedule defines the rate linked to the rate version. **Effective Date** defines the date when the rate version's rate components become effective. These fields are the unique identifier of the rate version. Both fields become protected after the rate version is added to the database.

Note:

Multiple rate versions may be prorated. When the system creates a bill segment for a service agreement, it checks if multiple rate versions are in effect during the bill period. If so, it uses the [rate schedule's Allow RVs Proration](#) switch and [RV Selection Date](#) flag to determine if it should prorate the various rate versions or if it should pick one of the rate versions effective during the bill period.

The **Rate Version Status** indicates the current state of the rate version. Refer to [Lifecycle of a Rate Version](#) for more information.

Warning:

Billing ignores rate versions that are not in the Finished status. This means that if you create a new rate version and forget to finish it, billing will use the prior rate version when it calculates the customers' bills.

Specify the description of the rate version in **Description on Bill**. This description is saved on bill calculation details created using this rate version. The following table illustrates the substitution variable(s) that may be used to substitute variables into the description during billing:

| Substitution Character | What It Does |
|------------------------|---|
| %D | <p>Replaces the substitution character with message 10101 from message category 4. This message is maintained in the standard message table.</p> <p>We recommend this message be set to "(prorated for %1 of %2 days)" where %1 will be substituted with the number of days of prorated consumption charged on the bill line and %2 will be the "normal" days associated with the rate's prices. This message will only be substituted when the rate version is prorated.</p> |

The following are examples of the content of common **Description on Bills** along with how the line would look on the bill:

| Description on Bill | How It Looks On A Bill |
|---------------------|--|
| Gas service %D | Gas service (prorated for 10 of 30 days) |

The [tree](#) that follows contains a summary of the rate version's rate components. You can use this tree to both view high-level information about these objects and to transfer to the respective page on which an object is maintained.

Note:

The duplicate action in the action button bar enables you to duplicate a rate version and its rate components. Refer to [Duplicate Button](#) in the system wide standards document for more information.

Rate Version - Bill Print Info

This page allows you to maintain the bill print information for all of the rate version's rate components. Note, you can also maintain this information for individual rate components on [Rate Component - Main](#).

Description of Page

The grid contains an entry for each rate component linked to the rate version. The following information is displayed in the grid:

Sequence uniquely identifies the rate component. It also controls the order in which the rate component is processed when the rate version is processed by billing.

Description is the rate component's description.

Description on Bill is the verbiage that appears on the bill line generated for this rate component. You can dynamically substitute variables into this description (such as, price and quantity) when billing calculates the rate component's charges. Refer to [How To Use Description on Bill](#) for a discussion of the substitution variables.

Turn on the **Print** switch if you want the bill line to appear on the customer's bill.

Note:

Some bill lines don't print. You may wonder why we give you the ability to not print a bill line. The reason is because ALL bill lines are shown on Bill Segment - Calculation Details. However, only those lines marked as **Print** are presented to the customer. This way, if you want to suppress some calculation details, you can, but still show the details to the customer service rep.

The **Print If Zero** switch is only enabled if the **Print** switch is turned on. It allows you to indicate if a bill line should print when the bill line's value is zero:

- Turn this switch on if the bill line should print when the calculated value is zero.
- Turn this switch off if the bill line should not print when the calculated value is zero.

Note:

The rate component results in the creation of a bill segment calculation line, but an indicator exists to tell the extract program that this should not be included. This is true, except in the following cases when the system does not create a zero bill segment calculation line:

- Apply To rate components where the cross-referenced amount is zero
- Summary, Minimum, Maximum and Exact Charge rate components that do not apply.
- Stepped rate components where both the low and high boundaries equal zero.

Designing Rate Components

Rate components are the fundamental building blocks of your bill calculation algorithms. All of the other rate and bill factor set up tasks are done in preparation of the creation of these records. This means that you must design your rate components before you can design bill factors, register rules, SQ rules, SQ identifiers, eligibility rules. We strongly recommend that you design "on paper" how every rate component looks on every rate schedule before you attempt to set up any of the rate control tables.

Fastpath:

All of the calculation details and financial information that appear on a bill segment are derived using information on rate components. If you want to see the results of what rate components do, refer to [Bill Segment - Calc Lines](#).

Warning:

There are innumerable ways to design rate components for a given rate. Some designs will result in easy long-term maintenance; others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your production rate components, we encourage you to gain intuitive understanding of these options by using the system to prototype the alternatives.

The topics in this section provide background information that will facilitate the construction of your rate components.

Rate Component Design Methodology

Designing rate components is an iterative process. Over time, you will develop intuitive skills that will allow you to avoid some iterations. However, when you're starting out, we recommend you follow these steps to design your rate components:

- Obtain copies of existing bills that use the rate in question. If the rate is new, then write up EXACTLY how the information should appear on the customers' printed bills. If the rate has optional charges (such as, employee discounts or charges that only apply after the customer has consumed a large volume), make sure your examples encompass every possible scenario.
- Next, look at the bill lines and ask yourself what are the variables that cause each line's charges to be calculated the way they are. Consider the following examples:
- "Monthly service charge: \$50.00". This is a simple service charge that appears regardless of how much the customer consumed. This line doesn't really have any variables that affect its amount. Rather, the amount is a constant value of \$50.00.
- "1,250 kWh at \$0.07892". This charge is based on how much the customer consumed. The variables involved are the number of kilowatt-hours (kWh) and the price per kWh.
- "1,000 20K Lumen Mercury Vapor Lamps at \$20.00 per lamp". The variables involved are the number of devices (also called "items") used by the customer and the price per item.
- "Minimum monthly charge of \$100.00". This is a charge that only appears if the total of the prior lines is less than \$100.00. The variables involved in this line are a little complicated because they must be calculated at billing time by adding up several other lines and comparing them to the minimum charge amount. This means the variables are the total of prior lines and the minimum charge amount.
- "1.25% County Surcharge". This charge is similar to the minimum charge in that it is calculated by adding up one or more prior lines and applying a percentage to the sum. This means the variables are the total of prior lines plus the tax percentage.
- After you've determined all of the potential bill lines you can start designing your rate components. Typically you create one rate component for every line that can appear on the customer's bill. When you create a rate component, you will categorize it as one of the following types:

| | |
|------------------|--|
| Flat Charge | This type of rate component is used to create bill lines that levy service charges and fees that aren't based on how much the customer uses. The monthly service charge shown above would be levied using this type of rate component. |
| Service Quantity | <p>This type of rate component is used to create bill lines that levy charges based on some type of consumption. The kWh charge shown above would be levied using this type of rate component.</p> <p>Frequently the amount consumed is measured by a meter's registers and sometimes it's calculated using Service Quantify (SQ) Rules linked to the rate and sometimes it's derived based on the type of item (e.g., for lamps). Regardless of how the amount consumed is calculated, the charge for the consumption amount is levied using this type of rate component.</p> <p>You'll find it helpful to differentiate your service quantity rate components into two categories - stepped and non-stepped. Stepped charges are those where there's a different price for different ranges of consumption (e.g., the first 50 therms are \$0.43 a therm, anything in excess of 50 therms is charged at \$0.71 per therm). We recommend doing this because a) you frequently show a subtotal of the steps on the customer's bill, b) steps, by definition, mean you have several rate components that are dependent on each other, and c) they frequently involve complex calculations in order to define the step boundaries.</p> |

| | |
|----------------|--|
| Item Type | <p>This type of rate component is used to create bill lines that levy charges based on the number and type of items used by a customer. The system keeps track of items on the service point(s) linked to the customer's service agreement. The lamp charge shown above would be levied using this type of rate component.</p> |
| Apply To | <p>This type of rate component is used to create bill lines that levy charges based on the amount calculated on other bill lines. The county surcharge shown above would be levied using this type of rate component.</p> |
| Summary | <p>This type of rate component is used to create a "subtotal" on the bill. It exists purely for aesthetic purposes.</p> |
| Minimum Charge | <p>This type of rate component is used to create bill lines that levy charges only when the sum of previously calculated lines is less than the minimum charge amount. The minimum monthly charge shown above would be levied using this type of rate component.</p> <p>Note that if the values being compared are negative values, the comparison is NOT done on the absolute values, but rather on the actual values. For example, imagine you have a minimum discount of \$ -2.00 and previous rate components have calculated a discount of \$ -1.00. You want a rate component to create a bill line for \$ -1.00 to apply a further discount. A minimum charge rate component will not work in this case because -1 is considered more than -2. For this business scenario you should use a maximum charge rate component.</p> |
| Maximum Charge | <p>This type of rate component is used to create bill lines that levy charges only when the sum of previously calculated lines is more than the maximum charge amount.</p> <p>Note that if the values being compared are negative values, the comparison is NOT done on the absolute values, but rather on the actual values. For example, imagine you have a maximum discount of \$ -2.00 and previous rate components have calculated a discount of \$ -3.00. You want a rate component to create a bill line for \$1.00 to reduce the discount. A maximum charge rate component will not work in this case because -3 is considered less than -2. For this business scenario you should use a minimum charge rate component.</p> <p>Note - these types of rate components are rare. You tend to only see them in deregulated markets where customers have agreed to pay the market rate but want a cap on the maximum they'll pay each bill period.</p> |

| | |
|-----------------------|--|
| Exact Charge | <p>This type of rate component is used to force a bill to add up to a given amount (regardless of how much the bill would be based on earlier rate components).</p> <p>Note - these types of rate components are rare. You tend to only see them in deregulated markets during the transition period between regulated rates and complete deregulation. In this situation, you show on the bill what the charges would be, given a deregulated environment, but then adjust the bill back to an amount equal to the regulated rate. This charge is called a Competition Transition Charge (CTC) in California.</p> |
| Calculation Algorithm | <p>This type of rate component enables you to produce bill calculation lines based on logic in an algorithm that you supply. Use this rate component when none of the other rate component functions will provide you with the logic you require.</p> |
| Interval Pricing | <p>This type of rate component is used to apply interval prices to interval quantities. See Interval Pricing Rate Application for more information.</p> |
| TOU Pricing | <p>This type of rate component is used to map and/or price interval quantities into time of use quantities given a TOU map. See Time of Use Mapping and Pricing for more information.</p> |

- For each rate component, determine if the customer must meet some form of eligibility criteria before the rate component is applied. For example, you may have a rate component that calculates an employee discount. This rate component may have eligibility criteria that requires the person to have a given characteristic value before the rate component is applied. Refer to [The Big Picture of Rate Component Eligibility](#) for more information.
- For each type of rate component (except summary), determine how you'll define its unit rate / percent / flat amount. You have four choices:
- Specify the value directly in the rate component.
- Tell the rate component to use the value defined in a *bill factor*.
- Tell the rate component to use the value calculated by a "*for calculation purposes only*" rate component.
- Tell the rate component to call an algorithm. The algorithm will return the value.

The following tables provide guidance in respect of which of the methods to use:

| | |
|-------------------------------------|---|
| Specify value in the rate component | <p>You'd specify the value in the rate component when the value in the rate is specific to that rate and is applied to all customers regardless. For example, if you see a provision in the rate that says to charge \$0.05674 per kWh, you'd specify 0.05674 directly in the rate.</p> |
|-------------------------------------|---|

Use a bill factor to define the value

The following paragraphs describe when you'd use a bill factor to define a unit rate / percent / flat amount.

The same charge exists in many rates. For example, if there are 3 rates that all contain the same service charge, it would make sense to use a bill factor to levy this charge rather than specify the same value on 3 rate components.

The amount being charged is dependent on some physical characteristic of the customer's equipment. For example, if the price differs depending on whether the customer owns the transformer, you would use a bill factor to specify the price.

The amount being charged is dictated by some external organization and therefore can change independently from the rate. For example, tax percentages and use fees are set by taxing authorities and can be changed at any time (and you don't want to change the rate when these charges change).

The amount being charged varies depending on WHERE the customer lives. If you have a rate where the price per gallon differs depending on where the customer lives, you should use a bill factor to levy this type of charge.

The price differs per customer. For example, you may have a rate for large gas customers where the price per therm is different for every customer. In this situation, you would use a bill factor to specify the price.

Use a "for calculation purposes only" rate component

This is complicated to explain and is not used very often, but it is very powerful and handles some very complicated algorithms. It works like this - you calculate the price / percent / flat charge on another rate component (marked as "for calculation purposes only" so it won't affect the bill amount), and then reference it on the "real" rate component. See the [Calculated Minimum Charges](#) example for an illustration of when this method is useful.

Call an algorithm

This is complicated to explain and is not used very often, but it is very powerful and handles some very complicated examples. It works like this - you call an algorithm and it calculates the price / percent / charge.

One example that would require the use of an algorithm would be when the price differs based on the total amount consumed. For example, if the customer uses less than 10 CCF, the price is \$1.50; whereas if the customer uses more than 10 CCF, the price is \$2.00.

We supply an example of one such algorithm in the base package. If your rates require additional algorithms, you will have to develop additional algorithms. Refer to [How to set up service quantity rate components under Rate Component - Main Information](#) for more information about this type of algorithm.

Please note that this scenario could also be implemented without invoking an algorithm by setting up two rate components that have eligibility rules to indicate their required respective consumption levels. Refer to [The Big Picture of Rate Component Eligibility](#) for more information.

- After you've categorized the bill lines into the various types and know how the price is defined, you determine how each line's charges are reflected in your general ledger. You will need to work with your accounting department as they will tell you the exact revenue, expense, and liability accounts that will be affected by the charges.
- Finally, read the provisions of your rate (the legal wording) and make sure you haven't left out something. This may involve having to discuss confusing provisions with your legal department.

At this point, you're ready to start entering your rate components.

Note:

Examples. Refer to [Rate Examples](#) for many sample rate components.

Rate Component Rounding

The topics in this section describe how to control how each rate component's final value is rounded.

Rounding Precision Is Defined on a Rate Component

A rate schedule references a currency code. A rate's currency code defines its maximum number of decimal places. These decimal places, in turn, control the smallest unit to which most rate components can be rounded (i.e., the rate component's precision). For example,

- If a rate's currency has two decimal places, the smallest rounding precision that most of its rate components can have is 0.01. In other words, the smallest unit to which most dollar-based rate components can be rounded is to the cent. Note, whether you round up / down / to the nearest is discussed below.
- If a rate's currency has no decimal places, the smallest rounding precision that most of its rate components can have is 1.00.

The system supports the notion of a rate component having a greater rounding precision than its currency. For example, a rate's currency may support two decimal places, but you can setup rate components to have a rounding precision of 0.05.

The reason that we underlined the word *most* in the previous paragraphs is that these rules do not apply to "for calculation purposes only" (FCPO) rate components. FCPO rate components don't contribute real amounts to a bill (they exist to calculate intermediate results that are used by later rate components) and therefore they can support a rounding precision of up to 0.00001 (five decimal places).

Rounding Method Is Defined on a Rate Component

When you setup a rate component you must define the rounding method. You are given the following choices:

- Always round up. This rounding method rounds a rate component up to the nearest value (as controlled by the rate component's precision). For example, if a rate component's precision is 0.01 and a value of 0.011 is calculated, the rate component's final value would be rounded up to 0.02.
- Always round down. This rounding method rounds a rate component down to the nearest value (as controlled by the rate component's precision). For example, if a rate component's precision is 0.01 and a value of 0.019 is calculated, the rate component's final value would be rounded down to 0.01.
- Round to the nearest value. This rounding method rounds a rate component to the nearest value (as controlled by the rate component's precision). For example, if a rate component's precision is 0.01 and a value of 0.019 is calculated, the rate component's final value would be rounded up to 0.02. Whereas, if a value of 0.012 is calculated, the rate component's final value would be rounded down to 0.01.

Rounding and FCPO Rate Components

As described above, for calculation purpose only (FCPO) rate components don't contribute real amounts to a bill. FCPO rate components exist to calculate intermediate results that are used by later rate components. We therefore allow FCPO rate components to have a rounding precision greater than the rate's currency code to a maximum of 0.00001 (five decimal places).

Please be aware of the following:

- As described under [How To Use Description on Bill](#), you can indicate that the final amount of a bill line should be substituted into the bill line's description by using the %A substitution variable in the rate component's **Description On Bill**. If you do this for an FCPO rate component, the system will show the number of decimal places as dictated by the FCPO's precision.
- While rate application calculates bill lines, the system maintains each rate component's value in memory. For FCPO rate components, this means that precisions greater than .01 are available during rate application. For example, you could indicate an FCPO rate component has a precision of .0001 and the resultant value will be maintained in memory and is available to other rate components while rate application executes.

When rate application completes, the FCPO's value will be either saved in the bill line's amount or discarded as per the value of the rate component's **FCPO retention rule**. If you indicate that the FCPO amount should be retained on the bill line and its precision is greater than two decimal places, the FCPO amount will be rounded to two decimal places before it's saved on the database. Keep in mind that this could result in an inconsistency if you used the %A substitution variable in the rate component's **Description On Bill** as the value substituted into the bill line will have a greater precision.

Interim Rounding For Apply To Rate Components

The calculations for Apply To rate components involve several steps with interim values stored along the way. For every interim value that is stored, rounding rules are applied. The following steps describe the interim rounding rules:

- If the value type is not Unit Rate, the amounts for all the cross-reference rate components are added together and stored in the database as the Base Amount. The base amount is stored with a precision of .01 and it is rounded to the nearest value based on the currency's precision.
- The rate component calculates its charge and keeps the result in a temporary field with a precision of .00001.
- The remaining steps depend on whether or not a tax exemption is applicable

- If NO tax exemptions are applicable, the temporary field is rounded based on the rate component's rounding rules to produce the final amount.
- If there are tax exemptions, the temporary field is rounded to the nearest .01 decimal precision prior to applying the tax exemptions. When the tax exemption is applied, the result is rounded according to the currency precision and stored as the Exempt Amount. The system calculates the final amount by subtracting the exempt amount from the rounded temporary amount and then applying the rate component's rounding rules.

Rounding At the End

The following is an example of a simple bill segment with three bill lines.

| Bill Segment - SA1 | | |
|--------------------|----------|--------------------|
| Line Description | Amount | GL Impact |
| Usage charge | \$501.00 | Revenue \$501.00 |
| Tax | \$5.01 | Tax payable \$5.01 |
| Total | \$506.05 | Rounding \$0.04 |

The first two bill lines are calculated using simple rate components that have a precision of .01. The last bill line is special, it rounds the bill up to the next highest 0.05 (this is an example from a country that doesn't have cents, their smallest coin is 0.05). The following would be necessary to calculate the last bill line:

- The rate component would be an exact charge rate component
- Its value (i.e., the exact charge) would be calculated using a value calculation algorithm that sums the first two rate components and rounds them up to the nearest .05. Refer to the RCVL-RNDXRF algorithm for a value calculation algorithm that can perform this function.

An alternative approach is to do the following:

- Use a summary rate component to calculate the exact charge. This rate component would require the following characteristics:
 - FCPO
 - Non printing
 - Rounding type would be round up
 - Precision would be 0.05
 - Reference the summary rate component as the exact charge rate component's value

The Big Picture of Rate Component Eligibility Rules

You can use eligibility rules to define the criteria when a rate component should be applied (or skipped). For example,

- You may have a rate component that calculates an employee discount. This rate component may have eligibility criteria that require the person to have a given characteristic type and value (this assumes you use a person characteristic to identify employees) before the rate component is applied.
- You may have a rate component that calculates a surcharge if the customer uses 25% more than they used in the same period in prior year.
- ...

Note:

Eligibility rules are optional. If you put eligibility rules on a [rate component](#), the rate component will be skipped or applied as per the instructions in the rules. If you don't put eligibility rules on a rate component, the rate component will be executed (i.e., rate components are eligible by default).

The topics in this section describe eligibility rules.

A Rate Component Is Eligible By Default

If you don't want to setup eligibility rules, you don't have to. If you don't specify eligibility rules on a rate component, it's eligible (meaning that it's going to be processed by rate application).

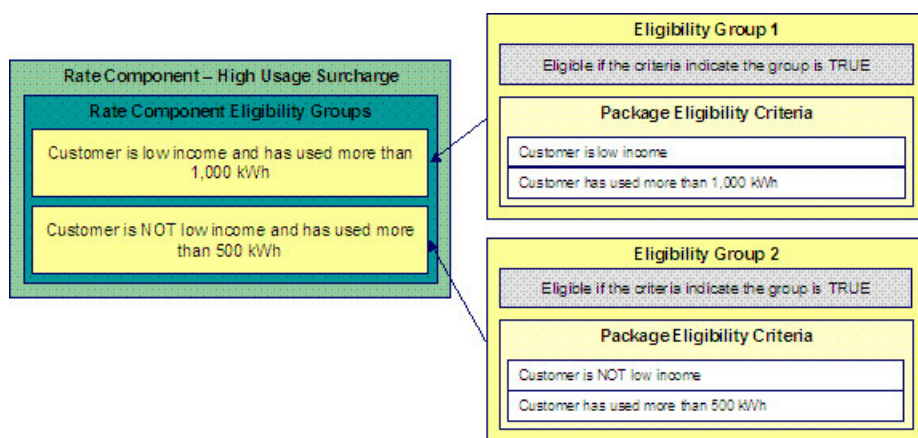

Criteria Groups versus Eligibility Criteria

Before we provide examples of eligibility criteria, we need to explain two concepts: Criteria Groups and Eligibility Criteria. A rate component's criteria groups control whether rate application executes a rate component. At a high level, it works like this:

- A criteria group has one or more eligibility criteria. A group's criteria control whether the group is considered TRUE or FALSE.
- When you create a group, you define what should happen if the group is TRUE or FALSE. You have the following choices:
 - The rate component should be applied
 - The rate component should be skipped
 - The next group should be checked

We'll use the following example to help illustrate these points. Assume a rate component is only eligible if:

- The customer is a low income customer and has used more than 1,000 kWh
- OR, the customer isn't a low income customer and has used more than 500 kWh

This rate component requires two eligibility groups because it has two distinct conditions:

- IF (Customer is low income AND the customer has used more than 1,000 kWh)
- IF (Customer is NOT low income AND the customer has used more than 500 kWh)

If either condition is true, then the rate component is eligible.

You'd need to setup the following criteria groups in order to support this requirement:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|--|------------------|-------------------|
| 1 | Customer is a low income customer and has used more than 1,000 kWh | Eligible | Check next group |

| | | | |
|---|--|----------|------------|
| 2 | Customer is NOT a low income customer and has used more than 500 kWh | Eligible | Ineligible |
|---|--|----------|------------|

The following criteria will be required for each of the above groups:

| Group 1: Customer is a low income customer and has used more than 1,000 kWh | | | | |
|---|---------------------------------------|---------------------------------|----------------------------------|----------------------|
| Seq | Logical Criteria | If Eligibility Criteria is TRUE | If Eligibility Criteria is FALSE | If Insufficient Data |
| 10 | Customer is low income | Check next condition | Group is false | Group is false |
| 20 | Customer has used more than 1,000 kWh | Group is true | Group is false | Group is false |

| Group 2: Customer is NOT a low income customer and has used more than 500 kWh | | | | |
|---|-------------------------------------|---------------------------------|----------------------------------|----------------------|
| Seq | Logical Criteria | If Eligibility Criteria is TRUE | If Eligibility Criteria is FALSE | If Insufficient Data |
| 10 | Customer is NOT low income | Check next condition | Group is false | Group is false |
| 20 | Customer has used more than 500 kWh | Group is true | Group is false | Group is false |

The next section describes how you'd setup the specific logical criteria in each of the groups.

Defining Logical Criteria

When you setup an eligibility criterion, you must define two things:

- The field to be compared
- The comparison method

You have the following choices in respect of identifying the **field to be compared**:

- You can retrieve a characteristic value linked to any of the following:
 - The service agreement being billed
 - The service agreement's account
 - The main person linked to the service agreement's account
 - The characteristic premise linked to the service agreement
 - One of the service points linked to the service agreement
- In addition, you can use a characteristic value that is derived while the rate is being calculated (characteristic values can be created by SQ rules, register rules and many other rate component algorithms)
- You can retrieve the value of a given service quantity
- You can retrieve the final value of an earlier rate component
- You can execute an algorithm to retrieve a field value from someplace else in the system. This is a very powerful feature, but it's not terribly intuitive. We'll present a few examples later in this section to illustrate the power of this approach.

You have the following choices in respect of identifying the **comparison method**:

- You can choose an operator (e.g., >, <, =, BETWEEN, IN, etc.) and a comparison value.
- You can execute an algorithm that performs the comparison (and returns TRUE, FALSE or INSUFFICIENT DATA). This is also a very powerful feature, but it's not terribly intuitive. We'll present a few examples later in this section to illustrate the power of this approach.

The [Examples Of Rate Component Eligibility Rules](#) provide examples to help you understand this design.

Examples of Rate Component Eligibility Rules

The topics in this section provide examples about how to setup rate component eligibility rules.

A Rate Component with a Service Quantity Comparison

Imagine a rate component that is only eligible if the customer is a low-income customer and has used more than 1,000 kWh. This rate component would need the following eligibility rules:

- Customer is a low income customer
- The customer has used more than 1,000 kWh during the bill period

These rules require only one eligibility group on the rate component. It would look as follows:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|--|----------------------|---------------------|
| 1 | Customer is a low income customer and has used more than 1,000 kWh | Apply rate component | Skip rate component |

The following criteria will be required for this group:

| Group 1: Has gas service and user is part of user group A, B or C | | | | | |
|---|---|-------------------|----------------------|----------------|----------------------|
| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
| 10 | Main person characteristic: Characteristic type = Low income indicator | = YES | Check next condition | Group is false | Group is false |
| 20 | SQ value: UOM = KWH | >= 1,000 | Group is true | Group is false | Group is false |

Both criteria are similar - they retrieve a value and compare it to something:

The first criterion is fairly simple:

- Field to Compare. We indicate that the value of the Low Income Indicator characteristic type kept on the main person linked to the account should be retrieved. We've assumed that this characteristic type has values of YES and NO.
- Comparison Method. We indicate that if the person has a characteristic value of YES, then we should check the next condition; otherwise we indicate the group is false (and if the group is false, the rate component is skipped).

The second criterion works similarly:

- Field to Compare. We indicate the service quantity (SQ) that holds the total amount of KWH should be retrieved.
- Comparison Method. We simply compare the value to 1,000.

If the second criterion is true, then the group is true and the rate component will be applied; otherwise, the group is false and the rate component will be skipped.

A Rate Component with a Time Span Comparison

A rate component that is only eligible for senior citizens has the following eligibility rule:

- Birth date equates to that of a senior citizen

This rule requires only one eligibility group on the rate component. It would look as follows:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|------------------------------|----------------------|---------------------|
| 1 | Customer Is A Senior Citizen | Apply rate component | Skip rate component |

The following criterion is required for this group:

| Group 1: Residential, Calif, Senior | | | | | |
|-------------------------------------|---|---------------------------|---------------|----------------|----------------------|
| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
| 10 | Main person characteristic: Date of Birth | Algorithm: True if senior | Group is true | Group is false | Group is false |

The criterion contains a time span comparison. Time span comparisons are used to compare a date to something. In our example, we have to determine the age of the customer based on their birth date. If the resultant age is > 65, they are considered to be a senior citizen. To pull this off, you can take advantage of a comparison algorithm supplied with the base rate component as described below.

- Field to Compare. The person characteristic in which the customer's birth date is held is selected.
- Comparison Method. We chose a comparison algorithm that returns a value of TRUE if the related field value (the customer's date of birth) is greater than 65 years (refer to the RECC-TIMESPN algorithm for an example of this type of algorithm).

You'll notice that if a value of TRUE is returned by the True if senior algorithm, the group is true (and we've setup the group to indicate a true group means the rate component is eligible).

Note:

The time span algorithm can be used to compare days, weeks, months, etc. Refer to the RECC-TIMESPN algorithm type for more information about this algorithm.

A Rate Component with Service Type Comparison

Imagine a rate component that is only eligible if the current customer has gas service AND electric service. This rate component would need the following eligibility rules:

- Customer has gas service, and
- Customer has electric service

These rules require only one eligibility group on the rate component. It would look as follows:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|--------------------------------------|----------------------|---------------------|
| 1 | Has gas service AND electric service | Apply rate component | Skip rate component |

The following criteria will be required for this group:

| Group 1: Has gas service AND electric service | | | | | |
|---|---|-------------------|----------------------|----------------|----------------------|
| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
| 10 | Algorithm: check if customer has gas service | = TRUE | Check next condition | Group is false | Group is false |
| 20 | Algorithm: check if customer has electric service | = TRUE | Group is true | Group is false | Group is false |

Both criteria are similar - they call an algorithm that performs a logical comparison. These algorithms are a bit counter intuitive (but understanding them will provide you with another way to implement complex eligibility criteria):

Both criterion works as follows:

- **Field to Compare.** We chose a "field to compare" algorithm that checks if the current account has service agreements that belong to a given set of service types. It returns a value of TRUE if the customer has an active service agreement that matches one of the service types in the algorithm. In our example, the "check if customer has gas service" algorithm returns a value of TRUE if the customer has at least one active service agreement whose SA type references the gas service type. The "check if customer has electric service" algorithm is almost identical, only the service type differs. Refer to the RECF-SRVTY and RECF-AUTOPAY algorithms for examples of this type of algorithm.
- **Comparison Method.** We simply compare the value returned by the algorithm to TRUE and indicate the appropriate response.

Note:

Bottom line. The "field to compare" algorithm isn't actually returning a specific field's value. Rather, it's returning a value of TRUE or FALSE. This value is, in turn, compared by the "comparison method" and the group is set to true, false or check next accordingly.

Defining Rate Components

Warning:

We strongly recommend that you familiarize yourself with the information under [Designing Rate Components](#) before using this transaction.

Rate components control exactly how your bill calculation lines are calculated. Every rate component exist in respect of a given *rate version* . This is because the rate version defines the date on which all of its rate components become effective.

Note:

Copying, deleting, and moving rate components. You can use the rate component maintenance transaction to duplicate, delete and move rate components. However, you may find these functions are easier to do using the [Rate Version Merge](#) transaction as this transaction can copy en masse and it also updates the relevant cross-reference information if you move or delete a rate component.

The topics in this section describe how to maintain a rate component.

Note:

Don't forget to finish the rate version. After you have added all necessary rate components to a rate version, don't forget to return to [Rate Version - Main](#) and change the state of the rate version to Finished; otherwise, it cannot be used by billing.

Rate Component - Main Information

Core information about a rate component is defined using **Menu > Rates > Rate Component Classic > Search.**

Description of Page

Rate Component contains a concatenation of basic information about the rate component. This information only appears after the rate component has been added to the database. The adjacent up and down arrows cause the rate component immediately before or after this rate component to be displayed.

Rate Version defines the rate version to which the rate component is linked. **Sequence** defines the relative position of this rate component in respect of the other rate components. The position is important because it defines the order in which the system calculates the charges AND the order in which the calculated charges appear on bills. **Rate Version** and **Sequence** form the unique identifier of the rate component. Both fields become protected after the rate component is added to the database.

Note:

Re-sequencing rate components. You must use the [Rate Version Merge](#) transaction to reposition a rate component. If you use the up / down arrows on the [Rate Version Merge](#), the system will change the rate component's **Sequence** and change all rate components that reference the old **Sequence** accordingly.

Leave gaps in the sequence numbers. Make sure you leave space between sequence numbers so that you can add new rate components between existing ones in the future. If you run out of space between rate components, you can use the [Rate Version Merge](#) transaction to re-sequence a rate version's rate components.

Eligibility criteria are highlighted. If the rate component has [eligibility criteria](#), an indication of such appears.

Select the **Rate Component Type** that corresponds with the rate component. The screen will display the appropriate fields, which correspond with the categories of rate components described in [Designing Rate Components](#). This field will be disabled when the rate component is referenced on other rate components.

Warning:

The Rate Component Type affects what you can enter on other parts of the window. The remainder of this section is devoted to those fields that can be entered regardless of RC Type. The subtopics that follow describe those fields whose entry is contingent on the RC Type.

Use **Description** to describe what the rate component does.

Rounding Type and **Precision** control how the system rounds the rate component's calculated value. Refer to [Rate Component Rounding](#) for a complete description.

Note:

Default note. **Rounding Type** defaults to Nearest and **Precision** defaults to a value consistent with the decimal positions defined on the rate schedule's currency code.

Turn on **For Calculation Purposes Only (FCPO)** if this rate component exists purely to calculate the percent / flat rate / unit rate used by another rate component. When this switch is on, the system does not include the calculated amount in the bill total.

When this switch is on:

- You must define what is calculated in **Result Type**; permissible values are Unit Rate, Charge, Step Multiplier and Percent.
- Use **Create a Bill Line** to define if a bill line should be created for the rate component (if you don't need to show the results to the customer or a user, there is no need to create a bill line).
- If a bill line is being created, use the **FCPO Retention Rule** to define if the FCPO amount should be set to zero on the bill line or whether the bill line's amount should be set equal to the FCPO amount.

For examples of rates that use the FCPO functionality, refer to [Calculated Minimum Charges](#), [Hours-Based Electric Rate](#) and [Step Boundaries Based On The Number Of Days Of Usage And The Region In Which The Customer Resides](#).

For each rate component, you will need to select the **Value Type** and **Value Source**. Valid values for the Value Type are Charge, Percentage and Unit Rate. More information to help determine which value type to choose are described in the How To sections below. Based on the Value Source entered, the remainder of this row will change.

If the Value Source is Bill Factor, then a prompt to indicate the **Bill Factor** will appear.

If the Value Source is Other Rate Component, then a prompt to indicate the **RC Sequence** will appear.

If the Value Source is Value, then a prompt to indicate the **Value** directly on the rate component will appear.

If the Value Source is Value Algorithm, then a prompt to indicate the **Value Algorithm** will appear.

If you plan to use this method, you must set up this algorithm in the system. This can be done with the following options:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that calculates a rate component's value.

Fastpath:

For more information about which method to use, refer to [Designing Rate Components](#).

If the charges associated with the rate component are only levied during a specific season, you must turn on the **Seasonal** options.

When **Seasonal** is turned on, you use **Prorate Method** to define how the system should prorate a seasonal charge when a bill segment's start and end dates are not entirely within the seasonal period (defined in **Season**). The following options are available:

- Accounting Date Dependent. This option will not prorate the charge calculated by this rate component. Rather, it will only calculate the charge if the accounting date associated with the bill segment is within the seasonal period.
- Bill End Date. This option will not prorate the charge calculated by this rate component. Rather, it will only calculate the charge if the bill segment end date is within the seasonal period.
- Bill Start Date. This option will not prorate the charge calculated by this rate component. Rather, it will only calculate the charge if the bill segment [consumption start](#) date is within the seasonal period.
- Prorate. This option will prorate the charge calculated by this rate component based on the number of days in the adjacent season that is included in the bill period. For example, if a bill period is from 15-April through 15-May and the seasonal period is from 1-May through 31-October, the system will assume 15 / 30 of the charge should be levied.
- Prorate seasonal SQ. This option is only pertinent if you have:
 - Seasonal service quantity (SQ) charges, AND
 - Meters that measure seasonal consumption on separate registers, AND
 - You have a bill that crosses seasonal boundaries, AND
 - You have multiple rate versions effective across the bill period.

If this option is used, the system will prorate the charge calculated by a SQ rate component based on the number of days in the adjacent season that is included in the rate version's calculation period. For example, if two rate versions are in effect on a bill segment and one of them only becomes effective during the summer;

only the summer consumption should be priced using the rate version (i.e., winter consumption should not be used on a rate version that is only effective during the summer period).

Note:

The **Seasonal** period is defined in the two adjacent fields. The first field contains the day and month when the season starts; the second field contains the day and month when the season ends. The day and month should be entered in the format defined in your [display profile](#).

Override Seasonal Proration. If the seasonal functionality provided with the system does not work for your organization, you may override the logic using the Override Seasonal Proration plug-in spot on the [installation](#) record. For example, perhaps the seasonal period is determined dynamically based on the scheduled meter read date of the bill cycle. Or perhaps a seasonal rate component should not be prorated and the date used to determine whether the rate component is applicable is not in the list provided by the system.

Description On Bill, Print, and Print If Zero all control if the rate component contributes a line to the customer's bill. These fields can also be modified on [Rate Version - Bill Print Info](#). You might find it easier to setup these fields on the rate version transaction as you can copy and paste descriptions between rate components. Refer to [Rate Version - Bill Print Info](#) for a description of these fields.

The other fields on this page are dependent on the type of rate component. See the "how to" subtopics below for more information.

How To

How To Set Up Flat Charge Rate Components

There are no special additional fields on this page available for setting up a Flat rate component. The following information will help you determine how to set up your Flat rate components.

The **Value Type** in this case would be Charge. This field will be disabled when the rate component is referenced on another rate component.

Refer to [Rate Component - Main Information](#) for information about defining the Value Source.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [How to use Description on Bill](#) for more information about these fields.

Move to the **GL Distribution** window to define how to book moneys associated with this rate component in the general ledger.

How To Set Up Service Quantity Rate Components

When setting up an SQ rate component, additional fields become available for you to define.

The following information will help you to set up your SQ rate components.

Select a **Value Type** of Unit Rate if the type of charge is an amount per some unit of consumption. In the rare situation where the amount of the charge is flat for the first X units of consumption, use the Value Type of Charge. This field will be disabled when the rate component is referenced on another rate component.

Refer to [Rate Component - Main Information](#) for information about defining the Value Source.

The amount that you specified using the bill factor / value field was a price per some unit of something. This thing must be identified using the **Unit Of Measure, Time Of Use, and Service Qty. Identifier** fields.

Fastpath:

For more information about UOM / TOU / SQI, refer to [UOM versus TOU versus SQI](#).

Turn on **Error if No Value** if a bill error should be generated if the UOM / TOU / SQI specified on the rate component was not supplied at billing time. For example, if every customer using a time-of-use rate should be on a meter with ON and OFF peak register, you'd turn on this switch for the ON and OFF rate components. This way,

if a customer somehow was put on a time-of-use rate, but their meter wasn't a time-of-use meter, an error would be generated.

If the charge is only applicable to consumption within some tier (e.g., the first 500 therms, or all kilowatt-hours in excess of 1,000), indicate that the rate component is **Stepped**. When this option is turned on, you must indicate the **Step Low Value** and **Step High Value** that the consumption charge is applicable to. For example, if the charge is applicable to the first 300 kilowatt-hours, you would enter **Step Low Value** 0 and **Step High Value** 300. When multiple tiers exist, the high value of the first tier is the low value of the second tier (and so on). To extend our example, the second tier would have a low value of 300; the high value may be left blank because the system assumes a blank high value means "to infinity".

Note: The **Step Low Value** and **Step High Value** fields support values of up to 9 digits and 2 decimal places (e.g. a maximum value of 999,999,999.99).

If the step boundaries are dynamic (i.e., they are calculated based on something that's only known at billing time), you can change the step boundaries using either of the following methods:

- Use **Step RC Sequence** to indicate the sequence number of the rate component whose value will be multiplied by the step's boundaries to calculate the step boundaries to use at billing time.
- Use **Step Algorithm** to indicate that an algorithm will be called to manipulate the step boundaries (note, this algorithm can manipulate the low and/or high boundaries). If you plan to use this method, you must set up this algorithm in the system. To do this:
 - Create a new algorithm (refer to [Setting Up Algorithms](#)).
 - On this algorithm, reference an Algorithm Type that manipulates a rate component's step boundaries.

Note:

Retaining Step Algorithm High/Low Boundaries. Step Algorithms are invoked during rate application to adjust step values prior to the system performing step value proration. Depending on the step value proration that occurs, the step value may be modified by the system after the rate component step algorithm has adjusted it. If you wish the adjusted step value to be modified by the system during step value proration, you must set up the Adjust Rate Component Step Values After Proration option type on the Financial Transaction Options [Feature Configuration](#). The Adjust Rate Component Step Values After Proration option must have a value of Y in order to have the adjusted step values modified by the system. Otherwise, set the value to N.

Fastpath:

For an example of when dynamic steps are needed, refer to [Hours-Based Electric Rate](#) and [Step Boundaries Based On The Number Of Days Of Usage And The Region In Which The Customer Resides](#).

Warning:

If you dynamically calculate step boundaries and the resultant high AND low values become zero, this signals the system that the rate component should be skipped (i.e., no bill line will be produced for the rate component).

Turn on **GL Statistical Quantity** if GL journal lines generated for this rate component should also contain the service quantity amount as a statistical quantity. You would use this option if you keep track of both dollar amounts and consumption units in your general ledger.

Warning:

When a bill segment is created, the system stores the statistical quantity on the journal line associated with the rate component's distribution code. If you book multiple UOM's to the same distribution code, you should only turn on GL Statistical Qty on one of the rate components. Otherwise, you will commingle different UOM's on a journal line's statistical quantity.

Fastpath:

Refer to [Determining the Statistical Quantity](#) for more information.

Turn on **Measures Peak Qty** if the UOM / TOU / SQI is associated with electric demand.

**Note:**

Default note. The value of **Measures Peak Qty** is defaulted from the **UOM** table (if a UOM is specified).

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [How to use Description on Bill](#) for more information about these fields.

Move to the **GL Distribution** window to define how to book moneys associated with this rate component in the general ledger.

How To Set Up Item Type Rate Components

When setting up an Item Type rate component, additional fields become available for you to define.

The following information will help you to set up your Item Type rate components.

Select a **Value Type** of Unit Rate. This field will be disabled when the rate component is referenced on another rate component.

Refer to [Rate Component - Main Information](#) for information about defining the Value Source.

Enter the item's **Item Type**.

Turn on **Error if No Value** if a bill error should be generated if the item type specified on the rate component was not supplied at billing time. For example, if every customer using a lamp rate must have at least one 20K lumen mercury vapor lamp and one pole, you'd turn this switch for the lamp and pole rate components.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [How to use Description on Bill](#) for more information about these fields.

Move to the **GL Distribution** window to define how to book moneys associated with this rate component in the general ledger.

**Note:**

Multiple bill lines. Most rate components cause one bill line to appear on a customer's bill. Item type rate components are unusual. If there are effective-dated changes to the customer's items during a bill period, one line will be generated for each time period. For example, if a customer had two lamps installed from 1-Jan to 15-Jan and had four lamps installed from 16-Jan to 31-Jan and the bill is from 1-Jan to 31-Jan, two lines will appear on the customer's bill - one for each period.

How To Set Up Apply To Rate Components

There are no special additional fields on this page available for setting up an Apply To rate component. The following information will help you determine how to set up your Apply To rate components.

Select a **Value Type** of Percent if the type of charge is a percent of the dollar value of previously calculated rate components. If the amount being charged is an amount per some unit of consumption, select the Value Type of Unit Rate. This field will be disabled when the rate component references other rate components.

Refer to [Rate Component - Main Information](#) for information about defining the Value Source.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [How to use Description on Bill](#) for more information about these fields.

Move to the **Cross Reference** window to define the rate components to which the charge will be applied.

Move to the **GL Distribution** window to define how to book moneys associated with this rate component in the general ledger.

How To Set Up Maximum Charge Rate Components

There are no special additional fields on this page available for setting up a Maximum rate component. The following information will help you determine how to set up your Maximum rate components.

Select a **Value Type** of Charge.

Refer to [Rate Component - Main Information](#) for information about defining the Value Source.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [How to use Description on Bill](#) for more information about these fields.

Move to the **Cross Reference** page to define the rate components against which the maximum charge will be applied.

Move to the **GL Distribution** page to define how any additional revenue associated with the maximum charge should be booked in the general ledger.

How To Set Up Minimum Charge Rate Components

There are no special additional fields on this page available for setting up a Minimum rate component. The following information will help you determine how to set up your Minimum rate components.

Select a **Value Type** of Charge.

Refer to [Rate Component - Main Information](#) for information about defining the Value Source.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [How to use Description on Bill](#) for more information about these fields.

Move to the **Cross Reference** window to define the rate components against which the minimum charge will be applied.

Move to the **GL Distribution** window to define how any additional revenue associated with the minimum charge should be booked in the general ledger.

How To Set Up Exact Charge Rate Components

There are no special additional fields on this page available for setting up an Exact Charge rate component. The following information will help you determine how to set up your Exact Charge rate components.

Select a **Value Type** of Charge.

Refer to [Rate Component - Main Information](#) for information about defining the Value Source.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [How to use Description on Bill](#) for more information about these fields.

Move to the **Cross Reference** window to define the rate components against which the exact charge will be applied.

Move to the **GL Distribution** window to define how any additional revenue associated with the minimum charge should be booked in the general ledger.

How To Set Up Summary Rate Components

Summary rate components use no other fields on this page other than those defined above.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [How to use Description on Bill](#) for more information about these fields.

Move to the **Cross Reference** window to define the rate components to summarize on this rate component.

How To Set Up Interval Pricing Rate Components

For more information about setting up interval pricing rate components, refer to [Setting Up Interval Pricing Rate Components](#) in the Interval Billing documentation.

How To Set Up TOU Pricing Rate Components

For more information about setting up TOU pricing rate components, refer to [Setting Up TOU Pricing Rate Components](#) in the Interval Billing documentation.

How To Set Up Calculation Algorithm Rate Components

Calculation Algorithm rate components are used when none of the other rate components will provide you with the functionality you need.

First, you must select a **Calc Algorithm**. This calculation algorithm will have the responsibility of producing your bill lines. All rate component options become available when you use this rate component type, based on the assumption that it is generally capable of doing anything you might require.

If you plan to use this method, you must set up this algorithm in the system. This can be done with the following options:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that calculates a rate component.

Note:

The calculation algorithm's main purpose is to create bill calculation lines. However, the algorithm may populate other information for the bill, for example, it may add to the SQ or register read collection or it may overwrite the description on bill.

If you wish to provide your users with the ability to audit the bill lines created by a rate component of this type, you may indicate an **Audit Algorithm**. Currently the only types of audit algorithms supplied by the system are those which [audit interval pricing details](#) or those which [audit TOU pricing details](#).

Fastpath:

Refer to [Setting Up Interval Pricing Rate Components](#) and [Setting Up TOU Pricing Rate Components](#) for more information about the audit algorithms provided with the system.

All the other fields on the page are optional fields available to you for use by your calculation algorithm.

Turn on **Error if No Value** if a bill error should be generated if the UOM / TOU / SQI specified on the rate component was not supplied at billing time.

Turn on the **Derive SQ** switch when your calculation algorithm will be creating entries in the SQ array for the UOM / TOU / SQI defined on your rate component. In this case, the system will not attempt to locate an entry in the SQ collection matching the rate component's UOM / TOU / SQI before calling your calculation algorithm.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [How to use Description on Bill](#) for more information about these fields.

Move to the **GL Distribution** window to define how any additional revenue associated with the minimum charge should be booked in the general ledger.

Rate Component - Cross Reference

Minimum charge, maximum charge, exact charge, apply-to, and summary rate components reference other rate components. For these types of rate components, open **Menu > Rates > Rate Component Classic > Search** and navigate to the **Cross Reference** page to define the other rate components to which it refers.

Description of Page

Rate Component contains a concatenation of basic information about the rate component. This information only appears after the rate component has been added to the database. The adjacent up and down arrows cause the rate component immediately before or after this rate component to be displayed.

Use the **Apply this Rate Component to** collection to specify the other rate component(s) on the Rate Version to which the rate component in question should refer. The list of rate components available for reference is displayed on the right. Use the left arrow to move the desired rate components into the grid. If a rate component appears in the apply to list in error, use the left arrow to remove the rate component.

Note:

An apply to rate component that has a charge type of unit rate can only reference SQ, item, interval pricing and calculation rate components. Apply to rate components with a charge type of percentage, along with summary, minimum charge, maximum charge and exact charge rate components can reference all types of rate components including summary.

The **This RC is referenced by** collection indicates what other rate components reference the rate component in question.

Rate Component - GL Distribution

Open **Menu > Rates > Rate Component Classic > Search** and navigate to the **GL Distribution** page to define each rate component's effect on the general ledger. GL distribution information is required for all rate components except for FCPO and summary rate components.

Description of Page

Rate Component contains a concatenation of basic information about the rate component. This information only appears after the rate component has been added to the database. The adjacent up and down arrows cause the rate component immediately before or after this rate component to be displayed.

If the rate component's charges should be booked to a single GL account regardless of the service agreement's SA Type's Revenue Class, enter a **Distribution Code**. If the rate component's charges are booked to a different GL account depending on the service agreement's Revenue Class, turn on **Use Revenue Class** and insert the appropriate **Revenue Class** and **Distribution Code** for each that uses the rate.

Rate Component - Characteristics

Your algorithms and reports may need additional rate component fields that aren't supported in the base-package. If so, you can set up a rate component characteristic for each such field.

Note:

Snapshotting characteristics on bill calculation lines. The system will automatically copy a rate component's characteristics onto the resultant bill lines for those characteristic types that are usable on bill lines.

Open **Menu > Rates > Rate Component Classic > Search** and navigate to the **Characteristics** page to define characteristic values for your rate component.

Description of Page

For each characteristic in the collection, indicate the appropriate **Characteristic Type** and **Characteristic Value**.

Note:

You can only choose characteristic types defined as permissible on the rate schedule record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Rate Component - Eligibility

This page is used to define the conditions under which a rate component will be applied. If you don't specify any **Eligibility Criteria Groups**, the system assumes the rate component should be applied (meaning that a rate component is eligible by default).

**Fastpath:**

Refer to [The Big Picture Of Rate Component Eligibility](#) for more information.

Open this page using **Menu > Rates > Rate Component Classic > Search** and navigate to the **Eligibility** page.

Description of Page

Rate Component contains a concatenation of basic information about the rate component. This information only appears after the rate component has been added to the database. The adjacent up and down arrows cause the rate component immediately before or after this rate component to be displayed.

**Warning:**

The following information is not intuitive; we strongly recommend that you follow the guidelines under [The Big Picture Of Rate Component Eligibility](#) before attempting to enter this information.

The **Eligibility Criteria Group** scroll contains one entry for each group of eligibility criteria. The following fields may be defined for each group:

- Use **Sequence** to control the relative order in which the group is executed when the system determines if the rate component should be applied (smaller numbers are executed before larger numbers).
- Use **Description** and **Long Description** to describe the criteria group.
- Use **If Group is True** to define what should happen if the eligibility criteria (defined in the following grid) return a value of True.
- Choose Apply Rate Component if this rate component should be executed.
- Choose Check Next Group if the next criteria group should be checked.
- Choose Skip Rate Component if this rate component should NOT be executed.
- Use **If Group is False** to define what should happen if the eligibility criteria (defined in the following grid) return a value of False.
- Choose Apply Rate Component if this rate component should be executed.
- Choose Check Next Group if the next criteria group should be checked.
- Choose Skip Rate Component if this rate component should NOT be executed.

The grid that follows contains the rate component's eligibility criteria. Think of each row as an "if statement" that can result in the related eligibility group being True or False. For example, you might have a row that indicates the customer is eligible for the rate component if the customer's birth date equates to that of a senior citizen. The following bullets provide a brief description of each field on an eligibility criterion. Please refer to [Defining Logical Criteria](#) for several examples of how this information can be used.

- Use **Sequence** to control the order in which the criteria are checked.
- Use **Criteria Field** to define the field to compare:
- Choose Characteristic if you want to compare a characteristic value that resides on any of the following to a given value (use the adjacent fields to define the object on which the characteristic resides and the characteristic type):
- The service agreement being billed
- The service agreement's account
- The main person linked to the service agreement's account
- The characteristic premise linked to the service agreement
- One of the service points linked to the service agreement (selected at random)
- The bill segment's bill
- In addition, you can use a characteristic value that is derived while the rate is being calculated (characteristic values can be created by SQ rules, register rules and many other rate component algorithms)

**Note:**

For effective-dated characteristics, the system selects the characteristic value effective on the start date of the bill segment consumption period. Refer to [Determine The Consumption Period For Metered Service](#) for information about how the consumption period is calculated before applying the rate.

- Get the most effective characteristic value for the given characteristic type and bill segment start date

- Choose Rate Component Value if you want to compare the final value of an earlier rate component to a given value. Push the adjacent search button to select the rate component's sequence number.
- Choose Service Quantity if you want to compare the final value of a service quantity to a given value. Push the adjacent search button to select the service quantity's **UOM / TOU / SQI**.
- Choose Algorithm if you want to compare anything other than the above options. Push the adjacent search button to select the algorithm that is responsible for retrieving the comparison value.
- Use **Criteria Comparison** to define the method of comparison:
- Choose Algorithm if you want an algorithm to perform the comparison and return a value of True, False or Insufficient Data.
- Choose any other option if you want to compare the **Criteria Field** using a logical operator. The following options are available:
 - Use >, <, =, >=, <=, <> (not equal) to compare the **Criteria Field** using standard logical operators. Enter the comparison value in the adjacent field.
 - Use In to compare the **Criteria Field** to a list of values. Each value is separated by a comma. For example, if a field value must equal 1, 3, or 9, you would enter a comparison value of 1,3,9.
 - Use Between to compare the **Criteria Field** to a range of values. For example, if a field value must be between 1 and 9, you would enter a comparison value of 1,9. Note, the comparison is inclusive of the low and high values.

Note:

The comparison value field expects the comma as a delimiter between values. This means that if the values involve decimals, the comma cannot be used as a decimal symbol regardless of what your implementation has set up in your [display profile](#). For decimal values, use "." as the decimal symbol.

- The next three fields control whether the related logical criteria cause the eligibility group to be considered True or False:
- Use **If True** to control what happens if the related logical criterion returns a value of True. You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false, then the rate component will be Skipped or Applied based on the values defined above in **If Group is False** and **If Group is True**.
- Use **If False** to control what happens if the related logical criterion returns a value of False. You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false, then the rate component will be Skipped or Applied based on the values defined above in **If Group is False** and **If Group is True**.
- Use **If Insufficient Data** to control what happens if the related logical criterion returns a value of "Insufficient Data". You have the options of Group is true, Group is false, or Check next condition. If you indicate Group is true or Group is false, then the rate component will be Skipped or Applied based on the values defined above in **If Group is False** and **If Group is True**.

Rate Version Merge for Component-Based Rates

The following point summarize the many diverse functions available on this transaction:

- A rate version's rate components have unique sequence numbers. This number controls the order in which a rate component is processed. If you need to insert a rate component and there's no space between existing sequence numbers, you can use this transaction to renumber the rate version's rate components.
- You can use this transaction to move a rate component to a different position within a rate version. When a rate version is moved, all references to the rate component are changed to reflect the new sequence number.
- You can use this transaction to delete a rate component. When a rate component is deleted, all references to the rate component are deleted.
- You can use this transaction to copy rate components from other rate versions. For example,
- You may want to create a rate version that is similar to an existing rate version. Rather than copying all the information from the existing rate version and then removing the inapplicable components, this page may be used to selectively copy specific rate components from the existing rate version to the new rate version.

- You may have customer-specific rates that are very similar, but still unique. You can use this transaction to build a customer-specific rate. In this scenario, you may choose to create special 'mini' rate versions, one for each of the various options. Then, you could use the rate version merge page to select the components applicable for the new custom rate version.

Note:

The target rate version must exist prior to using this page. If you are creating a new rate, you must first create the [Rate Schedule](#) and [Rate Version](#) and then navigate to the merge page to copy rate component information.

After creating your new rate version

Rate: Bakery-1, Monthly, US Dollars
Version: 3-Jan-2002

| Type | Description | Price |
|----------|---------------------|---------|
| SQ | kWh on-peak charge | \$0.212 |
| SQ | kWh off-peak charge | \$0.112 |
| SQ | kWh shoulder charge | \$0.092 |
| Apply To | Sales tax | 6.191% |

Rate: Bakery-2, Monthly, US Dollars
Version: 3-Apr-2001

| Type | Description | Price |
|------|-------------|---------|
| SQ | kW < 100 | \$0.455 |
| SQ | kW >= 100 | \$0.512 |
| Sum | kW Subtotal | N/A |

Rate: MFCTR-1, Monthly, US Dollars
Version: 1-Mar-2002

| Type | Description | Price |
|----------|---------------------|---------|
| SQ | kWh on-peak charge | \$0.212 |
| SQ | kWh off-peak charge | \$0.112 |
| SQ | kWh shoulder charge | \$0.092 |
| SQ | kW < 100 | \$0.455 |
| SQ | kW >= 100 | \$0.512 |
| Sum | kW Subtotal | N/A |
| Apply To | Sales tax | 6.191% |

...navigate to the merge page to copy components from other rate versions

Note:

Duplicate versus Merge. The [Rate Version](#) page itself has [duplication](#) capability. You would duplicate a rate version if you want to a) create a new rate version AND b) populate it with all the rate components from an existing rate version. The [Rate Component Maintenance](#) transaction also allows you to [duplicate](#) a rate component within a rate version.

Open **Menu > Rates > Rate Version Merge Classic** to open this page.

Description of Page

Select the **Original Rate Version**, which is the target for merging the rate component information.

Note:

Finished rate versions are protected. Only rate versions that are In Progress or Validated may be used as the target rate version in the merge functionality. If any changes are made to a Validated rate version on this page, the system will move the status back to In Progress. If a rate version with a status of Finished is selected, it will be displayed, but you will be unable to copy any information to it (and its description will appear in red). If you need to make changes to a Finished rate version, navigate to [Rate Version - Main](#) and change the rate version's status to In Progress. Refer to [Lifecycle of a Rate Version](#) for more information.

Select the **Merge From Rate Version**, which is your template rate version to copy the rate components from.

Note:

You may only copy components from one Merge From rate version at a time. If you want to copy components from more than one rate version, select the first Merge From rate version, copy the desired records, Save, and then select the next Merge From rate version.

The left portion of the page displays any existing rate components for the **Original Rate Version**. The right portion of the page displays the existing rate components for the **Merge From Rate Version**.

You can use the **Copy All** button to copy all the rate components from the **Merge From** rate to the **Original** rate. If you use **Copy All**, please be aware that the rate components are added to the end of the **Original** rate version.

Each time you save the changes, the system rennumbers the **Original** rate version using the **Start From Sequence Number** and **Increment By**.

The left portion of the page initially displays existing rate component records linked to the original rate version. In the **Merge Type**, you will see the word Original, for any of these records. The **Sequence**, **RC Type** and **Description** for each rate component are displayed. In the right portion of the page, the existing records in the merge from rate version are displayed initially.

The topics that follow describe how to perform common maintenance tasks:

Resequencing Rate Components

If there are no gaps between two rate components and you need to resequence the rate components:

- Make a change to the **Start From Sequence Number** or **Increment By** (so that the Save button becomes enabled).
- Click the Save button.

Removing a Row From a Grid

If you wish to remove a record linked to the Original rate version, press the delete button to the left of the record.

Adding a New Row to a Rate

You may move any of the rate components from the Merge From rate version to the original rate version by selecting the left arrow adjacent to the desired row. Once a record is moved it will disappear from the Merge From information and appear in the Original information with the word Merge in the Merge Type column.

Removing an Uncommitted Row from a Rate

If you have copied a row across by mistake, you may remove it by clicking on the right arrow adjacent to the appropriate record.

Moving Positional Rows Up and Down

A rate component's sequence number controls the order in which the rate component should be applied. You may modify the order execution using the up and down arrows.

The sequences need to be renumbered in order to ensure the correct order. The fields **Start from sequence number** and **Increment By** are used to define the sequence number to assign to the first rate component and the subsequent values to assign to subsequent rate components.

Rate Component Cross Reference Information

All information related to a rate component, including general ledger information, characteristics and eligibility rules, will be copied.

Special logic exists for merged rate components that reference other rate components. This includes the cross reference collection and the eligibility criteria.

This logic is difficult to explain succinctly, so we'll use an example. Imagine that the Merge From rate components look as follows:

| | Sequence | Type | Description |
|--|----------|------------------|------------------------------|
| | 10 | Service Quantity | Winter kWh charge, first 500 |
| | 20 | Service Quantity | Winter kWh charge, remaining |
| | 30 | Summary | Winter subtotal |
| | 40 | Service Quantity | Summer kWh charge, first 300 |
| | 50 | Service Quantity | Summer kWh charge, remaining |
| | 60 | Summary | Summer subtotal |
| | 70 | Apply-to | Employee discount |
| | 80 | Apply-to | City tax |
| | 90 | Apply-to | State tax |

The **Rate Component - Cross Reference** tab for the merge from rate version shows the following cross-reference information for the State tax rate component:

| Apply This Rate Component To: | | | This RC Is Referenced By: | | |
|-------------------------------|-------------|----------------------|---------------------------|-------------|-----------------|
| Sequence | Description | | Sequence | Description | |
| | 10 | Winter kWh charge, f | | 30 | Winter subtotal |
| | 20 | Winter kWh charge, r | | 60 | Summer subtotal |
| | 40 | Summer kWh charge | | | |
| | 50 | Summer kWh charge | | | |
| | 70 | Employee discount | | | |
| | 80 | City tax | | | |

Assume that only the following rate components are copied to the new rate version:

- Service Quantity (0 to 300 kWh Step)
- Service Quantity (300 to max)
- State tax

Also, assume that the original rate version already contains a rate component with a sequence number of one of the merging rate components.

| | Merge Type | Sequence | Type | Descript | Sequence | Type | Description | |
|--|------------|----------|------------------|----------|----------|------|------------------|------------------------------|
| | Original | 10 | Service Quantity | Charges | | 30 | Summary | Winter subtotal |
| | Merge | 10 | Service Quantity | Winter k | | 40 | Service Quantity | Summer kWh charge, first 300 |
| | Merge | 20 | Service Quantity | Winter k | | 50 | Service Quantity | Summer kWh charge, remaining |
| | Merge | 90 | Apply-to | State ta | | 60 | Summary | Summer subtotal |
| | | | | | | 70 | Apply-to | Employee discount |
| | | | | | | 80 | Apply-to | City tax |

After saving, the second service quantity rate component is renumbered and the State tax rate component will reflect the renumbering in the cross-reference and will not include the rate components that were not copied.

Here is the view on the merge page after saving:

| | | Merge Type | Sequence | Type | Description | | Sequence | Type | Description |
|--|--|------------|----------|------------------|-------------|--|----------|------------------|------------------------------|
| | | Original | 10 | Service Quantity | Charges | | 10 | Service Quantity | Winter kWh charge, first 500 |
| | | Original | 20 | Service Quantity | Winter kWh | | 20 | Service Quantity | Winter kWh charge, remaining |
| | | Original | 30 | Service Quantity | Winter kWh | | 30 | Summary | Winter subtotal |
| | | Original | 40 | Apply-to | State tax | | 40 | Service Quantity | Summer kWh charge, first 300 |
| | | | | | | | 50 | Service Quantity | Summer kWh charge, remaining |
| | | | | | | | 60 | Summary | Summer subtotal |
| | | | | | | | 70 | Apply-to | Employee discount |
| | | | | | | | 80 | Apply-to | City tax |
| | | | | | | | 90 | Apply-to | State tax |

If you navigate to the [Rate Component - Cross Reference](#) tab for the **merged** rate version for the State tax rate component, it looks as follows:

| Sequence | Description | Sequence | Description | Sequence | Description |
|----------|-------------------------------|----------|-------------|----------|-------------|
| | 20 Winter kWh charge, first 5 | | 10 Charges | | |
| | 30 Winter kWh charge, remai | | | | |

If any rate component refers to another rate component in the eligibility criteria, the sequence number of the eligibility criteria is also adjusted accordingly.

Note:

You will be warned by the system when you copy a rate component that has cross-references to other rate components that are not being copied.

Rate Check for Component-Based Rates

The Rate Check page allows you to test your rates under various scenarios. The topics in this section describe how to use this transaction.

Rate Check - Main

Open **Menu > Rates > Rate Check Classic** to enter the parameters required to check a rate.

Description of Page

Note:

Easiest way to use rate check. The easiest way to populate the above parameters is to select an existing bill segment on [Bill Segment - Calc Lines](#) and then use the rate schedule context menu to navigate to this transaction. When you do this, the system populates the above fields from the values on the bill segment. After these fields are populated, you can override the defaulted values to check various scenarios.

Indicate the primary **Rate Schedule** that you want to test. The version(s) used will be those in effect during the start and end dates. Only validated and finished rate versions will be used.

Note:

Default note. If **Rate Schedule** is blank and you enter a **SA ID**, the service agreement's current rate will be defaulted.

While using a **SA ID** is not strictly required to check a rate, we strongly recommend finding a representative service agreement to check a rate. Why? Because charges in a rate may be affected by values in a service agreement. For example, consider the following types of rate components that use service agreement-specific values:

- Rate components with bill factors that are subject to the presence of contract riders. In fact, if a bill factor requires a contract rider and you do not specify a **SA ID** rate check assumes that the rider is applicable.
- Rate components with bill factors that are subject to tax exemptions.
- Rate components with bill factors with customer-specific prices.
- Rate components with service quantity (SQ) rules that use characteristics on service agreement, account or the service agreement's characteristic premise.
- Rate components with SQ rules that use contract quantities.

In other words, if you don't specify a **SA ID**, you will not be able to check rates with the above characteristics.

Enter a **Bill Seg ID** if you want to test the rate with actual usage for a given bill segment. This is useful if you want to compare the actual bill segment results with the results of the same usage under a different rate schedule. If you indicate a **Bill Seg ID**, rate check's **SA ID** will be populated with the bill segment's service agreement ID (and **SA ID** will be protected).

Note:

Overriding consumption. If you enter a **Bill Seg ID**, the bill segment's consumption will be defaulted into the consumption array that follows. You may override this consumption to test various scenarios.

You must indicate a **Revenue Class**. This is needed for applying the appropriate GL distribution code for rate components where the GL account is based on the customer's revenue class.

Enter the **Start Date** and **End Date** that you are testing. If a **Bill Seg ID** is entered, the start and end dates are taken from the bill segment's period, but can be overwritten.

Note:

Consumption Period. Refer to [Determine The Consumption Period For Metered Service](#) for information about how the consumption period is calculated before applying the rate.

Indicate the **Accounting Date**. If a **Bill Seg ID** is entered, the accounting date on the bill segment is used but can be overwritten.

Enter the quantities that you want to test in the quantity collection. For every **UOM/ TOD/ SQI** combination, enter a register quantity.

Note:

Default note. If you indicate a bill segment, the quantity grid will be populated with data from the bill segment's meter read snapshot collection. This includes the **UOM/TOD/SQI** quantities and the **Service Points** associated with these quantities.

Enter the **Service Point ID** if your rate uses register rules that require characteristic values from the service point or premise. For example, the register rule that converts CCF to therms uses a bill factor to store the conversion factor. This bill factor may have been configured to use characteristics on the service point / premise (e.g., the conversion factor may differ based on the storage location associated with the service point).

Note:

Overriding service points. If you specify a **SA ID**, you may indicate a service point that is not connected to your service agreement (if you want to experiment with the effect of different service point characteristics on the rate).

The collection of **Characteristic Types** and **Characteristic Values** is used to apply the appropriate bill factor values. If these values are entered, these values will be used to apply the appropriate bill factors (even if you have specified a service agreement from which characteristics can be derived). If these values are blank AND there is no **SA ID**, then you will receive an error from the rate application indicating which values are needed.

Indicate the **Bill Language** to use for the resulting bill calc line descriptions.

When you have entered everything, click on the **Check Rate** button. This will cause your rate to be applied to the parameters entered above. If the system is successful, you will be transferred to the **Calc Lines** page on which the resulting calculation details can be viewed.

Rate Check Results - Calc Lines

After you have pressed the **Check Rate** button on the **Main** page, you will be transferred to the **Calc Lines** tab to view the lines that have been calculated by your rate.

Description of Page

The **Rate Schedule** and its description, the **Revenue Class** and its description and the **Bill Period** are displayed at the top.

More than one Rate Version may have been effective for the primary Rate Schedule (and any applicable sub rates) during this bill period. If so, multiple collections of calculation lines will be produced. Use the **Bill Seg Hdr** scroll to view each collection of calculation lines.

For each Bill Seg Hdr, the following information will be displayed above the calculation line grid.

Sequence This identifies which Bill Seg Hdr is being displayed.

Start Date, End Date This is the period, within the bill period, that the rate version, which produced these lines, was effective.

Amount This is the total amount calculated by this group of calculation lines.

Desc on Bill The description on bill for the rate version that produced these lines.

Rate Version The rate version that was used to produce these lines.

The grid, which displays the bill calculation lines for this rate version, shows one row exists for every calculation involved in this process. This information is very similar to what is displayed on the bill calculation lines page for a bill segment. The following information is displayed in the grid:

- **Sequence** is the system-assigned unique identifier of the calculation detail row.
- **Description on Bill** is the information about the bill line that appears on the customer's bill.
- **Calculated Amount** is the calculated amount associated with the bill line.
- The **Print** switch controls whether information about this line will print on the customer's bill.
- The **App in Summary** switch defines if this line's amount also appears on a summary line. This switch is turned on if the corresponding rate component is summarized on a summary rate component.
- **UOM** is the unit of measure of the service quantity priced on the calculation line.
- **TOU** is the time-of-use code of the service quantity priced on the calculation line.
- **SQI** is the service quantity identifier of the service quantity priced on the calculation line.
- **Billable Service Quantity** is the service quantity priced on the calculation line. This quantity will be different from the measured consumption if there are SQ rules or register rules in effect.
- **Base Amount** is used by calculation lines (e.g. taxes) that are cross-referenced to other calculation lines and whose value(s), therefore, depend on the amounts calculated by those other lines. The Base Amount shows the total amount derived from the cross-referenced line(s) that the current line then used to calculate its billed amount.
- **Sequence** refers to the sequence number of the rate component on the applicable rate version that was used to calculate the line.
- **Meas Peak Qty** is checked if the UOM priced on the calculation line is used to measure a peak quantity.
- **Exempt Amount** is the amount of the calculated charge that the customer doesn't have to pay because they are tax exempt. This will only be calculated if you have provided an SA ID on the main page.
- **Distribution Code** is the distribution code associated with the calculation line. This distribution code is used to build the general ledger details on the bill segment's financial transaction.

Rate Check Results - SQ Details

After you have pressed the **Check Rate** button on the **Main** page, you can navigate to the **SQ Details** tab to view the service quantities that supplied to (or derived by) you rate. Please be aware that a rate can derive service quantities if there are register rules, service quantity rules or time-of-use mapping rate components.

Description of Page

The **Rate Schedule** and its description, the **Revenue Class** and its description and the **Bill Period** are displayed at the top.

The SQ details grid is a snapshot of the service quantities amassed from:

- The quantities input on the main page OR the quantities taken from the service quantity collection for the bill segment, if it was input on the main page.
- The SQ rules defined on the input rate.
- The register rules defined on the input rate.

The following information is displayed in the grid:

- **UOM** is the unit of measure of the service quantity.
- **TOU** is the time-of-use code of the service quantity.
- **SQI** is the service quantity identifier of the service quantity.
- **Initial Service Quantity** is the initial quantity amassed by the system before application of the rate's SQ rules.
- **Billable Service Quantity** is the service quantity that will be priced by the service agreement's rate. This amount differs from the initial service quantity when the rate's SQ rules manipulate consumption.

Rate Check Results - Register Read

After you have pressed the **Check Rate** button on the **Main** page, you can navigate to the **Register Read** tab to view the final quantities (Final UOM, Final TOU and Final SQI) that were derived by your rate's register rules.

Description of Page

The **Rate Schedule** and its description, the **Revenue Class** and its description and the **Bill Period** are displayed at the top.

This page displays measured quantities from one of two places:

- From the values input on the main page of Rate Check
- From the Register Read collection for the bill segment indicated on the main page of Rate Check

The final quantities will reflect any changes to the measured quantities resulting from applied register rules.

The following information is displayed in the grid:

- **UOM** is the unit of measure of the measured quantity.
- **TOU** is the time-of-use code of the measured quantity.
- **SQI** is the service quantity identifier of the measured quantity.
- **Measured Quantity** is the initial quantity amassed by the system before application of the rate's register rules.
- **Final UOM** is the unit of measure of the resultant billing quantity.
- **Final TOU** is the time-of-use code of the resultant billing quantity.
- **Final SQI** is the service quantity identifier of the resultant billing quantity.
- **Register Quantity** is the resultant billing quantity.
- **Service Point ID** displays information about the service point used by rate check to determine any characteristic values needed for the register rules.

Rate Check Results - Characteristics

After you have pressed the **Check Rate** button on the **Main** page, you can navigate to the **Characteristics** tab to view the final characteristics collection as manipulated by your rate's plug-ins.

Description of Page

The **Rate Schedule** and its description, the **Revenue Class** and its description and the **Bill Period** are displayed at the top.

The collection of **Characteristic Types** and **Characteristic Values** reflects any changes made to the initial characteristics collection (input on the main page) after applying the rate.

Use Sub Rate Schedules to Encapsulate Common Rate Components

Many implementations have multiple rate schedules that share common rate components. For example, the following illustration shows two rate schedules that use identical rate components to calculate taxes:

Two rate schedules with identical rate components that are used to levy taxes

| Rate Schedule ERES1 (Stepped rate) | | | | | | |
|------------------------------------|----------|------------|---------|-------------|-------------|-----------------|
| Seq # | RC Type | Value Type | Value | Bill Factor | UOM/TOU/SQI | Step Range Xref |
| 10 | Flat | Charge | \$ 0.00 | | | |
| 20 | SQ | UnitRate | \$ 0.04 | | KWH | 0 to 300 |
| 30 | SQ | UnitRate | \$ 0.07 | | KWH | 300 to max |
| 40 | Summary | | | | | 20, 30 |
| 50 | Apply To | Percent | | CITYTAX | | 10, 20, 30 |
| 60 | Apply To | Percent | | STTAX | | 10, 20, 30 |
| 70 | Apply To | Percent | | CNTYTX | | 10, 20, 30 |

| Rate Schedule ERES2 (Minimum rate) | | | | | | |
|------------------------------------|----------|------------|----------|-------------|-------------|-----------------|
| Seq # | RC Type | Value Type | Value | Bill Factor | UOM/TOU/SQI | Step Range Xref |
| 10 | SQ | UnitRate | \$ 0.04 | | KWH | |
| 20 | Minimum | Charge | \$ 15.00 | | | 10 |
| 30 | Apply To | Percent | | CITYTAX | | 10, 20 |
| 40 | Apply To | Percent | | STTAX | | 10, 20 |
| 50 | Apply To | Percent | | CNTYTX | | 10, 20 |

Two Rate Schedules That Share Common Rate Components

Rather than duplicate the taxation rate components on both rates, a sub rate schedule can be constructed that references the shared rate components. The sub rate schedule can then be included on each of the primary rate schedules:

Primary rate schedules

| Rate Schedule ERES1 (Stepped rate) | | | | | | |
|------------------------------------|---------|------------|---------|-------------|-------------|-----------------|
| Seq # | RC Type | Value Type | Value | Bill Factor | UOM/TOU/SQI | Step Range Xref |
| 10 | Flat | Charge | \$ 0.00 | | | |
| 20 | SQ | UnitRate | \$ 0.04 | | KWH | 0 to 300 |
| 30 | SQ | UnitRate | \$ 0.07 | | KWH | 300 to max |
| 40 | Summary | | | | | 20, 30 |

| Rate Schedule ERES2 (Minimum rate) | | | | | | |
|------------------------------------|---------|------------|----------|-------------|-------------|-----------------|
| Seq # | RC Type | Value Type | Value | Bill Factor | UOM/TOU/SQI | Step Range Xref |
| 10 | SQ | UnitRate | \$ 0.04 | | KWH | |
| 20 | Minimum | Charge | \$ 15.00 | | | 10 |

Each of the primary rates references the same sub rate

| Rate Schedule ERES-TAX (Sub-rate) | | | | | | |
|-----------------------------------|----------|------------|-------|-------------|-------------|------|
| Seq # | RC Type | Value Type | Value | Bill Factor | UOM/TOU/SQI | Xref |
| 10 | Calc Adj | | | | | Y |
| 20 | Apply To | Percent | | CITYTAX | | 10 |
| 30 | Apply To | Percent | | STTAX | | 10 |
| 40 | Apply To | Percent | | CNTYTX | | 10 |

A sub rate schedule that contains the common taxation rate components

Setting Up a Sub Rate Schedule to Encapsulate Common Rate Components

The primary reason to encapsulate common rate components into sub rate schedules is to simplify long-term maintenance. For example, if a new tax is introduced, only the sub rate schedule in the above example would require modification. The converse is also true. For example, if pricing structures are changed, only the affected primary rate schedules require modification. Both of these scenarios result in reduced rate construction and testing time.

The topics in this section describe sub rate schedules in more detail.

Sub Rate Schedules and Primary Rate Schedules Have Similar Features

Most of the rich functionality described above is shared by both sub rate schedules and primary rate schedules. The following points highlight the major differences:

- Only primary rate schedules can be referenced on a customer's service agreement and on an adjustment type's generation algorithm.
- Only primary rate schedules can reference sub rate schedules.

- Sub rate schedules cannot reference a service type, a currency code, the allow estimates indicator, register rules or valid meter configurations. This is because these attributes are defined for the primary rate schedule used to drive the calculation.
- When charges are calculated for a primary rate schedule's sub rate schedules, the primary rate schedule's [frequency](#) is used. This allows a single sub rate schedule to be referenced on any primary rate schedule regardless of the primary rate schedule's frequency. This means that sub rate schedules do not reference a frequency.
- Because sub rate schedules inherit the frequency of the primary rate schedule at execution time, [Rate Check](#) cannot be used to verify sub rate schedules directly. Rather, use a primary rate schedule that references the sub rate schedule on Rate Check.

Primary Rates May Reference Many Sub Rates

There is no limit to the number of sub rate schedules that can be referenced on a primary rate schedule. If multiple sub rate schedules are defined on a primary rate schedule, the primary rate schedule defines the invocation order of each.

A bill segment that is calculated using a rate will contain separate bill calculation details for each primary rate schedule and sub rate schedule used in its calculation. Please be aware of the following special scenarios that can affect the number of bill calculation details on a bill segment:

- If a given primary or sub rate schedule has multiple rate versions effective during a bill segment's calculation period, a separate bill calculation detail will be created for each version of every primary and sub rate schedule.
- It is possible for a sub rate schedule to not contribute any charges to a bill segment (for example, if its rate components have eligibility rules that inhibit the creation of calculation lines). If a sub rate schedule does not contribute additional charges or service quantities to a bill segment, the system will suppress the bill calculation detail. In other words, an empty bill calculation detail is not created if a subsidiary rate schedule contributes nothing new to a bill segment.

An adjustment that is calculated using a primary rate schedule will contain a separate calculation line for every rate component on the primary and sub rate schedules that contribute charges to the adjustment.

How to Set Up a Sub Rate Schedule

Sub rate schedules are set up using the same transactions as primary rate schedules. With the exception of the differences outlined above, the design and construction of sub rate schedules is virtually identical to that of primary rate schedules.

The major difference occurs when a sub rate schedule has rate components that require the value of lines calculated by the primary rate schedule or earlier sub rate schedules. Rate components that levy taxes using the monetary value calculated by earlier rate schedules are good examples. In order to implement these types of rate components on a sub rate schedule, follow these instructions:

- Set up a Rate Component - Calculation Algorithm that references the base-package algorithm type called C1-RC-CLAMT. Algorithms of this type calculate the value of a rate component by summarizing the value of lines calculated by earlier rate components. Please note that you can limit the summarized lines to those calculated by rate components that are marked with a given characteristic type and value.
- Add a rate component to the sub rate schedule:
- Choose a **Rate Component Type** of Calculation Algorithm.
- Select the **Calculation Algorithm** defined above.
- Turn on **FCPO** (for calculation purposes only) to prevent the value of this line from being added to the total charges.
- Set up Apply To rate components as normal for each tax to be calculated. These rate components will reference the rate component described above in their cross-reference.

Component-Based Rate Examples

In this section, we provide examples of how to set up some charges that occur in many organizations. While your rates may not possess these exact charges, this section should help solidify your understanding of how to set up your company's rates.

A Simple Electric Rate

The following table illustrates the rate components necessary to levy a simple rate that contains the following charges:

- Monthly service charge: \$10.00.
- First 300 kilowatt-hours at \$0.0382 per kWh.
- Remaining kilowatt-hours at \$0.0673 per kWh.
- State Tax at the prevailing rate (this tax is a percentage of a dollar value).
- County Use Tax at the prevailing rate (this tax is an amount per kilowatt-hour).

| Seq # | RC Type | Value Type | Value | Bill Factor | Item Type | UOM/ TOU/SQI | Step Range | Cross Reference |
|-------|------------------|------------|--------|-------------|-----------|-----------------|-----------------|-----------------|
| 10 | Flat Charge | Charge | 10.00 | | | | | |
| 20 | Service Quantity | Unit Rate | 0.0382 | | | KWH | 0 to 300 | |
| 30 | Service Quantity | Unit Rate | 0.0673 | | | KWH | 300 to 99999999 | |
| 40 | Summary | | | | | | | 20, 30 |
| 50 | Apply To | Percent | | STTAX | | | | 10, 20, 30 |
| 60 | Apply To | Unit Rate | | COUNTY TAX | | | | 20, 30 |

The following table illustrates how you might want to define the Description on Bill for these rate components.

| Seq # | Description on Bill |
|-------|-----------------------------------|
| 10 | Monthly service charge of %R %D |
| 20 | First %Q kWh at %I per kWh %F |
| 30 | Remaining %Q kWh at %I per kWh %F |
| 40 | Subtotal |
| 50 | State sales tax %R %T |
| 60 | County use tax %R per kWh %T |

Adding Measured Quantities Together

Fastpath:

Refer to the how to section under [Setting Up Service Quantity \(SQ\) Rules](#) for more information.

CCF To Therm Conversion

Fastpath:

Refer to the how to section under [Setting Up Register Rules](#) for more information.

How To Adjust Measured Consumption By A Minimum Contract Quantity

Fastpath:

Refer to the how to section under [Setting Up Service Quantity \(SQ\) Rules](#) for more information.

Elevation Charges

Assume you have rates that charge a different amount per gallon depending on the elevation. For example, customers on rate X who live between sea level and 500 feet are charged \$0.001 per gallon; customers living over 500 feet are charged \$0.0015 per gallon. Customers on rate Y who live between sea level and 500 feet are charged \$0.002 per gallon; over 500 feet are charged \$0.0025.

Elevation Charges - Characteristics

Given the elevation gradients are the same for rates X and Y, you can set up a characteristic called ELEV and assign it characteristic values of < 500 and > 500 . If possible, you should indicate the appropriate characteristic value for each postal default so that new premises will receive their appropriate characteristic value. If premises already exist, you must populate this characteristic value accordingly.

Elevation Charges - Bill Factors

Because each rate charges a different price per gallon depending on the characteristic, you'll need two bill factors - **one for rate X, the other for rate Y. Both will reference the new ELEV characteristic.** The only difference will be their bill factor values.

Elevation Charges - Rate Schedule and Rate Components

You will create two rate schedules - one for rate X, the other for rate Y. Rate X will have a rate component that references the rate X elevation bill factor. Rate Y will have a rate component that references the rate Y elevation bill factor.

Note:

Alternatives. The design of the system would allow you to create a single rate rather than two rates. How? In the single rate you would have two rate components referencing the two elevation bill factors. You would indicate that both bill factors are contingent on the presence of a contract rider by turning on the bill factors' contract rider flags. When you set up a service agreement for a customer, you would create a contract rider referencing the necessary bill factor. We don't recommend this approach because you are not accurately reflecting your actual rates with corresponding rates in the system. We showed this approach to provide an alternative way of thinking about your rates.

Gas Pressure Factor Adjustments

Assume you have rates that require a cubic foot of gas converted based on the pressure factor associated with the premise. Assume there's a different pressure factor based on the take point from which the gas is pumped.

Pressure Factor - Characteristics

Create a characteristic called TAKEPT and assign it characteristic values for each take point in your service area. If possible, you should indicate the appropriate characteristic value for each postal default so that new premises will receive their appropriate characteristic value. If premises already exist, you must populate this characteristic value accordingly.

Pressure Factor - Bill Factors

Set up a bill factor called PF ADJ . On the bill factor, indicate that it uses the TAKEPT characteristic. Create a bill factor value for each take point to define its respective pressure factor.

Pressure Factor - Register Rule

Create a register rule called CCFPFADJ . Populate it with the following information:

| Field | Value |
|--------------------|----------------------------------|
| Register Algorithm | Bill factor based UOM conversion |
| UOM (Source) | CCF |
| UOM (Result) | CCF PF |
| Bill Factor | PF ADJ |

This register rule will convert a metered amount of cubic feet to a pressure factor adjusted amount of cubic feet using the bill factor.

Pressure Factor - Rate Schedule

Link the CCFPFADJ register rule to every rate that requires a pressure factor adjustment.

Pricing Interval Consumption Using Interval Prices

Assume you have interval meters that measure how much was consumed at various times during a day. You may need to price each interval read using the real time price that's effective on the read's start date and time.

Note:

This example assumes that you do not have the interval billing subsystem and are recording your interval reads in the Meter Read table.

Real Time Pricing - Bill Factors

Set up a bill factor called RTP. On the bill factor, indicate that it uses the N/A characteristic. Also, set the bill factor type to Interval. You will also have to [Maintain Interval Values](#) for the bill factor.

Real Time Pricing - Service Quantity Identifier

Set up a service quantity identifier called \$.

Real Time Pricing - Register Rule

Create a register rule called REALTIME. Populate it with the following information:

| Field | Value |
|--------------------|-------------------|
| Register Algorithm | Real time pricing |
| UOM | KWH |
| Bill Factor | RTP |
| SQI (Result) | \$ |

This register rule will convert a metered amount of KWH into a dollar value using the real time price in effect on the read's start date and time.

Interval Billing - Rate Schedule

Link the REALTIME register rule to every rate that requires such. These rate will also require a SQ rate component with a price of \$1 and a SQI of \$.

Pricing Non Interval Consumption Using Weighted Average Prices

Refer to [Interval Values Can Be Used For More Than Just Interval Meters](#) to understand the business situation.

Weighted Average Pricing - Bill Factors

Set up a bill factor called WAP. If you assume you have different WAP's depending on the customer's load profile, indicate that it uses the LOADPROF characteristic type. Also set the bill factor type to Interval. You will also have to [Define Interval Values](#) for the bill factor.

Weighted Average Pricing - RC Algorithm

Create an algorithm called WAP. Populate it with the following information:

| Field | Value |
|----------------|----------|
| Algorithm Type | PX VALUE |
| Bill Factor | RAP |

Refer to the PX VALUE algorithm type for information about this algorithm.

Weighted Average Pricing - Rate Component

Create a SQ rate component on the respective rate(s).

| Seq # | RC Type | Value Type | Value Source | Value Algorithm |
|-------|---------|------------|--------------|-----------------|
|-------|---------|------------|--------------|-----------------|

| | | | | |
|----|------------------|-----------|-----------|-----|
| 20 | Service Quantity | Unit Rate | Algorithm | WAP |
|----|------------------|-----------|-----------|-----|

Employee Discounts

Assume your organization provides discounts of 25% to employees for their residential consumption.

Employee Discounts - Characteristics

Because the discount amount is the same for all employees, you just need a dummy characteristic to keep the relational model consistent. You should set up a characteristic type called N/A and with a characteristic value of N/A. It's important that the characteristic value is identical to the characteristic type otherwise billing will generate an error.

Employee Discounts - Bill Factors

Set up a bill factor called EMPDISC. On the bill factor, indicate that it uses the characteristic described above and that it is contingent on the presence of a contract rider. Create a bill factor value with an amount of -25%.

Employee Discounts - Rate Schedule and Rate Components

On every residential rate that is eligible for employee discounts, you will have a rate component that references the EMPDISC bill factor.

Employee Discounts - Start Option

Create a start option for every SA type that can use one of your employee discount rates. The start option should contain a contract rider that references the EMPDISC bill factor.

Employee Discounts - Service Agreements

On existing service agreements of employees eligible for a discount, add a contract rider referencing the EMPDISC bill factor.

Customer Specific Prices

Assume your organization has some rates where the customer may negotiate specific prices.

Customer Specific Prices - Bill Factors

Set up a bill factor called KWHCUST. On the bill factor indicate that it:

- Uses a N/A characteristic (you need a characteristic on all bill factors). Refer to [Employee Discounts](#) for an example.
- Has a value type of Unit Rate.
- Has its value specified in a contract term.
- Should generate an error if it finds no value in the contract.

Define the standard bill factor value to use for those customers who do not elect to negotiate a specific price.

Customer Specific Prices - Rate Schedule and Rate Components

On every rate that may allow a customer specific price, you will have a rate component that references the KWHCUST bill factor.

Customer Specific Prices - Start Option

Create a start option for every permissible price on every SA type with such rates. The start option should contain a contract value that references the KWHCUST bill factor. You will also have a start option to use for those customers to do not elect to negotiate a specific price. This start option will not define a contract value.

Customer Specific Prices - Service Agreements

For existing service agreements using this rate where the customer has negotiated a specific price, add a contract value referencing the KWHCUST bill factor.

Hours-Based Electric Rate

Warning:

If your organization does not sell electric service (or if you do and don't use hour-based steps) you might want to skip this example as it involves understanding a fairly complex electric concept - kWh / kw = hours.

The following table illustrates the rate components necessary to levy a rate that contains the following charges:

- Monthly service charge: \$10.00.
- First 10 hours of use at \$0.0673 per kWh.
- Remaining hours of use at \$0.032 per kWh.
- State Tax at the prevailing rate (this tax is a percentage of a dollar value).
- County Use Tax at the prevailing rate (this tax is an amount per kilowatt-hour).

| Seq # | RC Type | Value Type | Value | Bill Factor | Item Type | UOM/ TOU/ SQI | Step Range | Cross Reference | Calc Only | Result Type |
|-------|------------------|------------|--------|-------------|-----------|---------------------|---|-----------------|-----------|-------------|
| 10 | Flat Charge | Charge | 10.00 | | | | | | N | |
| 20 | Service Quantity | Unit Rate | 1.0 | | | KW | | | Y | Unit Rate |
| 30 | Service Quantity | Unit Rate | 0.0673 | | | KWH | 0 to 10 Multiply by RC: 20 | | N | |
| 40 | Service Quantity | Unit Rate | 0.032 | | | KWH | 10 to 99999999 Multiply by RC: 20 | | N | |
| 50 | Summary | | | | | | | 30, 40 | N | |
| 60 | Apply To | Percent | | STTAX | | | | 10, 30, 40 | N | |

| | | | | | |
|----|-------------|--------------|-----------|--------|---|
| 70 | Apply To | Unit Rate | COUNTYTAX | 30, 40 | N |
|----|-------------|--------------|-----------|--------|---|

Hours-Based - For Calculation Purposes Only Rate Component

The strange thing about this rate is rate component 20. It is used "for calculation purposes only". Notice what it's calculating - the number of kilowatts (kW). Why is it necessary? Because hour-based steps have to be multiplied by the number of kW used by the customer in order to derive the real kWh based steps. Why? Because number of kWh / number of kW = number of hours. Therefore an hour * number of kW = number of kWh.

Hours-Based - Dynamic Stepped SQ Rate Components

Notice that rate components 30 and 40's step boundaries are multiplied by the amount calculated by rate component 20 (i.e., the number of KW).

Hours-Based - Descriptions On Bill

The following table illustrates how you might want to define the Description on Bill for these rate components.

| Seq # | Description on Bill | Print on Bill |
|-------|--|---------------|
| 10 | Monthly service charge of %R %D | Y |
| 20 | Calculate only rate to determine Hourly charge step multiplication factor. | N |
| 30 | First %Q hours of usage at %I per kWh %F | Y |
| 40 | Remaining %Q hours of usage at %I per kWh %F | Y |
| 50 | Subtotal | Y |
| 60 | State sales tax %R %T | Y |
| 70 | County use tax %R per kWh %T | Y |

Step Boundaries Based On The Number Of Days Of Usage And The Region In Which The Customer Resides

The following table illustrates the rate components necessary to levy a simple rate that contains the following charges:

- Monthly service charge: \$10.00.
- Charge \$.0832 for the first "x" kWh. X is equal to the number of days in the billing period multiplied by a factor that varies depending on where the customer lives.
- Charge \$.1112 for the remaining kWh.
- State Tax at the prevailing rate (this tax is a percentage of a dollar value).
- County Use Tax at the prevailing rate (this tax is an amount per kilowatt-hour).

| Seq # | RC Type | Value Type | Value | Bill Factor | Item Type | UOM/ TOU/ SQI | Step Range | Cross Reference | Calc Only | Result Type |
|-------|------------------|------------|--------|-------------|-----------|---------------|--|-----------------|-----------|-------------|
| 10 | Flat Charge | Charge | 10.00 | | | | | | N | |
| 20 | Service Quantity | Unit Rate | | BASEQTY | | DAYS | | | Y | Unit Rate |
| 30 | Service Quantity | Unit Rate | 0.0832 | | | KWH | 0 to 1 Multiply by RC: 20 | | N | |
| 40 | Service Quantity | Unit Rate | 0.1112 | | | KWH | 1 to 99999999 Multiply by RC: 20 | | N | |
| 50 | Summary | | | | | | | 30, 40 | N | |
| 60 | Apply To | Percent | | STTAX | | | | 10, 30, 40 | N | |
| 70 | Apply To | Unit Rate | | COUNTYTAX | | | | 30, 40 | N | |

Dynamic Steps - SQ Rule On The Rate Schedule

This rate's rate schedule must have an SQ rule that calculates the number of days in the rate's bill period. This SQ rule will add a new service quantity to the measured service quantities supplied to the rate by billing. This new service quantity would be labeled with an SQI of DAYS and would contain the number of days in the bill period. This service quantity is needed by rate component 20.

Dynamic Steps - For Calculation Purposes Only Rate Component

The strange thing about this rate is rate component 20. It is used for calculation purposes only. Notice what it's calculating - the number of days (SQI = DAYS) multiplied by some factor that differs based on the region (Bill factor = BASEQTY).

Dynamic Steps - Bill Factors

Because the daily amount differs based on the region in which the customer resides, you'll need a bill factor - BASEQTY - with a characteristic that matches the region. This characteristic will be specified on the customer's premise. Then, at billing time, the system extracts the appropriate base quantity based on where the customer lives and multiplies it times the number of days in the customer's bill. The step boundaries are then multiplied by the resultant value (notice that they are set to 1).

Dynamic Steps - Dynamic Stepped SQ Rate Components

Notice that rate components 30 and 40's step boundaries are multiplied by the amount calculated by rate component 20 (i.e., amount based on the number of days of consumption).

Dynamic Steps - Description On Bill

The following table illustrates how you might want to define the Description on Bill for these rate components.

| Seq # | Description on Bill | Print on Bill |
|-------|---|---------------|
| 10 | Monthly service charge of %R %D | Y |
| 20 | Calculate only rate component to determine Step multiplication factor | N |
| 30 | First %Q kWh at %I per kWh %F | Y |
| 40 | Remaining %Q kWh at %I per kWh %F | Y |
| 50 | Subtotal | Y |
| 60 | State sales tax %R %T | Y |
| 70 | County use tax %R per kWh %T | Y |

Calculated Minimum Charges

The following table illustrates the rate components necessary to levy a simple rate that contains the following charges:

- First 300 kilowatt-hours at \$0.0382 per kWh.
- Remaining kilowatt-hours at \$0.0673 per kWh.
- Minimum charge of \$0.15 per day.
- State Tax at the prevailing rate (this tax is a percentage of a dollar value).
- County Use Tax at the prevailing rate (this tax is an amount per kilowatt-hour).

| Seq # | RC Type | Value Type | Value | Bill Factor | Item Type | UOM/ TOU/ SQI | Step Range | Cross Reference | Calc Only | Result Type |
|-------|------------------|------------|--------|-------------|-----------|---------------|-----------------|-----------------|-----------|-------------|
| 30 | Service Quantity | Unit Rate | 0.0382 | | | KWH | 0 to 300 | | N | |
| 40 | Service Quantity | Unit Rate | 0.0673 | | | KWH | 300 to infinity | | N | |
| 50 | Summary | | | | | | | 30, 40 | N | |
| 52 | Service Quantity | Unit Rate | .15 | | | DAYS | | | Y | Charge |
| 54 | Minimum Charge | | | | 52 | | | 30, 40 | N | |
| 60 | Apply To | Percent | | STTAX | | | | 30, 40, 54 | N | |

| | | | | | |
|----|-------------|--------------|-----------|--------|---|
| 70 | Apply To | Unit Rate | COUNTYTAX | 30, 40 | N |
|----|-------------|--------------|-----------|--------|---|

Calculated Minimums - SQ Rule On The Rate Schedule

This rate's rate schedule must have an SQ rule that calculates the number of days in the rate's bill period. This SQ rule will add a new service quantity to the measured service quantities supplied to the rate by billing. This new service quantity would be labeled with an SQI of DAYS and would contain the number of days in the bill period. This service quantity is needed by rate component 52.

Calculated Minimums - For Calculation Purposes Only Rate Component

The strange thing about this rate is rate component 52. It is used for calculation purposes only. Notice what it's calculating - the number of days (SQI = DAYS) multiplied by 1 (i.e., the number of days in the billing period).

Calculated Minimums - Description On Bill

The following table illustrates how you might want to define the Description on Bill for these rate components.

| Seq # | Description on Bill | Print on Bill |
|-------|---|---------------|
| 30 | First %Q kWh at %I per kWh %F | Y |
| 40 | Remaining %Q kWh at %I per kWh %F | Y |
| 50 | Subtotal | Y |
| 52 | Calculate only rate component to determine number of days | N |
| 54 | Minimum charge %S | Y |
| 60 | State sales tax %R %T | Y |
| 70 | County use tax %R per kWh %T | Y |

Stepped Taxes

Warning:

This is a difficult example. You should take the time to understand it even if you don't have stepped taxes because it illustrates the power of the various rate algorithms.

The following table illustrates the rate components necessary to levy a simple rate that contains the following charges:

- \$0.10 per kWh.
- Service charge of \$6.00
- Taxes are stepped:
- 6.383% for the anything up to \$10
- 9.89% for everything above \$10

Note that the dollar amount should be prorated if the bill is prorated.

| Seq # | Description | RC Type | Value Type | Value | UOM/ TOU/SQI | Cross Reference | Calc Only | Result Type |
|-------|------------------------------------|---------------------|------------|---------|-----------------|--------------------|-----------|----------------|
| 10 | Energy Charge | Service Quantity | Unit Rate | 0.10 | KWH | | N | |
| 20 | Customer Charge | Flat | Charge | 6.00 | | | N | |
| 30 | Total Taxable Revenue | Summary | | | | 10, 20 | Y | Charge |
| 40 | Taxable Rev for 1st tax tier | Maximum | Charge | 10.00 | | 30 | Y | Charge |
| 50 | Taxable Rev for 1st tax tier | Summary | | | | 30, 40 | Y | Charge |
| 60 | Taxable Rev for 2nd tax tier | Apply To | Percent | -100.00 | | 50 | Y | Charge |
| 70 | Taxable Rev for 2nd tax tier | Summary | | | | 30, 60 | Y | Charge |
| 80 | Tax for 1st tier | Apply to | Percent | 6.383 | | 50 | N | |
| 90 | Tax for 2nd tier | Apply to | Percent | 9.89 | | 70 | N | |

Notice that sequences 30, 40, 50, and 60 are calculation-only rate components that are used to calculate the amount of revenue applicable for each tax rate. We'll let you work the math.

How To Add A New Service Quantity Rule Algorithm

Warning:

This section is meant for technicians only!

If the SQ rule algorithms that are supplied with the base package are not sufficient for your rating requirements, you will have to write a new SQ rule algorithm. This section describes how to do this. After you have followed the steps outlined below, you can then set up the control tables necessary to invoke this algorithm as described under [Setting Up Service Quantity Rules](#).

Warning:

Do NOT attempt to set up a new service quantity algorithm until you have a very good understanding of what your meters measure and how your rates charge for this consumption. In addition, you should completely understand the concepts described in [UOM versus TOU versus SQI](#) before creating a new algorithm. In addition, you should completely understand the concepts described in [When And How To Manipulate Measured Consumption](#) before creating a new algorithm.

Follow the following steps to define a new service quantity (SQ) rule:

- Assign a two-digit identifier to the SQ rule. This identifier should begin with an X or Y. For example, you could give your first SQ rule the identifier X1, the second X2, etc.
- Create an algorithm type for your new SQ rule. This algorithm type exists to define the types of parameters supplied to your SQ rule. Refer to [Base Package SQ Rules](#) for examples. This algorithm type must be identified by the two-digit identifier allocated above.

While SQ rules require an algorithm type, they do NOT require an algorithm. Why? Because you set up an SQ rule to define the values of the parameters passed to your program (and therefore you don't need an algorithm as algorithms exist to define the values of the parameters passed to a program).

- Go to [Look Up Options](#) and add a new lookup value for the field SQ_RULE_FLG. This should have a Field Value equal to the two-digit identifier allocated above.
- Write your new program. This program should be named CMPRQ 'nn' X - where 'nn' is the same two-digit identifier. When you create the new program, please copy an existing SQ rule program (their program names are all in the format CIPRQ__X). This way you will automatically inherit the copybooks necessary to support the routine.

Warning:

Do NOT alter any of the copybooks contained in the linkage section of an algorithm. If you do need extra information for your algorithm you should execute SQL to get the information. If you do alter a linkage section copybook the upgrade process will be greatly complicated. Note, however, that virtually all information available to the rate application is being passed to the rule algorithms - so it is likely the information you need will be at hand.

How to Add a New Register Rule Algorithm

Warning:

This section is meant for technicians only!

If the register rule algorithms that are supplied with the base package are not sufficient for your rating requirements, you will have to write a new register rule algorithm. This section describes how to do this. After you have followed the steps outlined below, you can then set up the control tables necessary to invoke this algorithm as described under [Setting Up Register Rules](#).

Warning:

Do NOT attempt to set up a new Register algorithm until you have a very good understanding of what your meters measure and how your rates charge for this consumption. In addition, you should completely understand the concepts described in [UOM versus TOU versus SQI](#) before creating a new algorithm. In addition, you should completely understand the concepts described in [When And How To Manipulate Measured Consumption](#) before creating a new algorithm.

Follow the following steps to define a new Register (register) rule:

- Assign a two-digit identifier to the register rule. This identifier should begin with an X or Y. For example, you could give your first register rule the identifier X1, the second X2, etc.
- Create an algorithm type for your new register rule. This algorithm type exists to define the types of parameters supplied to your register rule. Refer to [Base Package Register Rules](#) for examples. This algorithm type must be identified by the two-digit identifier allocated above.

While register rules require an algorithm type, they do NOT require an algorithm. Why? Because you set up a register rule to define the values of the parameters passed to your program (and therefore you don't need an algorithm as algorithms exist to define the values of the parameters passed to a program).

- Go to [Look Up Options](#) and add a new lookup value for the field REG_RULE_ALG_FLG. This should have a Field Value equal to the two-digit identifier allocated above.

- Write your new program. This program should be named CMPRR 'nn' X - where 'nn' is the same two-digit identifier. When you create the new program, please copy an existing register rule program (their program names are all in the format CIPRR__X. This way you will automatically inherit the copybooks necessary to support the routine.

Warning:

Do NOT alter any of the copybooks contained in the linkage section of an algorithm. If you do need extra information for your algorithm you should execute SQL to get the information. If you do alter a linkage section copybook, the upgrade process will be greatly complicated. Note, however, that virtually all information available to the rate application is being passed to the rule algorithms - so it is likely the information you need will be at hand.

United Kingdom VAT and CCL

The topics in this section provide information about value added tax (VAT) and climate change levy (CCL) charges that are specific to non-domestic customers in the United Kingdom market.

Note:

Applicable for UK market. This section is only relevant for the United Kingdom market. Other markets may disregard this section.

UK VAT Overview

Two rates of VAT, referred to as standard rate VAT and reduced rate VAT, are applicable to energy related charges in the UK. Domestic (i.e., residential) customers always pay VAT at the reduced rate. Non-domestic customers on the other hand normally pay standard rate VAT. However, part or all of the energy related charges for a non-domestic customer might be subject to reduced rate VAT. De minimis and VAT declarations affect the percentage of the energy related charges that is subject to each VAT rate:

- If average daily usage at a premise for a given service type does not exceed a certain threshold (the de minimis limit), all energy related charges at that premise / service type are taxed at the reduced rate.
- Some non-domestic customers, such as those with a mixed-use premise, may be eligible to pay reduced rate VAT on part or all of their energy related charges. Customers may file a VAT declaration specifying the percentage of their energy related charges that are eligible for reduced rate VAT - refer to [Maintaining Declarations](#) for more information. If the declared percentage exceeds a given threshold, the declared percentage is deemed to be 100% and the customer pays VAT at the reduced rate on all energy related charges at that premise. VAT declarations are non-transferable and must be filed for each account, premise, and service type combination.

In addition to the potential for different rates of VAT to be applicable on a bill, UK tax regulations require that excess credits are considered a prepayment of energy related charges together with VAT. Refer to [Excess Credits and UK VAT](#) for more information.

The system comes supplied with various algorithms types that can be used to perform the VAT calculations.

UK CCL Overview

The climate change levy (CCL) is based on the amount of energy used that is subject to standard rate VAT. Similarly to VAT declarations, customers may file for exemption from CCL. A CCL declaration specifies the percentage of the CCL charges that the customer is exempt from - refer to [Maintaining Declarations](#) for more information. CCL declarations are non-transferable and must be filed for each account, premise, and service type combination.

CCL charges themselves are subject to standard rate VAT.

UK VAT and CCL Bill Examples

The following examples show how a bill for a non-domestic customer is affected by de minimis, VAT declarations, and CCL declarations. In the examples, standard rate VAT of 17.5%, reduced rate VAT of 5%, a VAT declaration threshold of 60%, and a CCL charge of 0.43p per unit of energy are used.

Example 1 - Normal Account

This example shows the bill for a normal non-domestic account with no declarations and consumption above the de minimis limit. Standard rate VAT is applied to all energy related charges (the standing charge and the per unit charge) and to the CCL charge.

| Bill Line | Amount |
|----------------------------|--------|
| Standing Charge | 10.00 |
| 2,000 units @ 10p | 200.00 |
| CCL on 2,000 units @ 0.43p | 8.60 |
| VAT @ 17.5% on 218.60 | 38.25 |
| Total | 256.85 |

Example 2 - Account with Consumption Under the De Minimis Limit

In this example, consumption does not exceed the de minimis limit and therefore reduced rate VAT is applied to all the energy related charges. There is no climate change levy because only units subject to standard rate VAT are subject to CCL.

| Bill Line | Amount |
|---------------------|--------|
| Standing Charge | 10.00 |
| 2,000 units @ 10p | 200.00 |
| VAT @ 5% on £210.00 | 10.05 |
| Total | 220.05 |

Example 3 - Account with VAT Declaration

This example is for a non-domestic account with a VAT declaration of 20%. Consumption is above the de minimis limit. CCL applies to only 80% of the total units as 20% is subject to reduced rate VAT and therefore exempt. 80% of the energy related charges (the standing charge and the per unit charge) and all of the CCL charge are subject to standard rate VAT. 20% of the energy related charges are subject to reduced rate VAT.

| Bill Line | Amount |
|-----------------|--------|
| Standing Charge | 10.00 |

| | |
|----------------------------|--------|
| 2,000 units @ 10p | 200.00 |
| CCL on 1,600 units @ 0.43p | 6.88 |
| VAT @ 17.5% on £174.88 | 30.60 |
| VAT @ 5% on £42.00 | 2.10 |
| Total | 249.58 |

Example 4 - Account with VAT Declaration and CCL Declaration

This example is for a non-domestic account with a VAT declaration of 20% and a CCL declaration of 10%. Consumption is above the de minimis limit. CCL applies to only 80% of the total units as 20% is subject to reduced rate VAT and therefore exempt. The customer gets a credit (CCL relief) for 10% of the CCL charges as a result of the CCL declaration. 80% of the energy related charges (the standing charge and the per unit charge) and all of the CCL charge less the CCL reliefs are subject to standard rate VAT. 20% of the energy related charges are subject to reduced rate VAT.

| Bill Line | Amount |
|----------------------------|--------|
| Standing Charge | 10.00 |
| 2,000 units @ 10p | 200.00 |
| CCL on 1,600 units @ 0.43p | 6.88 |
| CCL relief | <0.68> |
| VAT @ 17.5% on £174.20 | 30.48 |
| VAT @ 5% on £42.00 | 2.10 |
| Total | 248.78 |

Billing and UK VAT

The following sections describe how VAT rules are implemented when a bill is produced.

Application of De Minimis

The de minimis rule specifies that all energy related charges at a premise be subject to reduced rate VAT if the total usage at a premise does not exceed a certain threshold. To determine if de minimis applies, the total billed consumption for a premise must therefore be known. However, energy usage at a premise may be measured with several meters and billed by multiple service agreements. To ensure that the final billed consumption for the premise is used to determine if de minimis applies, all service agreements for an account of a given service type at a given premise should be billed together and de minimis should be checked after the bill segments have been generated. In addition, all bill segments on one bill for consumption at a given premise must be for the same bill period.

Note:

Bill segments from different periods may not appear on the same bill. If a bill segment is canceled, all bill segments associated with consumption at a given premise for the same service type must be canceled and re-billed together. You cannot re-bill the bill segment on a bill for a different period.

An **Apply De Minimis Rule** Customer Class – Pre Bill Completion algorithm type CPBC-DMCH is supplied with the base package that checks for de minimis at bill completion time. The base bill completion algorithm type checks that for any service agreement that was billed, bill segments for all the account's service agreements with the same service type and characteristic premise exist on the bill. It then calculates the total consumption for the premise and determines if de minimis applies. If de minimis applies, it sets a bill characteristic whose value is the premise ID to indicate that de minimis applies and regenerates the bill segment. Refer to the **Apply De Minimis Rule** algorithm type CPBC-DMCH for more information on how this type of algorithm operates.

For calculation rule-based rates, the **Apply VAT to Cross-Referenced Charges** calculation rule business object (C1–**ApplyVatToCrossRefCharge**) calculates standard and reduced rate VAT and applies the de minimis rule if the bill characteristic for de minimis is found. Refer to [Calculation of VAT](#) for more information. Note that during the initial generation of each bill segment, the characteristic will not exist and standard rate VAT will be applied. This means that if you look at a bill before it is complete, VAT may not be accurately reflected.

For component-based rates, the **Apply VAT to Cross-Referenced RCs** Rate Component – Calculation Algorithm algorithm type that calculates standard and reduced rate VAT (RCAM-VAT) applies the de minimis rule if the bill characteristic for de minimis is found. Refer to [Calculation of VAT](#) for more information. Note that during the initial generation of each bill segment, the characteristic will not exist and standard rate VAT will be applied. This means that if you look at a bill before it is complete, VAT may not be accurately reflected.

Note:

Batch billing cannot regenerate re-billed bill segments. If you cancel and rebill a bill segment, you should complete the bill on-line so that the re-billed bill segments can be regenerated if de minimis applies.

Calculation of VAT

To calculate VAT, the percentages of energy related charges subject to standard rate VAT and reduced rate VAT must be determined. As these percentages vary from customer to customer and even from one bill to the next for the same customer, their calculation must take place at billing time and is handled by the following:

For calculation rule-based rates, the **Apply VAT to Cross Referenced Charges** business object (C1–**ApplyVatToCrossRefCharge**) is provided to calculate the percentages of energy related charges subject to standard rate and reduced rate VAT, taking into account de minimis and any VAT declaration that is in effect for the service type, account, and premise. The percentages can then be applied to the appropriate charges that are cross-referenced.

For component-based rates, the **Apply VAT to Cross-Referenced RCs** Rate Component – Calculation Algorithm algorithm type RCAM-VAT is provided to calculate the percentages of energy related charges subject to standard rate and reduced rate VAT, taking into account de minimis and any VAT declaration that is in effect for the service type, account, and premise. The percentages can then be applied to the appropriate charges that are cross-referenced.

Calculation of CCL

CCL is a charge per unit of energy subject to standard rate VAT. It is therefore dependent on the same percentage of energy related charges subject to standard rate VAT determined during the calculation of VAT.

For calculation rule-based rates, a **Calculate Climate Levy and Relief Charges** calculation rule business object (C1–**ApplyCCLCharges**) is provided to calculate CCL charges and CCL relief, taking into account any CCL declarations that are in effect for the service type, account, and premise.

For component-based rates, a **Calculate CCL** Rate Component – Calculation Algorithm algorithm type RCAM-CCL is provided to calculate CCL charges and CCL relief, taking into account any CCL declarations that are in effect for the service type, account, and premise.

Excess Credits and UK VAT

When a financial transaction that results in a credit balance for a service agreement is frozen, the amount of the excess credit must be accounted for as a prepayment of energy related charges and VAT. VAT is calculated at the reduced rate for domestic customers and at the standard rate for non-domestic customers. When the excess credit is used, the VAT liability is reversed.

A **Create Excess Credit GL Details** Customer Class FT freeze algorithm type CFTZ-VAT-GL is provided to create additional GL detail entries for unbilled revenue and VAT liability when the freezing of an FT results in a credit balance or a change to a service agreement's credit balance.

Excess Credit GL Accounting Example

The following example shows the additional GL details that are created when a service agreement's balance changes and the starting or ending balance is a credit. For this example, a single VAT rate of 10% is used simply to illustrate the principle.

The service agreement has a zero starting balance. Note the following:

- When the first payment is received, the overpayment results in a credit balance and additional GL entries are created to recognize the unbilled energy revenue and unbilled VAT liability.
- When the second bill segment is created, the credit balance is reduced and additional GL entries are created to back out the unbilled GL entries, up to the amount of the credit balance.
- When the bill segment is canceled, the service agreement again has a credit balance and additional GL entries are created to recognize the unbilled energy revenue and unbilled VAT liability.

| Event | Normal GL Accounting | Additional GL Accounting | SA Balance |
|-----------------------------------|--------------------------------------|---|------------|
| Bill segment for £110 created | A/R 110 Revenue <100> VAT <10> | | 110 |
| Payment of £330 is received | Cash 330 A/R <330> | A/R 220 Unbilled Energy <200> Unbilled VAT <20> | <220> |
| Bill segment for £275 created | A/R 275 Revenue <250> VAT <25> | A/R <220> Unbilled Energy 200 Unbilled VAT 20 | 55 |
| Payment of £55 is received | Cash 55 A/R <55> | | 0 |
| Bill segment for £275 is canceled | A/R <275> Revenue 250 VAT 25 | A/R 275 Unbilled Energy <250> Unbilled VAT <25> | <275> |

Setting Up The System For UK VAT and CCL

The following sections provide an overview of how to configure the system to apply UK VAT and CCL charges for non-domestic customers.

Bill Segment Freeze Installation Option

Select Freeze at Bill Completion as the bill segment freeze option. The system determines if de minimis applies at bill completion time and has to regenerate the bill segments as necessary.

Customer Class

Create a separate customer classes for non-domestic customers.

Service Agreements

You must configure the system so that each service agreement that must be checked for de minimis is only linked to service points at a single premise. The service agreement must reference that premise as its characteristic premise. Refer to [Application of De Minimis](#) for more information.

Bill Factors for UK VAT and CCL

- Standard Rate VAT
- Reduced Rate VAT
- VAT Declaration Percentage Threshold. Set up a separate bill factor for each service type as the thresholds differ based on service type.
- De Minimis Average Daily Amount Threshold. Set up a separate bill factor for each service type as the de minimis amounts differ based on service type.
- Climate Change Levy (CCL) Per Unit Price. Set up a separate bill factor for each service type as the CCL per unit prices differ based on service type.

Characteristic Type for De Minimis Amounts

Set up a characteristic type to use for the bill characteristic that indicates when de minimis applies. Define the type of characteristic value as a Foreign Key Value and specify a foreign key reference that points to the premise table. Specify this characteristic type as parameters to the algorithms that apply the de minimis rule and that apply VAT.

You need to define a characteristic type for every service type that is subject to the de minimis rule, as the de minimis limit may apply for one service type but not another on the same bill.

Note: A **De Minimis Premise** Characteristic Type is provided that may be used for a specific service type. For additional service types, additional characteristic types will need to be defined.

Distribution Code

Define the following distribution codes:

- Unbilled Prepaid Energy Related Charges
- Unbilled Prepaid VAT

These distribution codes are required as parameters to the algorithms to create the GL details for excess credit.

UOM / TOU / SQI

If using calculation rule-based rates, the calculation rule that calculates CCL requires the consumption that is subject to standard rate VAT as a service quantity.

If using component-based rates, the algorithm that calculates CCL requires the following service quantities:

- The percentage of energy related charges that is subject to standard rate VAT
 - Define the SQI used to store this service quantity. You will specify this SQI as a parameter to the algorithm used to calculate VAT. Refer to the RCAM-VAT algorithm type for more information about the base package algorithm.
- The total consumption

Define the UOM / TOU / SQI used to store these service quantities.

Service Quantities

If using calculation rules-based rates, the algorithm that checks if the de minimis applies, requires a service quantity containing the total consumption. Unless you have registers that measure the total consumption independent of time of use or interval, you will need to set up a pre-processing calculation group with a calculation rule to aggregate the usage into one service quantity.

If using component-based rates, the algorithms that calculate VAT and CCL require a service quantity containing the total consumption. Unless you have registers that measure the total consumption independent of time of use or interval, you will need to set up a SQ Rule to aggregate the usage into one service quantity.

Algorithms for UK VAT and CCL

Add the following [algorithms](#):

- Apply De Minimis Rule. Define an algorithm for each service type for which de minimis should be checked. Plug the algorithm(s) in on the customer class for the Pre Bill Completion system event. Refer to the CPBC-DMCH algorithm type for more information about the base package algorithm.
- If using component-based rates, Apply VAT to Cross-Referenced RCs. Define one algorithm to calculate VAT at the standard rate and one algorithm to calculate VAT at the reduced rate (specify whether to calculate standard rate or reduced rate VAT using the algorithm parameter). You will need to define a set of algorithms for each service type (the bill characteristic to store the premise when de minimis applies and the VAT Declaration percentage threshold bill factor referenced in the algorithm parameters are different for each service type). Plug these algorithms in on the Calculation Algorithm plug-in spot on the Calculation Algorithm RC Type rate component. Refer to the RCAM-VAT algorithm type for more information about the base package algorithm.
- Create Excess Credit GL Details. Plug this algorithm in on the customer class for the FT Freeze system event. Refer to the CFTZ-VAT-GL algorithm type for more information about the base package algorithm.
- If using component-based rates, Calculate CCL. Plug this algorithm in on the Calculation Algorithm plug-in spot on the Calculation Algorithm RC Type rate component. Refer to the RCAM-CCL algorithm type for more information about the base package algorithm.
- Highlight Effective Declarations for Account and Premise. Plug this algorithm in on the installation option for the Control Central Alert system event. Refer to the CCAL-DECL algorithm type for more information about the base package algorithm.

Calculation Rules to Charge VAT and CCL

Four additional calculation rules are required to charge for VAT and CCL on non-domestic rates:

- Calculate standard rate VAT
 - Calculation Rule Type= Apply VAT to Cross Referenced Charges
 - VAT Calculation Type = Standard Rate
 - Specify the De Minimis Characteristic Type
 - Specify Declaration Percentage Threshold Bill Factor
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Note that the calculation rule overrides description on bill

- Cross-reference the calculation line category for energy related charges that are subject to VAT
- Calculate reduced rate VAT
 - Calculation Rule Type = Apply VAT to Cross Referenced Charges
 - VAT Calculation Type = Reduced Rate
 - Specify the De Minimis Characteristic Type
 - Specify Declaration Percentage Threshold Bill Factor
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Note that the calculation rule overrides description on bill
 - Cross-reference the calculation line category for energy related charges that are subject to VAT
- Calculate CCL and CCL Relief
 - Calculation Rule Type = Calculate Climate Change Levy and Relief Charges
 - UOM/TOU/SQI = the identifier of the service quantity that the prices applies to
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Note that the calculation rule overrides description on bill
- VAT on CCL
 - Calculation Rule Type = Apply To
 - Value type = Percentage
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Cross-reference the calculation line category for the total CCL and CCL Relief related charges

Setting up the calculation rules as above produces separate lines for VAT on energy related charges and on CCL (i.e., lines will be created for standard rate VAT on energy related charges, reduced rate VAT on energy related charges, and standard rate VAT on CCL charges).

You can set up rates to calculate standard rate VAT on energy related charges and CCL together as follows:

- Calculate standard rate VAT charges
 - Calculation Rule Type = Apply VAT to Cross Referenced Charges
 - FCPO = Yes
 - VAT Calculation Type = Standard Rate
 - Specify the De Minimis Characteristic Type
 - Specify Declaration Percentage Threshold Bill Factor
 - Value Source = Value
 - Value = 100
 - Note that the calculation rule overrides description on bill
 - Cross-reference the calculation line category for energy related charges that are subject to VAT
- Calculate CCL and CCL Relief
 - Calculation Rule Type = Calculate Climate Change Levy and Relief Charges
 - UOM/TOU/SQI = the identifier of the service quantity that the prices applies to
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Note that the calculation rule overrides description on bill
- Calculate standard rate VAT
 - Calculation Rule Type = Apply To
 - Value type = Percentage
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Cross-reference the calculation line category for the total CCL and CCL Relief related charges

- Calculate reduced rate VAT:
 - Calculation Rule Type = Apply VAT to Cross Referenced Charges
 - VAT Calculation Type = Reduced Rate
 - Specify the De Minimis Characteristic Type
 - Specify Declaration Percentage Threshold Bill Factor
 - Specify Value Source. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Note that the calculation rule overrides description on bill
 - Cross-reference the calculation line category for energy related charges that are subject to VAT

Rate Components to Charge VAT and CCL

Four additional rate components are required to charge for VAT and CCL on non-domestic rates:

- Calculate standard rate VAT
 - RC Type= Calculation Algorithm
 - Value type = Percentage. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Specify the UOM/TOU/SQI of the service quantity that holds the total consumption
 - Turn on Derive SQ
 - Calculation algorithm = the algorithm you set up to calculate VAT at the standard rate
 - Cross-reference all rate components that contribute to the total bill amount for energy related charges
 - Note that the algorithm overrides description on bill
- Calculate reduced rate VAT
 - RC Type = Calculation Algorithm
 - Value type = Percentage. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for reduced rate VAT.
 - Specify the UOM/TOU/SQI of the service quantity that holds the total consumption.
 - Turn on Derive SQ
 - Calculation algorithm = the algorithm you set up to calculate VAT at the reduced rate
 - Cross-reference all rate components that contribute to the total bill amount for energy related charges
 - Note that the algorithm overrides description on bill
- Calculate CCL and CCL Relief
 - RC Type = Calculation Algorithm
 - Value type = Unit Rate. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for CCL per unit price.
 - UOM/TOU/SQI = the identifier of the service quantity containing the total units of energy consumed
 - Calculation algorithm = the algorithm you set up to calculate CCL
 - Note that the algorithm overrides description on bill
- VAT on CCL
 - RC Type = Apply-to
 - Value type = Percentage. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Cross-reference the rate component that calculates CCL and CCL Relief

Setting up the rate components as above produces separate lines for VAT on energy related charges and on CCL (i.e., lines will be created for standard rate VAT on energy related charges, reduced rate VAT on energy related charges, and standard rate VAT on CCL charges).

You can set up rates to calculate standard rate VAT on energy related charges and CCL together as follows:

- Calculate standard rate VAT charges

- RC Type = Calculation Algorithm
- Turn on For Calculation Purposes Only (Result Type = Charge)
- Value type = Percentage. Define a value source of Value and a value of 100.
- Specify the UOM/TOU/SQI of the service quantity that holds the total consumption.
- Turn on Derive SQ
- Calculation algorithm = the algorithm you set up to calculate VAT at the standard rate
- Cross-reference all rate components that contribute to the total bill amount for energy related charges.
- Calculate CCL and CCL Relief
 - RC Type = Calculation Algorithm
 - Value type = Unit Rate. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for CCL per unit price.
 - UOM/TOU/SQI = the identifier of the service quantity containing the total units of energy consumed
 - Calculation algorithm = the algorithm you set up to calculate CCL
 - Note that the algorithm overrides description on bill.
- Calculate standard rate VAT
 - RC Type = Apply-to
 - Value type = Percentage. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for standard rate VAT.
 - Cross-reference the rate component that calculates standard rate VAT charges and the rate component that calculates CCL and CCL Relief
- Calculate reduced rate VAT:
 - RC Type = Calculation Algorithm
 - Value type = Percentage. It is recommended that you use a value source of Bill Factor and reference the bill factor you set up for reduced rate VAT.
 - Specify the UOM/TOU/SQI of the service quantity that holds the total consumption.
 - Turn on Derive SQ
 - Calculation algorithm = the algorithm you set up to calculate VAT at the reduced rate
 - Cross-reference all rate components that contribute to the total bill amount for energy related charges.
 - Note that the algorithm overrides description on bill.

Quotes

A quote allows you to show a customer how their bill segments will look if a given set of pricing terms is applied to a given amount of consumption. If the customer accepts a quote, one or more real service agreements are created.

Fastpath:

Refer to [Defining Quotation Options](#) for how to setup the system to enable quotation functionality.

Note:

Separate module. Please note that the quoting functionality is part of the Contract Management module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

The topics in this section describe the quotation functionality.

The Big Picture Of Quotations

The topics in this section provide background information about a variety of quotation features and functions.

Warning:

If you are not familiar with the concepts described under [Sales and Marketing, Billing, Rates](#) and [Interval Billing](#) (assuming you have quotes generated using interval consumption) the quotation functionality will be difficult to understand.

Basic Quotation Concepts

The section describes basic quotation concepts.

A Quote Shows How Bill Segments Might Look

A quote shows how a customer's bill segments will look if a given set of pricing terms is applied to a given amount of consumption. The following example illustrates how a quote might look that provides a customer with two different options for their electric service. If the customer elects either option, a new service agreement would be created.

| Quote | | Account: 1231231123 - ABC Supply | |
|-----------------------------------|-------------|-----------------------------------|-------------|
| Quote Detail 1 | | Quote Detail 2 | |
| SA Type: Electric | Rate: EQ-10 | SA Type: Electric | Rate: AA-34 |
| 72 Market Street San Fran., CA | | 72 Market Street San Fran., CA | |
| Period: 1-Jan-00 - 31-Jan-00 | | Period: 1-Jan-00 - 31-Jan-00 | |
| Descript. | Amount | Descript. | Amount |
| Usage < Cap | \$500 | Hedge | \$400 |
| Usage > Cap | \$100 | > Hedge | \$201 |
| Period: 1-Feb-00 - 28-Feb-00 | | Period: 1-Feb-00 - 28-Feb-00 | |
| Descript. | Amount | Descript. | Amount |
| Usage < Cap | \$525 | Hedge | \$625 |
| Usage > Cap | \$111 | > Hedge | \$1 |

Please note the following about a quote:

- A quote is related to an account.
- A quote can contain many quote details. A quote detail shows how bill segments will look if a given set of pricing terms (e.g., rates, riders, contract quantities, time-of-use-maps, contract options, etc.) is applied to a given amount of consumption.
- A quote detail may contain many simulated bill segments. For example, a quote detail could show the customer what their monthly bills would be if a given set of pricing terms were used over the course of several months (where each month has different consumption levels and different prices).
- A quote may contain multiple quote details for the same service. For example, a quote can contain four different pricing options for the same service (where each option is shown using a separate quote detail). The customer can then compare them and choose the optimum option.
- A quote may contain quote details for multiple premises and multiple services at each premise. For example, a quote can contain quote details for electric and gas service at multiple premises.

Proposal Service Agreements Must Exist

You cannot create a quote unless its account has at least one proposal service agreement (SA). A proposal SA contains the pricing terms, legal terms, and template consumption used to generate the simulated bill segments that appear on

a quote. It might be helpful to view a proposal SA as special type of service agreement that is ignored when a bill is produced for an account.

The topics in this section provide detailed information about proposal SAs.

Proposal SAs Contain Pricing Terms

The pricing terms (e.g., rates, contract quantities, riders, bill factor values, load curves, TOU maps, etc.) used to generate a quote detail's simulated bill segments reside on a special type of service agreement (SA) referred to as a "proposal SA". Proposal SAs are like real SAs in many respects. In fact, you can view and change a proposal SAs pricing terms using the same transaction used to maintain real service agreements (i.e., [service agreement maintenance](#)).

Note:

Quote details are rather empty. A quote detail doesn't contain the pricing terms or template consumption. Rather, a quote detail references a proposal SA and the proposal SA contains the pricing terms and template consumption.

Legal Terms and Conditions May Be Specified On Both Proposal And Real SAs

In addition to containing pricing terms, proposal SAs also contain the legal terms and conditions (T&Cs) that govern the proposal.

Proposal Service Agreement

SA Type: **Electric**

72 Market Street
San Fran., CA

Rate: **EQ-10**

| Quantity Type | Value |
|-------------------|-------|
| Subscribed Demand | 10 |
| Hedge Percentage | 15 |

Terms & Conditions

This quote requires a commitment of at least 6 months. Early cancellation results in a fee of 2 times the average bill amount.

This quote was calculated using historical market prices. The historical market prices should not be assumed to be the same in the future.

Your master list of terms and conditions are defined when you setup your control tables. The system defaults a service agreement's T&Cs from the [start option](#) used to initially create it. You can change a SA's T&Cs at will.

Note:

Real SAs and proposal SAs can reference T&Cs. Both proposal and real SAs can reference T&Cs. The T&Cs on a proposal SA are those that will apply if the customer accepts the related quote detail. The T&Cs on a real SA are those that apply while the SA is active.

Proposal SAs Contain Billing Scenarios And Template Consumption

In addition to the pricing terms and the legal terms and conditions, a proposal SA also contains [billing scenarios](#). A billing scenario defines:

- The number of simulated bill segments that will be generated when a quote detail is produced for the proposal SA.
- The bill period of each simulated bill segment.
- The amount of consumption to be priced under each simulated bill segment. Note this statement is only true for non-interval consumption. Refer to [Proposal SAs And Interval Consumption](#) for a description of how interval consumption is defined on a proposal SA.

A proposal SA's billing scenarios can be created as follows:

- A plug-in spot exists on *SA type* called Proposal SA Creation. Algorithms plugged into this spot can setup billing scenarios. Refer to [Enabling The Automatic Generation Of Billing Scenarios](#) for more information about how to do this.
- A user can add / change / delete billing scenarios on a proposal SA using [Service Agreement - Billing Scenario](#).
- You could design a workflow process to initiate a request to the customer to send their template consumption to you. When the customer sends this information to you (via a notification), the proposal SA's billing scenarios can be setup. Refer to [Workflow and Notifications](#) for more information.

Proposal SAs Differ From Real SAs

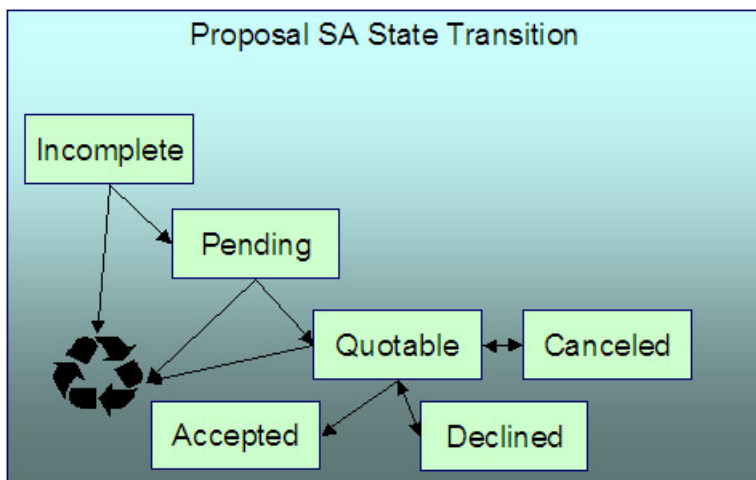

A proposal SA is just like any other SA in that it contains the pricing terms that are used to generate how much the customer owes for service. In fact, the [service agreement maintenance transaction](#) is used to maintain both types of service agreements (however, you cannot use this transaction to create a proposal SA; proposal SAs can only be created using the [order transaction](#)).

However, there are differences between proposal SAs and real SAs:

- Billing ignores proposal SAs.
- Proposal SAs cannot have financial transactions.
- Proposal SAs are not subject to credit and collections.
- Proposal SAs do not appear on lists of "active" SAs in the system's various zones, grids and trees.
- Fieldwork is not performed for proposal SAs.
- A proposal SA's state transition is very different from a real SA. Refer to [The Lifecycle Of A Service Agreement](#) for an illustration of a real SAs state transition. Refer to [Proposal SA State Transition](#) for an illustration of a proposal SAs state transition.

Proposal SA State Transition

The following diagram shows the possible lifecycle of a proposal SA.

You should never see an Incomplete proposal SA as this is a transitory state used when a proposal is first initiated using the [Order](#) transaction. The system always transitions such proposal SAs to the Pending state. Please note that when a proposal SA becomes Pending, the system executes any Proposal SA Creation algorithms plugged in on the

proposal SA's SA type. You might use such algorithms to generate billing scenarios or initiate a workflow process that requests template consumption from the prospect.

A proposal SA exists in the Pending state while you are working on the proposal. For example, you might want to leave the proposal SA in this state while you wait for the prospect to send you their historical consumption.

A proposal SA is Quotable when a quote detail can be generated for it (at least one billing scenario must be linked to the proposal SA before it can become Quotable). Note, proposal SAs can be modified when they are Quotable.

Note:

Automatically transitioning a proposal SA to the Quotable state when it's first created. As described earlier, you can setup a proposal SA creation algorithm to automatically create billing scenarios when a proposal SA is created. The base package algorithm can also automatically transition the proposal SA to the Quotable state (thus making it ready for quotation). Refer to [Enabling The Automatic Generation Of Billing Scenarios](#) for more information.

A proposal SA becomes Accepted when a customer accepts one of its quote details.

A proposal SA becomes Declined when a customer declines one of its quote details (or its quote expires). A Declined proposal SA can be "reopened" (by making it Quotable). You may need to do this if you want to change a proposal SA's terms in preparation of generating a new quote detail.

A proposal SA becomes Canceled when a quote detail is withdrawn (or its quote expires). You may need to do this if you want to change a proposal SA's terms in preparation of generating a new quote detail.

Incomplete, Pending and Quotable proposal SAs may be deleted.

Orders Are Used To Create Proposal SAs

Proposal SAs can only be created using the [order](#) transaction. This transaction allows a user to pose eligibility-oriented questions to a customer or prospect. The system determines which [packages](#) of goods and services for which they are eligible based on the answers to the questions. If the customer is interested in receiving a package, one or more SAs (real and/or proposal) are created using the [SAs To Create](#) information defined on the selected package.

Note:

You must setup campaigns and packages before you can create an order. If you are not familiar with the [order](#) transaction, you should take the time to form an intuitive understanding of the concepts described under [Sales & Marketing](#). With this knowledge in place, you can design and set up the campaigns and packages necessary to allow an order to create proposal SAs. Keep in mind that a single switch controls whether real SAs or a proposal SAs are created when a package is selected on the order transaction. This switch resides on [Package - SAs To Create](#).

A package could create a combination of real and proposal SAs. When a customer elects to take a package of goods and services (via the [order](#) transaction), the system creates a service agreement for each SA type / start options defined on the package's [SAs To Create](#). It is possible to setup a package to create both real and proposal SAs. For example, the customer may be calling you to start electric service, but they may also be interested in seeing a proposal for gas service.

You don't create special SA types for proposal SAs. The SA type on a proposal SA is the same as the SA type on the real SA that's created when the proposal SA is accepted. This is because the business rules on your SA types govern both real and proposal SAs.

You don't need special start options for proposal SAs. The start options that you setup to default information onto new, real service agreements are also referenced on the [SA To Create](#) information used to create proposal SAs.

Proposal SAs May Be Grouped Under An Umbrella Agreement

Each proposal SA may be part of a larger contract for multiple services that you are negotiating with a customer or group of customers. You may use an [umbrella agreement](#) and its collection of terms of service records to group together multiple proposal service agreements.

Proposal SAs And Interval Consumption

Note:

Assumption. This section assumes you are very comfortable with the concepts described under [Interval Billing](#).

Service agreements with interval data have rates that price the interval consumption using time-of-use prices and / or direct prices. Proposal SAs for interval service agreements require billing scenarios to define the time period of each simulated bill segment on the quote detail. However, these billing scenarios typically won't have template consumption (unless regular meters are used in addition to interval meters on the service agreement). Rather, interval billing proposal SAs require interval profiles and datasets, time-of-use maps, and contract options because their rates use this information to calculate the simulated bill segments.

The following points provide an overview of how interval information can be populated on proposal SAs:

- As described under [Orders Are Used To Create Proposal SAs](#), a proposal SA is populated using the start option defined on the package specified when an order is completed (note, a package can cause multiple proposal SAs to be created where each proposal SA references a different start option).
- Start options can reference all types of interval information (interval profiles, time-of-use maps and contract options). If you're familiar with interval billing concepts, you know that the system treats "common" interval information differently from "SA-owned" information when a start option is used to create a service agreement:
- "Common" interval information referenced on a start option is simply copied to the newly created service agreement. This is exactly what you want. For example, when you create a proposal SA using a start option that references a "deemed profile" or a "standard time of use (TOU) map", you don't want a new deemed profile or TOU map created. Rather, you want the start option's deemed profile and time-of-use map to be referenced on the proposal SA.
- "SA Owned" interval information on a start option doesn't work this way. Rather, the system creates new interval information and references these on the newly created service agreement. For example, if a start option indicates the service agreement should have an SA-owned interval profile for actual consumption and another for derived consumption (e.g., excess demand), the system creates two interval profiles and links them to the new service agreement. For real SAs, this logic is perfect. For proposal SAs, this logic is perfect for interval profiles that are derived during billing. However, for interval profiles that contain actual consumption, this isn't what you want. This is because, for actual consumption on proposal SAs, you just need to reference an existing profile whose consumption can be used as the template consumption. The next point provides a few options.

Note:

Although the above describes issues related to SA owned interval profiles, similar issues may apply for SA owned TOU maps or to contract options that are specific to a specific service agreement. To successfully generate a quote for a customer, you may need to create template data for these entities as well.

- You can choose from the following methods to populate a proposal SA with "actual consumption":
 - You could design a workflow process that asks the customer to send their template consumption to you. This could be done by creating a Proposal SA Creation plug-in on the proposal SA's [SA type](#) (note, as of the current release, this algorithm does not exist in the base package, but it would be very simple to write). When the customer sends this information to you (via a notification), the datasets on the interval profile that contain the proposal SA's simulated actual consumption can be setup. Refer to [Workflow and Notifications](#) for more information.
 - You could ask the user (during the order taking process) to define the type of consumption profile (e.g., are they a doctor's office, bakery, laundry, etc). If you're familiar with campaigns and orders, you'll know that you can do this by setting up a question on the campaign. For example, you could design the campaign to pose a question like, "Please choose the consumption profile to be used when the quote is generated". Then, based

on the user's answer, you could set up the proposal SA using profiles consistent with the selected type. The following would be required to setup this type of question:

- Create a "substitute" start option for each consumption profile. Each start option will contain the normal common and derived interval profiles that are used for a real interval SA. The interval profile on the start option that's used for actual consumption would also use a common profile. This common profile would contain the "template" actual consumption that will be used in place of the customer's actual consumption. This template consumption can be used on any interval profile created using this start option.
- Setup a campaign that asks a user to identify the consumption profile to be used to generate the quote as described above.
- Setup a package under the campaign for each consumption profile. Each package will have eligibility rules to indicate that it is only selectable if the respective consumption profile is chosen on the order.
- Each package will also reference the "substitute" start option that corresponds with its consumption profile.
- At this point, you have everything setup to create a proposal SA with a consumption profile that can be used to generate simulated bill segments (remember, the proposal SA's SA type needs a Proposal SA Creation algorithm that [creates billing scenarios](#)). If the customer accepts this proposal SA, you need to setup a real SA with the correct profiles (you don't want the consumption profile on the real SA, nor do you want any derived profiles that were created when the simulated bill segments were generated). The remaining points describe how to do this.
- You want these proposal SAs to contain a characteristic that defines the true start option that should be used to create the real SA. To do this, simply define a default char type / value on the "substitute" start option that contains the real start option (this default information is copied onto the proposal SA when it's created). **Note.** The SA type of the "real" start option should be the same as the proposal SA type.
- As described under [Accepting / Declining Quote Details](#), you must plug-in a Proposal SA Accepted algorithm that has a parameter of the char type on the proposal SA that contains the start option to use when the real SA is created. It then does the work for you. Refer to the PSAA-PS algorithm type for more information about this algorithm.
 - Other solutions are only limited by your imagination.

Creating Quotes And Quote Details

Once an account has quotable proposal SAs, you can generate a quote for the account using the quote maintenance transaction. When you generate a quote for an account, you can include quote details for any / all of the account's quotable proposal SAs.

The logic used to create a quote detail's simulated bill segments is not hard-coded. Rather, the system calls the algorithm plugged in on the proposal SA's [SA type](#) in the Proposal SA - Bill Segment Generation plug-in spot. Refer to [Enabling The Generation Of Simulated Bill Segments](#) for information about this plug-in spot.

The major difference between a bill segment linked to a quote detail and one linked to a bill is that a quote detail's bill segments are calculated using simulated consumption. This means that the financial information on quote details is not a guess - it's what the bill would be if a given amount of consumption was priced using the pricing terms (as long as you opt to use rate application to calculate the simulated bill segments).

In addition to this major difference, there are a few minor differences between a real bill segment and a simulated bill segment:

- A quote detail bill segment does not have a foreign key to a bill. Rather, it references a quote detail.
- A quote detail bill segment's prime key is inherited from its quote detail (rather than its bill).
- A quote detail bill segment can never have a financial transaction linked to it.
- A quote detail bill segment doesn't have read details (unless you perform TOU mapping of interval data).
- A quote detail bill segment's state transition is simpler (it's either in the Error state or OK).

Completing A Quote Creates Quote Routings (And More)

When a quote's quote details are all OK, you change the status of the quote to complete to indicate the quote is ready to be sent to the customer or prospect.

When a quote is completed, the system creates a [quote routing](#) for each person who receives a copy of the account's quotes. When you indicate a person should receive a copy of the account's quotes, you define the routing method (e.g., email, fax, post) and the appropriate address.

Note:

Recipients of quotes. You define who receives a copy of an account's quotes on the [Account - Persons](#) page. The system assumes (by default) that the main person linked to the account should receive the account's quotes. You can subsequently indicate any person linked to the account should receive its quotes (and turn off the creation of quotes for the main person). In addition, you can manually add additional quote routings to a quote if you need to send the quote to individuals not currently linked to the account. Refer to [How To Reprint A Quote](#) for more information.

The information that appears on the quote routing record is controlled by the *quote route type* specified on the respective account / person information:

- If the quote route type's routing method is email or fax and the system has been configured to use notification preferences for quote routing, a quote routing is created for each active contact preference whose notification type is associated with the **quote route type** specified on the respective account / person information. Refer to *Bill and Quote Routing in Designing Notification Types* for more information. Otherwise, quote routings are created as follows:
 - If the quote route type indicates the person's quotes are routed via fax, the person's fax number is used as the routing information. The system knows which of a person's person contacts is a fax number is by the contact routing or which of a person's phone numbers is a fax number by the phone type.
 - If the quote route type indicates the person's quotes are routed via email, the person's [Email address](#) is used as the routing information. The system knows which of a person's person contacts is an email or knows where to find the person email.
- If the quote route type indicates the person's quotes are routed via the postal service, the address constituents are populated with the address specified on the **bill** address source that is also specified on the [account / person information](#). Note, if the person has a [seasonal address](#) effective on the business date, the seasonal address will be used regardless of the value of **bill address source**.

Regardless of whether the quote is routed via fax, email or post; the routing record is also stamped with the batch process and run number that performs the download of the quote information. The batch process is defined on the quote route type. Refer to [Printing Quotes](#) for more information about this batch process.

In addition to creating routing information at completion time, the system executes any quote completion algorithms plugged in on the account's customer class. For example, you may want to create a workflow process to manage the processing of the quote. To do this, you plug in a Quote Completion Algorithm that creates a workflow process on the respective *customer class*.

Accepting / Declining Quote Details

A customer can accept or decline each quote detail on a quote.

When a quote detail is accepted, the system:

- Changes the state of the related proposal SA to accepted.
- Executes the Proposal SA - Acceptance algorithms plugged in on the proposal SA's SA type. The base package algorithm creates a real SA by copying the information from the proposal SA. The real SA is created in the pending start state. This new SA behaves similarly to a pending start SA that's created via the [Order](#) or [Start/Stop](#) transactions (e.g., field activities are initiated if the SA type has been setup accordingly).

When a quote detail is declined, the user must supply a decline reason. The system then changes the state of the related proposal SA to declined.

Fastpath:

Refer to [Proposal SA State Transition](#) for more information about a proposal SA's states.

**Note:**

Reopening a declined proposal SA. If a customer changes their mind about a declined proposal SA, you can return it to the quotable state using the [service agreement maintenance transaction](#).

Rejecting an entire quote. If all details on a quote are being declined, you can simply change the state of the quote to closed rather than reject each quote detail. Refer to [Closing Quotes](#) for more information.

Tinkering With Proposal SAs After Quote Generation

The system allows a quotable proposal SA to be changed, EVEN IF QUOTE DETAILS HAVE BEEN GENERATED. This is intentional as otherwise you would have to create an entirely new proposal SA if you wanted to send another quote for slightly different terms. Your technical team could always introduce a user exit to prevent this from happening if you really didn't want this to take place.

Because the system allows this, a potential issue is that the customer may end up accepting a proposal SA that differs from the terms on their quote (e.g., you could change the SA after the quote detail is generated). For this reason, we snapshot the version number of the proposal SA on the quote detail at the time it's generated. If a proposal SA is accepted and its version number differs from the value on its quote details, a warning is produced.

A warning is also issued if you change a proposal SA and a quote detail exists (reminding you to generate a new quote / quote detail).

In addition to the above, it's also important to understand that the system intentionally allows multiple quotes to reference a given proposal SA. This allows you to leave multiple quotes open that reference the same proposal SA(s).

Closing Quotes

Every quote has an expiration date. The [CLOSEQTE](#) background process closes quotes on their expiration date. This process changes the state of all related proposal SAs to canceled or declined (an input parameter of this process controls which state is used).

You can also close a quote real time using the quote maintenance transaction. When you do this, the system asks if the related proposal SAs should be left as quotable or if they should be changed to canceled or declined.

**Note:**

Reopening a declined proposal SA. If a customer changes their mind about a declined proposal SA, you can return it to the quotable state using the [service agreement maintenance transaction](#).

Alerts

The [alert zone](#) highlights if:

- The selected account has pending or complete quotes. Refer to [Quote Lifecycle](#) for more information.
- The selected account has pending or quotable proposal SAs. Refer to [Proposal SA State Transition](#) for more information.

Trees

The [account tree](#) highlights:

- The existence of non-closed quotes
- The existence of proposal SAs and their related quote details

Printing Quotes

The contents of this section describe the technical implementation of printing quotes.

Quote Routings Are Created For Each Recipient Of A Quote

Refer to [Completing A Quote Creates Quote Routings](#) for a description of how the system constructs the information used to route a quote to one or more recipients.

Quote Route Types Control The Information Merged Onto Quotes

Every quote routing references a [quote route type](#).

The quote route type controls the following quote functions:

- It contains an algorithm that is responsible for extracting the information merged onto your quotes. Specifically, algorithms of this type create the "flat file records" that are passed to your quote-print software. Algorithms of this type are called under the following scenarios:
 - The background process that builds the flat file that's passed to your quote-print software calls these algorithms to construct the "flat file records" for each quote. Refer to [Technical Implementation of Printing Quotes In Batch](#) for the details.
 - If your quote-print software has the ability to construct a real-time image of a quote (in a PDF), you can plug in an Online Quote Display algorithm on the [Installation Record](#). This type of algorithm calls the quote's dispatch group extract algorithm to extract the information that is merged onto the quote. Refer to [Technical Implementation Of Online Quote Display](#) for the details.
- Refer to [The Quote Extract Records](#) for examples of the record layouts passed to the document composition application.
- It contains the ID of the background process that builds the flat file that's passed to your quote-print software. The base package example of this background process (QUOTROUT) simply calls the extract algorithm on the routing record's route type to format the information placed onto the flat file.

Note: CIS Division can override the extract algorithm and/or the background process found on the quote route type. The system processes first check the quote's account's CIS Division for an override specific for the quote route type.

Technical Implementation Of Online Quote Display

Users can view an image of any quote if you set up the following:

- Plug in an Online Quote Display construction algorithm on the [Installation Record](#). Refer to ONQD-DOC1 for an example of such an algorithm. Note if your quote-print software is not capable of producing a PDF containing an image of a quote, users will not be able to view images of quotes.
- Plug in the appropriate extract algorithm on each [quote route type](#). Algorithms of this type format the records that contain the information that is passed to your printing software. Refer to QTEX-EX for an example of such an algorithm.

When you plug in these algorithms, a button appears on [Quote - Main](#). When a user clicks this button, the following takes place:

- The installation record's Online Quote Display algorithm is executed.
- This algorithm calls the quote's route type's extract algorithm. This algorithm constructs the information that's merged onto the quote and returns it to the Online Quote Display algorithm. This algorithm, in turn, passes it to the quote-print software.
- The quote-print software renders an image of the quote in a PDF and returns it to the Online Quote Display algorithm.
- And finally, the Online Quote Display algorithm displays the PDF in a browser session. Note that the client must have Adobe Acrobat Reader installed to view PDF files.

Technical Implementation Of Printing Quotes In Batch

The batch process that extracts quote information reads all quote routing records in a given run number that are marked with its batch control ID. For each quote routing record, it creates numerous records on a flat file. These records contain the information that is merged onto your quotes.

The base package example of this process ([QUOTROUT](#)) simply calls the extract algorithm on the routing record's route type to format the information placed onto the flat file. Refer to [Quote Route Types Control The Information On Quotes](#) for more information.

Note:

If your software doesn't support online quote display. The algorithm that formats quote extract records that's plugged in on [quote route type](#) serves two purposes: 1) it formats the records used to construct online images of a quote, and 2) it formats the records downloaded to your quote print software in batch. If your quote printing software does not support the rendering of quote images real time, there is no need to create an extract algorithm. Rather, you should simply develop your own download process that both formats the extract records and downloads them (and then specify this batch process on your quote route type).

Reproducing The Quote Print Flat File

You can reproduce the flat file at any time. Simply request the quote production background process and specify the run number associated with the historic run.

How To Reprint A Quote (For The Original Recipients or For Someone New)

A copy of a quote is sent to every individual / business specified in the [quote's routing details](#). The system creates the routing details when a quote is completed. Refer to [Completing A Quote Creates Quote Routings](#) for more information about how this information is compiled during quote completion.

If you want to reprint a quote OR if you want to send a quote to someone other than the original recipients:

- Navigate to the [Quote - Main](#) page.
- Transfer to the [Quote - Quote Routings](#) tab.
- Insert a new row (click the + button). Note that you can only insert information on a quote that is Complete.
- Specify the name and address to which the quote should be sent. If you want to send the quote to someone other than the original recipient, specify the individual's name and address.
- Save the quote.

If a quote is Complete but the print process hasn't yet executed, you may change the name and address on the original routing details; you don't have to insert a new routing row.

The Quote Extract Records

Numerous different types of records are interfaced to the document composition application. However, they all share a common structure:

- The first 4 bytes are called the **Printer Key**. This field is a record type used by the document composition application quote template.
- The next X bytes are called the **Sort Key**. This field is used to ensure the various records used to construct a printed quote appear in the correct order in the interface file.
- The next 12 bytes are called the **Mailing Key**. This field is used to control the order in which the formatted quotes are printed.
- The remaining bytes contain the **Quote Information** that appears on the printed quote. The type of information differs for each type of record.

The topics in this section describe each component.

Printer Key (Record Types)

The following table defines each printer key (i.e., record type) on the quote print flat file.

| Record Type | Description | Notes |
|-------------|-----------------------------|--|
| 0010 | Global extract information | Required. 1 per flat file |
| 0100 | Quote record | Required. 1 per Quote. |
| 0200 | Quote Detail record | 1 per quote detail. |
| 0300 | Terms and Conditions record | 1 per terms and conditions linked to the proposal SA. |
| 0400 | Bill segment record | 1 per bill segment linked to the quote detail. |
| 0500 | Bill calculation header | 1 per bill calculation header linked to the bill segment. |
| 0600 | Bill calculation line | 1 per bill calculation line linked to the bill calculation header. |
| 0700 | End of record type 0500 | 1 for each bill calculation header |
| 0800 | Read detail | 1 for each meter read detail linked to the bill segment. |
| 0900 | SQ detail | 1 for each service quantity detail linked to the bill segment. |
| 1000 | End of record type 0400 | 1 for each bill segment. |
| 1100 | End of record type 0200 | 1 for each quote detail. |
| 9999 | End of record type 0100 | 1 for each quote. |

Sort Key

The following table defines the structure of the sort key that appears on each quote print record. Please note that different components are filled in for each printer key.

| Field Name | Format | Source/Value/Description |
|--------------------|--------|---|
| Quote ID | A12 | |
| Sequence Number | N2 | The sequence number of the account / person information associated with this quote routing information. |
| Quote record group | A2 | 10 Quote 20 Quote Detail 30 Quote end |

| | | |
|---------------------------|-----|---|
| Quote Detail ID | A12 | |
| Quote Detail record group | A2 | 10 Quote Detail record 20 SA Terms and Conditions 30 Bill Segment 40 Quote Detail record end |
| SA T&C Short Description | A60 | |
| Bill Segment End Date | A10 | |
| Bill Segment Id | A12 | |
| Bill Segment Group | A2 | 10 Bill segment 20 Bill segment calculation group 30 Bill segment read detail 40 Bill segment SQ detail 50 Bill segment end |
| Bill Calc Header Sequence | N2 | |
| Bill Calc Header Group | A2 | 10 Bill calculation header 20 Bill calculation line 30 Bill calculation end |
| Line Seq | N4 | Defines order of rows for similar record types |

Mailing Key

The following table defines the structure of the mailing key that appears on each quote print record.

| Field Name | Format | Source/Value/Description |
|-------------|--------|--|
| Postal code | A12 | This is the postal code on the quote routing record. |

Quote Information

The topics in this section describe the information that appears on each on each bill print record. The following links are provided so that you can move easily to specific topic within this section:

- [Global Extract Information \(0010\) Record Definition](#)
- [Quote \(0100\) Record Definition](#)
- [Quote Detail \(0200\) Record Definition](#)
- [SA Terms and Conditions \(0300\) Record Definition](#)

- [End of Quote \(9999\) Record Definition](#)
- [Address Sub-Record Definition](#)

Global Extract Information (0010) Record Definition

This is a "header" record that contains information about the extract run as a whole.

Note:

Please be aware that if you do not sort your extract file by **CIS Sort Key** after it is produced, this record will physically be the last record on the extract file.

| Field Name | Format | Source/Value/Description |
|-----------------|--------|---|
| BATCH_CD | A8 | Batch Control Code of the extract process. |
| BATCH_NBR | N10 | Batch Number of the extract process |
| BATCH_RERUN_NBR | N10 | Batch Rerun number of the extract process. |
| QTE_CNT | N10 | Count of quotes on this extract. |
| EXTRACT_DTTM | A26 | System time of extraction. |
| QUOTE_ID_START | A12 | This is only used when a quote is produced as a result of an online request (from Quote - Main). It contains the Quote Id to extract. |
| QUOTE_ID_END | A12 | This is only used when a quote is produced as a result of an online request (from Quote - Main). It contains the Quote Id to extract. |
| THREAD_NBR | N10 | This field is only used if quotes are extracted in batch. It contains the thread number in which the quote was extracted. |
| THREAD_CNT | N10 | This field is only used if quotes are extracted in batch. It contains the total number of threads that were extracted. |

Address Sub-Record Definition

The address that appears in both the quote record (0100) and the quote detail record (0200) is composed of the following:

| Field Name | Format | Description |
|---------------|--------|--|
| COUNTRY | A3 | |
| ADDRESS1 | A64 | Refer to Completing A Quote Creates Quote Routings for a description of conditions when this field will contain a fax number or an Email address rather than the first line of a postal address (this only occurs for a bill record (0100)). |
| ADDRESS2 | A64 | |
| ADDRESS3 | A64 | |
| ADDRESS4 | A64 | |
| CITY | A30 | |
| NUM1 | A6 | |
| NUM2 | A4 | |
| HOUSE_TYPE | A2 | |
| COUNTY | A30 | |
| STATE | A6 | |
| POSTAL | A12 | |
| GEO_CODE | A11 | |
| IN_CITY_LIMIT | A1 | |

[Top of Page](#)

Maintaining Quotes

A quote allows you to show a customer how their bill segments will look if a given set of pricing terms is applied to a given amount of consumption. If the customer accepts the quote, real service agreements are created.

Fastpath:

Refer to [The Big Picture Of Quotations](#) for background information about quotes.

The topics in this section describe how to maintain quotes.

The Lifecycle Of A Quote And Quote Detail

The topics in this section describe the lifecycle of the various quote objects.

Quote Lifecycle

The following diagram shows the possible lifecycle of a quote.

Pending A quote starts its life in the Pending state. Refer to [Creating Quotes And Quote Details](#) for more information.

A quote remains Pending until you Cancel or Complete it.

You may delete a Pending quote. Deleting a pending quote also deletes its quote details.

Canceled You cancel a quote if you want a record of a Pending quote that was never sent to a customer.

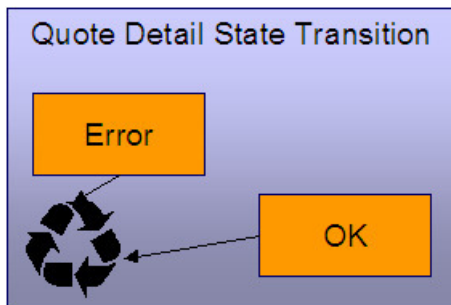

Complete A quote becomes Complete when it is ready to be sent to a customer. No changes may be made to a Complete quote. Refer to [Completing A Quote](#) for a description of what happens when a quote is completed.

A Complete quote may be reopened. You would only do this if you need to prevent blatant errors from being sent to the customer. For example, if you notice an incorrect quote detail, you could reopen the quote, regenerate or delete the erroneous quote details, and then recomplete the quote.

Closed A Complete quote becomes Closed when its terms are no longer valid. Refer to [Closing Quotes](#) for more information.

Quote Detail Lifecycle

The following diagram shows the possible lifecycle of a quote detail.

When a quote detail is generated, it is placed in the Error or Ok state depending on whether the system successfully generated simulated bill segments for each billing scenario linked to the related proposal SA. A quote detail may be deleted if its parent quote is Pending. Refer to [Creating Quotes And Quote Details](#) for more information.

Quote - Main

This page is used to maintain quotes. This page provides many diverse functions:

- You can [generate](#), [complete](#), [close](#), reopen, and cancel a quote.
- You can regenerate and delete quote details.
- You can [accept](#), [decline](#) and cancel the proposal SAs that contribute a quote detail to the quote.

You should not attempt to use this transaction until you are comfortable with the concepts described under [The Big Picture of Quotations](#).

Open this page using **Menu > Sales & Marketing > Quote > Search.**

Description of Page

Quote Info contains a concatenation of important information about the quote (e.g., its expiration date and status).

Quote ID is the system-assigned unique identifier of the quote. These values only appear after the quote is added to the database.

Account ID identifies the customer or prospect associated with the quote. The name of the account's main customer appears adjacent.

Quote Status contains the state of the quote. Refer to [Quote Lifecycle](#) for information about the valid values and the state transition rules.

If your system has been configured to display an online image of a quote, a **Display Quote** button appears adjacent to the quote's status. When clicked, an online image of the quote is displayed. Refer to [Technical Implementation Of Online Quote Production](#) for how to enable this feature.

Expiration Date / Time identifies when the quote's terms are no longer valid. Refer to [Closing Quotes](#) for how the system uses this information to automatically close a quote.

Refer to [Quote Actions](#) for a description of each **Quote Action** button.

This transaction has sophisticated logic that can be used to perform mass updates to the quote's quote details and their related proposal SAs. These mass update actions are executed by selecting quoted details (in the grid) and then clicking the desired action button at the bottom the page. The remainder of this section describes how to use this mass update functionality.

The **Select All / Clear All** buttons are used to select / unselect the quote details. These buttons are disabled when the quote is Closed.

Note:

100 quote details at a time. Clicking **Select All** selects the first 100 quote details in the grid. If more than 100 quote details exist, you must select them in batches.

The grid that follows contains the quote details linked to the quote. The following information appears in the grid:

- Select box. Before you can perform any of the mass update actions at the bottom of the page, at least one quote detail must be selected. This field is disabled when the quote is Closed. You can use the **Select All** and **Clear All** buttons to change the value of the switch for all quote details in the grid.
- Click the go to button to transfer to the [Quote - Quote Detail](#) tab with the corresponding quote detail positioned in the scroll. On this page, you can see the details of the quote detail's simulated bill segments (and, from there, drill down into the details of each bill segment).
- The **Quote Detail Info** column contains a concatenation of a quote detail's division, SA type, start option, status, start date, and premise information (this information comes from the quote detail's proposal SA).
- The **Total Amount** column contains the sum of the quote detail's simulated bill segments.
- The **Remarks** column highlights special circumstances associated with the quote detail.
 - Proposal SA has been changed since the quote was created appears if the proposal SA was modified after the quote detail was generated. If you'd like to recalculate this quote detail, select this row and click the **Regenerate** button at the bottom of the page to regenerate the quote detail's simulated bill segments.
 - Quote detail contains bill segments in error appears if any of the simulated bill segments linked to the quote detail are in error . Click the adjacent go to button to transfer to the [Quote - Quote Detail](#) tab where the state of each simulated bill segment is shown. You can correct simulated bill segments that are in error by **Regenerating** the quote detail (and you do this by selecting the quote detail and clicking the Regenerate button at the bottom of the page).

The **Quote Detail Actions** and **Proposal SA Actions** can be used to perform mass updates to the selected quote details in the grid. Refer to [Quote Detail Actions](#) and [Proposal SA Actions](#) for the details.

Action Buttons On Quote Main

The topics in this section describe the various action buttons on the [Quote - Main](#) page.

Quote Actions

The topics in this section describe the **Quote Action** buttons on the [Quote - Main](#) page. The following links are provided so that you can move easily to specific topic within this section:

- [Generate](#)
- [Complete](#)
- [Close](#)
- [Reopen](#)
- [Cancel \(Quote\)](#)

Generate

The **Generate** button causes one or more quote details to be created for the account's Quotable proposal SAs. This button is enabled when there is at least one Quotable proposal SA linked to the selected **Account ID**.

When clicked, the **Generate Quote** window opens.

You must specify the following parameters to generate quote details:

- Indicate if quote details should be created for All Proposal SAs or for a Specific Proposal SA.
- If you indicated a quote detail should be generated for a Specific Proposal SA, also specify the **Proposal SA ID**.

After specifying the parameters, click **Generate** to create the quote details for quotable proposal SAs.

Fastpath:

Refer to [Creating Quotes And Quote Details](#) for more information.

Warning:

If the quote has existing quote details for the designated proposal SAs, they are deleted when you generate quote details (i.e., the system regenerates existing quote details). You can also regenerate quote details by selecting them on the Main page and clicking the **Regenerate** button.

[Top of Page](#)

Complete

The **Complete** button causes the quote to become complete. This button is enabled when the quote is pending and all quote details linked to the quote are OK.

Fastpath:

Refer to [Completing A Quote Creates Quote Routings](#) for a description of what happens during quote completion.

[Top of Page](#)

Close

A quote is closed when its terms are no longer valid (i.e., when the related proposal SAs can no longer be accepted). Most quotes are closed automatically by the system (refer to [Closing Quotes](#) for how this takes place).

If you want to close a quote real time, click the **Close** button. When this button is clicked, the system opens the **Close Quote** window and asks if anything should be done with the related proposal SAs.

In the resulting window, you must specify one of the following **Proposal SA Actions**:

- Choose No Action if you don't want to change the status of the related proposal SAs.
- Choose Decline if you want the status of the proposal SAs that have contributed quote details to the quote to be changed to declined . You must also define a **Decline Reason**.
- Choose Cancel if you want the status of the proposal SAs that have contributed quote details to the quote to be changed to canceled .

[Top of Page](#)

Reopen

The **Reopen** button causes a quote to return to the pending state. You would only reopen a quote if you need to prevent blatant errors from being sent to the customer. For example, if you notice an incorrect quote detail, you could reopen the quote, regenerate or delete the erroneous quote detail, and then recomplete the quote.

This button is enabled if the quote is complete.

[Top of Page](#)

Cancel (Quote)

The **Cancel** button causes the quote to become canceled. You would cancel a quote if you want a record of a pending quote that was never sent to a customer. This button is enabled when the quote is pending.

Canceling the quote does NOT cancel the related proposal SAs. If you want to cancel the related proposal SAs, you have the following options:

- You can click the [Close](#) button rather than the **Cancel** button. When you close a quote, you are given the option of also canceling the proposal SAs that contributed a quote detail to the quote.
- Before canceling the quote, you can select the quote details and click the [Cancel](#) button at the bottom of the page (in the Proposal SA Actions section). When you click this button, the system cancels the proposal SAs linked to the quote details.
- You can transfer to the [Quote - Quote Details](#) tab and then drill down to the each proposal SA (using the SA context menu button). This transfers you to [Service Agreement - Main](#) where you can cancel the proposal SA.

Quote Detail Actions

The topics in this section describe the **Quote Detail Action** buttons on the [Quote - Main](#) page. These buttons are used to perform a given action to the quote details that are selected in the quote details grid.

- The **Regenerate** button is used to delete and recreate the selected quote details. This button is enabled if the quote is pending and at least one row in the quote details grid is selected.
- The **Delete** button is used to delete the selected quote details. This button is enabled if the quote is pending and at least one row in the quote details grid is selected.

Proposal SA Actions

The topics in this section describe the various **Proposal SA Action** buttons on the [Quote - Main](#) page. These buttons are used to perform a given action to the proposal SAs associated with the selected quote details.

The **Accept** button is used to accept the proposal SA associated with the quote detail. This button is enabled if the quote is pending or complete and at least one row in the quote details grid is selected.

When you accept a proposal SA, you are asked to supply the **Start Date** of the real service agreement that will be created.

Refer to [Accepting / Declining Quote Details](#) for more information about how accepting a quote detail causes a real service agreement to be created.

Decline

The **Decline** button is used to decline the proposal SA associated with the quote detail. This button is enabled if the quote is pending or complete and at least one row in the quote details grid is selected. When you decline a proposal SA, you are asked to supply a **Decline Reason**.

Refer to [Accepting / Declining Quote Details](#) for more information about declining a quote detail.

Cancel

The **Cancel** button is used to cancel the proposal SA associated with the quote detail. This button is enabled if the quote is pending or complete and at least one row in the quote details grid is selected.

Quote - Quote Details

This page is used to view a summary of the simulated bill segments linked to a quote detail.

Open this page using **Menu > Sales & Marketing > Quote > Search** and navigate to the **Quote Details** page to define this information. You can also display a quote detail by clicking the respective go to button in the quote details grid on the main tab.

Description of Page

Quote Info contains a concatenation of important information about the quote (e.g., its expiration date and status).

Quote ID is the system-assigned unique identifier of the quote. These values only appear after the quote is added to the database.

The **Quote Details** scroll contains one entry for every quote detail linked to the quote (a summary of these quote details also appears on the Main tab). The remainder of this section describes the information displayed for each quote detail.

Note:

You don't have to use the scroll. If the quote has many quote details, you don't have to use the scroll to work through them. Rather, you can use the go to button in the quote details grid on the main tab to position the respective quote detail in the following scroll. Also note, you can use Alt - and Alt + to scroll to the next and previous quote details in the scroll.

You cannot maintain quote details on this page. All maintenance functions (generate, delete, accept, decline and cancel) are performed on the **Main** tab.

Premise Info is the address of the main premise associated with the service agreement (as defined on the service agreement's characteristic premise). It's important to note that the service agreement may cover service at multiple premises, but only one may be defined as the main premise.

Quote Detail ID is the system-assigned unique identifier of the quote detail.

SA Info is a concatenation of the proposal SA's division, SA type, start option (if any), status and start date.

SA Version is a snapshot of the proposal SA's version number at the time the quote detail was generated. This information is used by the system to detect if the proposal SA was modified after the quote detail was created.

Total Amount is the sum of the quote detail's simulated bill segments.

Create Date / Time is the date and time the quote detail was generated.

Remarks highlight special circumstances associated with the quote detail. Please see the description of this field on the main tab for more information.

The grid contains a row for each simulated bill segment linked to the quote detail. The following information appears in the grid:

- The first go to button transfers you to the [bill segment page](#) where the details of the simulated bill segment are shown.
- **Bill Segment Period** defines the start and end dates of the simulated bill segment.
- **Amount** contains the amount of the bill segment.
- **Remarks** highlight special circumstances associated with the bill segment.
- **Billing Scenario ID** allows you to go to the proposal [SA's billing scenario](#) where you can tinker with consumption and the bill segment period used to generate this bill segment. Refer to [Proposal SAs Contain Billing Scenarios](#) for more information.

Quote - Quote Routings

This page is used to view the recipients of a quote. Refer to [Printing Quotes](#) for a discussion of how this information is used to produce quote images.

This page is also used to request a new copy of a quote.

Note:

No routing information until completion. A quote has no routing information until it is complete. At [completion time](#), the system creates a routing detail for every person linked to the account that receives a copy of its quotes. Refer to [Printing Quotes](#) for more information about how this information is constructed.

Use **Menu > Sales & Marketing > Quote > Search** and navigate to the **Quote Routings** page.

Description of Page

Quote Info contains a concatenation of important information about the quote (e.g., its expiration date and status).

Quote ID is the system-assigned unique identifier of the quote. These values only appear after the quote is added to the database.

The **Quote Routing Information** scroll contains an entry for each recipient of the quote. This information is disabled after the quote has been routed to the recipient. The remainder of this discussion describes the fields that can be defined for each recipient of the quote.

Person ID identifies the person who was originally associated with the routing record. You may change the **Person ID** to any person in the system as this information is only used to default the recipient's name and address information, below.

The **Quote Routing Parameters** area contains information explaining how and when the quote is routed to the recipient. This information is gray when the quote routing information has been extracted or if a quote is reopened:

- **Quote Route Type** is the method used to transmit the quote to the customer. This information defaults from [Account - Person Information](#).

- **Batch Control** is the identifier of the batch of quotes in which the recipient's copy was downloaded. Embedded in this identifier is the batch control ID and the batch number. Note, this batch process is defined on the Quote Route Type or CIS Division.
- **Sequence** is the system-assigned identifier assigned to this quote routing.
- Turn on **Do Not Extract** if the quote should not be routed to the individual for whatever reason.
- **Reprint** is checked if an operator created this routing. This switch is populated by the system and is always protected.
- **Extract Date/Time** is the date and time the quote was downloaded. This information only appears after the download has commenced.

The **Mailing Address Information** area contains the recipient's name and address.

- If the recipient has an *override mailing name*, **Name1**, **Name2** and **Name3** contain the person's override mailing name. Otherwise, **Name1** contains the recipient's primary name (this name might also include a prefix or suffix if the related [Account - Person](#) relationship has these fields defined).
- The remaining fields are the recipient's address. Refer to [Completing A Quote Creates Quote Routings \(And More\)](#) on page 904 for information about how the system constructs the recipient's address
- If the recipient's address is a mailing address (as opposed to fax or email), the **Country** associated with the address controls the fields that appear in the address. Refer to [Defining Countries](#) for more information on the address constituents.
- If a user manually adds a routing record, the mailing address information defaults from the information on the current routing record.
- If a user specifies a **Person ID** that is linked to the quote's account, the **Quote Route Type** defined for this person on the account is defaulted.
- If a user specifies a **Person ID** that is not linked to the quote's account, the **Quote Route Type** on the [installation record](#) is defaulted. Note, if the quote route indicates the quote is routed via the postal service, the system will only be able to default the person's address if the person has an override mailing address on their [correspondence information](#).
- If the user changes the **Quote Route Type** after the initial default, the system populates the address information as described above.

Service Credits

"Service credits" is a term used to describe a special program designed to reward a customer for service along with benefits related to such a program. For each program that a customer participates in, there is a service credit membership record. Service credit events are used to record the "points" earned and redeemed for the membership. The topics in this section provide further details related to the service credit functionality.

Fastpath:

For information about designing and setting up your control tables for configuring service credit functionality, refer to [Designing Your Service Credit Options](#).

Note:

Service credits are optional. Service credits may not be set up in your system; they are only used if your company offers rewards programs to customers.

Penalty Points. The service credits functionality is described in the documentation with the assumption that it is used for accumulating points to reward your customers. However, if your company has a business need to record penalty points for a customer, the service credits functionality may be used for that purpose as well.

The Big Picture Of Service Credit Membership

If a customer is participating in a rewards program, the customer has a service credit membership. The topics in this section provide background information about a variety of service credit membership features and functions.

Who are the Members?

Each membership has one or more "members". The members are defined by the accounts linked to the membership and by the financially responsible person(s) linked to each account.

A typical membership is linked to only one account. However, in some cases more than one account is linked to the membership. For example, a customer may have one account for residential service and one for commercial service, but both accounts are part of the same membership. In this example, one person with multiple accounts is linked to the membership, so there is only one member.

For each account linked to the membership, the service related to the account may be used to calculate the accumulated credits for the membership. Refer to [How Are Service Credits Earned?](#) for more information.

Note:

An account may not be linked to more than one membership of the SAME membership type at a given point in time. In other words, an account may not have two United Airlines frequent flier memberships (otherwise, the account would accumulate double miles). However, an account may be linked to more than one membership if they are of different membership types. For example, an account may have a capital credits membership and a United Airlines frequent flier membership.

When you find a customer's record on [Control Central - Search](#), you are transferred to the [Account Information](#) portal. One of the zones on this page contains information about memberships for the customer.

Note:

Portal Preferences. The service credit membership zone only appears if you have modified your preferences to display this zone. Refer to [Portal Preferences](#) for more information.

Joint Membership

It is possible for more than one person to belong to the same membership. These persons may be linked to the same account or to different accounts. A typical scenario would be a married couple that shares in a membership. This is considered a "joint" membership.

The number of "members" for a membership is mainly for information purposes and typically has no bearing on the service credit amounts calculated for the membership. There may be legal restrictions or business practice restrictions controlling how you may set up your members. For example:

- In an airline's frequent flier program, a separate frequent flier account would exist for each customer. It is possible for you to create a frequent flier membership with more than one "member", but for the system, the important information is the external frequent flier miles number linked to the membership. The customer linked to this number accumulates the miles. For this case, your business practice may be that the person with the frequent flier account must be the only financially responsible person.
- For a capital credits membership, you may be required to distinguish between "single" memberships and "joint" memberships. If a single person gets married and would like the spouse to be added as a member, your practice may be to expire the single membership and to create a new "joint" membership to include both spouses.

Note:

Co-op Members. Do not confuse the "members" of a co-op with the members linked to a service credit membership. At a cooperative, most customers are considered "members" of the co-op. However, in the system, separate membership records are created for each single or joint membership.

Changing the Membership Accounts

The link between the accounts and the membership is NOT effective dated. This means that if the list of accounts for a membership changes, you need to stop the membership and start a new one with the new list of accounts.

Note:

Stopping Memberships. Stopping a membership does not necessarily prevent new service credits from accumulating. Refer to [Stopping a Membership vs. Inactivating a Membership](#) for more information.

Membership Application

Your business practice may dictate that the customer complete an enrollment form. Depending on your practice, the form may need to be received prior to starting membership or it may simply be a mechanism to gather supplemental information once the membership has begun.

Either way, you may consider setting up the system to handle forms as follows:

- Design your membership type to include a creation algorithm that generates a letter when the membership is created. The letter template could include the form to be filled out.
- Create the new membership in pending status. The letter and form are sent to the customer and the pending status indicates that you are waiting for the completed form. Refer to the [Lifecycle of a Membership](#) for more information.
- When the paperwork is received, change the status of the membership to active.

Note:

Membership Events for Pending Memberships. The system allows events to be created for pending memberships assuming that paperwork is supplemental information that should not prevent service credits from accumulating. If your business practice dictates that the paperwork must be received prior to accumulating service credits, the algorithm or background process that creates events for memberships of this type should be coded to only create events for active memberships. Refer to [How Events Are Created](#) for more information.

Creation of a Membership

Memberships may be created using the [membership](#) page when a customer has signed up for a special program. In addition, it may be your business practice to automatically create a membership under certain circumstances when a customer has signed up for service.

For example, if you are a co-op, perhaps every new customer is automatically enrolled in a capital credits membership. Or perhaps signing up for cable service automatically entitles your customers to membership in the free pay-per-view movies program. For these cases, the recommendation is to use the [order](#) page to start service for your customer and to use questions and miscellaneous fields to record information needed to set up the new membership correctly. Refer to [Using Campaigns & Packages to Create a Membership](#).

Membership Fees

Some memberships may require a fee to be paid by the customer when joining. The behavior of this fee may differ depending on whether it is refundable or not.

- If the fee is nonrefundable, you create an SA with a simple adjustment or a one time billable charge to levy the fee. Refer to [Defining Control Tables for a Nonrefundable Fee](#).
- If the fee is refundable, in addition to defining the SA to hold the fee, you need to put code in place to initiate the refund. Refer to [Setting Up a Refundable Fee](#) for more information.

Stopping a Membership vs. Inactivating a Membership

You may stop a membership by entering an end date for the membership. However, depending on how events are created for your membership, stopping the membership may not prevent new events from being created. For example:

- If you stop a frequent flier membership on May 15th and a bill is subsequently created for the period May 1st through June 1st, your business rules may dictate that frequent flier miles should be accumulated for this bill because the membership was active for part of the period covered by the bill.
- For a capital credits membership, capital credit allocations are calculated for the prior year. If a membership stopped in the middle of the previous year, the membership should still get capital credits for the part of the year that the membership was still in effect.
- Capital credit retirements are calculated based on capital credit allocations accumulated in the past. If a membership has been expired, the members are still eligible for retirement amounts for the accumulated capital credit allocations. These retirements may continue for many years after a membership is stopped.

Note:

Membership Status. For all the above scenarios, the system assumes that the status of the membership remains active.

You may have some circumstances where you do not want new events to accumulate after a membership is stopped. To prevent new events from being created, you must change the status of the membership to inactive.

If a customer moves away or otherwise stops service with your company, your business rules dictate whether or not the membership should be stopped or changed to inactive. The following issues must be considered:

- Will service credit events still get created for these memberships? If so, is that acceptable?
 - For frequent flier memberships, the miles are calculated based on new bill amounts for the membership's service agreements. If the SAs that contribute to the membership are expired, no new bills are generated so no new miles are accumulated.
- For capital credits, after a customer moves away, the capital credit allocation for the final year of the customer's service may still need to be calculated. In addition, this customer is eligible for the capital credit retirement amounts, even though they are no longer a customer.
- What happens if the customer returns to your company and signs on for service again? Assuming that the same account number is used, is it ok for the membership to be automatically reinstated? Or should the customer reapply? If the customer should reapply, you may consider updating the membership with a stop date when the customer originally stopped service.

Note:

There is nothing in the system logic that automatically updates the membership stop date or the status when service agreements that contribute to the membership are stopped.

The Big Picture of SC Events

The service credit events record the accumulation and redemption of awards earned by the membership. The topics in this section provide background information about a variety of service credit event features and functions.

Note:

Events. For convenience, this document often refers to service credit events simply as "events".

Event Amounts May Contribute to a Balance

The event amount may be positive or negative, based on whether the event is accumulating points earned for the membership or redeeming points for the membership. For some types of memberships, these credit and debit amounts should be added together to produce the overall balance for the membership.

For some types of memberships, a balance is not applicable. This is true for memberships where the redemption of the points does not occur within the system. For example, if the membership accumulates frequent flier miles on behalf of

an airline, the customer redeems the earned miles with the airline, not with your company. As a result, there is no need to calculate a balance for the membership.

If you want the system to calculate a balance, you must set a switch on the [membership type](#) page. For memberships that calculate a balance, the balance may be viewed on the membership page.

Events May Indicate a Fiscal Year

For some types of memberships, the amount of each event is associated with a specific fiscal year. This is true for capital credit memberships where capital credit allocations are calculated for a fiscal year. When the capital credits are redeemed (also called retired), the retirement events must also indicate a fiscal year. Because all events for this type of membership are related to a fiscal year, the system can calculate the balance for the events by fiscal year.

If you want the system to require a fiscal year for every event in the membership, you must set a switch on the [membership type](#) page. For memberships that calculate a balance and indicate a fiscal year, the balance for each fiscal year may be viewed on the membership page.

Events May Indicate a Subcategory

For some types of memberships, the amount of each event is further grouped by a subcategory. This is common for capital credit memberships where multiple capital credit allocations are calculated. For example, each year, you may calculate allocations for generation and for transmission. Events for memberships of this type must indicate a subcategory.

Cooperatives that allocate capital credits for more than one subcategory, typically want to view the balance of the events over time broken down into these subcategories. When the capital credits are redeemed or retired, the retirement events must also indicate a subcategory. Because all events for this type of membership are related to a subcategory, the system can calculate the balance for the events by subcategory.

Note:

Partial Retirement. For some cooperatives, it is common that certain capital credit allocations are never retired. Refer to [Partial Retirement](#) for more information.

If you want the system to require a subcategory for every event in the membership, you must define the valid subcategories on the [membership type](#) page. For memberships that calculate a balance and indicate a subcategory, the balance for each subcategory may be viewed on the membership page.

Note:

Calculating Subcategory Balances. If events for your membership indicate a subcategory and fiscal year, balances for the membership are calculated for both groupings.

An Event May Cause Other Actions to Occur

When an event is generated, there are often other actions that need to take place. For example:

- If an event is created that allocates points for the customer, you may want to generate a temporary message on the customer's next bill.
- If a capital credit allocation event is created, the general ledger is affected so an adjustment must be created to post to the general ledger. Refer to [Financial Transactions for an Event](#) for more information.
- If an event is created to add frequent flier miles, the event must be marked for extraction so that the information is sent to the appropriate airline. Refer to [Interface Membership Information to a Third Party](#) for more information.
- If an event to retire capital credits is created, the customer's balance is affected so an adjustment must be created to transfer the capital credit to the members' service agreements. Refer to [Financial Transactions for an Event](#) for more information.

The system relies on algorithms linked to the event type to perform the actions described above and any other action that may be required by your business.

Fastpath:

Refer to [Service Credit Event Types](#) for more information about the algorithms provided with the base product.

Note:

Event Cancellation Algorithms. The event type also defines algorithms to be executed when an event is canceled.

Financial Transactions for an Event

An event may be related to financial transactions. There are two types of financial transactions that may be linked to the event:

- Financial transactions that contributed to the event. These are bills, payments or adjustments that caused the event to be created. For example, if you generate an event for frequent flier miles as a result of some amount billed for the customer, the bill segments associated with the billed amount are linked to the event. The FTs are linked to the event for audit purposes.
- Financial transactions that are created by the event. In [an event may cause other actions to occur](#), we saw examples where an event completion algorithm may cause adjustments to be created. The FT ID for these adjustments is linked to the event as audit.

Note:

Automatically Canceling Event Financial Transaction. The created by financial transactions may get canceled if the event is canceled AND you have plugged in an appropriate [Event Cancellation Algorithm](#).

For financial transactions that are created by the event, the system must post the financial transactions to one or more appropriate service agreements. The service agreement to use depends on your business rules. For example:

- If the event affects the balance of accounts linked to the membership, the event completion algorithm may create adjustments for [service agreements that contribute to the membership](#).
- If the event affects the general ledger and does not affect any balance for the account, the event completion algorithm simply needs a service agreement to use for the resulting adjustment. Rather than arbitrarily picking any service agreement in this case, a special [miscellaneous service agreement](#) should be linked directly to the membership for such adjustments.

How Events Are Created

Although a user may create an event manually on the [service credit event](#) page, most events are created automatically by an algorithm or by a background process. The following topics further describe these options.

Events Created by an Algorithm

You would design an algorithm to create your events if the event should be triggered by an occurrence in the system, such as starting service or generating a bill. For example, perhaps every time you are billed for electric and/or gas service, the system adds one frequent flier mile for every \$10 spent on service. Refer to [How Are Service Credits Earned?](#) for more information.

The base product provides a bill completion algorithm to create an event as a result of the amount billed for service agreements linked to the membership. Refer to CBCM-SC for more information.

Events Created as a Result of a Background Process

You would use a background process to create the event if the calculation is done periodically or on an ad-hoc basis and does not get triggered by something occurring in the system. For example, the capital credit allocation and retirement processes are typically run once a year, when the business has determined that they are ready to calculate these amounts.

Fastpath:

Refer to [Allocating Capital Credits](#) and [Capital Credit Retirement](#) for more information.

Creating Pending Events

Events may be created in pending or complete status. Only complete events cause the completion event algorithms to run and [cause other actions to occur](#). You may use the status of pending if you want to review the calculated amount prior to completing the event.

For example, when a cooperative runs the background process to [allocate capital credits](#), it may create the new events in the pending status. This allows the co-op to review the total amount of capital credits calculated for all members. If this total is in line with the co-op's expectations, they run the background process again creating the new events in complete status. Only at this point do the completion event algorithms run.

Events May Be Transferred

In some situations, you may want to transfer service credit events from one membership to another on the [service credit event](#) page. For example, if a member dies, you may decide to transfer earned service credits to the membership for a beneficiary. When transferring a service credit:

- The target membership must be of the same membership type as the original membership.
- The original service credit event is canceled and any event cancellation algorithms linked to the [SC event type](#) are executed.
- A new service credit event is created and completed and any event completion algorithms linked to the [SC event type](#) are executed.
- The new service credit event references the original event ID in the **Transferred From** event field.

Note:

Contributed to FTs linked to the original event are not transferred to the new event. If you have created by FTs linked to the original event, the recommendation is to ensure that an event cancellation algorithm cancels this FT and that an event completion algorithm for the new event creates an appropriate new FT for the new membership.

CPCRALOC - Allocating Capital Credits

The base product provides a background process (CPCRALOC) that allocates capital credits to members of a cooperative. The result of this process is the creation of new service credit events for capital credit memberships. This background process is typically run after the profits for the previous year are calculated. During that time, this job could be run a number of times for any of the following reasons:

- At the beginning of the allocation process, you may know the total amount to allocate to all members; however, you may estimate the allocation factor that determines the individual amounts that get distributed to the members. You may need to change your estimate and rerun the process until all the individual allocations add up to the desired total amount. To run the job with the estimated allocation factors, indicate that you want events created as pending. When you confirm the correct allocation factor, a final run should be executed with an indication that the events should be created as complete. Every time the process runs, it will first remove any pending events for the same input event type, subcategory and fiscal year. Refer to [Creating Pending Events](#) for more information.
- If the cooperative has more than one subcategory, the process must be run for each subcategory. In fact, the above trial-and-error process may need to be followed for each subcategory.

You must provide the [service credit event type](#) to use for the new events. This process determines the membership type related to the event type. The process then finds all pending and active memberships for this membership type. To calculate the capital credit allocation, the system finds all applicable bill segments for each [service agreement that contributes to the membership](#).

Capital credit allocations are calculated for a specific [fiscal year](#). The fiscal year is input to the background process and is stamped on any new events created by the process. The system also uses the fiscal year to determine the applicable bill segments for the membership's SAs. It uses the bill segment's accounting date and the [accounting calendar](#) to determine the fiscal year for each bill segment.

Note:

Canceled Bill Segments. Any bill segments that were canceled in the fiscal year are included as well.

Accounting Calendar. This process assumes that only one accounting calendar exists for the company. This is the case for companies that operate in a single jurisdiction, which is true for cooperatives.

Allocation Period. If the membership was only effective for part of the fiscal year, the allocations are only calculated for the period of time that the membership was in effect.

For each applicable bill segment, the system determines the SQ total and the total sales amount for each segment. To calculate the totals correctly, a characteristic type and value to identify SQ bill lines must be provided to the background process and a characteristic type and value to identify bill lines contributing to the total sales amount must be provided to the background process.

Fastpath:

Refer to [Identifying SQ and Sales Information for Historical Bill Segments](#) for more information.

If your membership type indicates subcategories to be used for the events, you must provide a subcategory as input. If you have multiple subcategories for your membership, this process must be run once for each subcategory.

The calculation of the capital credit allocation amount typically uses an allocation factor. This factor is often different for each subcategory. You will probably define a different bill factor for each subcategory and use the appropriate bill factor when submitting the process for each subcategory.

This process also assumes that the allocation factor differs by the customer's revenue class. It assumes that the bill factor's characteristic type is revenue class. Refer to [Designing Bill Factors for Credit Allocation](#) for more information. For each service agreement linked to the membership, the appropriate allocation factor is determined based on the revenue class for the SA type.

Capital credits for the input subcategory are calculated as follows:

Fiscal year sales amount - (fiscal year SQ amount * revenue class allocation factor) = Allocation Amount

The calculated amount is compared against a minimum amount, input to the background process. If the calculated amount is less than the minimum, no event is stored for this amount.

After determining the amount, a new service credit event is created for the membership. The event is stamped with the input subcategory, service credit event type and fiscal year.

The FTs for all the bill segments used to determine the allocation amount are linked to the event as contributed to FTs. Refer to [Financial Transactions for an Event](#) for more information.

Note:

Rerunnable Process. This process is restartable and rerunnable. When running the process, for each membership the system checks whether there is already a complete event for the input service credit event type, subcategory and fiscal year. If so, it does not create a new event.

Fastpath:

Refer to CPCRALOC for more information.

CPCRRETR - Capital Credit Retirement

**Note:**

Calculation Method. There are various calculations that different cooperatives may use when determining the amount to retire. The base product has provided one calculation method.

This background process is run when a cooperative is ready to pay out allocated capital credits to its members. This process is referred to as retirement. The result of this process is the creation of new service credit events for capital credit memberships. Capital credits are paid as the cooperative's financial position permits. During that time, this job could be run a number of times for any of the following reasons:

- You may choose to run the process and [create pending events](#) to review the results prior to finalizing the retirement. When you are happy with the results, a final run should be executed with an indication that the events should be created as complete. Every time the process runs, it will first remove any pending events for the same input event type and subcategory.
- If the cooperative has more than one subcategory, the process may be run separately for each subcategory. You may also run the process with no subcategory indicated and then all subcategories are processed.

**Note:**

Partial Retirement. For some cooperatives there may be capital credits for some allocated amounts that are never retired. If that is the case, simply run this process for each subcategory whose amounts do get retired.

You must provide the [service credit event type](#) to use for the new events. This process determines the membership type related to the event type. The process then finds all pending and active memberships for this membership type.

This process receives a percentage to retire as input. It determines the current balance of all completed events for the subcategory. The retirement amount for the subcategory is calculated as the current balance * input percentage to retire. The process then determines the outstanding balance for each subcategory and fiscal year combination. For every combination that still has a balance, the process creates events to relieve the outstanding balance for the oldest fiscal year first. It creates events for subsequent fiscal years until the full retirement amount is used.

In order for the process to be rerunnable and restartable, a Control ID is used to mark retirement events that are created by the process. The Control ID is input to the routine and is determined by the user. When the process runs, it determines whether an event already exists for the subcategory / Control ID combination. If so, new events are not created for that subcategory. If you run the process multiple times for the reasons described above, you should use the same Control ID each time. This way the system knows that the process is being run again for the same retirement calculation.

**Fastpath:**

Refer to [CPCRRETR](#) for more information.

Maintaining Service Credit Memberships and Their Events

The topics in this section describe how to maintain a service credit membership and its events.

**Fastpath:**

Refer to [The Big Picture Of Service Credits](#) for background information about service credits.

Service Credit Membership

The topics in this section describe how to maintain service credit memberships. Refer to [The Big Picture Of Service Credit Membership](#) for background information about memberships.

Lifecycle of a Membership

The following diagram shows the possible lifecycle of a service credit membership.

Pending A service credit membership may start out in the Pending state. A membership is typically created in this state if the creation of the membership requires approval or any manual step (e.g. waiting for paperwork) that needs to be completed prior to activation.

Note:

Events for Pending Memberships. Service credit events may still be created for membership records in the Pending state.

Active A service credit membership is in the Active state when a customer is actively participating in a service credit membership. A membership may be created in the Active state or it may transition to the Active state from Pending when all the necessary approval or paperwork is complete.

Note:

Manual Activation Only. There is no system functionality that automatically changes the status of a membership from Pending to Active. This is a manual step.

Inactive If a customer is no longer actively participating in a service credit membership, change the status to Inactive. This will prevent any new events from being created for the membership.

Service Credit Membership - Main

This page is used to maintain and display general information about a service credit membership. Open this page using **Menu > Customer Information > Service Credit Membership > Search**.

Description of Page

Membership Info and **Membership ID** are displayed on every page. These values only appear after the membership exists on the database. The **ID** is a system-assigned random number. The **Membership Info** is a concatenation of important details about the membership.

Membership Status defines the state of the membership.

Fastpath:

Refer to [Lifecycle of a Membership](#) for more information about membership status.

Click the **Activate** button to activate a Pending membership. When this button is clicked, the system executes any Membership Activation algorithms that are linked to the [service credit membership type](#).

Click the **Inactivate** button to transition an Active membership to Inactive. When this button is clicked, you are prompted to provide an **Inactive Reason** and the system executes any Membership Inactivation algorithms that are linked to the [service credit membership type](#).

Indicate the **SC Membership Type**. This field is important as it controls numerous aspects of the behavior of the membership and its events.

Fastpath:

For more information about what the membership type controls, refer to [Setting Up Service Credit Membership Types](#).

Indicate the **Start Date** and **End Date**, which define the period for which this membership is effective. Leave the end date blank if this membership is effective indefinitely. Refer to [Stopping a Membership vs. Inactivating a Membership](#) for more information.

If this membership is related to a record in an external system, use the **External ID** to indicate the unique identifier of the record in the external system.

If events linked to your membership may generate miscellaneous adjustments, indicate the **Service Agreement** to use for these [miscellaneous transactions](#). The account for this service agreement must be one of the accounts linked to the membership.

The **Events** grid displays the events linked to the membership. To view any of the events use the drill down button.

If your SCM type indicates that the membership has a balance, the tree at the bottom displays information about the balance of the membership based on the amounts for completed events. If the SCM Type indicates subcategories and/or a fiscal year is required, subtotals for completed events are also displayed for each subcategory / fiscal year and by fiscal year / subcategory, if applicable. If any pending events exist, the tree includes a node with information about these events.

Service Credit Membership - Account

This page is used to maintain the accounts linked to a service credit membership. Open this page using **Menu > Customer Information > Service Credit Membership > Search** and navigate to the **Account** page.

Description of Page

Indicate the **Account ID** for each account linked to this membership. Typically a membership will be linked to only one account. However, if a person has multiple accounts and the service credits should span the accounts, multiple accounts are linked to the same membership.

The Service Credit Membership zone on the Account Information portal contains information about memberships for the current customer. (When you find one of the customer's records on [Control Central - Search](#), you are automatically transferred to the [Account Information](#) portal.)

Note:

Portal Preferences. The Service Credit Membership zone only appears if you have modified your preferences to display this zone.

Service Credit Membership - Characteristics

The characteristics page contains information that describes miscellaneous information about the service credit membership. Open this page using **Menu > Customer Information > Service Credit Membership > Search** and navigate to the **Characteristics** page.

Description of Page

Note:

Characteristic Types. You can only choose characteristic types defined as permissible on the service credit membership record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

To modify a characteristic, simply move to a field and change its value. To add a new characteristic, click + to insert a row then fill in the information for each field. The following fields display:

Effective Date Define the date on which the characteristic becomes effective. The effective date defaults from the [Installation Record](#).

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

**Note:**

Default Note. A service credit membership's characteristics default from the [service credit membership type](#).

Service Credit Membership - Membership Tree

The membership tree page displays accounts, SAs and persons linked to the service credit membership. Open this page using **Menu > Customer Information > Service Credit Membership > Search** and navigate to the **Membership Tree** page.

Description of Page

The tree displays each account linked to the membership. For each account, a node exists for:

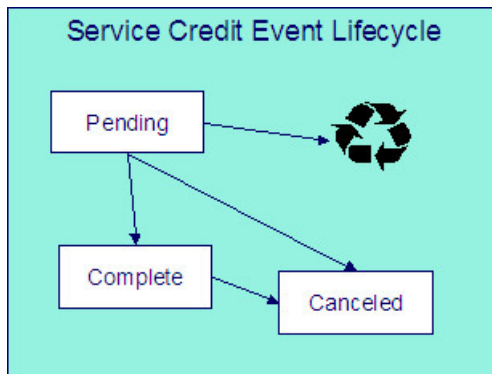

- Each service agreement whose SA type is included in the service credit [membership type](#)'s SA type collection.
- Each financially responsible person linked to the account. These persons are considered the [members](#).

Maintaining Service Credit Events

Service credit events record credits earned or redeemed for a given membership. The topics in this section describe how to maintain service credit events. Refer to [The Big Picture of Service Credit Events](#) for background information about memberships and their events.

Lifecycle of a Service Credit Event

The following diagram shows the possible lifecycle of a service credit event.

Pending A service credit event may start out in the Pending state. An event is typically created in this state when a review of the event is desired before completing it. Refer to [Creating Pending Events](#) for more information.

Complete A service credit event is typically created in the Complete state. When an event is completed, the system executes any event completion algorithms indicated on the [service credit event type](#).

Canceled If a service credit event is no longer valid, it may be Canceled. When an event is canceled, the system executes any event cancellation algorithms indicated on the [service credit event type](#).

Service Credit Event - Main

Open this page using **Menu > Customer Information > Service Credit Event > Search**.

Description of Page

The **Service Credit Event Info** is a concatenation of important details about the service credit event. The **Service Credit Event ID** is a unique system-assigned random number. These values only appear after the service credit event exists on the database.

Service Credit Event Status defines the state of the service credit event.

Fastpath:

Refer to [Lifecycle of a Service Credit Event](#) for more information.

Click the **Complete** button to change a Pending event to Complete. When this button is clicked, the system executes any event completion algorithms that are linked to the [service credit event type](#).

Click the **Transfer** button to transfer this event to another membership. When this button is clicked, you are prompted to provide the membership ID to transfer the event to. The new membership must have the same membership type as the original membership. Refer to [Events May Be Transferred](#) for more information.

Click the **Cancel** button to cancel this event. When this button is clicked, the system executes any event cancellation algorithms that are linked to the [service credit event type](#).

The **Create Date/Time** captures the date and time that this event was created. This defaults to the system date/time.

Indicate the service credit **Membership ID** to which this event should be linked.

Indicate the **Service Credit Event Type**. This field may define algorithms to be executed when the event is completed or canceled. Refer to [Setting Up Service Credit Event Types](#) for more information.

If your [service credit membership type](#) indicates one or more subcategories to be associated with events for this type of membership, indicate the appropriate **Subcategory Name** for this event.

If your [service credit membership type](#) indicates that fiscal year is required, indicate the appropriate **Fiscal Year** for this event.

Enter the **Service Credit Event Amount**. If your [service credit membership type](#) indicates that your membership has a balance, this amount is used to calculate the overall balance for the membership as well as a balance for the subcategory and/or fiscal year, if applicable.

If this event was created as a result of a transfer from another membership, the **Transferred From Event ID** is displayed.

If the information about this event may be [downloaded to a third party](#) system, you should have an event completion algorithm that stamps the appropriate **Batch Control** and **Batch Number** onto the event.

The FT collection displays information about [financial transactions related to this event](#). Two different categories of financial transactions may be linked to the event.

- FTs that contributed to this event. These financial transactions played a part in the creation of this event. For example, if frequent flier miles are earned as a result of newly created bill segments, the FTs related to these bill segments are linked to the event and marked as contributed to FTs. This information is purely for audit purposes. It is the responsibility of the algorithm or background process that creates the event to populate the collection of contributed to FTs. Refer to [How Events Are Created](#) for more information.

Note:

The amount of the contributed to FTs will not necessarily add up to the amount of the event. Refer to the algorithm or background process that calculates the amount of the event to understand how the event amount is calculated based on the amount of the contributed to FTs

- FTs that were created by this event. These financial transactions are created as a result of this event. For example, if you have generated a capital credit allocation event, perhaps you need to post information to the general ledger. An allocation event should therefore generate an adjustment to post the effect on the GL. The adjustment's FT is linked to the event as an audit. In order to create a financial transaction related to this event, you must plug in an appropriate event completion algorithm on your [service credit event type](#).

Fastpath:

Refer to [An Event May Cause Other Actions to Occur](#) for more information.

Appointments

**Note:**

Separate module. Please note that the Appointments functionality is associated with a separate Appointments module. If this module is not applicable to your business, you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

An appointment is an agreement with a customer to perform one or more field activities at a given premise on a specific date / time band. The topics in this section describe how you manage appointments and schedule appointments.

The Big Picture of Appointments

The topics in this section provide background information about appointments.

An Appointment Is Made With A Dispatch Group

A dispatch group is a logical group of work crews located at an operations area. When a [field activity is created](#), the system assigns it a dispatch group based on the type of activity, the type of service point, and the operations area that manages the service point. Refer to [Defining Field Order Options](#) and [The Big Picture Of Field Orders](#) for more information about field activity creation and dispatch groups.

When you make an appointment, you are booking time with one of the dispatch group's crews to perform one or more field activities located at a premise.

A Dispatch Group Has Appointment Periods

An appointment period is a time-band on a given date range when an appointment can be scheduled with a dispatch group. For example, you might have an appointment period from 1 pm to 5 pm on 15-Jan-2003 for the "new service" crew.

A dispatch group can have many appointment periods on a given date. For example, if you offer appointments in two-hour time bands and your crews work 8 hours per day, then your dispatch groups will have four appointment periods (e.g., 8am to 10am, 10am to 12pm, 1pm to 3pm, and 3pm to 5pm).

The [Appointment Periods](#) transaction is used to maintain a dispatch group's appointment periods.

An Appointment Is Notional

The [Appointment](#) transaction is used to make / break an appointment for a premise. When you make an appointment, you are actually linking one or more field activities to an appointment period. There is no entity in the system called "appointment". Rather an appointment is a group of field activities located at a premise that are linked to an appointment period.

Navigating To The Make / Break Appointment Page

Any of the following methods can be used to navigate to the [Appointment](#) transaction:

- An alert in the [Alert Zone](#) highlights if an appointment exists for the current premise. The user is transferred to the appointment transaction if they drill down on the alert.

- You can setup an order's [campaign](#) to automatically transfer a user to the appointment transaction whenever an order is completed for a given campaign. This might be useful for campaigns that cause field activities to be created.
- A user can setup a [favorite link](#) associated with the appointment transaction.
- The [field activity](#) transaction allows a user to transfer to the appointment page when an appointment exists for a field activity
- Via any of the following menus:
 - Premise context menu
 - Field activity context menu
 - Menu menu

Appointments Are Not Applicable To All Field Activities

For each [FA type](#), you mark which types of field activities are eligible for dispatch. For those FA types that may be dispatched, you can indicate that an appointment is required for dispatch, optional or not applicable. Field activities for which appointments are not applicable are not displayed on the [appointment](#) transaction.

If your field activity requires an appointment but an appointment has not yet been made, the system does not allow you to associate the field activity with a field order.

Determining Available Appointments

On the [Appointment](#) transaction, you can view available appointments for selected field activities by clicking a button. When this button is clicked, the available appointment periods are constructed by an algorithm plugged-in on the selected [dispatch group](#). This means your implementation can construct whatever rules it needs to determine the list of available appointments that are presented to a user. Refer to the AAVL-AVLAPPT algorithm type for a description of a base package algorithm.

Limiting The Number Of Appointments In An Appointment Period

When you set up an appointment period for a dispatch group, you can define the maximum number of appointments that can be scheduled in the period. For example, you can indicate that the "meter installation crew for the northern region" has three appointments available between 1 pm and 5 pm on 15-Jan-2003.

Note:

An appointment is notional. As described above, an appointment is a group of field activities located at the same premise that are linked to an appointment period.

The appointment validation algorithm plugged-in on the [dispatch group](#) controls whether a new appointment can be scheduled at a premise. This means your implementation can construct whatever rules it needs to prevent overbooking an appointment period. Refer to the AAVL-AVLAPPT algorithm type for a description of a base package algorithm.

Canceling An Appointment

The [Appointment](#) transaction also allows a user to cancel an appointment. This simply breaks the linkage between a field activity and an appointment period.

The following points describe other mechanism that can cause appointment cancellation:

- If a user changes the start or stop date associated with a service agreement on the Start/Stop page, the system cancels all pending field activities and creates new ones. When the pending field activities are canceled, the appointments are implicitly canceled. The new field activities will NOT be linked to an appointment period when they are created (the user must make new appointments).

- If a user deletes a field activity, the appointment is implicitly canceled.

Compensating A Customer For A Missed Appointment

In some locales, if an appointment is missed, the company has to pay a fine to the customer. No specific functionality exists in the system to support this practice. However, your implementation could implement this requirement as follows:

- Field activities that can have penalties should have a step that records a customer contact (note, a field activity's [field activity type](#) controls the steps that must be entered to complete a field activity).
- When a user adds such a contact, the contact date/time should be the date/time the crew showed up for the appointment.
- The field activity types associated with such field activities should have a completion algorithm that compares the appointment period's date/time to the customer contact's date/time and levies a penalty via the creation of an adjustment. Note, this algorithm is not supplied with the base package.
- In addition, you may want to create an implementation-specific table to record the linkage between the adjustment and the field activity.

Enabling Appointments

This section describes set up tasks necessary to allow appointments to be made for a dispatch group.

Plug In The Appropriate Algorithms On Each Dispatch Group

Set up each dispatch group that can have appointments as follows:

- Define the appropriate "available appointments" plug-in on the dispatch group. Refer to [Determining Available Appointments](#) for more information.
- If you want to validate that an appointment period is valid for a field activity, plug-in the appropriate "appointment validation" algorithm on the dispatch group. Refer to [Limiting The Number Of Appointments](#) for more information.

Set Up Appointment Periods

Use [Appointment Period Maintenance](#) to set up appointment periods for the dispatch group. Refer to [A Dispatch Group Has Appointment Periods](#) for more information.

Appointment Maintenance

This page allows you to manage appointments for a premise's field activities. The following functions can be performed on this page:

- You can make an appointment for one or more field activities
- You can view existing appointments
- You can view historical appointments
- You can cancel an appointment

Note:

The field activity may change. When an appointment period is linked to a field activity, the field activity's scheduled date is changed to reflect the appointment date and the field activity's dispatch group is changed to reflect the appointment period's dispatch group.

Open this page using **Menu > Field Order > Appointment**.

Description of Page

Premise is a concatenation of summary information about the premise. **Premise ID** is the unique identifier of the premise.

The **Existing Appointments** grid contains an entry for every field activity (regardless of status) that is linked to an appointment period at this **Premise**.

You can cancel an appointment for a field activity by clicking **Cancel**. The **Cancel** button is only enabled if the cancellation of the field activity would cause it to appear in the **Field Activities Without Appointments** grid (i.e., you can only cancel appointments for pending field activities).

Note:

External System Integration. If the [FA integration](#) module is not **turned off** and the dispatch group for this field activity references an FA Integration external system feature configuration, clicking **Cancel** triggers a real-time message to be sent to the external system to **cancel the appointment**.

The **Field Activities Without Appointments** grid contains an entry for every field activity that meets the following qualifications:

- The field activity's status is Pending.
- The field activity's activity type indicates that it is eligible for dispatch and that appointment booking is required for dispatch or optional.
- The field activity isn't linked to a field order whose status is Work Done, Not Recorded.
- The field activity isn't linked to an appointment period.

The **Search for an Appointment** section is used to view possible appointments for the selected field activities (and make an appointment by selecting of the available appointments).

Note:

External System Integration. The remaining information for this page is applicable to organizations that are not using the [FA integration](#) module, i.e. it is **turned off**. If your organization uses this module, refer to [Appointments And External System Integration](#) for information about how this section may behave.

Click **Show Appointments** to populate the **Available Appointments** grid with appointment periods. You have the following options before you click this button:

- Specify a **Dispatch Group**. If you do this, available appointments for the specified dispatch group will be shown in the following grid.
- Leave **Dispatch Group** blank. If you do this, the system will look for available appointments for the "lowest common denominator" dispatch group shared by the selected field activities. Refer to [Using Alternate Dispatch Groups To Find The Lowest Common Denominator](#) for more information.
- Specify **On/Around Date**. If you do this, available appointments on / before this date will be shown in the following grid.
- Leave **On/Around Date** blank. If you do this, the system looks for available appointments on / before the earliest date from the selected field activities.

The **Available Appointments** grid is populated after you click **Show Appointments**. Note, an algorithm that's plugged-in on the [dispatch group](#) constructs the list of available appointments. Refer to [Determining Available Appointments](#) for more information.

Note:

Assumptions at open. The system selects all **Field Activities Without Appointments** and clicks **Show Appointments** when this page opens (assuming you want to schedule an appointment for these field activities). This can result in an error (e.g., if there is no common dispatch group amongst the selected field activities). When an error occurs, it is displayed adjacent to **Search for an Appointment**.

The **Available Appointments** grid contains an entry for every possible appointment period. In addition, adjacent to the grid is the **From** and **To** date range from which these appointment periods were extracted. You have the following options at this point:

- Click **OK** to create an appointment for the selected field activities. This simply links the selected field activities to the respective appointment period.
- Click the < or > buttons that surround the **From** and **To** dates. Clicking these buttons causes the system to look for appointment periods in the previous / next date range.

Note:

The field activity may change. When an appointment period is linked to a field activity, the field activity's scheduled date is changed to reflect the appointment date and the field activity's dispatch group is changed to reflect the appointment period's dispatch group.

The field order may change. When an appointment period is linked to a field activity that has been dispatched (i.e., linked to a field order), the field order's schedule date/time is updated with the earliest appointment date/time of all non-canceled non-completed field activities that are linked to the field order.

Appointments And External System Integration

If the [FA integration](#) module is [turned off](#) and the [dispatch group](#) references an external system feature configuration, the **Search for an Appointment** section of the page is built based on the configuration of the external system [feature configuration](#) options.

For a **Dispatch Group** referencing an external system feature configuration:

The **From Date** defaults to the earliest scheduled date of the selected field activities. The **To Date** defaults to the From Date plus the value of the Default Days of Available Appointment feature configuration option whenever a dispatch group is selected.

If your external system allows [forced appointments](#), the **Forced** checkbox is displayed. The user should check this box when attempting to book an appointment that is not available in the system.

If your external system options include [user defined search criteria](#) fields, these fields are displayed below the from date and to date.

Click **Show Appointments** to invoke the external system to display available appointments. If the communication is successful, the **Available Appointments** grid displays the results.

Each available appointment includes an **OK** button to click to choose the desired appointment.

If your external system allows [forced appointments](#), or allows [manual appointments](#) is set to Y, then the grid includes "+" and "-" buttons to allow you to add or remove appointments.

If your external system allows [forced appointments](#), allows [manual appointments](#) or allows the user to [narrow the appointment window](#), then the start date / time and end date / time may be modified by the user.

If your external system options include [user defined result fields](#), additional columns are included after the end date / time for each user defined field.

When the user clicks **OK** for the desired appointment a message is sent to the external system to [book the appointment](#).

Note:

The field activity may change. If a message appointment is successfully sent, the field activity's scheduled date is changed to reflect the appointment date and the field activity's dispatch group is changed to reflect the appointment period's dispatch group.

Fastpath:

Refer to [Booking Appointments Via An External System](#) for more information about this integration.

Appointment Period Maintenance

An appointment period is a time-band on a given date range when an appointment can be scheduled with a dispatch group. For example, you might have an appointment period from 1 pm to 5 pm on 15-Jan-2003 for the "new service" crew. This page is used to maintain a dispatch group's appointment periods. Refer to [The Big Picture of Appointments](#) for more information about appointments and appointment periods.

Note:

Mass update functionality exists. This page has mass-update functionality that can be used to add / update / delete many appointment periods at once. Refer to [How to](#) for more information

External System Integration. If your organization uses the [FA integration](#) module, you do not need to set up appointment periods for dispatch groups that reference an external system. The system automatically creates [appointment period](#) records as an audit when an appointment is booked via the external system.

Open this page using **Menu > Field Order > Appointment Period.**

Description of Page

The grid on this page contains one row for every appointment period linked to the **Dispatch Group**.

This grid is initially populated with appointment periods starting from today's date and ending 7 days in the future when you select a **Dispatch Group**. If you wish to see appointment periods for a different date range, enter a **Start Date** and/or **Number of Days** and then click the search button; the system will populate the grid with all appointment periods starting from **Start Date** and ending X days in the future (where X is **Number of Days**).

Each appointment period in the grid contains the following information:

- **Start Date** and **Start Time** define the start of the appointment period.
- **End Date** and **End Time** define the end of the appointment period. The end date is defaulted to the start date.
- **Maximum Appointments** defines the maximum number of appointments in the appointment period. Refer to [Limiting The Number Of Appointments](#) for more information about the uses of this field.
- **Scheduled Appointments** indicates the number of field activities that are currently linked to this appointment period. You can use the go to button to view the field activities in the appointment period.
- **Appt Period ID** indicates the unique identifier that has been assigned to this record.

Refer to [How To Copy Appointment Periods](#) for information about the **Copy Appointment Periods** button. This button is disabled if the dispatch group references a WFM system.

Refer to [How To Update Maximum Number Of Appointment Periods](#) for information about the **Update Max Appointments** button. This button is disabled if the dispatch group references a WFM system.

How To

The topics in this section describe how to perform common appointment period functions.

How To Copy Appointment Periods

You can click **Copy Appointment Periods** to quickly create multiple appointment periods for a dispatch group by copying appointment periods from the same or a different dispatch group. The **Copy Appointment Periods** window opens when this button is clicked.

Note:

Mass overwrites and deletes. See the following description for how this pop-up can be used to overwrite and/or delete existing appointment periods.

In the **Copy Appointment Periods** window, you can:

Use **Copy From Dispatch Group** to define the dispatch group from which you want to copy appointment periods.

Use **Copy To Dispatch Group** to define the dispatch group for which you are creating appointment periods.

Use **Copy To Start Date** and **End Date** to define the period for which you are creating appointment periods. The system will display each date's day of the week and the **Total Days** in the period.

Use **Copy Method** to define how appointment periods will be copied from the **Copy From Dispatch Group** to the **Copy To Dispatch Group**. The following options are possible:

- Use Copy from the matching day in the template week if you want to copy the appointment periods from a matching day of the week from a template week. When this option is selected, you must identify the **Start Date of Template Week**. Adjacent to this date, the system will display:
 - The day name of the start day
 - The number of appointment periods in the start day
 - The last day in the 7 day period (i.e., a day 7 days in the future)
 - The day name of the last day
 - The number of appointment periods in the last day
- For example, if you enter a **Copy To** period of 1-Jan-2004 to 31-Jan-2004, the system will create appointments for every Monday in this period by copying the appointment periods from the Monday in the **Template Week** (it will do the same for Tuesdays, Wednesdays, etc. in the **Copy To** period).
- Use Copy the same day repeatedly if you want to copy the appointment periods from a **Template Day**. Adjacent to this day, the system displays:
 - The day name of the start day
 - The number of appointment periods in the start day
- For example, if you enter a **Copy To** period of 1-Jan-2004 to 31-Jan-2004, the system will create appointments for every day in this period by copying the appointment periods from the **Template Day**.

Before you press **OK**, consider if holidays during the **Copy To** period should be treated differently than the template days. If so:

- Use **Calendar in which Holidays are Defined** to define the [work calendar](#) that the system should use to identify holidays. The system will display the number of holidays it finds in the **Copy To** period adjacent.
- Use **For Holidays, Copy the Periods from this Date** to define the template day whose appointment periods should be used for holidays.

After you have carefully verified this information, press OK. Please see the following notes if you detect a mistake after you press OK.

Note:

You can also use this transaction to overwrite appointment periods. This transaction is also capable of overwriting existing appointment periods for a dispatch group. If the **Copy To Dispatch Group** has appointment periods in the **Copy To** period, the system will ask if you want to delete them and then create fresh appointment periods. If there are any appointment periods in the **Copy To** periods with appointments, you may not overwrite the appointment periods.

Mass Delete. If the **Copy To** period has existing appointment periods (and they don't already have appointments) and the **Copy From Dispatch Group** doesn't have corresponding appointment periods, the **Copy To** periods will be deleted. Refer to [How To Delete Appointment Periods](#) for more information.

How To Update Maximum Number Of Appointments

You can click **Update Max Appointments** to quickly update the maximum number of appointments on existing appointment periods. The window that appears is identical to that described under [How To Copy Appointment Periods](#); the only difference being that when this window is invoked in "update mode", only existing periods linked to the **Copy To Dispatch Group** will be updated; appointment periods will never be created or deleted. Follow the following instructions when you need to update the maximum number of appointment periods.

Use **Copy From Dispatch Group** to define the dispatch group whose appointment period(s) contain the desired maximum number of appointments.

Use **Copy To Dispatch Group** to define the dispatch group whose appointment periods will be updated.

Use **Copy To Start Date** and **End Date** to define the period for which you are updating appointment periods. The system will display each date's day of the week and the **Total Days** in the period.

Use **Copy Method** to define how appointment periods will be updated. The following options are possible:

- Use Copy from the matching day in the template week if you want to update the appointment periods from a matching day of the week from a template week. When this option is selected, you must identify the **Start Date of Template Week**. Adjacent to this date, the system will display:
 - The day name of the start day
 - The number of appointment periods in the start day
 - The last day in the 7 day period (i.e., a day 7 days in the future)
 - The day name of the last day
 - The number of appointment periods in the last day
- For example, if you enter a **Copy To** period of 1-Jan-2004 to 31-Jan-2004, the system will update appointment periods for every Monday in this period by copying the maximum number of appointments from the Monday in the **Template Week** (it will do the same for Tuesdays, Wednesdays, etc. in the **Copy To** period).
- Use Copy the same day repeatedly if you want to update the appointment periods from a **Template Day**. Adjacent to this day, the system displays:
 - The day name of the start day
 - The number of appointment periods in the start day
- For example, if you enter a **Copy To** period of 1-Jan-2004 to 31-Jan-2004, the system will update appointments for every day in this period by copying the maximum number of appointment periods from the **Template Day**.

Before you press **OK**, consider if holidays during the **Copy To** period should be treated differently than the template days. If so:

- Use **Calendar in which Holidays are Defined** to define the [work calendar](#) that the system should use to identify holidays. The system will display the number of holidays it finds in the **Copy To** period adjacent.
- Use **For Holidays, Copy the Periods from this Date** to define the template day whose appointment periods should be used for holidays.

After you have carefully verified this information, press OK.

How To Delete Appointment Periods

You can delete a dispatch group's appointment periods one-by-one by clicking the delete button in the appointment periods grid. To quickly delete many appointment periods for a dispatch group you can click **Copy Appointment Periods**. We understand this is counterintuitive. The following instructions describe how to do this:

Determine the period of time during which you want to delete appointment periods (note, you cannot delete an appointment period if there are any appointments linked to the appointment period). We refer to this period as the "deletion period" below.

Use **Copy From Dispatch Group** to define a dispatch group that doesn't contain appointment period(s) during the deletion period.

Use **Copy To Dispatch Group** to define the dispatch group whose appointment periods will be deleted.

Use **Copy To Start Date** and **End Date** to define the deletion period. The system will display each date's day of the week and the **Total Days** in the period.

Use the Copy the same day repeatedly **Copy Method**. You should identify a **Template Day** that has no appointment periods. Adjacent to this day, the system displays:

- The day name of the start day
- The number of appointment periods in the start day. Please confirm that this value is zero.

You don't have to specify the holiday period options.

After you have carefully verified this information, press OK.

How To Overwrite Appointment Periods

The window that appears when you click **Copy Appointment Periods** has the ability to delete existing appointment periods (as long as they don't have appointments) and then create new ones. It works like this - if the **Copy To Dispatch Group** has appointment periods in the **Copy To** period, the system will ask if you want to delete them and then create fresh appointment periods. Please follow the instructions described under [How To Copy Appointment Periods](#) for a description of the **Copy Appointment Periods** functionality.

Loans

There are many reasons why your company may loan money to customers. For example, your company may loan money to:

- Finance service upgrades (e.g., to change to dual fuel)
- Support economic development (e.g., to extend a power line)
- Promote energy conservation (e.g., customers borrow to insulate their house)

Note:

Loans are optional. You need only set up loans if your organization loans money to customers. For information on setting up the system to enable loans, refer to [Defining Loan Options](#).

The Big Picture Of Loans

The topics in this section provide background information about loans.

Loans Are Service Agreements

Loans are initiated by creating a loan service agreement for a customer. The loan service agreement (and its SA type) contains the loan's terms, including the loan amount, periodic payment amount, the number of amortization periods, the interest rate, and the periodicity of the bills. Loan service agreements are just like other service agreements in many ways:

- The system bills the customer for the periodic payment amount using information on the service agreement.
- The customer pays the billed amount.
- If the customer doesn't pay, [credit and collections](#) may start a collection process to encourage the customer to pay (depending upon how the loan debt class has been set up on your system).

Loan service agreements differ from other service agreements in the following ways:

- Loans have [interest charges](#).
- Loans have [amortization schedules](#).
- Loan SAs are maintained on a separate transaction (refer to [Loan - Main](#) for more information).

Note:

Loan service agreements are created using Start/Stop. Loan service agreements are created using [start/stop](#) just like all other service agreements. The start/stop transaction has special loan functionality that allows an operator to specify the service agreement-specific loan terms described above. A start option can be specified to override the SA type's interest bill factor.

Loan Interest Charges

When a bill is generated for a loan, the interest charge is calculated using an algorithm. The base package loan interest charge algorithm type (LINT-SI) calculates simple interest based on:

- Unbilled principal (i.e., the payoff balance minus the current balance)
- The number of billing periods covered by the bill
- The interest rate

Note:

No interest on interest and no interest on past due amounts. Just like a classic home loan, the base package algorithm does not calculate interest on interest, nor does it calculate interest on past due amounts. However, your system may be set up to levy a late payment charge.

After the interest charge is calculated, the bill segment FT algorithm generates the financial transactions for the bill. The base package FT algorithm generates a financial transaction that adds the interest charge to the payoff balance. In other words, if the customer wanted to pay off the loan, they would owe the principal balance plus the interest charge.

Fastpath:

For more information, refer to [Billing For Loans And Interest Calculation](#).

Loan Amortization Schedules

A loan's periodic payment amount is calculated such that the customer repays the loan in equal amounts over the term of the loan (with the exception of the first and last bill segments, which are typically for different amounts). The amortization schedule is a projection of the amount of principal and interest in each payment over the life of the loan. The amortization schedule may change, for example if the interest rate changes or the customer makes an overpayment (reducing the principal balance).

The amortization schedule is a theoretical projection of the future. The term theoretical is used because the customer's actual payments can cause the schedule to change. For example, if a customer overpays a bill, the loan's length decreases and the amount of principal and interest in each scheduled payment changes.

A loan's amortization schedule is calculated when you click the **Calculate** button on [Loan - Main](#) . When this button is clicked, an algorithm plugged in on the loan SA type actually calculates the amortization schedule.

You can view a loan's latest amortization schedule using [Loan - Main](#) . You can also change the loan's payment periods or periodic payment amount on this page and recalculate the loan's amortization schedule.

Negative Amortization

The system does not allow you to use a periodic payment amount that is less than the periodic interest amount. If it did, the customer's payoff balance would increase over time (this is referred to as "negative amortization"). There are two methods you can use to specify a payment amount in the system. Depending on which method you use, the system informs you of negative amortization differently:

- If you enter a payment amount that is too small on the Start confirmation page or in the **Renegotiate Future Payments** grid on [Loan maintenance](#), you get an error message when you click the **Calculate** button. You must fix the payment amount before you can start the loan or save your changes.
- If you manually override the **Payment Amount** on [Loan maintenance](#), you can save a payment amount that is too small to cover the interest charges. However, the system notifies you that it is not able to calculate the **Forecasted Schedule** because of negative amortization. Additionally, bill segments for the loan SA are produced in error until the payment amount is adjusted appropriately.

Loan Overpayments

Overpayments reduce the principal amount (the amount owed on the loan), which follows the philosophy adopted by a typical home loan. When the payment is made, any overpayments are distributed according to the overpayment distribution algorithm defined for the customer class. Typically, loan service agreements should be set up so that the overpayment is applied to the principal balance.

When the payment transaction is frozen, the system checks to see if there is a credit amount on the loan SA's current balance. If a credit exists, the customer has made an overpayment and an adjustment is created to transfer the amount of the credit from the SA's current balance to its payoff balance, thus reducing the principal by the amount of the overpayment.

Fastpath:

For more information about the adjustments created for loan overpayments, refer to [Overpayments On Loans](#).

Note:

Overpayments and interest. The base package interest calculation algorithm (plugged in on the loan's SA type) does not take into consideration the exact date that the overpayment is made when calculating the interest for the period. It only takes into consideration the outstanding principal amount (payoff balance - current balance) at the time of the interest calculation.

The Lifecycle Of A Loan

Loans have the same [lifecycle as other service agreements](#) (e.g., pending start, active, pending stop). You should rarely have to manually change a loan service agreement's status. Why? Just like other service agreements, the system changes the status behind-the-scenes when various events take place. For example, loans in the pending start state are automatically activated by a system background process.

If you need to manually change a loan service agreement's status (e.g., you need to cancel a loan that was inadvertently started), you can do so from [Service Agreement - Main](#).

Finalizing And Closing A Loan

A loan SA is automatically stopped when the last bill segment is generated for the loan. If the remaining principal balance (plus accrued interest) is less than or equal to the loan payment amount, the SA status is changed to pending stop and the bill segment is marked as the closing bill segment. The SA can then be stopped by the user (manually using the SA page) or by the SA activation background process. When the customer pays the last bill, the loan SA is closed.

Fastpath:

For more information about transitioning SAs from pending stopped, refer to [Finalizing Pending Stops](#).

Navigating To The Loan Maintenance Page

Any of the following methods can be used to navigate to the [Loan Maintenance](#) transaction:

- A user can set up a [favorite link](#) associated with the loan transaction.
- Via any of the following menus:
 - Account context menu
 - Service agreement context menu
 - Menu

Note:

Alerts and Loans. If the loan SA type is set up with an alert, the [Alert Zone](#) highlights if a loan exists for the current account. You are transferred to the SA maintenance transaction (not the loan maintenance transaction) if you drill down on the alert.

Loan Maintenance

You can use loan maintenance to view the loan's amortization schedule and financial history as well as to change the terms of a loan, including the loan amount (prior to SA activation only), interest rate, payment amount and number of payment periods.

Note:

Starting Loans. You cannot start a loan from Loan - Main; you must use Start/Stop. Refer to [How To Start A Loan Service Agreement](#) for information.

Open **Menu** > **Customer Information** > **Loan** > **Search** to maintain a loan.

Description of Page

The fields at the top of the page are informational only. The **Payoff Balance** is the total amount owed by the customer (excluding any interest that may have accrued since the last bill). The **Current Balance** is the amount currently owed by the customer. The **Principal Balance** is the total principal amount left unbilled. Refer to [Payoff Balance and Current Balance for Loans](#) for more information.

The **Loan Amount** is the amount originally loaned to the customer. The **Standard Interest Rate** is the standard interest rate defined on the loan's SA type. If the SA type allows, the standard interest rate may be overridden by a start option and/or manually. The **Next Payment Amount** is the effective periodic payment amount as of the next bill.

The **Payment(s)** shows the number of payments that were used to calculate the original loan schedule.

The **Override Interest Rate** grid is used to override the standard interest rate. The interest rate can only be modified if the loan's SA type allows it. Note that changing the interest rate changes the loan amortization schedule. To override the interest rate:

- Specify an **End Date** for the override rate in effect if there is one.
- Click + and specify the **Start Date** and the new **Interest Rate**. You can also specify the **End Date** of the new override rate, but this is not required.

The **Payment Amount** grid is used to maintain the effective periodic payment amount. Note that changing the payment amount changes the amortization schedule. To change the payment amount:

- Click + and specify the **Effective Date** and the new payment **Amount**.

Note:

Entering a payment amount that is too small. If you save a payment amount that is too small to cover the periodic interest charges, this causes [negative amortization](#). The system is not able to recalculate the amortization schedule and bill segments are produced in error until the problem is corrected.

The **History** grid shows the loan's financial history in reverse chronological order. The financial history grid displays the following information:

- The **Arrears Date** is used to compute how many days old the debt is. In the context of a loan, debt only refers to the billed amount (the amount the customer needs to pay to stay current).
- **Financial Transaction Type** displays the type of financial transaction except for adjustments. For adjustments, the adjustment type's description is shown.
- **Current Amount** is the effect of the FT on the service agreement's current balance.
- **Current Balance** is the amount owed by the customer at the time of the transaction.
- **Payoff Amount** is the effect of the FT on the service agreement's payoff balance. The value is grayed out if it is the same as the current amount.
- **Payoff Balance** is the total amount owed by the customer. The value is grayed out if it is the same as the current balance.

Warning:

If you do not understand the difference between payoff balance and current balance, refer to [Payoff Balance And Current Balance For Loans](#).

The **Forecasted Schedule** displays the loan amortization schedule. The first row of the schedule shows the current cumulative interest, current cumulative principal and the current principal balance. All other rows show the future amortization schedule based on the loan details. The forecasted schedule includes the following information:

- The **Loan Period** displays the forecasted payment period dates based on the billing frequency and the payment periodicity. The Loan Period is blank for the first row, which shows current cumulative amounts.
- The **Amount** displays the projected amount of that payment. The Amount is zero for the first row, which shows current cumulative amounts only.
- The **Interest** displays the projected amount of interest in the payment amount. The Amount is zero for the first row, which shows current cumulative amounts only.
- The **Principal** displays the projected amount of principal in the payment amount. The Amount is zero for the first row, which shows current cumulative amounts only.
- The **Cumulative Interest** is the total interest amount that would theoretically be billed at that loan period.
- The **Cumulative Principal** is the total principal amount that would theoretically be billed at that loan period.
- The **Principal Balance** is the remaining principal balance that would theoretically be remaining at the loan period.

Note:

Forecasted schedule. The loan schedule algorithm calculates the values in the forecasted schedule. Depending on the algorithm set up for your installation, the values may have a different meaning.

The **Renegotiate Future Payments** area allows you to change the terms of the loan. You can modify the following options:

- You can modify the **Loan Amount** only if the SA has not been activated. After the SA is activated, this field is for information only.
- The **Interest Rate** allows you to change the interest rate. When changing the interest rate, specify either the number of payment amounts or the payment amount and click Calculate to recalculate the amortization schedule.
- The **Number of Payment Periods** allows you to change the number of periods remaining in the loan's term. The **Frequency** displays the periodicity of the payments. If you change the number of payment periods, use the Calculate button to recalculate the payment amount.
- The **Payment Amount** allows you to change the amount of individual payments. If you change the payment amount, use the Calculate button to recalculate the number of periods.
- The **Calculate** button recalculates the payment amount (when you specify the interest rate and the number of payment periods) or the number of payment periods (when you specify the interest rate and the payment amount) and recomputes the loan amortization schedule based on these new terms.

Note:

Implementing New Loan Terms. The changes that you make using **Override Interest Rate, Payment Amount** and **Renegotiate Future Payments** do not take effect until you save the loan. Changes made to the **Renegotiate Future Payments** section are only valid for save after you click Calculate, and they override any other changes.

Saving Renegotiated Future Payments. When you save a loan that has renegotiated payments, the system may add new records for the override interest rate, payment amount, or both. It uses the start date of the next loan period as the start date of the new interest rate and/or as the effective date of the new payment amount. If the loan has not yet been billed, the system updates the interest rate and/or payment amount created when the loan was started.

How To

The topics in this section describe how to perform common loan functions.

How To Start A Loan Service Agreement

Loan service agreements are created using [start/stop](#) just like all other service agreements. The start/stop transaction has special loan functionality that allows an operator to specify the service agreement-specific loan terms described above.

Creating a loan service agreement involves the following steps:

- Select the account on Control Central then open Start/Stop.
- Enter a **Start Date** and a **Start Method** of Start a SA.
- Indicate the **CIS Division / SA Type** of the loan service agreement and click the **Start** button.

Note: If the service agreement's account's CIS Division's **Restrict to Account CIS Division** flag is set to *Restricted*, the CIS Division is set to the account's CIS Division and cannot be changed.

- After you click **Start**, the Start Confirmation page appears. When you select a loan service agreement type, the Start Confirmation page displays special fields that allow you to specify the loan's terms.
- Select a loan **Start Option**. The start option includes the adjustment type for booking the principal amount, and can also include defaults for the initial loan amount, periodic payment amount, payment periods, and interest rate. The system uses the information on the start option to populate the service agreement's default parameters. You can manually override these parameters:
 - Enter the **Loan Amount** (the amount that the customer is borrowing). Note that the label for the Total Amount To Bill (e.g., Loan Amount) may appear differently depending on how the SA type was defined.
 - The system can automatically calculate either the payment amount (based on the loan amount and the payment periods) or the payment periods (based on the loan amount and the payment amount). Enter either the **Payment Amount** or the **Payment Periods** and click **Calculate**. Note that the label for the Recurring Charge (e.g., Payment Amount) may appear differently depending on how the SA type was defined.
 - Once the loan parameters are populated, click **Start**.

The loan is created in the pending start state. The next time the SA activation process runs, it will activate the loan SA. If you want to activate the loan immediately, navigate to the service agreement page and click **Activate SA**.

Note:

Overriding the Interest Rate. The **Interest Rate** is a display only field. The interest rate is taken from the value of the interest bill factor defined on the SA type or the contract value of the interest bill factor on the start option if one is defined. After starting a loan, you can manually override the interest rate using [Loan - Main](#) if the SA type allows it.

Changing The Loan Amount. You can use loan maintenance to change the loan amount for an SA as long as the SA has not yet been activated. It may be helpful to transfer to [Loan - Main](#), and verify the amortization schedule before activating the SA.

How To Modify The Terms Of A Loan

After a loan is active, you may want to modify its terms. You can change number of payment periods, the payment amount, and the interest rate (if allowed by the SA type). To modify the terms of a loan:

- Navigate to the [Loan maintenance](#) page.
- If you used the account context menu, the loan you want to modify may be displayed. If not, use the search dialog that appears to search for and select the loan you want to modify.
- In the **Renegotiate Future Payments** section, change the interest rate (if allowed), the number of payments, or the payment amount. Note that either the number of payments or payment amount must be blank.
- Click **Calculate**. The **Forecasted Schedule** is recalculated along with either the new payment amount or the new number of payments (depending on which was left blank).
- If the renegotiated payments are satisfactory to the customer, save the changes.

When you save the changes, appropriate entries are made in the **Override Interest Rate** and **Payment Amount** grids.

Note:

Saving Loan Modifications. You must save the renegotiated payments after clicking Calculate for the loan modifications to be effective.

How To Adjust Loans

You issue ad hoc adjustments if you need to change a loan's principal and/or current balance outside of the normal billing and payment functions.

An adjustment can:

- Change a loan's payoff balance.
- Change a loan's current balance (i.e., how much the customer thinks they currently owe).
- Change both the loan's payoff and current balance.

Fastpath:

For details about the adjustment types to apply, refer to [Adjusting Loan Amounts](#). For information about creating adjustments, refer to [Adjustments](#).

How To Stop A Loan Service Agreement

Normally, a loan SA is automatically stopped when the bill segment for the last payment in the amortization schedule is generated for the loan (refer to [Finalizing And Closing A Loan](#)).

If a customer decides to payoff a loan before the term is complete, you can:

- Transfer to the SA maintenance page for the loan service agreement, specify an **End Date** for the loan, and click Save. This transitions the loan SA to pending stop.

Note:

End Date. The loan SA cannot be stopped until the specified end date is reached, so do not specify an end date that is in the future unless you do not want to stop the loan until that date.

Once the loan is in pending stop and the end date has been reached, the system transitions the loan SA to stopped. On the service agreement's normal bill cycle, the system final bills the SA for any outstanding balance plus accrued interest charges.

If you want to stop the loan and create the final bill immediately, complete these additional steps:

- On the loan's SA maintenance page, click the Stop SA button to transition the loan SA to stopped.
- Manually, [create a bill](#) for the loan service agreement. Remember that if you only want to generate a bill segment for a specific service agreement (e.g., the loan service agreement), transfer to the bill segment page. From there, you can generate and freeze a bill segment for a specific service agreement. When finished, return to the bill page and complete the bill.

When the customer pays the final bill, the loan SA is closed by the system.

Fastpath:

For more information about SA states, refer to [The Lifecycle Of A Service Agreement](#).

Non-Billed Budgets

A Non-Billed Budget (NBB) is a payment plan used to level out a customer's payments over time. Non-billed budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. For example:

- Rather than receive a bill once a quarter, a customer could set up a Non-Billed Budget to pay fortnightly

- Rather than pay two large bills a year, the customer could set up a Non-Billed Budget to pay 10 out of 12 months (sparing themselves during the holiday season)

Non-Billed Budgets can cover one or more service agreements linked to the same account. You can have multiple active Non-Billed Budgets for an account, but any given service agreement can only be covered by a single Non-Billed Budget at any point in time.

Note:

Non-Billed Budgets are optional. The business processes described in this section are only relevant if your organization offers Non-Billed Budgets to its customers.

Fastpath:

For information about setting up non-billed budget functionality for your system, refer to [Defining Non-Billed Budget Options](#).

The Big Picture Of Non-Billed Budgets

The following topics provide background information about Non-Billed Budgets.

Non-Billed Budget Service Agreements

Non-Billed Budgets are initiated by creating a Non-Billed Budget service agreement for a customer. The Non-Billed Budget SA and its SA type maintain the details of the Non-Billed Budget, such as recommendation rules, covered SAs, scheduled payments and credit balance. Non-Billed Budgets are just like other service agreements in some ways:

- Non-Billed Budgets have a current and a payoff balance.
- If the customer doesn't pay a monitored Non-Billed Budget, credit & collections may start a collection process to encourage the customer to pay (depending upon how the debt class has been set up on your system).

Non-Billed Budgets differ from other service agreements in the following ways:

- Non-Billed Budgets have a special role of Non-Billed Budget.
- Non-Billed Budgets have scheduled payments.
- Non-Billed Budgets maintain a list of covered SAs (utility and other service agreements to which the Non-Billed Budget applies)
- Non-Billed Budgets are started and maintained on a separate transaction (refer to [Non-Billed Budget - Main](#) for more information).

Which SAs Are Covered By A Non-Billed Budget?

A Non-Billed Budget can apply towards one or more of the account's billable SAs whose SA type is flagged as Eligible for Non-Billed Budget. SAs can be added to or removed from a Non-Billed Budget at any time. Additionally, an SA can be linked to more than one Non-Billed Budget as long as the Non-Billed Budgets to which it is linked do not have overlapping start and end dates.

A list of the SAs covered by a non-billed budget is maintained with the Non-Billed Budget SA. This list is used at bill completion to determine the financial transactions that should occur.

Non-Billed Budgets Versus Other Plans For Payment

Unlike a regular budget but like a payment plan, a Non-Billed Budget has one or more scheduled payments. However, unlike payment plans, bills are not produced for the scheduled payment amounts. Instead, customers are simply notified of the payment schedule and it is their responsibility to make the scheduled payments. In general, the following statements highlight the differences between Non-Billed Budgets and other payment plans.

- There is a payment schedule that is not dependent on billing, unlike [budget plans](#).
- Non-Billed Budgets are not limited to SAs of a single debt class, unlike [pay plans](#).
- Debt is not transferred from regular SAs to the non-billed budgets, unlike [payment arrangements](#).

Warning:

Non-Billed Budgets and Budget Plans! An SA should not be on a Non-Billed Budget if it is on a [budget plan](#). A Non-Billed Budget overrides any budget functionality in most cases. However, placing an SA that is on a budget on a Non-Billed Budget may result in indeterminate results. For example, when the Non-Billed Budget is broken, the stop algorithm for the Non-Billed Budget syncs current and payoff balances for those utility SAs that were covered by the Non-Billed Budget.

There Are Two Types Of Non-Billed Budgets

There are two types of Non-Billed Budgets: monitored and unmonitored. As the terms suggest, the difference between monitored and unmonitored Non-Billed Budgets is whether they are monitored by the account debt monitor. However, this also means that monitored and unmonitored Non-Billed Budgets receive different financial treatment by the system.

In general, monitored Non-Billed Budgets have their current balances monitored by the account debt monitor while the current balances of any covered SAs are zero (and therefore don't violate any debt collection criteria). With monitored Non-Billed Budgets, customers make required prepayments that are applied towards their utility bills (until the Non-Billed Budget is stopped). They are responsible for making sure the payments on their Non-Billed Budget are up to date, but they do not have to payoff any balances on covered SAs.

Unmonitored Non-Billed Budgets do not have their current balances monitored by the account debt monitor while the current balances of any covered SAs are maintained and therefore subject to the account debt monitor. When customers are set up on an unmonitored Non-Billed Budget, the payments that they make towards the budget are optional. They are, however, financially responsible for paying the current balances of any covered SAs.

Fastpath:

Refer to [Financial Transactions For Unmonitored Non-Billed Budgets](#) for detailed information about the financial differences between monitored and unmonitored Non-Billed Budgets.

Note:

SA Type Determines Monitored Status. The SA type that you select when setting up a Non-Billed Budget determines whether it is monitored or unmonitored (i.e., it's a setting on the SA type). Your company may choose to implement only monitored non-billed budgets, only unmonitored Non-Billed Budgets, or both.

Navigating To The Non-Billed Budget Maintenance Page

Any of the following methods can be used to navigate to the [Non-billed Budget Maintenance](#) transaction:

- An alert in the [Alert Zone](#) highlights if a Non-Billed Budget exists for the current account. You are transferred to the non-billed budget transaction if you drill down on the alert.
- You can setup an order's [campaign](#) to automatically transfer a user to the Non-Billed Budget transaction whenever an order is completed for a given SA. This might be useful for campaigns that are associated with services that are typically on a Non-Billed Budget.
- A user can setup a [favorite link](#) associated with the Non-Billed Budget transaction.
- Via any of the following menus:
 - Account context menu
 - Service agreement context menu
 - Menu menu

Recommending Scheduled Payments

When creating a Non-Billed Budget, you must select a recommendation rule. The recommendation rule establishes the amount to be paid and the dates on which the payments are due. In other words, the recommendation rule creates a recommended payment schedule.

The recommendation rules that you can use are specific to your implementation. The recommendation rule that you select can have default values for its parameters. If your implementation allows, you can manually override one or more of these default values. For example, you may be able to specify the period covered by the Non-Billed Budget and the day of the month on which the payments are due.

If your implementation allows, you can manually modify the recommended payment schedule to suit the needs of a particular customer.

Fastpath:

Refer to [Designing Recommendation Rules](#) for more information.

Maintaining Non-Billed Budgets

Non-Billed Budget service agreements are started and maintained on a different transaction than other SAs. The topics in this section explain how to start and maintain Non-Billed Budgets.

Non-Billed Budget - Main

The Main page contains basic information about the Non-Billed Budget. Open **Menu > Customer Information > Non-Billed Budget > Search** to maintain this information.

Description of Page

Non-Billed Budget SA (service agreement) information and **SA ID** are displayed on each page. These values only appear after the service agreement exists on the database. The **SA ID** is a system assigned random number that stays with a service agreement for life. The **Non-Billed Budget SA** information is a concatenation of important details about the service agreement and its account.

The **Account ID** is identification of the account that is financially responsible for the service agreement.

Indicate the **CIS Division** and **SA Type**. These fields control aspects of the service agreement's behavior, such as whether the Non-Billed Budget is monitored or unmonitored. These fields are gray when the status is not Pending Start.

Note: If the service agreement's account's CIS Division's **Restrict to Account CIS Division** flag is set to *Restricted*, the CIS Division is set to the account's CIS Division and cannot be changed.

Fastpath:

For more information about Non-Billed Budget SA types, refer to [Defining Non-Billed Budget Options](#).

If **Scheduled Payment Auto Pay** is Included in Auto Pay and the account is set up for automatic payment, the scheduled payments are covered by auto pay. If Excluded from Auto Pay, the scheduled payments are excluded from auto pay if it is set up for the account.

Recommendation Rule is used to create a recommended payment amount and payment schedule. The SA type controls which recommendation rules are allowed for the Non-Billed Budget SA.

Current Balance indicates the amount the customer currently owes on the Non-Billed Budget. If the Non-Billed Budget is unmonitored, the current balance is always zero.

Payoff Balance displays the total amount the customer would owe if they wanted to close the service agreement. For Non-Billed Budgets, the payoff balance typically represents an accumulated credit that has not yet been distributed to the covered SAs (at bill completion time or when the Non-Billed Budget is stopped).

The **Start Date** defines when the financial relationship begins. The **End Date** is a display only field that indicates when the financial relationship terminates. The **Expiration Date** is the date on which the SA expires. The **Renewal Date** is the date on which the SA is scheduled to be renewed by the SA renewal background process. If the SA is not renewed by the expiration date, the stop process is initiated.

The **Recommendation Rule Parameter Values** grid specifies the parameters and their values to use for the selected recommendation rule:

- **Parameter** is the name of the parameter from the recommendation rule algorithm type.
- **Value** is the value used for the parameter. If the recommendation rule allows, you can override the default values by specifying your own.

Note:

The recommendation rule's payment schedule algorithm type (NBPS-MON) controls the number and type of parameters. The recommendation rule controls the default values and whether they can be overridden.

The **Covered Service Agreements** grid lists the utility and other SAs that are on the Non-Billed Budget. You must create the list of covered SAs before the recommendation rule can recommend a payment amount and list of scheduled payments. The grid displays the **SA ID**, **SA Information**, **Current Balance** and **Payoff Balance** for covered SAs.

The scheduled payments grid displays the scheduled payments created by the recommendation rule (after you click the Recommend NBB button). You can manually create or modify the **Scheduled Date** and or **Scheduled Amount** of any scheduled payment in the list. The **Total of Scheduled Payments** shows the total of all scheduled payments in the list.

Fastpath:

Refer to [Scheduled And Actual Payments On The Non-Billed Budget](#) for more information on what occurs when the base [Non-Billed Budget scheduled payment background process](#) processes scheduled payments that are due.

In the Action grid:

- Click **Recommend** to create a recommended payment schedule based on the recommendation rule.
- Click **Renew** to manually renew the Non-Billed Budget. This executes the SA renewal algorithm for the SA type and returns new renewal and expiration dates for the SA.
- Click **Break** to manually cancel the Non-Billed Budget. This executes the break Non-Billed Budget algorithm defined for the SA type, and changes the status of the SA to pending stop.

Non-Billed Budget - History

The Financial History page displays the Non-Billed Budget's historical financial transactions. Open **Menu > Customer Information > Non-Billed Budget > Search** and navigate to the **History** page to view this information.

Description of Page

Non-Billed Budget SA (service agreement) information and **SA ID** are displayed on each page. These values only appear after the service agreement exists on the database. The SA ID is a system assigned random number that stays with a service agreement for life. The Non-Billed Budget SA information is a concatenation of important details about the service agreement and its account.

The **Account ID** identifies who is financially responsible for the service agreement.

The grid shows the Non-Billed Budget's financial history in reverse chronological order, including:

- The **Arrears Date** is used to compute how many days old the debt is. For monitored Non-Billed Budgets, debt refers to the scheduled payment amounts (i.e., the customer only owes the scheduled payment amounts up to the most recent scheduled payment date). The arrears date for a schedule payment is the scheduled payment date.
- **Financial Transaction Type** displays the type of financial transaction except for adjustments. For adjustments, the adjustment type's description is shown.

- **Current Amount** is the effect of the FT on the service agreement's current balance.
- **Current Balance** is the amount owed by the customer at the time of the transaction.

How To

The topics in this section describe how to perform common Non-Billed Budget functions.

How To Start A Non-Billed Budget Service Agreement

To set up a new Non-Billed Budget:

- Navigate to the Non-Billed Budget maintenance page.
- If the account is not already specified, select the **Account** for which you want to start the Non-Billed Budget.
- Define the **CIS Division** and **SA Type** to use for the Non-Billed Budget service agreement.
- If necessary, change the **Start Date** (the current date is defaulted).
- Select the **Recommendation Rule** to use and modify any of the default parameters to meet the needs of the customer.
- Verify the list of **Covered Service Agreements**. All the account's SAs that are eligible for Non-Billed Budget are listed. Click  to remove unwanted SAs from the list.
- Click **Recommend**.
- On the pop-up dialog, specify the **Schedule Start Date** and click **Recommend**.
- Make any necessary changes to the expiration date, renewal date and scheduled payments grid and click Save.

How To Cancel / Stop Non-Billed Budget SAs

To stop a Non-Billed Budget:

- Navigate to the Non-Billed Budget maintenance page.
- If the account with the Non-Billed Budget you want to stop is not specified, select the **Account** of the Non-Billed Budget you want to stop.
- If the account has more than one Non-Billed Budget SA, select the Non-Billed Budget you want to stop.
- Click **Break**.

How To Renew Non-Billed Budgets

Most Non-Billed Budgets are renewed automatically by a background process. However, you may manually renew Non-Billed Budgets that are eligible for renewal if desired.

To renew a Non-Billed Budget:

- Navigate to the Non-Billed Budget maintenance page.
- If the account with the Non-Billed Budget you want to renew is not specified, select the **account** of the Non-Billed Budget you want to renew.
- If the account has more than one Non-Billed Budget SA, select the Non-Billed Budget you want to renew.
- If desired, change the recommendation rule or any of the parameters.
- Click **Renew**.

The new expiration and renewal dates are calculated and the new payment schedule is appended to the list of scheduled payments.

How To Set Up Automatic Payment For A Non-Billed Budget

If a customer wants to pay their non-billed budget scheduled payments automatically:

- Set up the account for automatic payment (as described under [How To Set Up A Customer To Pay Automatically](#)).
- Navigate to the Non-Billed Budget Maintenance page and select the Non-Billed Budget for the account.
- Set the **Scheduled Payment Auto Pay** field to indicate that the scheduled payments are Included in Auto Pay.

Asset Inventory

In addition to maintaining a simple list of your meters and items, you may want to keep track of their locations when they are not installed at a service point. The topics in this section describe how you set up stock locations and manage your asset inventory.

Note:

Asset. We use the term "asset" to refer to both meters and items in the following discussion.

Equipment is not tracked. The functionality provided for tracking items that are installed at a service point are specifically referring to items that are linked to the service point via [SP / item installation](#). Items that are linked to service points as equipment are not included in this functionality.

The Big Picture Of Asset Inventory

The topics in this section provide background information about keeping track of the stock locations at which meters and items are located when they aren't installed at a service point.

The Big Picture Of Stock Locations

There are two types of stock locations:

Inventory stock location. An inventory stock location is one at which an asset can reside when it's not installed at a service point.

Parent location. Stock locations that are used to organize inventory locations are called "parent" stock locations. You would create parent locations to provide a hierarchical perspective as to the location of your assets.

For example, assume you have a large warehouse with many different logical areas in which assets can be stored. You could create an inventory stock location for each specific shelf / storage area in the warehouse and then group all of these inventory locations under a parent location (where the parent location would be the "large warehouse").

Parent locations are not necessary. Parent locations are only needed if you want to view stock locations in a hierarchy on the [Stock Location Inventory](#) page.

Stock Location History Is Created Behind The Scenes

An asset's stock location history is only maintained if the asset's respective [meter type](#) / [item type](#) indicates that stock location history is maintained. If stock location is tracked, the system will create stock location history records in the following situations:

- Whenever an asset is installed at a service point, a stock location history record is stored. The stock location is blank on such a record (because the asset is installed at a service point).
- Whenever an asset is removed from a service point, an "installation" stock location history record is stored. The default stock location into which a removed asset is placed is defined on [Postal Code Default - Service Defaults](#).
- Whenever a meter or item is replicated, the operator must indicate the stock location at which the replicated meters / items reside. Refer to [Meter Replicator](#) and [Item Replicator](#) for more information.

**Note:**

If location tracking for an item type or meter type is turned off and then subsequently turned on again, any change in the location of the item / meter during the period in which location tracking is off will not be recorded. This will result in gaps in the asset's location history.

A User May Manually Change An Asset's Stock Location

[Stock Location History Is Created Behind The Scenes](#) most of the time. However, the following points describe situations that will cause an operator to manually change an asset's stock location.

- If an asset is not installed at a service point, an operator may change its current stock location using either [Meter - Location History](#) or [Item - Location History](#). This would typically be done when an asset is transferred to a different stock location.
- Whenever a new meter / item is initially added, the operator must indicate the stock location at which the meter / item resides. This is done using either [Meter - Location History](#) or [Item - Location History](#).

Viewing What Is At A Stock Location

You can view all assets at a stock location using [Stock Location Inventory](#).

Viewing Where An Asset Is / Was

You can use [Meter - Location History](#) and [Item - Location History](#) to view the history of the service points and stock locations at which an asset has been located. It's important to be aware that you may only view this history if the asset's [meter type](#) / [item type](#) indicates that the inventory location is tracked.

How To Handle A Shipment Of New Assets

If you receive a shipment of new items, follow the following steps:

- Create a new [item](#) for each type of item that's received. These items serve as the "templates".
- Go to the [Item Replicator](#) to create multiple copies of the template item(s). Before you are allowed to replicate the new item, you must define the stock location at which the items will be stored.

If you receive a shipment of new meters, follow the following steps:

- Create a new [meter](#) for each type of item that's received. These meters serve as the "templates".
- Add a meter configuration for each template meter using [Meter Configuration Maintenance](#).
- Go to the [Meter Replicator](#) to create multiple copies of the template meter(s). Before you are allowed to replicate the new meter, you must define the stock location at which the meters will be stored.

How To Transfer Assets To Another Location

To move assets from one stock location to another, perform the following steps:

- Navigate to either [Stock Location Inventory - Item Inventory](#) or the [Stock Location Inventory - Meter Inventory](#) as appropriate and select the stock location where the assets that you want to transfer are located.
- Display the items / meters that you want to transfer using the filters and pressing the search button.
- Select the items / meters that you want to transfer.
- Click on the **Transfer Location** button. The **Transfer Stock Location** window opens.
- Specify the **Stock Location** where you want to transfer the assets to and enter the effective date/time of the transfer in **Location Date/Time**. Click on the **Transfer** button to perform the transfer.

Setting Up Asset Inventory Options

This section describes tables that must be set up before you can associate meters / items with inventory locations.

Setting Up Postal Defaults

On [Postal Code Default](#), define the respective stock location into which a meter / item will be placed by default when its removed from a service point. Refer to [Stock Location History Is Created Behind The Scenes](#) for more information.

Turn On Stock Location Tracking On Your Meter Types / Item Types

Enable stock location tracking for the [meter types](#) / [item types](#) whose stock location is to be tracked in the system.

Maintaining Stock Locations

Every meter / item whose [meter type](#) / [item type](#) indicates that its stock location is tracked resides at a stock location. The topics in this section describe how to maintain your stock locations.

Stock Location - Main

Open this page using **Menu > Meter > Stock Location > Search**.

Description of Page

A stock location is a physical or logical location at which meters / items are stored while they are not installed at a service point. Refer to [The Big Picture Of Stock Locations](#) for more information.

Enter a unique ID and a **Description** for each **Stock Location**.

Indicate that this stock location is Allowed to **Hold Inventory** if it is one at which meters and items can be stored. Otherwise, indicate that it is Not Allowed.

Note:

Hold Inventory is typically Not Allowed on "notional" stock locations used to group together detailed stock locations. You can view a stock location's subsidiary locations in the tree at the bottom of this page.

If the **Stock Location** is subsidiary to a higher-level stock location, define its immediate **Parent Stock Location**. Refer to [The Big Picture Of Stock Locations](#) for more information about parent locations.

Enter any **Comments** about the stock location.

The [tree](#) at the bottom of the page shows the hierarchy of stock locations associated with the **Stock Location** selected in the search.

Where Used

Stock location history records reference a stock location. Refer to [Stock Location History Is Created Behind The Scenes](#) for more information.

Stock Location - Characteristics

The characteristics page contains information that describes miscellaneous information about the stock location. Open this page using **Menu > Meter > Stock Location > Search** and navigate to the **Characteristics** page.

Description of Page

Use the **Characteristics** collection to define miscellaneous information to be kept for stock locations. For example, a premise ID can be specified as a characteristic to identify the address of a stock location.

Note:

You can only choose characteristic types defined as permissible on the stock location record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

To modify a characteristic, simply move to a field and change its value. To add a new characteristic, click + to insert a row, then fill in the information for each field. The following fields display:

Effective Date Define the date on which the characteristic becomes effective. The effective date defaults from the [Installation Record](#).

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Maintaining Stock Location Inventory

The topics in this section describe how to view and maintain the contents of a given stock location.

Refer to [The Big Picture Of Asset Inventory](#) for more information.

Stock Location Inventory - Main

This page contains a tree that shows:

- A summary of the number of items and meters located at a stock location (that can hold inventory).

Refer to [The Big Picture Of Asset Inventory](#) for more information.

Open this page using **Menu > Meter > Stock Location Inventory**.

Description of Page

This page contains a **tree** that shows a summary of the types of meters and items stored at the location. Refer to [The Big Picture Of Stock Locations](#) for more information.

If you click an **Item Count** node, you will be transferred to the [Stock Location Inventory - Item Inventory](#) page where you can see the details of the individual items of a given type located at the **Stock Location**.

If you click on a **Meter Count** node, you will be transferred to the [Stock Location Inventory - Meter Inventory](#) page where you can see the details of the individual meters of a given type located at the **Stock Location**.

Stock Location Inventory - Item Inventory

This page is used to display the individual items of a given type that are stored at a stock location. Refer to [The Big Picture Of Asset Inventory](#) for more information.

Open this page using **Menu > Meter > Stock Location Inventory** and navigate to the **Item Inventory** page.

Description of Page

This page displays the individual items that are stored at a **Stock Location** as of a given **Date/Time**.

The easiest way to display inventory for a given **Item Type** at a **Stock Location** is to navigate to the [Stock Location Inventory - Main](#) tab and find the **Stock Location**. Then, click on an **Item Count** line.

You can restrict the list using the following filter options:

- Use the **Item Type** filter to restrict the meters to those of the given meter type.

- Use the **Badge Number** filter to restrict the list to meters that have a badge number beginning with or matching this value.

Don't forget to click the search button after changing the filters.

The **Select All / Clear All** buttons are used to select items to be transferred to another stock location. These buttons are enabled if at least one item is displayed in the grid.

The grid contains the item inventory at the selected stock location on the given date/time that match your filter criteria. The following information is displayed in the grid:

- Select box. Use this checkbox to select items that you want to transfer to another stock location. This checkbox is enabled if the item is currently stored at this location and location is tracked for the item's item type. Refer to [How to Transfer Assets To Another Location](#) for more information.
- The description of the item's **Item Type**.
- The item's **Badge Number**.
- The item's **Serial Number**.
- The **Manufacturer/ Model** of the item.
- The **Location Date/Time** when the item was added to this stock location.
- If the item was subsequently removed from this stock location, the **Subsequent Location** column shows either the stock location it was transferred to or the service point it was installed at.

Pressing the **Transfer Location** button enables you to transfer the selected items to another stock location. This button is enabled if at least one meter in the grid is selected. Refer to [How to Transfer Assets To Another Location](#).

Stock Location Inventory - Meter Inventory

This page is used to display the individual meters of a given type that are stored at a stock location. Refer to [The Big Picture Of Asset Inventory](#) for more information.

Open this page using **Menu > Meter > Stock Location Inventory** and navigate to the **Meter Inventory** page.

Description of Page

This page displays the individual meters that are stored at a **Stock Location** as of a given **Date/Time**.

The easiest way to display inventory for a given **Meter Type** at a **Stock Location** is to navigate to the [Stock Location Inventory - Main](#) tab and find the **Stock Location**. Then, click on a **Meter Count** line.

You can restrict the list using the following filter options:

- Use the **Meter Type** filter to restrict the meters to those of the given meter type.
- Use the **Badge Number** filter to restrict the list to meters that have a badge number beginning with or matching this value.

Don't forget to click the search button after changing the filters.

The **Select All / Clear All** buttons are used to select meters to be transferred to another stock location. These buttons are enabled if at least one meter is displayed in the grid.

The grid contains the meter inventory at the selected stock location on the given date/time that match your filter criteria. The following information is displayed in the grid:

- Select box. Use this checkbox to select meters that you want to transfer to another stock location. This checkbox is enabled if the meter is currently stored at this location and location is tracked for the meter's meter type. Refer to [How to Transfer Assets To Another Location](#) for more information.
- The description of the meter's **Meter Type**.
- The meter's **Badge Number**.
- The meter's **Serial Number**.
- The **Manufacturer/ Model** of the meter.
- The **Location Date/Time** when the meter was added to this stock location.

- If the meter was subsequently removed from this stock location, the **Subsequent Location** column shows either the stock location it was transferred to or the service point it was installed at.

Pressing the **Transfer Location** button enables you to transfer the selected meters to another stock location. This button is enabled if at least one meter in the grid is selected. Refer to [How to Transfer Assets To Another Location](#) for more information.

Case Management

Note:

Separate module. The Case Management functionality is associated with a separate Case Management module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

Your organization can use case management functionality to manage a variety of situations, such as:

- a high-bill complaint,
- a bankruptcy,
- an inspection of a premise,
- a customer's request for literature,
- a contractor's request to extend a line,
- a customer's rejection of a quote,
- a customer's request to change information on a future date,
- the processing of a market message in a deregulated environment

Note:

Your implementation controls how your cases behave. Since virtually all aspects of case management functionality are controlled by your implementation, you can use it to handle a myriad of business requirements. Refer to [Defining Case Management Options](#) for the details.

Background Topics

The topics in this section provide background information about case management functionality.

Case Type

A case is controlled by the case type that it references. Some aspects of the case that are controlled by the case type include:

- The [lifecycle](#) of the case
- The [applicability](#) of a person, account, and/or premise on the case
- Which [fields are required](#) during the various stages of a case's life
- Which users can [access cases](#) of a given type
- Additional processing that should take place when a case enters or leaves a given state

Refer to [Case Type Controls Everything](#) for a description of the business rules that you control when you set up your case types.

Creating Cases

To create a case, open the [case management](#) page in add mode, select the appropriate case type, fill in the other necessary fields, and click save. Oracle Utilities Customer Care and Billing also includes scripts that can help create cases. Refer to [Scripts and Cases](#) for more information.

You can also develop plug-ins and user exits to so that the system will create cases when specific events take place. For example, you could set the system to create a case when an umbrella agreement is ready for renewal or when a quote is created.

Please refer to [Maintaining Cases](#) for a detailed description of the case page and field descriptions.

Log Information

A case log contains an entry for every recorded event during the lifecycle of the case. There are two types of log entries:

- **Automatic entries.** The system automatically creates an entry in the log when a case is created or there is a [status change](#). Users cannot modify or delete these log entries.
- **Manual entries.** Users can add manual entries to record significant events at their discretion.

Refer to [Case - Main](#) for the page used to view the log.

Refer to [Case Statistics for a Given Status](#) for information about a report that uses the log to provide productivity statistics.

Alerts

The [alert zone](#) will highlight if the person / account / premise in context have cases in a state that is configured as "alertable" if you plug-in the appropriate algorithm on the installation record. Refer to [Alert Info Is Controlled By An Installation Plug-In](#) for the details.

To Do's and Cases

You can configure the system to inform users of cases that require their attention. Refer to [To Do's and Cases](#) for the details.

Reports

Several reports summarize case information. Refer to the [Reports](#) chapter for the details.

Maintaining Cases

Your organization can use the case management functionality to manage a variety of situations, such as:

- a high-bill complaint,
- a bankruptcy,
- an inspection of a premise,
- a customer's request for literature,
- a contractor's request to extend a line,
- a customer's rejection of a quote,
- a customer's request to change information on a future date,
- the processing of a market message in a deregulated environment

Note:

Since an implementation can configure virtually every aspect of a case, the look and feel of the case management page are dynamic based on how [case types](#) have been configured.

Case - Main

Open the case management page by selecting **Menu > Customer Information > Case > Search**.

Main Information

Case Info contains a concatenation of important information about the case. **Case ID** is the system-assigned unique identifier of the case. These values only appear after the case is added to the database.

Note:

Formatting may be performed by a plug-in. Refer to [Case Info May Be Formatted By An Algorithm](#) for more information.

Case Type defines the type of case. This field is protected after the case has been added. Refer to [Case Type Controls Everything](#) for more information.

Note: Available case types can be restricted by CIS Division. The restriction of case type by CIS division is dynamic. It is based on the account in context, the premise in context, or the current user. The restriction of case type is applied using these rules in sequence.

- If there is an account in context and that account has a CIS Division, that CIS Division is used to restrict the case types that appear.
- If there is a premise in context and that premise has a CIS Division, that CIS Division is used to restrict the case types that appear. Note: If there are both an account and premise in context, the account CIS Division is used.
- If there is no account or premise in context with a CIS Division and the current user is associated with CIS Division(s) those CIS Division(s) are used to restrict the case types that appear. See [Users and CIS Division](#) for more information.

Status shows the current state of the case. Refer to [Case Lifecycle](#) for more information.

If the case has any To Do entries associated with it, a hyperlink will appear summarizing the number and status of the entries. You can select the link to view these entries. Refer to [To Do's and Cases](#) for more information.

Date / Time Opened shows when the case was created. If the case is in a final state, the **Date / Time Closed** will also be shown. Refer to [One Initial State and Multiple Final States](#) for more information.

Script references the business process assistant script that can help you work on the case. You can click on the hyperlink to execute this script. This field is hidden if no script is associated with this case's current Status. Refer to [Scripts and Cases](#) for more information.

The **Actions** section contains buttons you can use to action the case. This area is suppressed if no actions can be performed for the case given its current status. A button will be gray if you do not have security rights to the action. Refer to [Buttons Are Used To Transition A Case](#) for more information.

When the user adds a new case or changes the state of a case manually the system attempts to auto-transition the case to subsequent statuses as necessary. If auto-transition rules apply to the new state (and to subsequent ones) they would be executed right away. If the case has been automatically transitioned to its current state the following message area appears right after the action area. If an error is encountered in the process a corresponding error message is displayed in the Auto-transition Message Area. Refer to [Automatic Transition Rules](#) for more information.

Note:

The Auto-transition Message Area only appears when a case has just been automatically transitioned to its current state online. It only remains visible until the data for the case is refreshed.

Use the **Comments** area to describe anything interesting or unusual about the case.

Person references the person associated with this case. This field is suppressed if the Case Type indicates that a person is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final). This value is defaulted to the Person currently displayed in the Sidebar.

Account references the account associated with this case. This field is suppressed if the Case Type indicates that an account is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final). This value is defaulted to the Account currently displayed in the Sidebar.

Premise references the premise associated with this case. This field is suppressed if the Case Type indicates that a premise is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final). This value is defaulted to the Premise currently displayed in the Sidebar.

Note:

The case type controls the relationship validation among person, account, and premise.

Responsible User references the user who has overall responsibility for the case. This field is suppressed if the Case Type indicates that a responsible user is not allowed on cases of this type. This field is protected if the case is closed (i.e., if its status is defined as being final).

The **Contact Information** area is used to define how to contact the individual who initiated the case. These fields are suppressed if contact information is not allowed on cases of this type. The fields cannot be modified if the case is in a closed status. The following information can be defined.

Contact Person references the person who should be contacted. This defaults to the Person defined above.

Preferred Contact Method indicates how the person prefers to be contacted. The following options are available:

- Not Applicable. If the person doesn't want to be contacted (or the contact method is unusual), use this option. You might want to consider describing the situation in the Contact Instructions.
- Person Contact. If this method is selected, select a person contact related to the Person link to the customer contact. The customer contact must contain a Person to use this method.
- Postal. If this method is selected, the Contact Person's address appears. Refer to [Where Does The Address Come From](#) for a description of which address the system displays.

The following methods appear when the Legacy Person Phone and Email **Option Type** on the Customer Information Options [Feature Configuration](#) has been enabled.

- Email. If this method is selected, the Contact Person's email address appears adjacent.
- Phone. If this method is selected, the Contact Person's phone number appears.
- Fax. If this method is selected, the Contact Person's fax number appears (the system knows which of a person's phone numbers is a fax number by the phone type).
- SMS. If this method is selected, the Contact Person's short message service (SMS) information displays.

Note: While on a case, users can add a person contact by selecting Add Person Contact from a Person Context menu. This will open a portal-based page that allows a person contact to be added. This process will not lose context or information that has been added to the case. The new person contact can be used within the case.

Contact Instructions indicates any special instructions indicated for when or how to return a call.

Callback Phone Type, Callback Phone Number, and Extension indicate the actual phone number and phone type that should be used to call.

Characteristics

The **Characteristics** grid contains fields that contain important information about the case. This grid is suppressed if the Case Type does not use characteristics. This grid is protected if the case is closed (i.e., if its status is defined as being final).

You can only choose **Characteristic Types** defined as permissible for this case type. Refer to [Additional Information](#) for more information. If you attempt to use an **Action** to transition a case into a status that requires additional information, a pop-up will prompt you for the additional fields. Refer to [Required Fields Before A Case Enters A State](#) for more information.

Case - Log

To view the log entries associated with a case, open by selecting **Menu > Customer Information > Case > Search** and navigate to the **Log** page.

Description of Page

The **Log** grid displays log entries (in reverse chronological order) that audit the progress of the case. Please note the following about the entries in this grid:

- The system automatically creates log entries when a case is created, every time its status changes, or whenever an error occurs during the transition of a case. Algorithms plugged into a case type state can also be configured to create log entries. You cannot modify or delete the log entries.
- You can manually add a log entry by pressing the + button and enter the **Details**. You cannot modify or delete this information after saving it.
- The following information appears in the grid:
- **Log Date/Time** contains the date and time the log entry was created.
- **Details** contains user-specified or system-generated information about the log entry.
- **Related Object** is populated on log entries that were created to record the creation of some other object. For example, if a case plug-in creates a customer contact, the related object contains information about the customer contact. Please note that if the object description is shown in blue, you can click on the object's description to drill down to the object.
- **Log User** contains the user who caused the log entry to be created.
- **Log Type** indicates how the log entry was created. The possible values are:
 - Created. Only one entry per case will be of this type. This entry is automatically created by the system when the case is created.
 - User Details. A user creates this type of entry manually.
 - Status Transition. This type of entry is created by the system each time the case's status is changed (as a result of pressing one of the Action buttons).
 - System. An algorithm on the case type state may be designed/configured to create this type of entry when it does something auditable. For example, an algorithm that creates a customer contact could insert a log entry to show that it did this (it will also populate the FK to the customer contact, which will appear in the **Related Object** column).
 - Transition Error. The background status transition process creates an entry of this type if an error occurs when automatically updating a case to a subsequent status (as directed by either an Enter Status algorithm or an Auto-Transition algorithm). An entry of this type lists the case states involved with the failed transition, and the algorithm in which the error was generated.
 - Exception. The background status transition process creates an entry of this type under the same circumstances as a Transition Error. A log entry of this type indicates why the background transition failed.

Note:

The values for this field are customizable using the Lookup table. This field name is CASE_LOG_TYPE_FLG.

Premise Management

Note:

Separate module. The Premise Management functionality is associated with a separate Premise Management module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

The premise management functionality facilitates the following:

- Grouping premises together under a single parent premise
- Quick & efficient setup and maintenance of apartment complexes and high-rises
- A single view of properties for a landlord, including service status
- Ability to change the landlord or service status for a group of premises in one transaction
- And more...

The topics in this section describe premise management functionality.

Overview

The topics in this section provide background information about premise management functionality.

Define Premise Hierarchy

Premise management allows you to define premise hierarchy. For example, you could also have the notion of

- A building
- Multiple floors
- Multiple apartments per floor

To define this hierarchy you must create a [premise](#) for each level in the hierarchy and for each "child" premise, indicate its appropriate parent premise. Once you have set up your premise hierarchies, you may view the hierarchies on trees on the premise page and on the control central [premise tree](#).

In addition, the system provides the following [alerts](#):

- When viewing a parent premise, an alert indicates how many child premises exist
- When viewing a child premise, an alert indicates that it is linked to a parent premise.

Manage Premises for a Landlord

The premise management page provides the ability to view all the premises for the landlord along with information about the accounts linked to each premise.

You may use this page to assign, change or remove the landlord agreement for multiple premises in a single action. For example if a landlord sells their properties to another person, this page facilitates updating all premises with one action rather than changing the landlord for each premise separately. For example, if the landlord sells only a portion of their properties.

This page may also be used to start or stop service for one or more premises for the landlord. For example, a landlord plans to sell a high-rise apartment complex with 100 apartments. Imagine that 8 of these apartments are vacant and the landlord's account is currently paying for any usage to these apartments. In addition to changing the landlord agreement for all 100 apartments to the new landlord, the service for the vacant apartments should be transferred to the new landlord. A user can go to premise management, use the search criteria to view all premises for this landlord in a given apartment complex whose service is currently being paid for by the landlord and start service for these premise for the new landlord. (Using the back-to-back start/stop functionality, service will be stopped for the old landlord.)

Manage Groups of Premises

The powerful search criteria on the premise management page allows you to view different groups of premises based on any combination of account information, landlord information, parent premise address information and general geographic type information. You may also define search criteria such as "premises **not** linked to account 1234567890" or "premises linked to **any** landlord" or "premises **not** linked to any parent premise". For example, you could display all premises in a given latitude / longitude that are not linked to any parent premise.

Once your search results display the desired list of premises, you could perform mass updates such as assigning a parent premise or starting service. Following are examples of situations where this page would be helpful:

- The developer of a high-rise condominium complex is ready to start service for a group of condos. A user uses the premise management search criteria to display the premises linked to a give parent premise (representing the condo complex) that are not linked to any account. The user selects the premises in this list that the developer would like to start and starts service for all premises at once.
- There is a shopping mall in your service territory and each store in an individual premise. You may decide to define a parent premise for the entire shopping mall and link each store's premise to the parent. Once the parent premise is defined, a user navigates to the premise management page and displays the individual premises based on a similar address or based on a similar geographic type. The user then assigns the parent premise for all the individual premises using a single action.

Premise Management Page

This page allows you to display a list of premises using a combination of search criteria. In addition, you can perform actions on one or more of the resulting premises, including:

- Assigning a parent premise to one or more premises
- Removing the link to a parent premise from one or more premises
- Assigning a landlord to one or more premises
- Removing the link to a landlord from one or more premises
- Start service for one or more premises
- Stop service for one or more premises

Open this page using **Menu > Customer Information > Premise Management**.

Description of Page

The top half of the page is where you enter the criteria used to search for premises.

Note:

Multiple search criteria may be specified. You can search for premises using a combination of search criteria. For example, if you enter both a **Parent Premise Filter** of Linked To Any Premise and an **Account Filter** of Not Linked to Any Account; only those premises that have a parent premise but are not linked to an account will be displayed.

At least one positive criterion is required. You may not define your search criteria to only use filter values that start with "Not Linked...". At least one "positive" filter value is required.

The following table describes each of the different search methods.

| Search Method | Description |
|-----------------|--|
| Landlord Filter | <p>Use this filter to narrow down your search based on landlord. Enter one of the following values:</p> <p>Not Applicable</p> <p>Linked To This Landlord - for this option, you must enter a Landlord Agreement</p> <p>Not Linked To This Landlord - for this option, you must enter a Landlord Agreement</p> <p>Linked To Any Landlord</p> <p>Not Linked To Any Landlord.</p> <p>A filter value of Not Applicable defaults.</p> |

Parent Premise Filter

Use this filter to narrow down your search based on parent premise. Enter one of the following values:

Not Applicable

Linked To This Parent Premise - for this option, you must enter a **Premise ID** for the parent premise

Not Linked To This Parent Premise - for this option, you must enter a **Premise ID** for the parent premise

Linked To Any Parent Premise

Not Linked To Any Parent Premise.

A filter value of Not Applicable defaults.

Account Filter

Use this filter to narrow down your search based on account. Enter one of the following values:

Not Applicable

Linked To This Account - for this option, you must enter an **Account ID**

Not Linked To This Account - for this option, you must enter an **Account ID**

Linked To Any Account

Not Linked To Any Account.

A filter value of Not Applicable defaults.

Premise Filter

Use this filter to narrow down your search based on account. Enter one of the following values:

Located At This Address - for this option, you must enter address constituents

Located At This Geographic Type / Value - for this option, you must enter a **Geo Type** and **Value**

Not Applicable

Show This Specific Premise - for this option, you must enter a **Premise ID**

A filter value of Not Applicable defaults.

The **Select All** / **Clear All** buttons are used to select premises if you plan on issuing any of the mass update actions at the bottom of the page. Refer to the description of the "mass update" actions below for more information.

**Note:**

50 premises at a time. Clicking **Select All** selects the first 50 premises in the grid. If more than 50 premises exist, you must select them in batches.

The grid that follows contains the premises that match your search criteria. The following information appears in the grid:

- Select box. Use this checkbox to select premises for mass update actions.
- The **Premise Information** column shows information about each premise. Click the hyperlink to transfer to the [Premise](#) page where you can update information about the premise in question.

- The **Account Information** column shows information about all accounts linked to the premise, if any. Only accounts with non-canceled, non-closed service agreements linked to this premise are displayed. The column displays the name of the customer's main person followed by a list of status values for any of the account's service agreements linked to this premise. For example, you may see Customer A (pending stop), Customer B (pending start). If multiple service agreements linked to the account & premise have the same status, the status is only displayed once.
- The **Parent Premise Information** column displays information about the premise's parent premise, if one exists.
- The **Landlord Information** column displays the landlord agreement description for the premise's landlord, if there is one.

This transaction has sophisticated logic that can be used to perform "mass updates" to the premises that appear in the grid using the buttons at the bottom of the page. The buttons are enabled if you select at least one row from the premise grid. The following points describe these mass update actions:

Start Service

The **Start Service** button is used to start service for one or more premises. When clicked, the **Start SA Groups Confirmation** window opens.

Note:

Similar to Start/Stop. This page is similar to the Start SA Confirmation page that appears on start/stop. The differences are to accommodate starting multiple premises.

In order to start service for the selected premises, select the **Account ID**.

The **Start Date** is the date on which the service is scheduled to start.

Use **Start Requested By** to indicate the name of the person who requested the start.

Check **Include Child Premises** if all the child premises in the hierarchy below the selected premises should also be started for this account.

Click **Show SA Groups** to populate the remainder of the page.

The **Service Points** section summarizes the service points that exist for all the chosen premises. A row is displayed for each different **SP Type** along with a **Count** of the number of service points of that type. By default, all rows are checked, assuming that you want to start service for all service points (and the SA Groups To Start scroll below displays proposed SAs to start for each SP type). You may uncheck any SP Type row if you do not wish to start service for that SP type. Click **Show SA Groups** to rebuild the SA Groups To Start information.

Warning:

This page displays summary information about the service agreements and service points that are being turned on. It is recommended that you start groups of premises that have similar service point configurations. If you attempt to start service for many premises, each with different service point configurations, the start logic may be very complicated to verify on this page.

The **SA Groups To Start** scroll contains an entry for every service agreement that will be created if you click the **Start** button. If you do not want a service agreement to be created, click the - button or uncheck **Start this SA Group**. If you would like to start service agreements that are not SP-based service agreements (for example a deposit or a connection charge), click the + button to add a new SA group. The system assumes that you want to create a new service agreement for each selected premise.

Turn on the **Start this SA Group** switch if you want service agreements of this type to be created. If this is the first customer at the selected premises, this switch is checked for all service agreements that appear in the scroll. For each premise that was linked to a previous customer, this switch is on only for those types of service agreements used by the previous customer(s). (We assume the new customers only want the services used by the previous customers). Service agreements that are possible, but were not used by the previous customers, appear in the scroll with this switch turned off.

If **Start This SA Group** is checked, the system displays a message indicating the number of service agreements (for the number of service points) that will be created if you choose **Start**.

For a description of the remaining fields, refer to [Start/Stop - Start Confirmation](#).

Click **Start**. Standard [start](#) logic is followed when clicking start.

Note:

The start button is disabled if changes are made to fields on the page that may impact the SA Groups To Start collection. You must click **Show SA Groups** to rebuild the SA groups and enable the start button.

Stop Service

The **Stop Service** button is used to stop service for one or more premises.

Note:

that this functionality stops service for any account linked to the selected premises. If you want to stop service at the selected premises for only certain accounts, use the account filter criteria to narrow down the selection of premises prior to clicking **Stop Service**.

When clicked, the **Stop SA Group Confirmation** window opens.

In order to stop service for the selected premises, enter a **Stop Date**.

Enter a **Restrict to Account** if you want to stop only service agreements linked to this account. If not specified, all active services agreements for the premise are stopped regardless of the account.

Use **Stop Requested By** to indicate the name of the person who requested the stop.

Check **Include Child Premises** if the child premises in the hierarchy below the selected premises should also be stopped.

Click **Show SA Groups** to populate the remainder of the page.

The system builds a collection of service agreements currently linked to the service points for the selected premises. The grid contains the **CIS Division** and **SA Type** for each SA "group" and displays the number of service agreements in the **SA Group Summary**.

By default, the system checks each SA group assuming that you want to stop service for all SAs. You may uncheck any of the SA groups to not stop service for those SAs.

Click **Stop**. Standard [stop](#) logic is followed when clicking stop.

Note:

The stop button is disabled if changes are made to fields on the page that may impact the SA collection. You must click **Show SA Groups** to rebuild the SA collection and enable the stop button.

Assign Parent Premise

The **Assign Parent Premise** button is used to assign a parent premise to one or more premises. When clicked, the **Assign Parent Premise** window opens.

Specify the **Parent Premise ID** and click **Assign**.

Remove Parent Premise

The **Remove Parent Premise** button is used to remove the parent premise from one or more premises. When clicked, the parent premise ID of all selected premises is reset.

Assign Landlord

The **Assign Landlord** button is used to assign a landlord to one or more premises. When clicked, the **Assign Landlord** window opens.

Specify the **Landlord** agreement ID.

Check **Include Child Premises** if the child premises in the hierarchy below the selected premises should also be assigned this landlord.

Click **Assign**.

Remove Landlord

The **Remove Landlord** button is used to remove the landlord agreement from one or more premises. When clicked, the **Remove Landlord** window opens.

Check **Include Child Premises** if all the child premises in the hierarchy below the selected premises should also have their landlord agreement removed.

Click **Remove**.

Umbrella Agreement Management

Your organization may use umbrella agreement functionality to manage many situations, including (but not limited to) the following:

- Creating a "negotiated contract" with a large customer with many sites.
- Creating a "negotiated contract" with all customers in a common geographic area, for example a specific city or an apartment complex
- Grouping and managing the proposal service agreements created during the quoting process
- Managing the renewal process for special contracts
- Applying override rate terms to one or more service agreements for a given effective period
- more...

Note:

Separate module. The umbrella agreement functionality is part of the Contract Management module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

Overview Of Umbrella Agreement & Terms Of Service

An umbrella agreement is used to group together terms for a contract. It contains high level information about the contract such as the effective dates, the renewal date, if applicable and an account management group, if applicable. You may also define characteristics and [contacts](#) for the umbrella agreement.

The terms of the umbrella agreement are defined using one or more terms of service (TOS) records. For each TOS record, you must link one or more service agreements to indicate the services covered under the TOS.

| UA | | | | | | | | | | | |
|--|-----------------------------------|-------------------------------|---------------------------------|-------------|---|----------------------------------|--------------------|-----------------------------------|--------------|---|----------|
| ID: 41786547792 | | Descr: McDonald's Contract | | | | | | | | | |

The Terms of Service may point to a 'template service agreement' as a way to specify the rating terms and conditions to be used by all service agreements linked to the TOS. If a TOS does not define a template SA, then the TOS is used largely as a grouping mechanism rather than a billing mechanism.

Umbrella agreements and their terms of service records are used to support specific business scenarios that your organization supports.

TOS Covered Entities

Your implementation may configure a Terms of Service type to require that entities "covered" by the terms of service record be referenced on the TOS. For example, imagine that you define an umbrella agreement to provide special discounts to all the McDonalds franchises in your service area. When creating the terms of service record for the umbrella agreement, you may link the person record representing the McDonalds corporate entity as a covered entity for the TOS.

Note:

that there is no base product functionality that uses this collection. However, your implementation may use this information in an algorithm, for example, it could be used in a campaign / package eligibility algorithm.

Refer to [Terms Of Service Covered Entities](#) for information about defining covered entities for a terms of service type.

Rate Terms Overridden By Terms Of Service

Your organization may require rate information to be temporarily overridden for a service agreement that is linked to a TOS. In order to do this, the TOS record must reference a template SA. Refer to [Overriding Rate Terms](#) for information about defining your Terms of Service types to support template service agreements.

The topics in this section further describe the possible rate term overrides that may occur when a service agreement is linked to a terms of service record.

Rate Schedule Override by TOS

If a service agreement is linked to a terms of service, you may configure the system to use the rate schedule from the terms of service record's template SA rather than the one from the customer's service agreement. The customer's SA type controls this option.

Fastpath:

Refer to [Configure SA Types for Umbrella Agreements](#) for more information.

If a service agreement is linked to a terms of service record, the rate information tree on the service agreement's rate info tab tells the user whether the rate from the service agreement or from the template SA on the TOS is currently applicable.

If a given service agreement's rate schedule is being taken from the terms of service record's template SA, then the override rate schedule is used not just in bill calculations, but for any logic that requires the service agreement's rate schedule. For example, one of the recommended budget amount algorithms may estimate consumption and apply the service agreement's rate. In this case, the rate used by the algorithm is the one linked to the terms of service record's template SA.

Override Of Other Rate Terms By TOS

There are other terms associated with a rate that may change when linking a service agreement to a terms of service record that has a template SA. These include contract riders, contract terms and tax exemptions.

When applying the rate to create the customer's bill segment, if a bill factor on any of the calculation rules indicates that it is eligible for tax exemptions, contract terms or contract riders, a flag on the bill factor indicates where the system should look for the appropriate value. The Terms of Service Usage flag tells the system to find applicable information either on the TOS's template SA only, on the customer's SA only or it should first check the TOS, then check the customer's SA.

Fastpath:

Refer to [Configure Bill Factors for Umbrella Agreements](#) for more information.

Note:

Independent of rate source. The flag values on the bill factors are independent of the rate source setting for the SA type. For example, your implementation may configure the SA type's rate source to indicate that rate should be taken from the TOS template SA. However, if a bill factor is eligible for tax exemptions, your implementation may configure the bill factor to indicate that the exemption information should be taken from the customer's SA, not the template SA.

Umbrella Agreement Renewal

Although umbrella agreement records require an end date, your organization probably allows for renewal of agreements. A renewal may involve full re-negotiation of all terms, or may be as simple as extending the current terms. If umbrella agreements of a given type are eligible to be renewed, you configure the UA type to indicate how to calculate the renewal date and which algorithm to execute when the renewal date is reached.

Umbrella Agreement Renewal Background Process

The UA renewal background process ([UARENEW](#)) finds complete umbrella agreements whose renewal date has arrived and executes the renewal algorithm for the associated UA type.

Note:

It is the responsibility of the renewal algorithm to update the renewal date as per the business practice. Refer to [Renewable Umbrella Agreements](#) for more information.

Umbrella Agreements & Proposals

Umbrella agreements and their terms of service records may reference proposal service agreements. This functionality allows you to create the full contract for your customer during the quoting stage.

Additional Umbrella Agreement Topics

The following topics describe additional functionality related to umbrella agreements.

Umbrella Agreement Alerts

The [alert zone](#) will highlight if any of the account's SAs are linked to an effective umbrella agreement (via a non-canceled terms of service record).

Orders And Umbrella Agreements

When starting new service for a given account and premise, you may know ahead of time that the new service should be linked to an existing umbrella agreement. For example, perhaps all the service in a specific low income housing area qualifies for a special negotiated contract for the next year.

The system provides algorithms to allow you to add a new service agreement to an existing terms of service record when using the [Order](#) transaction to start service.

Refer to [Configure A Campaign To Link An SA To A Terms Of Service](#) for more information.

Umbrella Agreement Reports

The system supplies a [Report](#) providing umbrella agreement information for one or more umbrella agreements.

Umbrella Agreement Maintenance

Umbrella agreements help you manage your contracts by allowing you to group together service agreements for the contract with one or more terms of service records for the umbrella agreement.

Lifecycle Of An Umbrella Agreement

The following diagram illustrates the lifecycle of an umbrella agreement.

Pending The umbrella agreement is created in pending status.

You may delete a pending umbrella agreement. Deleting a UA also deletes its terms of service records.

Complete Only complete umbrella agreements are considered effective. You may transition a UA to complete if there is at least one terms of service record linked to it and if none of its TOS records are in pending status.

Under unusual circumstances, a complete umbrella agreement may be changed back to pending to correct errors.

Umbrella Agreement - Main

Open this page using **Menu > Umbrella Agreement Management > Umbrella Agreement > Search**.

Description of Page

Umbrella Agreement Info contains a concatenation of important information about the umbrella agreement.

Umbrella Agreement ID is the system-assigned unique identifier of the umbrella agreement. These values only appear after the UA is added to the database.

Umbrella Agreement Status shows the current state of the UA. The buttons adjacent to the status allow you to transition the UA's status.

- Click **Complete** to change the status of a pending umbrella agreement to complete.
- Click **Reopen** to change the status of a complete umbrella agreement back to pending.

Fastpath:

Refer to [Lifecycle of an Umbrella Agreement](#) for more information.

Enter a **Description** for the umbrella agreement.

The **Umbrella Agreement Type** defines the type of umbrella agreement. Refer to [Setting Up Umbrella Agreement Types](#) for more information.

The **Start Date** and **End Date** define the effective dates of the contract. If the UA type is renewable, the **Renewal Date** indicates the date the umbrella agreement is processed by the [renewal background process](#).

You may assign an **Account Management Group** to this umbrella agreement. The AMG controls the roles assigned to [To Do entries](#) associated with the umbrella agreement. Refer to [Setting Up Account Management Groups](#) for more information.

Use the **Comments** area to describe anything interesting or unusual about the umbrella agreement.

This bottom of this page contains a [tree](#) that shows the various objects linked to the umbrella agreement. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Umbrella Agreement - Contacts

The contacts page defines persons associated with the umbrella agreement. Open this page using **Menu > Umbrella Agreement Management > Umbrella Agreement > Search** and navigate to the **Contacts** page.

Description of Page

The contacts collection allows you to define persons that are associated with the umbrella agreement. For each contact, define the **Person ID** for the person record that contains the demographic information for the contact. For each contact, use the **Comments** to define information about the contact.

Umbrella Agreement - Characteristics

The characteristics page contains information that describes miscellaneous information about the umbrella agreement. Open this page using **Menu > Umbrella Agreement Management > Umbrella Agreement > Search** and navigate to the **Characteristics** page.

Description of Page

Note:

Characteristic Types. You can only choose characteristic types defined on umbrella agreement's [umbrella agreement type](#).

The following fields display:

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Note:

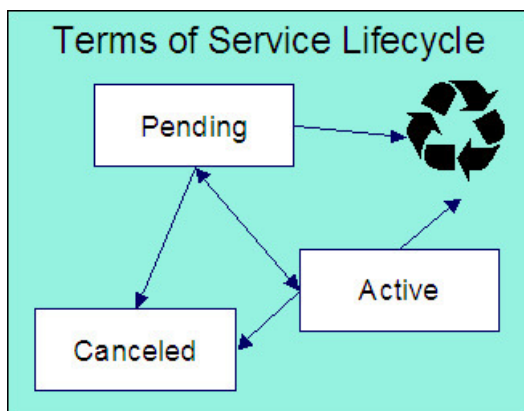

Default Note. An umbrella agreement's characteristics default from the [umbrella agreement type](#).

Terms Of Service Maintenance

A terms of service (TOS) record defines one or more service agreements participating in a given umbrella agreement. The TOS record may also reference a template SA that could be used to override rate terms for the participating service agreements.

Lifecycle Of Terms Of Service

The following diagram illustrates the lifecycle of a terms of service record.

Pending The terms of service record is created in pending status. You may delete a pending TOS. If you want to keep a record of the TOS, you may cancel it rather than deleting it.

Active Only active terms of service records are considered effective. Change the status to active when you have entered all the desired information for this TOS. You may delete an active terms of service if the umbrella agreement is still pending. (Otherwise you must cancel the TOS.)

Canceled You may cancel a pending or active terms of service if it should no longer be used. Canceling a terms of service record unlinks all its service agreements.

Terms Of Service - Main

Open this page using **Menu > Umbrella Agreement Management > Terms of Service > Search.**

Description of Page

Terms of Service Info contains a concatenation of important information about the terms of service record. **Terms of Service ID** is the system-assigned unique identifier of the terms of service record. These values only appear after the TOS is added to the database.

The **Umbrella Agreement ID** defines the umbrella agreement to which this terms of service is linked.

Status shows the current state of the terms of service record. The buttons adjacent to the status allow you to transition the TOS record's status.

- Click **Activate** to change the status of a pending terms of service record to active.
- Click **Pend** to change the status of an active terms of service record back to pending.
- Click **Cancel** to change the status of a pending or active terms of service record to canceled.

Fastpath:

Refer to [Lifecycle Of Terms of Service](#) for more information.

Enter a **Description** for the terms of service record.

The **Terms of Service Type** defines the type of terms of service record. Refer to [Setting Up Terms of Service Types](#) for more information.

Use the **Comments** area to describe anything interesting or unusual about the umbrella agreement.

The **Characteristics** collection contains information that describes miscellaneous information about the terms of service record.

Note:

Characteristic Types. You can only choose characteristic types defined on the terms of service record's [terms of service type](#).

The following fields display:

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Note:

Default Note. A terms of service record's characteristics default from the [terms of service type](#).

The **Covered Entities** collection allows you to define specific entities that are "covered" by this terms of service record. Refer to [TOS Covered Entities](#) for more information.

Note:

Characteristic Types. You can only choose covered entity characteristic types defined on the terms of service record's [terms of service type](#).

The following fields display:

Covered Entity Characteristic Type Indicate the type of characteristic used to define this covered entity type.

Characteristic Value Indicate the value of the characteristic used to define the covered entity value.

Note:

Default Note. A terms of service record's covered entity types default from the [terms of service type](#).

Terms Of Service - SAs

This page is used to maintain the service agreements linked to the terms of service record.

Open this page using **Menu > Umbrella Agreement Management > Terms of Service > Search** and navigate to the SAs page.

Description of Page

Terms of Service Info contains a concatenation of important information about the terms of service record. **Terms of Service ID** is the system-assigned unique identifier of the terms of service record.

The filters control the service agreements that appear in the grid. The following points describe the various options:

- Use the **SA Filter** to define the types of service agreements that appear in the grid. The following options are available:
 - **Account.** Use this option to restrict service agreements to those linked to a given **Account ID**.
 - **Address.** Use this option to restrict service agreements to those linked to service points associated with a given **Address, City** and/or **Postal** code. Note, you can specify any combination of these fields.
 - **All.** Use this option if you do not wish to restrict service agreements based on service agreement attributes.
 - **All Proposals.** Use this option to restrict service agreements to only proposal service agreements.
 - **All Real SAs.** Use this option to restrict service agreements to only "real" service agreements (i.e., not proposal SAs).
 - **Geographic Type.** Use this option to restrict service agreements to those linked to service points associated with a given **Geographic Type** and **Geographic Value**.
 - **SA Type.** Use this option to restrict service agreements to those linked to a given **CIS Division** and **SA Type**.
 - **Specific SA.** Use this option to reference a specific **SA ID**.
- Use **Status Filter** to restrict the service agreements based on their status. Status values for both proposal service agreements and regular service agreements are included in the filter. The following options are available:
 - **All.** This option shows all service agreements, including proposal service agreements, regardless of status.
 - Refer to [Service Agreement Lifecycle](#) for the various status values for real service agreements.
 - Refer to [Proposal SA State Transition](#) for more information about status values for proposal service agreements.

Don't forget to click the search button after changing the filters.

The grid that follows contains the **Service Agreements** that match your search criteria along with its **Account Info**.

Use the "+" to link new service agreements to the terms of service record.

Note:

Link SA Using Order. You may also [link a service agreement to a TOS through orders](#) if you have configured an appropriate campaign and package.

Note you may remove a service agreement from the TOS using the delete button as long as the change has not been committed to the database. As soon as the SA's link to the TOS has been committed to the database, you must use the **Remove** action to unlink the service agreement.

The **Select All / Clear All** buttons are used to select service agreements if you plan on issuing the mass update action **Remove** at the bottom of the page. Clicking **Remove** removes the service agreement from the terms of service record.

Job Streams

The term "job stream" refers to a suite of batch jobs that run periodically. Most organizations have multiple job streams. For example,

- You'll have a job stream that contains batch jobs that run nightly
- You'll have a different job stream that contains the hourly batch jobs
- You'll have a different job stream that contains the batch jobs that extract data for your data warehouse
- Etc.

The topics in this section describe how to execute and monitor your job streams.

Fastpath:

Refer to [The Big Picture of Scheduling Batch Jobs](#) for a description of how to set up the system to enable this functionality.

Note:

Only used by some organizations. Many organizations use a third party tool to manage the periodic execution of batch jobs rather than the system batch scheduler. If this is true for your organization, this section is not applicable.

Separate module. The batch scheduler functionality is associated with a separate Workflow Scheduling module. If this module is not applicable to your business, you may turn it off. Refer to [Turn Off A Function Module](#) for more information. .

Job Stream Summary

This page presents a summary of your job streams. Open this page using **Menu > Batch > Job Stream Summary**.

Description of Page

This page summarizes the status of your job streams.

Note:

Only job streams defined on the [Feature Configuration](#) for the Batch Scheduler appear on this page.

The following information is displayed for each job stream:

- **Job Stream.** This is the description of the job stream. Click the hyperlink to transfer to the job stream's workflow process template (the workflow process template defines the number and type of batch jobs in the job stream as well as their dependencies).
- **Cancel Button.** If the job stream is executing, a **Cancel** button appears. Pushing this button will cancel the execution of any batch jobs in the job stream that have not already started. Batch jobs that are currently executing will continue to execute until they conclude or are stopped in the operating system.
- **Start Button.** If the job stream is not executing, a **Start** button appears. Pushing this button submits the request to execute the job stream's batch jobs. The job stream's batch jobs will only execute when the batch submitter next runs. The batch submitter's [frequency of execution](#) is configured by your organization.
- **Last Completed Run.** This is the start date / time when the job stream last executed. In addition, the job stream's total elapsed time is displayed. Click the hyperlink to transfer to the [Job Stream Details](#) page where you can see the execution status of each batch job in the job stream.
- **Run In Progress.** This column only contains information if a job stream is executing. The date / time that the job stream was requested is shown as well as a colorful status bar. Clicking the hyperlink under the date / time transfers you to the [Job Stream Details](#) page where you can see the execution status of the job stream's batch jobs.
- The status bar provides a visual clue as to the execution status of the job stream's batch jobs. The bar's segments and their colors are used to highlight the relative number of batch jobs in a given state. For example, it will highlight the relative number of Pending versus Complete versus Error batch jobs.

You can hover the mouse over a section of the bar to see the number of batch jobs in each state. You can click on a segment of the bar to drill down to the [Job Stream Details](#) page. When this page appears, only the batch jobs in the respective state are displayed.

The message Other(s) running appears if more than one instance of this job stream is running (this should be rare).

- **Next Scheduled Run.** This is the start date / time when the job stream is next scheduled to run. Click the hyperlink to transfer to the [Job Stream Creation Schedule](#) page where you can define when the job stream runs. You can also use this transaction to hold prescheduled runs.

Job Stream Details

Job streams execute many times over their lifetime. For example, the nightly job stream executes every night; the hourly job stream executes hourly; the data warehouse extract executes weekly; etc.

Every time a job stream executes, a workflow process is created. The workflow process's events cause the job stream's batch jobs to be submitted.

This page shows the status of the job stream's workflow events and the batch jobs that they submit. Open this page using **Menu > Batch > Job Stream Details**.

Description of Page

Job Stream is a concatenation of important information about the execution of the job stream (e.g., its description, status, start date).

Job Stream ID is the system-assigned unique identifier of an execution of the job stream.

Note:

The Job Stream ID is the unique identifier of the workflow process used to manage the execution of the job stream's batch jobs.

The colorful status bar summarizes the execution status of the job stream's batch jobs. This bar's segments and their colors are used to highlight the relative number of batch jobs in a given state. For example, it can highlight the relative number of Pending versus Complete batch jobs (Pending jobs are one color, Complete jobs another).

You can hover the mouse over a section of the bar to see the number of batch jobs in each state. You can click on a segment of the bar to cause the grid to be refreshed with batch jobs in the respective state. For example, if you click on the color used to highlight jobs in Error, only these jobs will appear in the grid. You can achieve the same results by selecting the desired **Event Status**.

If the job stream is executing, a **Cancel Job Stream** button appears. Pushing this button will cancel the execution of any batch jobs in the stream that have not already started. Batch jobs that are currently executing will continue to execute until they conclude or are stopped in the operating system.

The grid contains a summary of the job stream's workflow events and the batch jobs that they submit. The following information is displayed for each workflow event:

- **Event** describes the workflow event that submits the batch job (the code following the description is the workflow event's type).
- The colorful box that prefixes the event provides a visual clue of the event's status (e.g., Pending events are one color, Waiting another, etc.). These colors correspond with the "status bar" at the top of the page.

Click on the hyperlink to transfer to the [workflow event](#). You might need to display a workflow event if:

- You need to cancel a Pending or Waiting event. To do this, display the event and change its status to Canceled. Note, if the Waiting event is associated with a batch job that is currently executing, canceling the event will NOT abort the execution of the batch job. The only way to abort the execution of a batch job that is executing is via the operating system.
- You need to restart a batch job that's in Error. To do this, display the workflow event and change its status to Pending.
- **Batch Run** provides an overview of the batch job submitted by the workflow event:
 - If the corresponding workflow event is Pending, the batch job has not been submitted yet. There are two reasons why an event may be Pending:
 - If the event is waiting for the batch submitter to run, the message Starting soon... appears. The next time the batch submitter runs, the batch run will be executed. The batch submitter's [frequency of execution](#) is configured by your organization.
 - If the event is waiting for the successful completion of other events, a message describing the events on which it is waiting is shown. You define the dependencies between events (i.e., batch jobs) when you set up the job stream's workflow process template.
 - If the corresponding event is Waiting, the batch job is currently executing and a summary of the execution status is shown. You can click on the hyperlink to transfer to the Batch Run Tree where the details of the run's parallel threads and errors are shown. Note, a summary of the various threads and errors is shown in the next column.
 - If the corresponding event is Complete, Failed, or Error; the batch job has completed and a summary of its execution is shown. You can click on the hyperlink to transfer to the [Batch Run Tree](#) where the details of the run's parallel threads and errors are shown.

- **Batch Run Details** provides more extensive details about a batch run's execution. The following information is shown:
 - You can configure the workflow event to execute multiple parallel threads of a given batch job. For example, rather than running a single instance of the BILLING batch job, you can indicate 40 parallel threads should run (thus improving throughput). This column always contains a summary of the execution status of the parallel threads.
 - The number of records processed by the job. For example, if this is the BILLING job, the number of records shows the number of accounts for which bills were created.
 - The number of errors detected during the batch job (this information appears in red).
 - The average, minimum and maximum execution time per thread.
- You can click on the hyperlink in the adjacent column to transfer to the [Batch Run Tree](#) where the details of the run's parallel threads and errors are shown.

Workflow and Notifications

We use the term "notification" to reference the electronic transactions that you exchange with third parties when:

- They need information about a customer
- They need to change something about a customer

For example, an energy service provider sends a notification to a distribution company when a customer chooses them as their energy provider. When a notification is received by the distribution company, the system responds by creating a workflow process. The workflow process contains workflow events. These events perform the processing necessary to execute the notification.

In addition to processing incoming notifications, workflow processes can be used to automate many different types of multi-event processes. For example, you can use workflow processing to manage the events associated with the inspection of a new premise.

This section describes how to manage your workflow and notification processing.

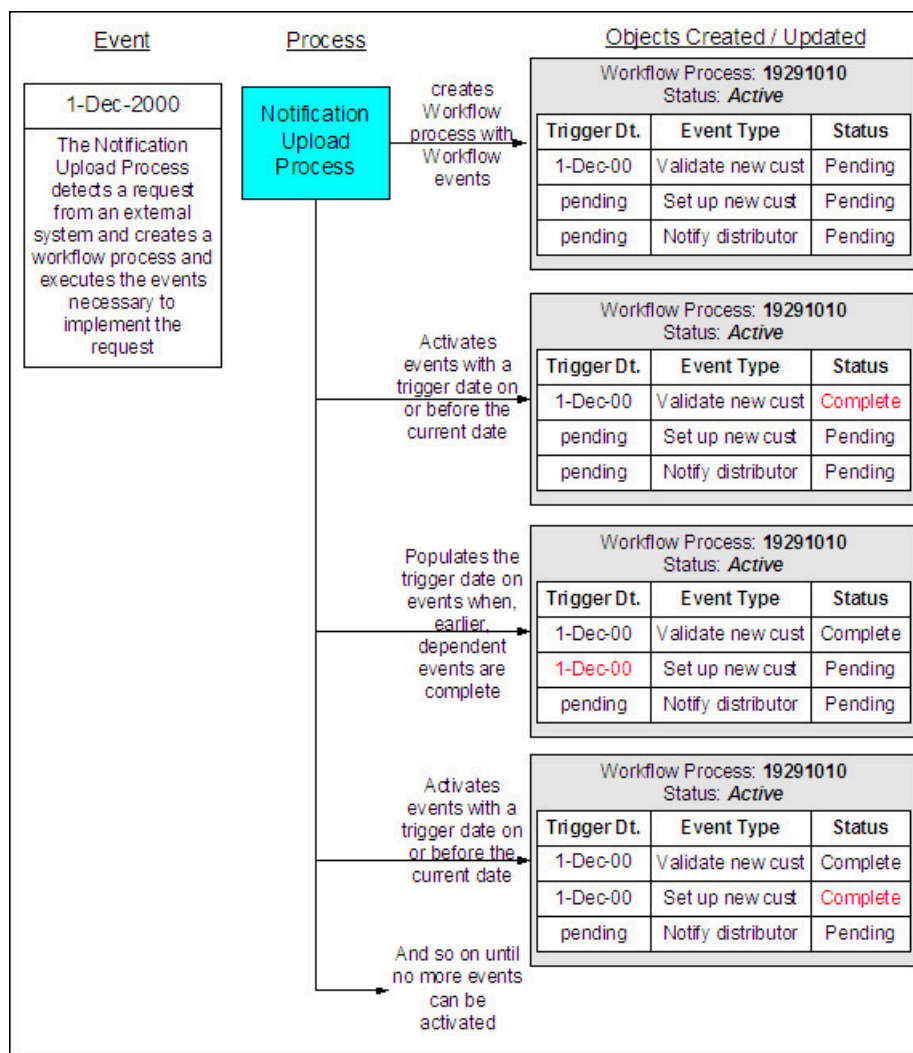

Note:

In the section, [Defining Workflow and Notification Options](#), we describe how to set up the control tables that automate most of your notification and workflow processing. If you set these tables up properly, little or no operator intervention should be necessary. You should only have to access the workflow and notification pages when you need to override the standard procedures embodied in your workflow processes.

The Lifecycle Of A Workflow Process And Its Events

The following diagram illustrates the lifecycle of a typical workflow process and its workflow events:

The preceding diagram is referenced in the following topics.

What Is A Workflow Process?

A workflow process is difficult to define because its flexible design can be used to automate many different types of multi-event processes. For example,

- You can use a workflow process to manage the events associated with the inspection of a new premise.
- You can use a workflow process to manage the events that transpire in a deregulated market when a customer wants to switch energy service providers.
- You can use a workflow process to notify interested parties when something about a customer changes. For example, if a customer changes their phone number, a workflow process can send notifications to the customer's various service providers.

The following is an illustration of a workflow process that could be used to process a request from an energy service provider to switch a customer's electric supplier on a specified date.

Note:

Bottom line: A workflow process contains one or more workflow events. Each event is activated on its respective trigger date. When an event is activated, the system executes the activation algorithm associated with the event's event type. It's up to you to define exactly what algorithms should be associated with your workflow event types. Refer to [Designing Workflow Event Types](#) for sample events.

A Workflow Process Contains Relevant Data

Linked to a workflow process are the relevant data associated with the process. This information can be for audit purposes or it may be needed by one or more of the event algorithms linked to the process to do its work. For example,

- If a workflow process is associated with the inspection of a premise, the premise is linked to the workflow process.
- If a workflow process is associated with new service, many pieces of information are needed to be linked to the workflow including the address of the new service location, the date service should start, perhaps the desired rate and perhaps customer information, if this is for a new customer.
- If a workflow process is triggered when we receive a notification that we have a new customer, the notification is linked to the workflow process.

This data may be linked to the workflow process in one of two ways: as context or as characteristics. The following points describe each method:

- Context Collection
- Uses a context type to identify the type of data. The values of the context type are stored in a lookup field and must be customized by your implementers.
- The values are stored in the context value field. Values may be up to 50 bytes long.
- The primary key of the record includes context type and context value so multiple values may be entered for the same type.
- Note, the context value is a generic field. If the value of the field is a foreign key, there is no way for the system to enable drill down capability to this foreign key's entity.
- Characteristic Collection
- Uses the [characteristic type](#) table to identify the type of data. Characteristic types may be pre-defined, ad-hoc, foreign key or file location.

- The values are stored in different characteristic value fields depending on the type of characteristic. The ad-hoc and file location values may be up to 254 bytes long.
- The primary key of the record includes characteristic type and a sequence number so multiple values may be entered for the same type.
- If the characteristic is of type foreign key reference, a search is available for selecting an appropriate value and a drill down key is available for viewing the related record.

Note:

The original design included only the context collection. The characteristic collection was added later as a result of limitations in the context functionality that was supported in other parts of the system by characteristic functionality. It is expected that characteristics will be the preferred method to use for implementations. Context will continue to be supported for earlier releases.

Information in a workflow process' context or characteristics collection is referenced by the workflow process' event algorithms when they are activated.

If a workflow process is created to process an incoming notification from a third party, the first event algorithm for your workflow process must populate the workflow process' context or characteristics with individual fields specified on the incoming notification.

Fastpath:

Refer to [Uploading Notifications Into The System](#) for more information.

Note:

If an account ID or premise ID in Oracle Utilities Customer Care and Billing is linked to an active workflow process either via context or via a characteristic, you may configure your system to display an alert when that account or premise is displayed in the current context. To display this alert, create one or more algorithms for the CCAL-WF algorithm type, setting the parameters as appropriate to display account or premise and indicate whether or not the account/premise will be found in the context or characteristic collection. Plug in your new algorithm(s) to the [installation option - algorithm](#) collection.

How Are Workflow Processes Created?

A workflow process may be created as follows:

- The Notification Upload background process (WFPRINIT) creates a workflow process when a notification is interfaced into the system. The workflow process has one or more workflow event(s). Workflow processes created as a result of a notification upload staging record will reference the NUS ID that created it. Refer to [The Big Picture Of Notification Processing](#) for more information about notifications.
- An operator may create an ad hoc workflow process at will.
- If you customize the system accordingly, the system will create a workflow process when a significant event occurs. The purpose of this type of workflow process is to send outgoing notifications to other interested parties to apprise them of the event. For example, assume you are a distribution company, you probably have to advise a customer's energy supply company whenever their meter is exchanged. In this example, when a meter exchange transpires, you'd want to create a workflow process that would, in turn, send outgoing notifications to the energy supply company. Refer to [Designing Notification Downloads](#) for more information.

Whenever a workflow process is created, the system uses a workflow process *template* to create the workflow process. The workflow process template defines the various events that will transpire over the course of the process. Refer to [Designing Workflow Process Templates](#) for more information.

In the above diagram, the event on 1-Dec-00 shows the creation of a workflow process with three workflow events. Notice that the events all exist in the Pending state. The events will exist in this state until their trigger date is on or before the current date.

Fastpath:

Refer to [What Type Of Workflow Process Is Created?](#) to understand how the Notification Upload Process creates workflow processes when notification requests are interfaced into the system. Refer to [The Big Picture Of Workflow Events](#) for more information about a workflow process's events.

How Are Workflow Events Completed?

Several background processes can cause a workflow event to complete as described below:

- A background process (WFET) activates events whose trigger date is no longer in the future. (An event's trigger date can be set to a future date when its earlier, dependent events are completed if the workflow process template so indicates). After it activates an event, this process also activates later dependent events until there are no more events to activate. Refer to [Workflow Event Dependencies & Trigger Date](#) for more information.

Note:

WFET attempts to activate workflow events for a workflow process. The system orders the workflow process records by their workflow process ID, which is a system-generated random number. As a result, you should ensure that the activation algorithms do not expect WF process records to be processed in any other order, such as the order that the WF process records were created. For example, if a "drop request" and an "add request" are both received for the same customer, two workflow processes are created. The activation algorithms for the events for these two processes should work regardless of whether the "drop request" is processed first or the "add request" is processed first.

- The various waiting background processes are responsible for activating events when the thing they are waiting on is complete. For example, if an event creates a pending field activity, it goes into the Waiting state. The WAITFA background process will activate the Waiting event when the field activity becomes Complete. Refer to [Waiting Events And Their Waiting Process](#) for more information.

In addition, if the [workflow event type](#) indicates that manual completion is allowed, a user may change the status of the event to complete using the [workflow process](#) user interface. When an event is manually completed, the system also activates later dependent events until there are no more events to activate.

Fastpath:

Refer to [The Big Picture Of Workflow Events](#) for more information about the various types of workflow events and what happens when they are completed.

How Are Workflow Processes (and their Events) Canceled?

The background process that is responsible for activating events (WFET) automatically cancels a workflow process when one of its events fails. Refer to [Some Workflow Events May Fail](#) for more information.

Refer to [How Are Workflow Events Canceled](#) for more information.

Besides these automatic cancellations, an operator may cancel a workflow process at will.

Workflow Process Maintenance

A workflow process is hard to define because its flexible design can be used to automate many different types of multi-event processes. For example,

- You can use a workflow process to manage the events associated with the inspection of a new premise.
- You can use a workflow process to manage the events that transpire in a deregulated market when a customer wants to switch energy service providers.

Fastpath:

For more information about workflow processes, refer to [The Lifecycle Of A Workflow Process And Its Events](#).

The topics in this section describe the pages on which workflow process-related information is maintained.

Workflow Process - Main

The Main page contains core workflow process information. Open this page using **Menu > Workflow and Notification > Workflow Process > Search**.

Description of Page

The top portion of every page contains the following information:

Workflow Process is a concatenation of summary information about this workflow process. It is composed of the workflow process template's name and description, the workflow process's status, and the creation date of the process.

Workflow Process ID is the unique system-generated identifier for this workflow process.

The remaining fields are maintained on the main workflow process page.

The **Create Information** describes how the workflow process was created. If the workflow process was created by the system, the identity of the process, and related control table references are displayed. If the workflow process was created by a user, the message indicates this.

Workflow Status defines the state of the workflow process. The following values may exist:

Active The system creates a workflow process in the Active state. A workflow process remains in this state until the last event linked to the process is complete OR an event fails OR you want to cancel the process for whatever reason.

Inactive A workflow process becomes Inactive when the last event linked to the process is completed OR an event fails OR you want to cancel the process for whatever reason. The **Status Reason** field tells you how a workflow process became inactive.

Fastpath:

To completely understand the significance of a workflow process's status, refer to [The Lifecycle Of A Workflow Process And Its Events](#).

Status Reason defines how a workflow process became Inactive or why a workflow process is Active. The following values may exist:

Canceled by User This reason should be used when an operator manually inactivates a workflow process (for whatever reason).

Canceled by System This reason is populated by the system when it cancels a workflow process.

Events Pending This reason is populated by the system when a process has pending events.

Complete by System This reason is populated by the system when it completes the last event linked to the workflow process.

Complete by User This reason is populated by an operator when they manually complete a workflow process.

Workflow Process Template defines the workflow events in the process. You can override these events on the **Events** page.

Note:

Changing the template. If you change the template when all events are pending, the system will remove the pending events and replace them with the new template's events.

Fastpath:

For more information, refer to [Setting Up Workflow Process Templates](#).

If your event has been canceled by the system, a **Message** appears indicating the reason for cancellation.

Create Date/Time defines the start date/time of the workflow process. This is important as it affects the trigger dates of the process's workflow events. If you change this date after events exist, the system will NOT update the trigger

date on the events. If you need to change the trigger date on the events, you can do this manually on the **Events** page OR you can change the Workflow Process Template to something (anything) and then change it back to the desired template. When you change the template, the system removes the events and creates new ones using the creation date / time on the process.

The workflow process was created by a **Notification Upload** staging record, information about the [notification upload staging](#) record is displayed.

Enter any **Comments** about the workflow process.

This bottom of this page contains a [tree](#) that shows the various objects linked to the workflow process. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Workflow Process - Char/Context

The Process Char/Context page lists the context collection and/or the characteristic collection associated with the workflow process. Open this page using **Menu > Workflow and Notification > Workflow Process > Search** and navigate to the **Process Char/Context** page.

Fastpath:

Refer to [A Workflow Process Contains Relevant Data](#) for more information about context and characteristics.

Description of Page

Use characteristics and/or context to capture data to be used by your workflow process' event algorithms. Refer to [A Workflow Process Contains Relevant Data](#) for more information.

The **Characteristics** grid displays the **Characteristic Type** and **Characteristic Value** for each attribute that can be accessed by the workflow process' event algorithms.

The **Context** grid displays the Context Type and Context Value for each attribute that can be accessed by the workflow process's event algorithms.

Note:

The values for Context Type are customizable using the Lookup table. This field name is WF_PROC_CTXT_FLG.

Workflow Process - Events

The events page contains the activities that will be performed over the course of the workflow process. Open this page using **Menu > Workflow and Notification > Workflow Process > Search** and navigate to the **Events** page.

Note:

We strongly recommend that you understand the information described in [How Are Workflow Events Completed?](#) before using this page.

The number and type of events associated with a workflow process are defined by the process's workflow process template (which is defined on the first page). Refer to [Setting Up Workflow Process Templates](#) for more information.

Description of Page

The top portion of every page in this page contains the following information:

Workflow Process is a concatenation of summary information about this workflow process. It is composed of the workflow process template's name and description, the workflow process's status, and the creation date of the process.

Workflow Process ID is the unique system-generated identifier for this workflow process.

The scroll controls the display of the individual workflow events that comprise the workflow process. The grid shows the events that must be completed before the workflow event is triggered. Only one workflow event is displayed at a time.

Event Sequence is the unique identifier of the event.

Workflow Event Status defines the state of the event.

Fastpath:

For more information, refer to [Workflow Event Lifecycle](#).

If the workflow event status is Error, then the message related to the error is displayed adjacent.

Note:

Failed events are special. If the workflow event's status is Failed, the system displays the **Failure Algorithm** that was executed (the type of failure algorithm is defined on the event's event type) and, if the failure algorithm created a workflow process, the system displays information about the **Created Workflow Process**.

The **Workflow Event Type** defines the event's activity.

Fastpath:

For more information, refer to [Setting Up Workflow Event Types](#).

If **Dependent on Other Events** is turned on, then the event's trigger date is only determined after the event(s) on which it depends are completed. When this switch is on, a grid appears at the bottom of the page in which you define the event(s) on which this event depends.

Fastpath:

For more information about dependent events, see [Workflow Event Dependencies & Trigger Date](#).

The **Trigger Date** defines the date when the system completes (i.e., executes) the event. This field is gray when the event is dependent on the completion of other events.

Fastpath:

For more information about a workflow event's trigger date, see [Workflow Event Dependencies & Trigger Date](#).

Days After Previous Response defines how a dependent event's trigger date is calculated. The trigger date is set equal to X days after the last dependent event is completed, where X is the number in this field. This field is gray when the event is not dependent on other events.

Fastpath:

For more information about dependent events, see [Workflow Event Dependencies & Trigger Date](#).

The **Status Change Date/Time** is date and time the event's status was last changed.

If the event can go into the Waiting state, the **Wait Date/Time** is populated with the date / time on which the event started waiting.

Fastpath:

Refer to [Waiting Events And Their Waiting Process](#) for more information.

The grid at the bottom of the page contains the events on which this event depends. This grid is only visible when the event is dependent on other events (as defined by the Dependent on Other Events switch).

Workflow Process - Event Char/Context

The Event Context page lists the entity(ies) that were created as a result of the execution of a workflow event. For example, if an event creates a field activity, the field activity would be displayed on this page. The event algorithm

may choose to record the entity using a characteristic or a context entry. Open this page using **Menu > Workflow and Notification > Workflow Process > Search** and navigate to the **Event Char/Context** page.

Fastpath:

Refer to [A Workflow Process Contains Relevant Data](#) for more information about context and characteristics.

Description of Page

Your event algorithms may record information that was created by the algorithm. The information may be recorded as a characteristic or in a context entry. This information is for audit purposes only.

If **Characteristics** are used to record entities created by the algorithm, this grid displays the **Characteristic Type** and **Characteristic Value** for each entity that was created as a result of the execution of workflow event.

If **Context** entries are used to record entities created by the algorithm, this grid displays the **Context Type** and **Context Value** for each entity that was created as a result of the execution of workflow event.

Note:

The values for Context Type are customizable using the Lookup table. This field name is WF_EVT_CTXT_FLG.

Workflow Event Exception

As described in [Workflow Events May Be In Error](#), a record is written the workflow event exception record for every workflow event record that is in error.

To view the messages associated with the exception records, schedule the TD-WEXTL background process. This process generates a To Do entry for every record in the workflow event exception table.

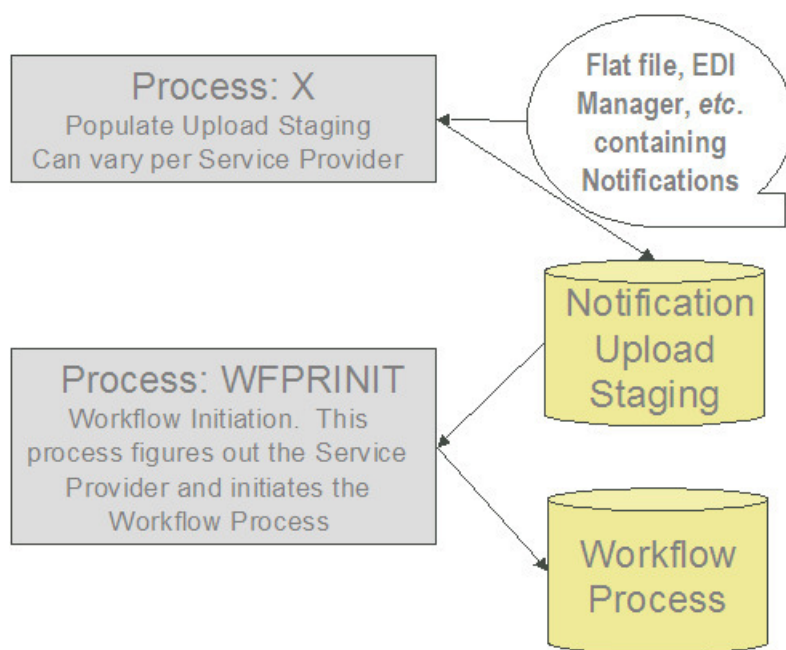

After correcting the cause of the error, drill into the [Workflow Process - Events](#) tab and change the status from Error to Pending. The next time the event activation process runs, it attempts to process this record again.

Uploading Notifications

This section describes how the system uploads notifications. Refer to [Uploading Notifications Into The System](#) for more information.

Notification Upload Background Process

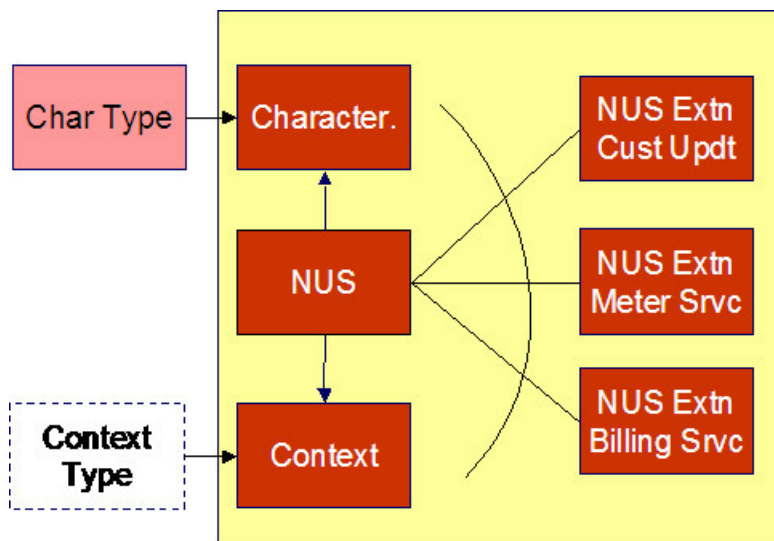

The following diagram illustrates the processes involved in the uploading of notifications into the system.

The topics in this section describe how these processes work.

Process X - Populate Notification Upload Staging

Process X refers to the mechanism used by your organization to populate the various staging tables (shown in the yellow section of the following entity relationship diagram).

The NUS record contains only key header information, but it does not contain detailed information that would be required to process the notification. To define the other required information, like Account ID and meter number, you have three options:

- **NUS Characteristics:** This is a collection of characteristic values, where the characteristic type describes the data that is contained in the characteristic values. In order to set this up correctly, the appropriate [characteristic types](#) need to be defined.
- **NUS Context:** This is a collection of context values, where the context type describes the data that is contained in the context values. In order to set this up correctly, the appropriate context types need to be defined by your implementers.

- **NUS Extension:** This is a separate table, with explicit columns defining the data. In order to set this up correctly, a new table and new user interface will need to be created by your implementers, along with a new Extension type.

For any of the methods, the first Workflow Event in your workflow process will have the responsibility to retrieve the core information from the Characteristic collection, the Context collection or the Extension record and populate the workflow process context or characteristic collection accordingly.

The topics in this section describe each of these tables.

Notification Upload Staging

You must create an upload staging record for each notification being processed in the system. The name of this table is CI_NT_UP. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|---|
| NT_UP_ID | 12 | Y | A/N | <p>This is a sequential unique key. This key is referenced on the NUS extension record. (The NUS extension record contains almost all of the fields associated with the notification.)</p> <p>This key is a sequential number so you can use a database function to assign the value when populating the table.</p> |
| NT_XID_CD | 30 | Y | A/N | <p>This identifies the external system that sent the notification (e.g., a DUNS number).</p> <p>This must correspond with the prime key of one of your external systems. Refer to Designing External Systems for more information.</p> |

| | | | | |
|-----------------|----|---|----------|---|
| NT_UP_XTYPE_CD | 30 | Y | A/N | This identifies the transaction type of the notification. This must correspond with the prime key of one of your notification upload types. Refer to Designing Notification Upload Types for more information. |
| NT_UP_STAT_FLG | 2 | Y | A/N | This must be set to P for Pending. |
| NT_UP_EXTSN_FLG | 4 | Y | A/N | This identifies the type of notification upload staging extension record that contains the details of this notification upload. Valid values: NONE, SPL. Use NONE if you will use the context collection for your related data. |
| CRE_DTTM | 26 | Y | DateTime | This is the date / time on which the notification upload staging record was created. This must be populated with the current date / time. |

Notification Upload Staging Context

If desired, you may insert rows into the upload staging context collection. The context collection enables you to define all the core information associated with the upload staging record. Context flag values will need to be defined for every piece of data you wish to capture. This option may be used in favor of the extension record option, defined below, because you do not need to define new database tables or new user interfaces for each new notification upload type.

The name of this table is CI_NT_UP_CTXT. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|--|
| NT_UP_ID | 12 | Y | A/N | This is the unique key of the NUS record to which this collection is linked. |

| | | | | |
|----------------|----|---|---|---|
| NT_UP_CTXT_FLG | 4 | Y | A | This field describes the data that is stored in the Context Value. Refer to Notification Upload Staging for more information. |
| CTXT_VAL | 50 | Y | A | This is the value of the context. |

Notification Upload Staging Characteristics

If desired, you may insert rows into the upload staging characteristics collection. The characteristics collection enables you to define all the core information associated with the upload staging record. [Characteristic types](#) will need to be defined for every piece of data you wish to capture. This option may be used in favor of the extension record option, defined below, because you do not need to define new database tables or new user interfaces for each new notification upload type.

The name of this table is CI_NT_UP_CHAR. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|----------------|--------|-------|-----------|--|
| NT_UP_ID | 12 | Y | A/N | This is the unique key of the NUS record to which this collection is linked. |
| CHAR_TYPE_CD | 8 | Y | A | This field describes the data that is stored in the characteristic value field. Refer to characteristic type for more information. |
| SEQ_NUM | 3 | Y | N | This value is used to differentiate multiple characteristics of the same type. Values are typically incremented by 10. |
| CHAR_VAL | 16 | N | A | Populate this field if your characteristic type is predefined. |
| ADHOC_CHAR_VAL | 254 | N | A | Populate this field if your characteristic type is ad-hoc or file location. |

| | | | | |
|--------------------------------|---------|---|---|--|
| CHAR_VAL_FK1 - CHAR_VAL_FK5 | 50 each | N | A | Populate these fields if your characteristic type is foreign key reference. Up to five columns of 50 bytes each are provided to accommodate compound keys. |
|--------------------------------|---------|---|---|--|

Notification Upload Staging Extension - Base Sample

A notification upload staging EXTENSION record may be used in lieu of Context to contain the core information associated with a notification upload record. This option enables you to be explicit in your definition of the fields that must be captured for each notification upload type.

The sample extension record that is supplied with the system is just that - a sample. If you use this option, you will need one such extension record for each different type of notification upload record layout you support. It's important to understand that all of your different notification upload extension record types must reference the core [Notification Upload Staging](#) record because the system uses the core record to drive the notification upload process.

The name of the sample notification upload extension record is CI_NT_UP_XSPL. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|---------------|--------|-------|-----------|--|
| NT_UP_ID | 12 | Y | A/N | This is the reference to the Notification Upload Staging record that this record is an extension of. |
| REC_DTTM | 26 | Y | Date/Time | This is the date / time the record was received. |
| RESPONSE_CODE | 1 | Y | A/N | This column is used when the notification is an indication of the acceptance or a rejection of an earlier notification request. If specified, this must be either A - accept or R - reject. |
| SDR_ACCT_ID | 20 | Y | A/N | This is the customer's account ID in the sender's system. |
| RCV_ACCT_ID | 20 | Y | A/N | This is the customer's account ID in the receiver's system. |

| | | | | |
|--------------|----|---|-----|--|
| SDR_REC_ID | 16 | Y | A/N | This is a transaction identifier supplied so responses to this record may be identified. The contents of this field will be returned on notification download records that respond to this notification upload record. |
| RCV_REC_ID | 16 | Y | A/N | This is the transaction identifier received in a previous request record. This field is only populated if the notification being uploaded is an acceptance / rejection of a previously sent notification download record. |
| BILL_OPT_FLG | 4 | Y | A/N | This defines the billing relationship between the service provider and your organization. This value is used in conjunction with BILL_CALC_OPT_FLG to determine the service provider associated with the NT_XID_CD on the CI_NT_UP record. Valid values are: DUAL, ESP, UDC. |

| | | | | |
|-------------------|----|---|-----|---|
| BILL_CALC_OPT_FLG | 4 | Y | A/N | This defines the bill calculation method used when your organization provides billing services for the service provider. This value is used in conjunction with BILL_CALC_FLG to determine the service provider associated with the NT_XID_CD on the CI_NT_UP record. Valid values are: BILL (bill ready), RATE (rate ready). |
| MTR_NBR | 16 | Y | A/N | The customer's meter number. This is used to help identify the service agreement associated with the notification. |
| BILLING_DATE | 2 | Y | N | This is the day of the month used to derive the service cycle define on SA relationship records associated with service providers who provide MR services. |
| POSTAL_CD | 12 | Y | A/N | The service address's postal code. This is used as a crosscheck to ensure the notification is referencing the correct customer. |

Process WFPRINIT - Initiate Workflow Processes To Execute Notification Upload Staging Records

This process creates a workflow process for all [Notification Upload Staging](#) records in the Pending state. It determines the workflow process using a combination of the External Id and the NUS Type. Refer to [What Type Of Workflow Process Is Created](#) for more information. It stamps the NUS ID onto the newly created workflow process.

If the External ID on the staging record is not a valid External ID in our system, rather than creating an error, this process will find a workflow process template with a notification condition of Unknown Notification ID and create a workflow process. If the NUS Type on the staging record is not a valid NUS Type in our system, rather than creating an error, this process will find a workflow process template with a notification condition of Unknown Notification ID and create a workflow process. Refer to [Setting Up Workflow Process Templates](#) for more information. For these cases, the status of the notification upload staging record will be set to Complete.

Any errors detected during this process will be written to the [Notification Upload Exception](#) table. You can fix errors using the [Notification Upload Staging](#) page (don't forget to change the record's status back to Pending).

Fastpath:

Refer to [Uploading Notifications Into The System](#) for more information.

Validation of Data Related to the Notification Upload Staging Records

As mentioned above, the sole purpose of the Initiate Workflow Process (WFPRINIT) is to successfully create a workflow process. Once a workflow process is created, the NUS status is set to Complete.

At this point, neither the extension record, the context collection nor the characteristics collection have been processed. It is the responsibility of the first event in the workflow process to validate the fields in the extension record, the context collection and/or the characteristics collection. This algorithm will decide what to do when a problem is detected with the data. Some possible options are

- Set the algorithm status to Fail. Use this option when a critical error is detected, which probably cannot be fixed by a user. This will cause the remaining events to be canceled.
- Set the algorithm status to Error. Use this option when an error is detected, which can be corrected by a user. This will cause an [exception](#) record to be created. The user should be able to correct the source data in the extension record, the context collection or the characteristics collection, change the status back to Pending and rerun the Workflow Event Activation process. Note that if the validation algorithm uses this option, the ability to rerun this event should be handled by the coding of this algorithm. It should prevent duplicate logic from being performed.
- Send a To Do list entry and continue the workflow process by setting the algorithm status to Complete. Use this option when someone should be alerted of an unusual condition, but the process should not be halted. For this option, the To Do Type and User to use for posting the To Do entry should be parameters to the algorithm.

Note:

We said that a possible correction for the validation workflow event in the Error is to modify data in the extension record, the context collection or the characteristics collection. You may find this a bit unusual because the parent NUS record is in the status of Complete. Remember that this NUS status indicates whether or not the system was able to successfully create a workflow process. There is no status for the data related to the NUS - only the status of the event, which validates it.

Notification Upload Staging Maintenance

The Notification Upload Staging page is used to view notification upload records.

Fastpath:

Refer to [Process X - Populate Notification Upload Staging](#) for more information about these records.

Notification Upload Staging - Main

Use this page to define common attributes of notification upload staging records. Open this page using **Menu > Workflow and Notification > Notification Upload Staging > Search**.

Description of Page

The **Upload Staging ID** is the unique identifier of the notification upload staging (NUS) record.

Status shows the state of the NUS record. Potential values are: Pending, Complete, Error. To have the system reprocess a record that's in Error, change the status back to Pending. The system will revalidate the record the next time the notification upload process executes.

Create Date and **Time** are just that.

External System identifies the sender of the notification.

Notification Upload Type identifies the transaction type of the notification.

Extension identifies the type of notification upload staging extension record that contains the details of this notification upload. Valid values: No Extension , Sample Extension Record. You would use No Extension when you plan to define the data related to the NUS record in the characteristic collection or in the context collection rather than in an extension table. If your [notification upload type](#) indicates a navigation option associated with your extension record, a drill down button is enabled adjacent to this field.

Note:

Default Note. The extension value defaults from the value specified on the notification upload type.

The values for this field are customizable using the Lookup table. This field name is NT_UP_EXTSN_FLG.

If a **Workflow Process** has been created for this NUS record, information about the workflow process will be displayed.

This bottom of this page contains a [tree](#) that shows the various objects linked to the notification upload staging record along with information about the workflow process, if one has been created for the NUS. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Notification Upload Staging - Characteristics/Context

Use this page to either characteristic records or context records to define data related to the NUS record. Either collection may be used as an alternative to defining an extension record. Refer to [Process X - Populate Notification Upload Staging](#) for more information.

Open this page using **Menu > Workflow and Notification > Notification Upload Staging > Search** and navigate to the **Characteristics/Context** page.

Description of Page

The **Upload Staging ID** is the unique identifier of the notification upload staging (NUS) record.

The **Characteristics** collection enables you to define a collection of **Characteristic Types** and **Characteristic Values** defining data related to the NUS record.

The **Context** collection enables you to define a collection of **Context Types** and **Context Values** defining data related to the NUS record.

Note:

The values for this field are customizable using the Lookup table. This field name is NT_UP_CTXT_FLG.

You will notice that both the characteristic collection data and the context collection data may be modified even when the parent NUS record is Complete . This is to enable a user to correct problems with this data as detected by the validation event. Refer to [Validation of Data Related to the Notification Upload Staging Records](#) for more information.

Notification Upload Staging - Sample Upload Extension Record

The Notification Upload Staging page is used to maintain notification upload records.

Fastpath:

Refer to [Process X - Populate Notification Upload Staging](#) for more information about these records.

Open this page using **Menu > Workflow and Notification > Sample Upload Extension > Search**.

Description of Page

Receive Date and **Time** are just that.

Response is used when the notification is an indication of the acceptance or a rejection of an earlier notification request. If specified, this must be either Accept or Reject.

Sender's Customer's Account ID is the customer's account ID in the sender's system.

Receiver's Customer's Acct ID is the customer's account ID in your system.

Sender Record ID is a transaction identifier supplied so responses to this record may be identified. The contents of this field will be returned on notification download records that respond to this notification upload record.

Receiver Record ID is the transaction identifier received in a previous request record. This field is only populated if the notification being uploaded is an acceptance / rejection of a previously sent notification download record.

Billing Option defines the billing relationship between the service provider and your organization. This value is used in conjunction with **Billing Calculation Option** to determine the service provider associated with the sender's external system (stored on the related notification upload staging record). Valid values are: Dual Billing, ESP Consolidated, UDC Consolidated.

Billing Calculation Option defines the bill calculation method used when your organization provides billing services for the service provider. This value is used in conjunction with **Billing Option** to determine the service provider associated with the sender's external system (stored on the related notification upload staging record). Valid values are: Bill Ready and Rate Ready.

Meter Number is the customer's meter number. This is used to help identify the service agreement associated with the notification.

Billing Date is the day of the month used to derive the service cycle define on SA relationship records associated with service providers who provide meter reading services.

Postal is the service address's postal code. This is used as a cross check to ensure the notification is referencing the correct customer.

Note:

You will notice that the extension data may be modified even when the parent NUS record is Complete. This is to enable a user to correct problems with this data as detected by the validation event. Refer to [Validation of Data Related to the Notification Upload Staging Records](#) for more information.

Notification Upload Exception

A record is written the notification upload exception record for every notification upload staging record that is in error.

To view the messages associated with the exception records, schedule the TD-NTUPL background process. This process generates a To Do entry for every record in the notification upload exception table.

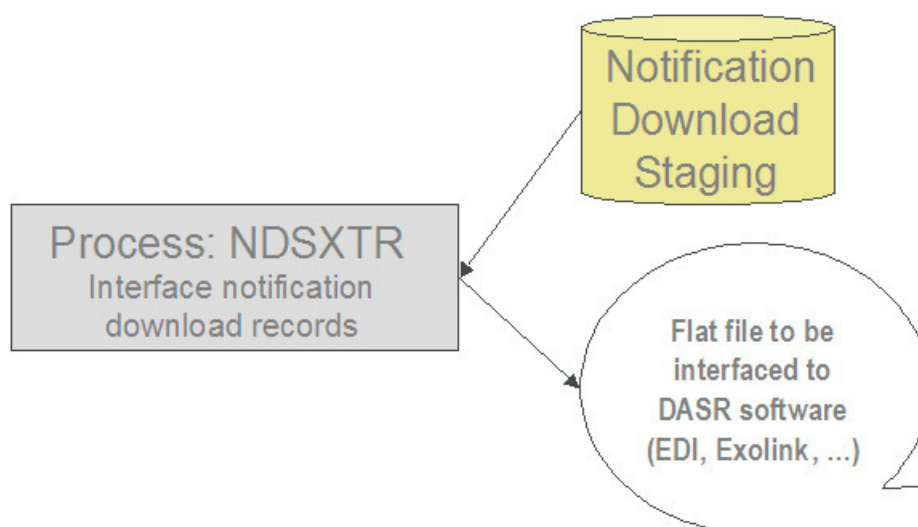

After correcting the cause of the error, drill into the [Notification Upload Staging](#) page and change the status from Error to Pending. The next time the notification upload process runs, it attempts to process this record again.

Downloading Notifications

This section describes how the system downloads notifications. Refer to [How Are Notifications Sent Out Of The System?](#) for more information. Information may be extracted from the system using a batch process, which runs in the background or using the XAI tool, which continuously searches for new NDS records and builds XML documents to send to an external recipient.

Notification Download Background Processes

The following diagram illustrates how a batch process, which runs in the background may be used to route notifications out of the system.

The topics in this section describe how this process works.

Process NDSXTR - Interface Notification Download Records (out of the system)

This process reads all notification download staging records marked with a given batch control ID & run number and creates the flat file that's passed to the outgoing notification software. Every NDS record references the recipient service provider and a notification download type. This process uses the service provider's notification download profile to determine the format of records interfaced out of the system. Refer to [Designing Notification Downloads](#) for more information.

Note:

This process is rerunnable. You can reproduce the flat file at any time. Simply request this job and specify the run number associated with the historic run.

If you require different routing methods, you will need to create additional versions of this program.

NDS Contains Interesting Data

The NDS record also contains interesting data

- The main use for this is to indicate the workflow process and event that created the NDS
- The process that extracts the data may then find the other data related to this NDS by looking at the workflow process context or characteristics

This interesting data may be stored in one of two ways

- Through NDS context collection. Use this method if your NDS is interfaced to the outside world using XAI. Refer to [Designing Notification Download Types](#) for more information.
- Through NDS characteristics collection. For NDS records that are interfaced through a batch process, it is expected that using characteristics is the preferred method because if your characteristic references a foreign key, your user can easily drill down to the related record.

Note:

The algorithms provided with the base product use the context collection to populate the interesting data for an NDS.

Notification Download Staging

The Notification Download Staging page is used to view notification download records. This is especially useful if you send out a notification and request a response.

Fastpath:

Refer to [Notification Download Background Processes](#) for more information about these records.

Notification Download Staging - Main

Open this page using **Menu > Workflow and Notification > Notification Download Staging > Search**.

Description of Page

The **Download Staging ID** is the unique identifier of the notification download staging (NDS) record.

Service Provider is the service provider to whom this download staging record will be sent. The description of the service provider is displayed adjacent.

Notification Download Type indicates the reason for this notification. The description is displayed adjacent.

Fastpath:

Refer to [Designing Notification Download Types](#) for more information about notification download types.

The **Processing Method** indicates whether this record will be processed by a Batch extract process or through the XAI tool. The processing method defined on the Notification Download Profile will be used to populate this value.

If the processing method is Batch, then **NDS Extract Process** indicates the process that will extract this record. This value is populated based on the service provider's notification download profile. **NDS Extract Run** indicates in which batch run this record was extracted or will be extracted.

Fastpath:

Refer to [Designing Notification Download Profiles](#) for more information about the NDS Extract Process.

The **Retry Count** is used by the XAI tool to keep track of how many times the tool tried to process this record and could not process the record, resulting in an error.

The **Create Date/Time** indicates the date and time that this record was created.

Status defines the state of the NDS record. This is only used when the processing method is XAI and will be protected when the processing method is Batch. Refer to [Lifecycle of Notification Download Staging](#) for more information.

This bottom of this page contains a [tree](#) that shows the various objects linked to the notification download staging record. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Notification Download Staging - Characteristics/Context

This page displays the characteristics and/or context associated with the download staging record. Refer to [NDS contains interesting data](#) for more information.

Open this page using **Menu > Workflow and Notification > Notification Download Staging > Search** and navigate to the **Characteristics/Context** page.

Description of Page

The **Download Staging ID** is the unique identifier of the notification download staging (NDS) record.

If **Characteristics** are used by the algorithm that created this record, to record information related to the record, this grid displays the **Characteristic Type** and **Characteristic Value** for each entity associated with the download staging record.

If **Context** entries are used by the algorithm that created this record, to record information related to the record, this grid displays the **Context Type** and **Context Value** for each entity associated with the download staging record.

**Note:**

The values for **Context Type** are customizable using the Lookup table. This field name is NT_DWN_CTXT_FLG.

Notification Download Staging - XAI Download Staging

Open this page using **Menu > Workflow and Notification > Notification Download Staging > Search** and navigate to the **XAI Download Staging** page.

Description of Page

For XAI messages, an NDS Type may point to multiple XAI Route Types. Each route type is linked to an message sender. The system keeps track of each routing and each response. This collection of **XAI Route Type** includes the **XAI Download Status** and **Message**. To look at more detail, drill down into a specific XAI Routing and you are transferred to the XAI Download Staging page, where you may view the XML Request and XML Response.

Notification Download Exception

A record is written the notification download exception record for every notification download staging record that is in error. This is only applicable to records with a processing method of XAI.

To view the messages associated with the exception records, schedule the TD-NTDWN background process. This process generates a To Do entry for every record in the notification download exception table.

**Fastpath:**

Refer to [Lifecycle of Notification Download Staging](#) for more information.

Overdue Financial Obligations

The system periodically monitors how much your customers owe to ensure they haven't violated your overdue rules. When a violation is detected, the system creates an overdue process. The overdue process contains the events meant to prod the customer to pay (e.g., letters, disconnect field activities, To Do entries, write-off outstanding debt, etc.). This section describes how to manage your overdue (i.e., collections) processing.

**Note:**

The overdue processing module has been designed to collect on virtually anything from an unpaid bill to an unmatched financial transaction. You tell the system what you collect on by configuring the various overdue processing control tables. In this release, the base-package is delivered with the algorithms that support collecting on overdue bills. If your organization practices [balance-forward accounting](#) (i.e., collection is based on overdue service agreement balances), you will not use this functionality. Rather, you will use the functionality described under [Credit and Collections](#).

Overdue Processing Background Information

In the section, [The Big Picture Of Overdue Processing](#), we describe how overdue processing works and how to set up the control tables that automate most functions. You will find that many of your questions regarding when and how overdue and cut processes are created and canceled are described in this section.

Overdue Process Maintenance

An overdue process is a series of events (e.g., letters, To Do entries) meant to encourage an account to pay its delinquent debt. The topics in this section describe the pages on which overdue processes are maintained.

Fastpath:

Refer to [The Big Picture Of Overdue Processes](#) for background information.

Overdue Process - Main

The Main page contains core overdue process information. Open this page using **Menu > Credit & Collection. > Overdue Process > Search**

Description of Page

Note:

Refer to [How To Perform Common Overdue Process Functions](#) for more instructions describing how to use this page.

Overdue Process contains a concatenation of important information about the process. **Overdue Process ID** is the system-assigned unique identifier of the process. These values only appear after the overdue process is added to the database.

Note:

Summary information may be overridden. Refer to [Overdue Process Information Is Overridable](#) for how your implementation can override the summary information that appears throughout the system.

Account ID identifies the overdue process's account.

Note:

Multiple overdue processes may be linked to an account. It's important to be aware that it's possible for multiple, active overdue processes to be linked to an account. The [Alert zone](#) will contain a summary of the account's overdue processes.

Status defines the state of the overdue process. The following values may exist:

- Active, Events Pending. Overdue processes are initially created in this state. An overdue process remains in this state until there are no Pending or Waiting events.
- Inactive, Canceled by User. An overdue process will exist in this state when it's been manually canceled by a user. Navigate to the **Log** tab to see when this happened and who did it.
- Inactive, Canceled by System. An overdue process will exist in this state when it's been canceled by the system (typically because the overdue obligations were satisfied). Navigate to the **Log** tab to see when this happened.
- Inactive, Completed. An overdue process will exist in this state when the system completes its last event. Navigate to the **Log** tab to see when this happened.

The **Cancel** button appears if the overdue process is Active, Events Pending and the process's **Overdue Process Template** has a Cancel Logic plug-in. Click this button to [cancel the process](#).

The **Trigger Events** button appears if the overdue process is Active, Events Pending. Click this button to activate all pending events that are [ready for activation](#).

Note:

If you can't wait for the Overdue / Cut Event Manager to run. The [Overdue / Cut Event Manager](#) is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button on the **Main** tab to activate the process's events (that are ready for activation).

Overdue Process Template defines the template that was used to [create the overdue process's events](#). You can override these events on the **Events** page. This field is unprotected when the process is Active and all events are in either the Pending or Canceled states.

**Note:**

Changing the template. If you change the template, the system will delete the events and replace them with the new template's events.

Start Date/Time defines the start date/time of the overdue process. This field is protected after the overdue process is saved on the database. This field is used to derive the trigger date of some overdue events when the process is first created. Subsequent changes to the start date change the trigger dates on the events accordingly.

Inactive Date/Time is the date and time that the overdue process became Inactive. This field is hidden if the process is Active. You can see more details about when and how the inactivation occurred by navigating to the **Log** tab.

Base Date is reserved for future releases. This field is protected when the overdue process is Inactive.

Enter any **Comments** about the overdue process. This field is protected when the overdue process is Inactive.

The **Collecting On** grid holds the [overdue objects](#). For example, if this process manages overdue bills, the grid contains a list of the bills being collected on by this process. This grid is unprotected when the process is Active . The following points describe the columns that appear in the grid:

- Press the + button to add a new overdue object to the process.
- Press the - button to remove an overdue object to the process.
- The next column contains the unique identifier of the overdue object. For example, if this process manages overdue bills, this column will contain the bill ID. The type of object that's specified in this column is control by the [overdue process template](#).
- **Original Amount** contains the [original amount](#) of the overdue object.
- **Unpaid Amount** contains the [unpaid amount](#) of the overdue object.

The **Trees** at the bottom of the page shows a variety of information about the overdue process including its events and cut processes. You can click on hyperlinked tree nodes to navigate to the page on which the related object is maintained.

Overdue Process - Events

This page contains the activities that are performed to persuade the customer to pay the outstanding debt. Open this page using **Menu > Credit & Collection > Overdue Process > Search** and navigate to the **Events** page.

Description of Page

**Note:**

Refer to [How To Perform Common Overdue Process Functions](#) for more instructions describing how to use this page.

Refer to the first tab for a description of **Overdue Process** and **Overdue Process ID**.

The **Overdue Events** scroll contains the process's overdue events. Refer to [Overdue Processes Are Created From Templates](#) for information about how the system defaults a process's events from its template.

- Note, all information in the scroll is protected if the event's Status is Complete or Canceled.
- **Event Sequence** is the unique identifier of the event.
- **Status** defines the [state of the event](#).
- The **Cancel** button appears if the event is Pending or Waiting, and the event's **Overdue Event Type** has a Cancel Logic plug-in. Click this button to cancel the event.
- The **Overdue Event Type** defines the event's activity (e.g., Email sent, a To Do entry is generated, a letter is sent).
- The remaining fields work in unison:
 - If **Dependent on Other Events** is turned on, the event can only be triggered after the events specified in the **Event Dependencies** grid are all Complete or Canceled. You use the **Days After** field to define when this event is activated. For example, if you enter 5, this event will be activated 5 days after all of the dependent events are completed / cancelled. If you enter 0, this event will be activated immediately after the dependent events are completed / cancelled. Refer to [Calendar vs Work Days](#) for a descriptions of how days are counted.

If all dependent events are already Completed or Canceled, you cannot specify **Days After**. Rather, you must enter the desired activation date in the **Trigger Date** field.

- If **Dependent on Other Events** is turned off, enter the desired activation date in the **Trigger Date** field. If this field is off, the **Days After** field and the **Event Dependencies** grid are hidden.

Note:

If you can't wait for the Overdue / Cut Event Manager to run. The **Overdue / Cut Event Manager** is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button to activate the process's events (that are ready for activation).

Overdue Process - Log

This page contains [log entries](#) that highlight significant events in the process's life. Open this page using **Menu > Credit & Collection > Overdue Process > Search** and navigate to the **Log** page.

Description of Page

Please note the following about the entries in this grid:

- The system automatically creates log entries when significant events occur. Refer to [Overdue Log](#) for more information.
- You can manually add a log entry to an Active process by pressing the + button and enter the **Details**. You cannot modify or delete this information after saving it.
- The following information appears in the grid:
 - **Date/Time** contains the date and time the log entry was created.
 - **Details** contain the user-specified or system-generated information about the log entry.
 - **Relate Object** is populated on log entries that were created to record the creation of some other object. For example, if an overdue event creates a customer contact, the related object contains information about the customer contact. Please note that if the object description is shown in blue, you can click on the object's description to drill down to the object.
 - **Related Process / Event** appears if the log entry was created by an overdue event, a cut process or a cut event. It references the unique identifier of the process / event.
 - **Log User** contains the user who caused the log entry to be created.
 - **Log Type** indicates how the log entry was created. The possible values are:
 - User. A user manually created this entry.
 - System. This system created this entry.

How To Perform Common Overdue Process Functions

The topics in this section describe how to perform common overdue process maintenance functions. Refer to [The Big Picture Of Overdue Processing](#) for high-level information about overdue processing.

How To Create An Overdue Process

99.9% of all overdue processes are created by the [Overdue Monitor](#) and require no human intervention. The other 0.1% are created by users on-line / real time. The following points describe how to create the 0.1%.

- Use **Control Central** to choose the account that requires a new overdue process.
- After the account is populated on Control Central, choose the **Overdue Process +** option on the account context menu to transfer to the overdue process transaction in add mode for the account.
- After the [Overdue Process - Main](#) page appears, specify the appropriate **Overdue Process Template**. The template is used to default the process's events (the template also controls numerous business rules, for example,

when it will be canceled, how it will be canceled, etc). Refer to [How To Change Overdue Events](#) for a description of how you can override these events.

- Enter the overdue object(s) in the **Collecting On** grid. You must define at least one object.
- Save the overdue process.

How To Change Overdue Events

When an overdue process is first created, it has one or more overdue events. The events are the activities that will be performed to persuade the customer to pay the outstanding debt.

The number and type of events that are created when an overdue process is initiated are defined on the overdue process's overdue process template. The following points describe how to add / change / delete events on an overdue process if the defaulted events are not satisfactory.

- Use **Control Central** to choose the account with the overdue process whose events need to be changed.
- After the account is populated on Control Central, choose the **Overdue Process** option on the account context menu to transfer to the overdue process transaction in update mode for the account. Note, an account's Active overdue processes can be selected from the [Alerts zone](#).
- To add a new event, transfer to the [Overdue Process - Events](#) tab and press the + button in the **Overdue Events** scroll. At this point, the event has not been added to the database; rather, it just exists in memory. Before you add the event to the database, you must specify the following information:
 - Choose an **Event Sequence** so that the new event will be positioned properly in respect of the other events.
 - Choose a **Status** of Pending.
 - Choose the desired **Overdue Event Type**.
- If the activation of the new event is dependent on the successful completion of earlier events, turn on **Dep on Other Event** and then:
 - specify the sequences of the dependent events in **Event Dependencies** and
 - specify the how many days after the completion of the last dependent event that the new event should be triggered.
 - If the activation of the new event is NOT dependent on the successful completion of earlier events, turn off **Dep on Other Event** and use **Trigger Date** to define the date on which the event should be activated (i.e., completed).
- To delete an existing event, click on the event in the tree on [Overdue Process - Main](#). This will transfer you to the **Events** tab where you can click the - button to remove the event. At this point, the event has not been removed from the database; rather, it's been removed in memory.
- To change an existing event, click on the event in the tree on [Overdue Process - Main](#). This will transfer you to the **Events** tab where you can make the desired changes.
- After all desired changes have been made, save the overdue process.

How To Cancel An Overdue Process

The system will cancel an overdue process when the [cancel criteria defined on the overdue process are satisfied](#). The following points describe how to manually cancel an overdue process.

- Use **Control Central** to choose the account with the overdue process to be cancelled.
- After the account is populated on Control Central, choose the **Overdue Process** option on the account context menu to transfer to the overdue process transaction in update mode for the account. A list of all overdue processes associated with the account appears. If only one overdue process exists, it is automatically selected for you. Note, an account's Active overdue processes can be selected from the [Alerts zone](#).
- On the **Main** tab, click Cancel and answer any prompts.

Cut Process Maintenance

A cut process contains the activities to stop a service agreement (in the hopes that lack of service will inspire the customer to pay). It should be noted that a separate cut process is created for each service agreement. The topics in this section describe the pages on which cut processes are maintained.

Fastpath:

Refer to [The Big Picture Of Cut Processes](#) for background information.

Cut Process - Main

The Main page contains core cut process information. Open this page using **Menu > Credit & Collections > Cut Process > Search**.

Description of Page

Note:

Refer to [How To Perform Common Cut Process Functions](#) for more instructions describing how to use this page.

Cut Process contains a concatenation of important information about the process. **Cut Process ID** is the system-assigned unique identifier of the process. These values only appear after the cut process is added to the database.

Note:

Summary information may be overridden. Refer to [Cut Process Information Is Overridable](#) for how your implementation can override the summary information that appears throughout the system.

Overdue Process and **Overdue Event** define overdue event that created the process. Refer to [Cut Processes Exist Under An Overdue Process](#) for more information.

Service Agreement identifies the service agreement being cut.

Premise identifies the service agreement's characteristic premise (if any).

Note:

Multiple cut processes may be linked to an overdue process / event. It's important to be aware that it's possible for multiple, active cut processes to be linked to the overdue event. You can see all cut processes associated with an overdue process on the tree of [Overdue Process - Main](#). The [Alert zone](#) will contain a summary of the account's cut processes.

Status defines the state of the cut process. The following values may exist:

- Active, Events Pending. Cut processes are initially created in this state. A cut process remains in this state until there are no Pending or Waiting events.
- Inactive, Canceled by User. A cut process will exist in this state when it's been manually canceled by a user. Navigate to the overdue process's [Log](#) tab to see when this happened and who did it.
- Inactive, Canceled by System. A cut process will exist in this state when it's been canceled by the system (typically because the overdue obligations on the overdue process were satisfied). Navigate to the **Log** tab to see when this happened.
- Inactive, Completed. A cut process will exist in this state when the system completes its last event. Navigate to the overdue process's [Log](#) tab to see when this happened.

The **Cancel** button appears if the cut process is Active, Events Pending and the process's **Cut Process Template** has a Cancel Logic plug-in. Click this button to [cancel the process](#).

The **Trigger Events** button appears if the cut process is Active, Events Pending. Click this button to activate all pending events that are [ready for activation](#).

Note:

If you can't wait for the Overdue / Cut Event Manager to run. The [Overdue / Cut Event Manager](#) is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button to activate the process's events (that are ready for activation).

Cut Process Template defines the template that was used to [create the cut process's events](#). You can override these events on the **Events** page. This field is unprotected when the process is Active and all events are in either the Pending or Canceled states.

Note:

Changing the template. If you change the template, the system will delete the events and replace them with the new template's events.

Start Date/Time defines the start date/time of the cut process. This field is protected after the cut process is saved on the database. This field is used to derive the trigger date of some cut events when the process is first created. If you need to subsequently change the trigger date on the events, navigate to the **Events** tab and change the dates manually. Alternatively, you can perform the following "trick":

- Change the **Cut Process Template** to something (anything). Doing this causes the **Start Date/Time** to become unprotected.
- Specify the base date of the cut events in the newly unprotected **Start Date/Time**.
- Change the **Cut Process Template** back to the desired value. When you change the template, the system removes the events and creates new ones using the **Start Date/Time**.

Inactive Date/Time is the date and time that the cut process became Inactive. This field is hidden if the process is Active. You can see more details about when and how the inactivation occurred by navigating to the overdue process's [Log](#) tab.

Enter any **Comments** about the cut process. This field is protected when the cut process is Inactive .

The [tree](#) at the bottom of the page shows a variety of information about the cut process including its events. You can click on hyperlinked tree nodes to navigate to the page on which the related object is maintained.

Cut Process - Events

This page contains the activities that are performed to cut the service agreement. Open this page using **Menu > Credit & Collection > Cut Process > Search** and navigate to the **Events** page.

Description of Page

Note:

Refer to [How To Perform Common Cut Process Functions](#) for more instructions describing how to use this page.

Refer to the first tab for a description of **Cut Process** and **Cut Process ID**.

The **Cut Events** scroll contains the process's cut events. Refer to [Cut Processes Are Created From Templates](#) for information about how the system defaults a process's events from its template.

- Note, all information in the scroll is protected if the event's Status is Complete or Canceled.
- **Event Sequence** is the unique identifier of the event.
- **Status** defines the [state of the event](#).
- The **Cancel** button appears if the event is Pending or Waiting, and the event's **Cut Event Type** has a Cancel Logic plug-in. Click this button to cancel the event.
- The **Cut Event Type** defines the event's activity (e.g., Email sent, a To Do entry is generated, a letter is sent).
- The remaining fields work in unison:
 - If **Dependent on Other Events** is turned on, the event can only be triggered after the events specified in the **Event Dependencies** grid are all Complete or Canceled. You use the **Days After** field to define when this event is activated. For example, if you enter 5, this event will be activated 5 days after all of the dependent events are completed / cancelled. If you enter 0 (zero), this event will be activated immediately after the

dependent events are completed / cancelled. Refer to [Calendar vs Work Days](#) for a descriptions of how days are counted.

If all dependent events are already Completed or Canceled , you cannot specify **Days After**. Rather, you must enter the desired activation date in the **Trigger Date** field.

- If **Dependent on Other Events** is turned off, enter the desired activation date in the **Trigger Date** field. If this field is off, the **Days After** field and the **Event Dependencies** grid are hidden.

Note:

If you can't wait for the Overdue / Cut Event Manager to run. The [Overdue / Cut Event Manager](#) is a background process that activates events on their trigger date. If you don't want to wait for this process to run, you can click the **Trigger Events** button on the **Main** tab to activate the process's events (that are ready for activation).

How To Perform Common Cut Process Functions

The topics in this section describe how to perform common cut process maintenance functions. Refer to [The Big Picture Of Cut Processing](#) for high-level information about cut processing.

How To Create A Cut Process

Cut processes are created when an overdue event is activated. You cannot create an ad hoc cut process.

How To Change Cut Events

When a cut process is first created, it has one or more cut events. The events are the activities that will be performed to persuade the customer to pay the outstanding debt.

The number and type of events that are created when a cut process is initiated are defined on the cut process's cut process template. The following points describe how to add / change / delete events on a cut process if the defaulted events are not satisfactory.

- Use **Control Central** to choose the account with the cut process whose events need to be changed.
- After the account is populated on Control Central, choose the **Cut Process** option on the account or service agreement context menus to transfer to the cut process transaction in update mode. Note, an account's Active cut processes can be selected from the [Credit and Collections zone](#).
- To add a new event, transfer to the [Cut Process - Events](#) tab and press the + button in the **Cut Events** scroll. At this point, the event has not been added to the database; rather, it just exists in memory. Before you add the event to the database, you must specify the following information:
 - Choose an **Event Sequence** so that the new event will be positioned properly in respect of the other events.
 - Choose a **Status** of Pending.
 - Choose the desired **Cut Event Type**.
- If the activation of the new event is dependent on the successful completion of earlier events, turn on **Dep on Other Event** and then:
 - specify the sequences of the dependent events in **Event Dependencies** and
 - specify the how many days after the completion of the last dependent event that the new event should be triggered.
- If the activation of the new event is NOT dependent on the successful completion of earlier events, turn off **Dep on Other Event** and use **Trigger Date** to define the date on which the event should be activated (i.e., completed).
- To delete an existing event, click on the event in the tree on [Cut Process - Main](#). This will transfer you to the **Events** tab where you can click the - button to remove the event. At this point, the event has not been removed from the database; rather, it's been removed in memory.

- To change an existing event, click on the event in the tree on [Cut Process - Main](#). This will transfer you to the **Events** tab where you can make the desired changes.
- After all desired changes have been made, save the cut process.

How To Cancel A Cut Process

The system will cancel a cut process when the [cancel criteria defined on the overdue process are satisfied](#). The following points describe how to manually cancel a cut process.

- Use **Control Central** to choose the account with the cut process to be cancelled.
- After the account is populated on Control Central, choose the **Cut Process** option on the account or service agreement context menu to transfer to the cut process transaction in update mode for the account. A list of all cut processes associated with the account appears. If only one cut process exists, it is automatically selected for you. Note, an account's Active cut processes can be selected from the [Credit and Collections zone](#).
- On the **Main** tab, click Cancel and answer any prompts.

Payment Arrangement for Bills

A payment arrangement is an agreement with a customer to payoff severely overdue debt in installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

Organizations that practice [open-item accounting](#) who collect on overdue bills may allow customers to pay off their overdue bills in installments by setting up a payment arrangement for one or more bills. This transaction is used to maintain bill-oriented payment arrangements.

Fastpath:

Refer to [Bill-Oriented Payment Arrangements](#) for background information.

Open this page using **Menu > Credit & Collection > Payment Arrangement for Bills > Search** page.

Description of Page

The **SA** (service agreement) **Info** is a concatenation of important details about the payment arrangement service agreement (PA SA). The **SA ID** is the unique identifier of the PA SA. These values only appear after the PA SA exists on the database.

The **Current Balance** that appears beneath **SA Info** contains the PA SA's current balance. When you initially set up a PA SA this balance will be zero. It is only non-zero if the customer has not paid a billed installment.

Payoff Balance beneath **SA Info** contains the PA SA's payoff balance. The payoff balance is the total amount to be paid off over the PA SA's life. It is only non-zero after delinquent funds have been transferred to the PA SA. This balance is only displayed when it differs from the **Current Balance**.

Fastpath:

Refer to [Current Amount versus Payoff Amount](#) for more information.

Account ID is the account associated with the PA SA.

The occurrences of **Current** and **Payoff Balance** beneath **Account** are the account's respective balances. These values are displayed to help you confirm exactly how much the customer currently owes versus how much they will have to payoff over time (remember, after you transfer funds to a payment arrangement, the amount transferred is reduced from the account's current balance).

The **Unpaid Bills** grid contains a row for each of the account's unpaid bills.

Adjacent to each Unpaid Bill is its **Unpaid Amount** and a check box used to select the bill. Every selected bill's unpaid amount will be transferred to the PA SA when you click the **Create** button.

**Warning:**

The system automatically indicates that all unpaid debt should be transferred to the payment arrangement. It does this by checking each bill by default.

Total Candidates is the sum of ALL unpaid bills (not just the selected bills).

New Payoff Balance contains the PA SA's payoff balance. This is the total amount of debt that will be paid off over the lifetime of the PA SA. This value equals the current payoff balance on the PA SA plus all selected debt from the **Candidate SAs** scroll.

The next fields work in unison.

- If you want to define the number of future bills that the customer has to payoff the selected unpaid amount, enter the number of **Installments**. When you tab out of the field, the system sets the **Arrange Amount** equal to **New Payoff Balance / Installments**.

**Note:**

Arrange Amount may not add up. The **Arrange Amount** is rounded up so that if you multiply the number of installments by the calculated installment amount, the result will be greater than the PA SA's payoff amount. Don't worry - only the actual dollar amount of the PA SA's total debt will be billed by the system. The last installment will be slightly lower than the other installments.

- If you want to define the amount charged on future bills to payoff the unpaid amount, enter the **Arrange Amount**. For example, if the customer agrees to pay off their delinquent debt by paying an additional \$50 on each bill, you'd enter "50" in this field. Note - If you enter a dollar amount in this field and tab out, the system will calculate the number of installments and display the number in the **Installments** field.

Define the **CIS Division** and **SA Type** of the payment arrangement service agreement.

**Note:**

Payment arrangement SA types. There is a field on SA type called **Special Role**. Only those SA types with a role of Payment Arrangement may be selected.

Clicking the **Create** (or **Change**) button causes the system to perform the following:

- It creates / updates a payment arrangement service agreement (PA SA). It sets the installment amount on this service agreement equal to the installment amount specified on the page.
- It transfers unpaid debt from the selected bills to the PA SA. The adjustment type used to transfer these funds is defined on the PA SA's SA type.
- It links the "transfer from" adjustments to the unpaid financial transactions on the bills. This will cause the unpaid FT's to be linked to Balanced match events. This means that any Active Overdue Processes for the bills should Inactivate (i.e., cancel) because the bills will no longer be consider unpaid. Refer to [How Are Overdue Processes Cancelled](#) for more information..
- It reduces the current balance on the PA SA by the amount of debt transferred to the PA SA. Why? Because when delinquent debt is transferred to the PA SA, its current balance increases. Because current balance contains the amount the customer currently owes, this balance must be reduced because the customer is going to pay off the debt in installments (and therefore they don't currently owe anything). The adjustment type used to transfer these funds is defined on the PA SA's SA type.

Clicking **Break** causes the PA SA to become broken. Please refer to the note below for what transpires when a PA is broken.

**Note:**

Break logic is in a plug-in. Please be aware that the logic that is executed when a payment arrangement is broken exists in a plug-in algorithm (plugged-in on the account's [Collection Class Overdue Rules](#)). The base package algorithm performs many functions (refer to [Breaking A Bill Oriented Payment Arrangement](#) for the details). The bottom line is that when a PA SA is broken, the originating bills will have their debt reinstated and this will again be subject to the [Overdue Monitor](#). Because this logic is in a plug-in, you can develop alternative logic and plug it in if the base package logic is not satisfactory.

Clicking **Cancel** causes the PA SA to become canceled. Cancellation should be used when you want to "logically delete" a PA SA because it shouldn't have been created.

The logic described above for breaking a payment arrangement is executed when a user cancels a payment arrangement; the only difference is that the PA SA is marked with a different characteristic type / value than when it is broken.

How To Set Up A Payment Arrangement

To set up a new payment arrangement:

- Open [Payment Arrangement for Bills](#) in add mode.
- Select the **Account** in question.
- Select the debt to be transferred to the payment arrangement (by turning on/off the checkboxes adjacent to the **Unpaid Bills**).
- Enter the number of **Installments** or the **Arrange Amount**.
- Define the **CIS Division** and **SA Type** of the new payment arrangement service agreement.
- Click the **Create** button.

How To Add Additional Debt To A Payment Arrangement

To transfer additional debt to an existing payment arrangement:

- Open [Payment Arrangement for Bills](#) in update mode.
- Select the existing payment arrangement in the search.
- Select the debt to be transferred to the payment arrangement (by turning on/off the checkboxes adjacent to the **Unpaid Bills** amounts).
- Enter the number of **Installments** or the **Arrange Amount**.
- Click the **Change** button.

Note:

After transfer. After transferring the funds to the payment arrangement service agreement, confirm the account's payoff and current balances make sense (the payoff balance is the total amount of debt that the account will eventually have to payoff, the current balance is how much they currently owe. The account's payoff and current balances are displayed in the page's second section. If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

How To Break A Payment Arrangement

You would break a payment arrangement when a customer doesn't make the agreed payments. Typically, your overdue processes will break a payment arrangement behind-the-scenes if a customer doesn't pay. Refer to [Breaking A Bill Oriented Payment Arrangement](#) for information about how the system monitors payment arrangements.

If you want to manually break a payment arrangement,

- Open [Payment Arrangement for Bills](#) in update mode.
- Select the existing payment arrangement in the search.
- Click the **Break** button.

How To Cancel A Payment Arrangement

You would cancel a payment arrangement if you made a mistake and never intended to set up the payment arrangement in the first place. To cancel a payment arrangement

- Open [Payment Arrangement for Bills](#) in update mode.
- Select the existing payment arrangement in the search.
- Click the **Cancel** button.

Dashboards

About Dashboards

Dashboards provide a broad view of numerous metrics used with Oracle Utilities Customer Care & Billing . The data presented on each dashboard is tailored to provide operational as well as analytical information for management. On some graphs, drill down options are provided to retrieve more detailed information about the metrics provided.

For information on configuration, reference the related section for [Defining Dashboard Options](#) in the *Oracle Utilities Customer Care & Billing Administrative User Guide* .

Using the Customer Operational Dashboard

This portal is used to display the Customer Operational Dashboard.

You can access the portal from the **Main > Dashboards > Customer Operational Dashboard**. Once you've selected this menu option, you're immediately brought to the initial tab of the dashboard.

The **Billing** tab displays the following zones:

- **Billing Trend**: displays bill completion counts and billed amounts by date.
- **Bill Print Trend**: displays bill print counts by date.
- **Open Bill Issues Trend**: displays open bill issue counts by date.

The **Payment** tab displays the following zones:

- **Payment Trend - All Sources**: displays payment counts and payment amounts from all sources.
- **Payment Trend - Upload**: displays upload payment counts and payment amounts.

The **To Do** tab displays the following zones:

- **To Do Completion By User**: displays To Do completion counts by user.
- **To Do Work Time By User**: displays average To Do work time by user.

The **Batch Performance** tab shows a series of zones related to any defined Performance Targets for batches. More information on Performance Targets can be found in the Framework guide.

Refer to [About Dashboards](#) for additional functional information. For information on configuration, refer to the related section for [Configuring the Customer Operational Dashboard](#) in the *Oracle Utilities Customer Care & Billing Administrative User Guide* .

Refer to each zone's embedded help for more information.

Rebate Claims

The Rebate Claims feature allows you to search, view, and maintain rebate claims submitted as part of a conservation program.

Fastpath:

For more information about conservation programs, see [Conservation Programs](#).

Rebate Claim Query Portal

You use the Rebate Claim Query Portal to search for rebate claims. Use the following procedure to search for rebate claims:

- Select **Menu > Customer Information > Rebate Claim > Search** to open the Rebate Claim Query portal.
- Enter search criteria in the Rebate Claim Search zone and click **Refresh**. You can search by:
 - Customer Name
 - Account ID
 - Conservation Program
 - Start and End Dates
- A list of rebate claims matching the search criteria appears, displaying the following for each:
 - Claim Date
 - Rebate Claim (Status, Claim Date, Conservation Program, and Total Amount)
 - Account (Name, Customer Class, Current Balance, and Account ID)
 - Total Rebate Amount
- To view a rebate claim, click the **Rebate Claim** link. The selected rebate claim opens in the Rebate Claim portal.

Rebate Claim Portal

You use the Rebate Claim portal to view, edit, and maintain rebate claims. To add a rebate claim, open **Menu > Customer Information > Rebate Claim > Search**.

The topics in this section describe the base-package zones that appear on the Rebate Claim portal.

Rebate Claim Zone

You use the Rebate Claim zone to view the details of rebate claims. The Rebate Claim zone opens when you first create a new rebate claim, or when you select a rebate claim on the Rebate Claim Search zone. The Rebate Claim zone displays the following information about the selected rebate claim:

- **Basic Information:** information about the claim, including:
 - Conservation Program
 - Status (Pending, Issue Detected, Approval in Progress, Receipt Verification, Complete, or Canceled)
 - Rebate Claim number
 - Claim Date
 - Total Rebate Amount
- **Customer Details:** details about the customer who submitted the claim, including:
 - Person
 - Account
 - Premise
 - Mailing Address
- **Contact Details:** contact information for customer who submitted the claim, including:
 - Name
 - Phone Number
 - Fax Number
 - Email Address
- **Premise Information:** information about the physical premise of the customer who submitted the claim, including:
 - Premise Property Type
 - Residential Property Type
 - Building Vintage

- **Payment Release Authorization Details:** details about the person to whom the rebate payment should be made, including:
 - Authorized By
 - Authorization Date
 - Payee Name
 - Phone Number
 - Mailing Address
- **Issue Details:** issues related to the rebate claim, including manually submitted issues as well as those detected through the Verify action.
- **Approval Details:** details related to users assigned to approve the rebate claim, including:
 - Current Approver
- **Reject Details:** details related to why a claim was rejected, including:
 - Reject Reason
 - Date Rejected
 - Rejected By

To view a different rebate claim, select the rebate claim from the **Select a Rebate Claim** drop- down list and click **Go**.

Rebate Claim Status

Rebate claims are assigned a status to indicate the current state of the claim within the system. Valid statuses include:

- **Pending** indicates the claim is pending. This is the initial state of a rebate claim when first created.
- **Issue Detected** indicates that one or more issues have been detected with the claim. Issues can include those manually created as well as issues detected through the Verify action.
- **Approval in Progress** indicates the claim is awaiting approval.
- **Receipt Verification** indicates that receipts associated with the rebate claim's claim lines need verification.
- **Complete** indicates the claim was approved and is complete.
- **Rejected** indicates the claim was rejected.
- **Canceled** indicates the claim has been canceled.

Rebate Claim Actions

You can perform a number of actions on a rebate claim, including:

- **Edit:** Used to edit the details of the rebate claim.
- **Verify:** Used to verify the supplied details of the rebate claim, and change its status to either Approval in Progress (if the claim passes the verification) or Issue Detected (if any issues are detected). This helps ensure the rebate claim has been properly set up.
- **Approve:** Used to approve a submitted rebate claim, and change its status to Complete or Receipt Verification (if receipts had not been previously verified).
- **Reject:** Used to reject a submitted rebate claim, and change its status to Complete.
- **Issue Detected:** Used to note an issue related to the rebate claim, and change its status to Issue Detected.
- **Cancel:** Cancels a rebate claim, changing its status to Canceled.

The actions available are based on the current status of the rebate claim. The table below summarizes the actions available at each status.

| Status | Valid Action |
|---------|--------------------------------------|
| Pending | Edit, Verify, Issue Detected, Cancel |

| | |
|----------------------|---------------------------------|
| Issue Detected | Edit, Verify, Cancel |
| Approval in Progress | Approve, Reject, Issue Detected |
| Receipt Verification | Issue Detected |
| Completed | None |
| Rejected | Issue Detected |
| Canceled | None |

Editing Rebate Claims

Use the following procedure to edit a rebate claim:

- Click **Edit**.
- Edit the details of the rebate claim as needed.
- Click **Save**.

Verifying Rebate Claims

To verify a rebate claim, click **Verify**.

Approving Rebate Claims

To approve a rebate claim, click **Approve**.

Rejecting Rebate Claims

Use the following procedure to reject a rebate claim:

- Click **Reject**.
- Select the **Reject Reason** on the Reject Rebate Claim dialog.
- Click **OK**. To close the dialog without rejecting the claim, click **Cancel**.

Noting Issues Related to a Rebate Claim

Use the following procedure to note an issue related to a rebate claim:

- Click **Issue Detected**.
- Enter details about the issue in the Comments field of the Issue Comments dialog.
- Click **OK**. To close the dialog without saving the comment, click **Cancel**.

Canceling Rebate Claims

Use the following procedure to cancel a rebate claim:

- Click **Cancel**.
- Select the **Cancel Reason** on the Cancel Rebate Claim dialog.
- Click **OK**. To close the dialog without cancelling the rebate claim, click **Cancel**.

Adding Rebate Claims

You can also add rebate claims from the Rebate Claim Query portal. Use the following procedure to add a rebate claim:

- Select **Menu > Customer Information > Rebate Claim > Add**, or click **Add** on the title bar of the Rebate Claim Search zone. The user is navigated to Control Central to select the customer filling the rebate claim. Click **Continue** once the correct account is in context.
- Select the Conservation Program associated with the rebate claim and click **OK**.
- Complete the Rebate Claim details, including:
 - Claim Date for the rebate claim
 - Customer Details
 - Contact Details
 - Premise Information
 - Payment Release Authorization Details
- Click **Save**. The rebate claim is displayed on the Rebate Claim portal.
- Edit the claim as needed in the Rebate Claim zone.
- Add claim lines to the claim using the Rebate Claim Line zone.

Rebate Claim Line Zone

You use the Rebate Claim Line zone to add, view, and edit rebate claim lines associated with a rebate claim. A rebate claim can have one or more claim lines, one for each item for which a rebate is requested. For example, if a customer purchases new energy efficient appliances (such as a washing machine and dryer), the rebate claim they submit would have a rebate claim line for each appliance. The Rebate Claim Line zone displays the following details for each claim line:

- Rebate Definition
- Manufacturer/Model
- Rebate Amount
- Icons to Edit, Delete, and Verify claim lines

Adding Rebate Claim Lines

Use the following procedure to add a rebate claim line to a rebate claim:

- Click **Add Rebate Claim Line** in the title bar of the Rebate Claim Line zone.
- Select the **Service Agreement** associated with the claim line from the dropdown list.
- Select the **Rebate Definition** for the claim line from the dropdown list. This list is filtered based on the Conservation Program associated with the rebate claim.
- Select the **Manufacturer/Model** for the claim line from the dropdown list. This list is filtered by the Rebate Definition selected.
- Enter the **Install Date** for the claim line.
- Enter the **Number of Units** being claimed.
- Click **Save**. To return to the Rebate Claim Line zone without adding the claim line, click **Cancel**.

Deleting Rebate Claim Lines

Use the following procedure to delete a rebate claim line from a rebate claim:

- Click the delete icon for the claim line you wish to delete.
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the claim line, click **Cancel**.

**Note:**

You can delete a rebate claim line only when the rebate claim is in Pending status.

Editing Rebate Claim Lines

Use the following procedure to edit an existing rebate claim line on a rebate claim:

- Click the edit icon for the claim line you wish to edit.
- Edit the details of the claim line as appropriate.
- If you are revising the data based on updated information, check the **Data Revised** checkbox and select the reason for the revision from the **Data Revised Reason** dropdown list. The **Original Data Details** section displays the data originally entered for the claim line.
- If the claim line contained bad data, check the **Bad Line** checkbox and select the reason for the revision from the **Bad Line Reason** dropdown list. The **Original Data Details** section displays the data originally entered for the claim line.
- Click **Save**. To return to the Rebate Claim Line zone without changing the claim line, click **Cancel**.

**Note:**

You can edit a rebate claim line only when the rebate claim is in Pending status. In addition, you cannot edit a rebate claim line after it has been verified.

Verifying Rebate Claim Lines

Use the following procedure to verify a rebate claim line on a rebate claim:

- Click the **Verify** button for the claim line you wish to verify.
- Verify that the details of the claim line match the submitted receipts.
- Click **Verify**. To return to the Rebate Claim Line zone without adding the claim line, click **Cancel**.

**Note:**

You cannot edit a rebate claim line after it has been verified.

Rebate Claim Log Zone

This is a standard [log zone](#). You use the Rebate Claim Log zone to view logging details associated with a rebate claim.

Adding Rebate Claim Log Entries

Use the following procedure to add a rebate claim log entry:

- Click **Add Log Entry** in the title bar of the Rebate Claim Log zone.
- Enter the log entry details in the Add Rebate Claim User Log dialog.
- Click **OK**. To close the dialog without saving the log entry, click **Cancel**.

Interval Billing

**Note:**

The transactions described in this section are only available if the interval billing module is turned on. This Customer Care and Billing functionality has essentially been deprecated and should be performed within a

Meter Data Management system. This functional area remains within Customer Care and Billing exclusively for upgrading customers who currently use Interval Billing within an earlier version of this system.

Note:

The interval rating and billing functionality described in this chapter was designed and developed prior to the big data requirements of the smart grid. Implementations should use a meter data management application, such as Oracle Utilities Meter Data Management, for smart grid requirements.

The interval billing functional area is responsible for managing the following:

- Collecting interval data. Any time increment can be supported. For example, electrical meter read data might be recorded in 10 minute, 15 minute, 30 minute, ... intervals; whereas daily gas consumption may have intervals that span 24 hours.
- Maintaining interval prices. Again, any time increment can be supported.
- Deriving billable interval consumption from multiple interval consumption sources. For example, actual interval consumption can be compared against a customer-specific "maximum demand" profile to derive an "excess demand" profile.
- Deriving time-of-use consumption by applying time-of-use maps to a customer's interval consumption.

This chapter describes the above points in detail.

Note:

The transactions described in this document are available only if the [interval billing](#) modules are not [turned off](#).

Interval Pricing Background Topics

The topics in this section provide background information about a variety of interval billing issues.

Billable Interval Quantities for a Service Agreement

Billable interval quantities are linked to the service agreement. These quantities are linked through an Interval Profile. The interval data that is received over time is linked to the service agreement in one of the following ways:

- It is uploaded from an external source. Refer to [Upload Interval Data](#) for more information.

- It may be created in the system through data derivation algorithms. Refer to [Creation of Profile Data through Data Derivation](#) for more information.

All the data received throughout time could be plotted as a curve. For interval quantities, the curve is referred to as an Interval Profile.

The profile references a Profile Type that defines the physical attributes of the data curve. It defines the unit of measure, the interval size and may also contain data derivation algorithms, which actually populate the profile with data based on other information. Refer to [Designing Interval Profile Types](#) and [Creation of Profile Data through Data Derivation](#) for more information.

Interval Quantities are Stored in Data Sets

Interval data in the system may have many different origins.

- It may be contract-related data that is set up at the beginning of the contract or contract year.
- It may be data that is periodically interfaced from an external source.
- It may be data that is derived and created through a system algorithm.

Regardless of the origin of the data, all data has similar characteristics:

- Data is received by the system or created by the system periodically. The system stores whatever new data needs to be stored.
- The period represented by the batch of new data is variable.
- New data may be an update to previously received data.

The system accepts the new batches of data for a given profile and stores the data grouped together by a data set.

Prices for Bill Factor “Market Price” and Characteristic Value of “Market A”

| Market Prices for Market A | |
|---------------------------------------|---------|
| Prices received 29/Oct/2000 16:38:278 | |
| Date/Time | Value |
| ... | |
| 30/Oct/2000 18:00:00 | \$0.051 |
| 30/Oct/2000 19:00:00 | \$0.042 |
| 30/Oct/2000 20:00:00 | \$0.039 |
| 30/Oct/2000 21:00:00 | \$0.038 |
| 30/Oct/2000 22:00:00 | \$0.039 |
| ... | |

← Data Set

← Data

| Market Prices for Market A | |
|---------------------------------------|---------|
| Prices received 18/Nov/2000 08:37:109 | |
| Date/Time | Value |
| ... | |
| 30/Oct/2000 19:00:00 | \$0.058 |
| 30/Oct/2000 21:00:00 | \$0.043 |
| 31/Oct/2000 02:00:00 | \$0.021 |
| 31/Oct/2000 03:00:00 | \$0.022 |
| 31/Oct/2000 04:00:00 | \$0.021 |
| 31/Oct/2000 05:00:00 | \$0.019 |
| ... | |

← Data Set

← Data

There are two effective dates referenced in the interval pricing information: **Set Date/Time** and **Interval Value Date/Time**. Think of the **Set Date/Time** as the effective date of the entire set of interval data. Think of **Interval Date/Time** as the effective date of the associated piece of data.

Refer to [Algorithms Find the Most Up To Date Data](#) for information about processing this data.

Fixing Errors with Complete Data Sets

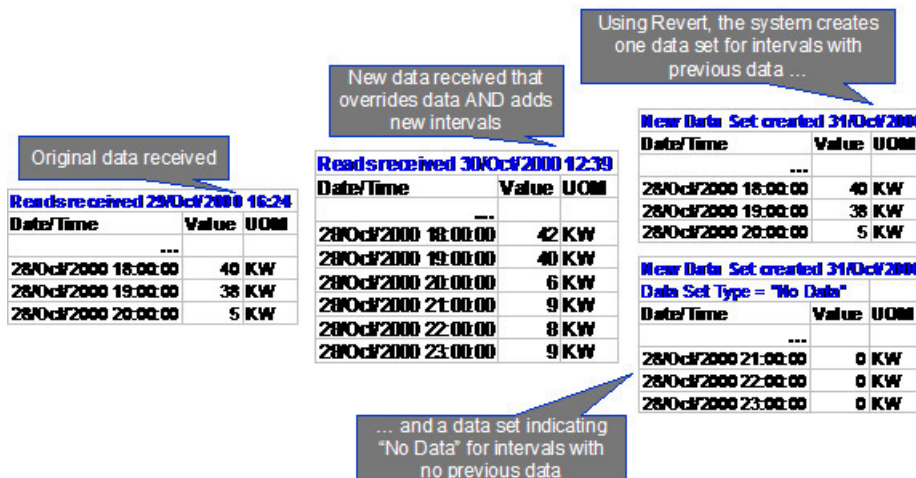

If a data set is complete, but the values are incorrect, you are not able to cancel the data set. In order to reverse the effect of a completed data set, you must create a new completed data set with corrected data.

What happens if no previous values exist for the incorrect data? There are no values available to replace the incorrect values. You essentially want to indicate to the system that no data exists for this interval. To do this, you create a data set with a special data set type of No Data.

The system provides a Revert button on the appropriate interval data pages to help the user to reverse the effect of a data set. When reverting, the system creates a new data set and populates the intervals with the most recent values for those intervals, ignoring the values in the data set being reverted. If there are no other values for any of the interval, then a "No Data" data set is created for these intervals.

Fastpath:

Refer to [Interval Data Maintenance](#), [TOU Data Maintenance](#) and [Interval Register Data Maintenance](#) for more information about setting the data set type flag and using the Revert button.

Algorithms Find the Most Up To Date Data

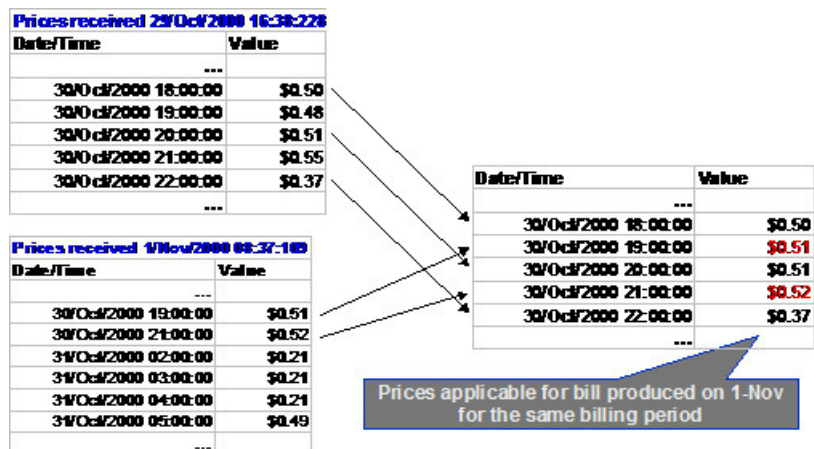

Any algorithm that must retrieve interval data, whether it is bill factor interval values or time of use map data or interval profile data, needs to ensure that it accesses the most up to date data. This includes algorithms used by the rates to process interval data and any derivation algorithm.

Refer to [Interval Quantities are Stored in Data Sets](#) for information about how interval data is stored.

The following diagram illustrates data retrieved by rates to use for billing a customer on a given date.

The following diagram illustrates what happens when data is received by the system that is a correction of previously received data. A bill produced after this data is received uses the most up to date values.

Whenever a collection of interval data needs to be accessed, the system checks the following:

- As of what date? This enables the system to find the data sets that existed in the system on that date. It looks for the appropriate data within these data sets.
- What is the time period? This enables the system to get the correct collection of interval data.

If you want to verify the data used to produce a bill,

- The "as of what date" is the bill segment creation date
- The bill segment start and end dates define the time period

Time Issues

Start and End Times for Billing

As you know, there is logic in billing to determine the start date and end date for a bill segment. Refer to [Ways to Control The End Date Of A Bill](#) for more information. When billing for a customer with interval data, the system also needs to know the time.

The time used by billing, referred to as the cutoff time, is stored on the service agreement. There is also a control on the service agreement called Start Day Option that determines which day to use for the start time. Billing algorithms use the billing date, the cutoff time, and the start day option to determine the correct interval data to process.

Billing Time Examples

Let's look at some examples for:

- Current Day Option
- Previous Day Option
- First Bill Segment

Current Day Option

- Assume that the [consumption period](#) is from the 1st of October through the 29th of October.
- Assume the cutoff time on the service agreement is 2 a.m. and the start day option is Current Day.

| Date/Time | Data |
|----------------------|--------|
| --- | |
| 01/Oct/2000 01:00:00 | \$0.51 |
| 01/Oct/2000 02:00:00 | \$0.52 |
| 01/Oct/2000 03:00:00 | \$0.21 |
| 01/Oct/2000 04:00:00 | \$0.21 |
| --- | |
| 30/Oct/2000 00:00:00 | \$0.51 |
| 30/Oct/2000 01:00:00 | \$0.52 |
| 30/Oct/2000 02:00:00 | \$0.21 |
| 30/Oct/2000 03:00:00 | \$0.21 |
| 30/Oct/2000 04:00:00 | \$0.21 |
| --- | |

The first interval used is the one AFTER the cutoff time on the bill start date

The last interval used is the one that includes the cutoff time on the day AFTER the bill end date

To determine the starting interval, the system finds the first interval after the cutoff time on the billing start date. The system uses all the intervals up to and including the cutoff time for the DAY AFTER the billing end date.

Previous Day Option

- Assume that the [consumption period](#) is from the 1st of October through the 29th of October.
- Assume the cutoff time on the service agreement is 10 p.m. and the start day option is Previous Day.

| Date/Time | Data |
|----------------------|--------|
| --- | |
| 30/Sep/2000 22:00:00 | \$0.51 |
| 30/Sep/2000 23:00:00 | \$0.52 |
| 01/Oct/2000 00:00:00 | \$0.21 |
| 01/Oct/2000 01:00:00 | \$0.21 |
| --- | |
| 29/Oct/2000 21:00:00 | \$0.51 |
| 29/Oct/2000 22:00:00 | \$0.52 |
| 29/Oct/2000 23:00:00 | \$0.21 |
| 30/Oct/2000 00:00:00 | \$0.21 |
| 30/Oct/2000 01:00:00 | \$0.21 |
| --- | |

The first interval used is the one AFTER the cutoff time on the day BEFORE the bill start date

The last interval that is the one which includes the cutoff time on the bill end date

To determine the starting interval, the system finds the first interval after the cutoff time on the DAY BEFORE the billing start date. The system uses all the intervals up to and including the cutoff time for the billing end date.

Fastpath:

Refer to [Bill Period and Seasonal Time Shifts](#) for more information about the effect of time shifting on determining the bill period.

First Bill Segment

When billing calculates the consumption period for the very first bill segment for your service agreement, it uses a flag on your SA type to correctly calculate the *initial consumption period*. For your interval billing service agreements, you typically configure your SA types to indicate that the start of the consumption period for the first bill should include the SA start date unless this is a 'back-to-back' situation (i.e., a previous customer was already billed for that day as its end date).

Let's look at an example. Imagine your SA type is configured to Add 1 Day for Back-to-back and this is not a back-to-back situation. Also imagine that your service agreement has the following defined:

- Start Date: April 1, 2003
- Start Day Option: Current
- Cutoff Time: 2am

The start period for the consumption period would be set to April 1, 2003; 2am.

Imagine the same SA exists, but this is a back-to-back situation. In other words, the previous customer ended service on April 1, 2003. Assuming the previous customer has the same start day option and cutoff time, they are billed through April 2, 2003; 2am. Refer to [Current Day Option](#) for more information. In this case, billing calculates the start period for the consumption period as April 2, 2003; 2am.

First and Last Bill Segment Considerations

Billing provides the consumption period used for defining the start and ending intervals by the interval pricing and TOU pricing algorithms.

However, for the very first bill segment for the customer, perhaps your business practice dictates that the first interval is at some time other than the cutoff time. For example, rather than billing from 2 a.m. on the first day, perhaps the meter is only installed at 3 p.m. and that is when billing should begin. Similarly, for the final interval on the last bill segment for your service agreement, you may require billing to end when the meter is removed at 4 p.m., rather than through 2 a.m. on the day after the end date.

To accomplish this functionality, follow these guidelines:

- When starting or stopping a service agreement, navigate to the [service agreement interval info](#) tab to define the appropriate starting or ending interval for each interval profile or classic TOU map linked to the service agreement using the start and end date/times in the profile or map collection.

Note:

If the start/end intervals are defined based on the date/time a meter was installed or removed, the recommendation is to design a mechanism for updating the SA/profile and SA/TOU map date/times via an interface. For example, perhaps a field activity completion algorithm could update the profile and/or map date/times according to when the meter was installed. Or perhaps a notification & workflow process is designed to update this information.

- Design your interval pricing and/or TOU pricing algorithms to override the consumption period information passed in for the first interval of the first bill segment or for the last interval for the final bill segment. These algorithms receive the service agreement effective dates so that your algorithms can easily detect whether it is the first or last bill segment for your SA. If the algorithm detects that this is the first or last bill segment for the service agreement, it can use the profile and/or TOU map start and end date/times on the service agreement rather than the calculated consumption period passed in.

Note:

The interval pricing and TOU pricing algorithms provided with the product use the consumption period calculated and passed in from billing for the first and last bill segment.

Defaulting Service Agreement Time Options

In order to facilitate setup of your service agreements with their appropriate time options, cutoff time and start day option may be defined on an [SA Type Start Option](#).

Cutoff time and start day option must also be defined on the [installation option](#) record. If your service agreement is not created with a start option, the values on the installation record are used.

Changing Service Agreement Time Options

As described above, billing uses the service agreement's cutoff time and start day option to calculate the consumption period to the interval pricing algorithms. The system currently allows you to change the cutoff time and start day option in the middle of a contract, but this is very unusual. In fact, for a given company, these settings are often the same for all interval billing customers (or at least the same for an entire class of customers). For example, a company may designate that all transportation gas customers bill from 11pm to 11pm and all other interval billing customers bill from 2 a.m. to 2 a.m..

If this information changes in the middle of a contract and non-canceled bills exist, a warning is issued. Changing either of these fields after a bill segment has been generated will cause either a gap or an overlap in intervals billed for the next bill segment. A user must manually adjust the charges accordingly.

Time Zone and Time Changes

This section describes interval data considerations when operating in different time zones and when handling seasonal time changes, such as daylight savings time.

Data is Stored in the Base Time Zone

With data stored at an interval level, provisions need to be made to cater for data captured from other time zones.

- On the installation record, you indicate the base time zone for your company data.
- ALL data must be stored in Standard time for this base time zone.

In order to help interfaces to adjust data received from a different time zone, you may store the customer's time zone on its Premise. The interface may be written to check the premise's time zone, compare it to the base time zone, and shift the data accordingly.

Fastpath:

Refer to [Designing Your Time Options](#) for more information.

Seasonal Time Shifts

A more common problem related to interval data is the problem of adjusting time for seasonal time changes. Interval data cannot be stored in "legal" time (i.e., in the summer, storing data in daylight savings time or summer time) because the shift from summer time back to standard time causes a duplicate hour. For example, in the United States, the 2 a.m. hour is repeated when shifting from Daylight Savings Time (DST) back to standard time.

| Date/Time | Value | UOM | Local time as displayed |
|----------------------|-------|-----|---------------------------------------|
| 28/Oct/2000 21:00:00 | 2000 | KW | 28/Oct/2000 22:00:00 |
| 28/Oct/2000 22:00:00 | 2302 | KW | 28/Oct/2000 23:00:00 |
| 28/Oct/2000 23:00:00 | 234 | KW | 29/Oct/2000 00:00:00 |
| 29/Oct/2000 00:00:00 | 2352 | KW | 29/Oct/2000 01:00:00 |
| 29/Oct/2000 01:00:00 | 2525 | KW | 29/Oct/2000 02:00:00 |
| 29/Oct/2000 02:00:00 | 5324 | KW | 29/Oct/2000 02:00:00 DST -> Std, +1hr |
| 29/Oct/2000 03:00:00 | 464 | KW | 29/Oct/2000 03:00:00 |
| 29/Oct/2000 04:00:00 | 25252 | KW | 29/Oct/2000 04:00:00 |
| 29/Oct/2000 05:00:00 | 252 | KW | 29/Oct/2000 05:00:00 |
| 29/Oct/2000 06:00:00 | 3453 | KW | 29/Oct/2000 06:00:00 |

To avoid the problem of duplicate records, all data must be stored in standard time. However, when entering and viewing data online, users probably want to see the data in the current "legal" time (i.e., in the summer, data is shown in daylight savings time or summer time).

The following links are provided so that you can move easily to specific topic within this section:

- [Logical Time versus Server Time](#)
- [Bill Period and Seasonal Time Shifts](#)
- [Interval Time Display](#)
- [Evenly Sized Intervals](#)

Logical Time versus Server Time

Fields may be defined as being system date / time stamps or logical data to be captured in standard time.

In the case of interval data:

- Each interval record has a Set Date / Time, which is considered server or physical time and uses the time shift information defined on the base time zone.
- The interval date/time is considered logical time and the time shift information is defined on the related "type" entity for the interval data.

[Top of Page](#)

Bill Period and Seasonal Time Shifts

As described in [Start and End Times for Billing](#), the service agreement cutoff time is used to determine the start and end times for billing.

This time is assumed to be in legal time, according to the seasonal time shift linked to the time zone for the service agreement's characteristic premise. It means that when this service agreement is billed, the system adjusts the cutoff time to standard time prior to accessing the appropriate intervals. The diagram below illustrates this point.

Cutoff Time is 2 a.m.; Standard Time begins 22,Oct

| Date/Time | Data |
|---------------------|--------|
| --- | |
| 01Oct/2000 01:00:00 | \$0.51 |
| 01Oct/2000 02:00:00 | \$0.52 |
| 01Oct/2000 03:00:00 | \$0.21 |
| 01Oct/2000 04:00:00 | \$0.21 |
| --- | |
| 30Oct/2000 00:00:00 | \$0.51 |
| 30Oct/2000 01:00:00 | \$0.52 |
| 30Oct/2000 02:00:00 | \$0.21 |
| 30Oct/2000 03:00:00 | \$0.21 |
| 30Oct/2000 04:00:00 | \$0.21 |
| --- | |

1st Oct. is during DST. The first interval is the one AFTER 2am legal time (1am standard time)

30th Oct. is during standard time. The last interval used is the one that includes the cutoff time (2 a.m.)

[Top of Page](#)

Interval Time Display

By default, the system displays interval data in legal time.

- For server related time fields, the time is displayed according to the seasonal time shift record on the base time zone.
- For interval related data, the time is displayed according to the seasonal time shift record on the interval entity's type.
- For the effective date/time links between a service agreement and its interval collections, the time is displayed according to the seasonal time shift record on the SA's characteristic premise's time zone.

A message indicates this to the user, for example, "Date /Time Info is expected in local legal time". The user can opt to change the display to show the data in standard time.

When entering new data, the user is expected to enter data in the same time that is displayed. If the message states that intervals are expected in legal time, the system assumes that the user enters new values in the legal time and converts them to standard time for storing.

Note:

If seasonal time shift information is missing for an entity or for the base time zone, data is always displayed and expected in standard time.

[Top of Page](#)

Evenly Sized Intervals

As mentioned earlier, the main drive behind shifting data to standard is to counter the effect of missing and duplicate intervals at entry to and exit from a seasonal time shift period. Storing data shifted to standard time ensures all interval records for a given curve are of equal size, which allows for simpler business logic, ignorant of seasonal time shifts considerations.

While this is obvious for hourly or less than an hour interval sizes, we would like to stress that the same concept applies to all interval sizes. If the legal time of an interval shifts during a seasonal time shift you should "counter-shift" it to standard time. If its legal time does not shift year-round, no shifting is needed.

For example, let's assume interval data being recorded in 1440 minute intervals (each read spans a full day).

- If when entering a seasonal time shift period, the legal time for these intervals shifts, say from midnight to 1 am, then when interfaced to the system data should be shifted back to standard to achieve evenly sized intervals.
- However, if the legal time does not shift, i.e. reads are taken at the same legal time, shifting is not applicable. As a matter of fact, shifting in this case causes the stored intervals to be of un-even size, thus complicating the logic that processes the data.

Note:

Base Plug-ins. If you decide to configure the system to not follow the evenly sized interval concept described above you may not be able to use the base sample plug-ins and common routines as they assume interval data is stored in evenly sized intervals.

If you are using the interval entities but your interval data have interval sizes larger than hourly (for example, daily), you may decide not to use any seasonal time shift logic. You may set a switch on the installation record to indicate whether or not your interval data should observe seasonal time shifting. Refer to [Installation Options - Billing](#) for more information.

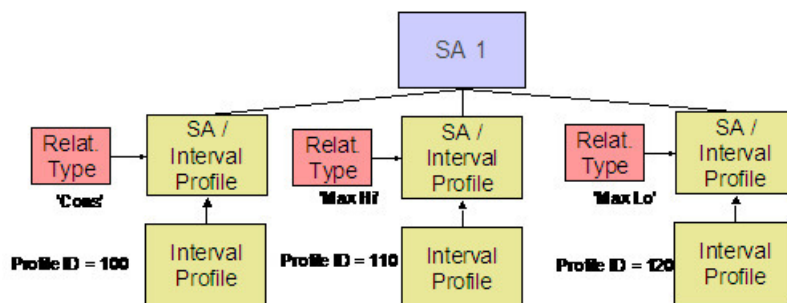

Interval Data Serves a Role for a Service Agreement

All interval quantities are linked to an Interval Profile. An interval profile may be linked to a service agreement to serve a variety of purposes, for example:

- It is used by rates algorithms to produce bill calculation lines.
- It is used by data derivation algorithms to produce other interval data.
- It is available to the company for statistical analysis or reports.

When linking an interval profile to a service agreement, the role that it is serving must be indicated. The "role" is specified using a profile relationship type. Refer to [Physical Attributes of Interval Data vs. Its Role](#) for more information.

The following diagram illustrates one service agreement with three different profiles linked to it. One profile is serving the role of Consumption, one is serving the role of Maximum High Demand, and one is serving the role of Maximum Low Demand.

If the rate for this service agreement bills for consumption, there is a rate component that references the CONS profile relationship type. Refer to [Setting Up Interval Pricing Rate Component](#) for more information.

Note:

Profiles linked to a service agreement may or may not be billable. How do we know which ones are billable? We know because for billable profiles, the rate component for the SA's rate will indicate its profile relationship type.

It is also likely that data derivation algorithms will be written use the profile relationship type as parameters for determining the correct data to process.

Common Profiles vs. SA Owned Profiles

Interval Profiles are segregated into two categories:

- Profiles that are SA Owned are linked to a single "owner" SA. For example data related to the SA's interval meters. This data may be available for calculations on other service agreements. For example, maybe you have separate service agreements for distribution and transportation and both service agreements use the same data for calculations.
- Profiles that are Common typically contain data that is not related to a specific SA and can be used by many SAs. Some examples are:
 - Contract Demand or Subscribed Demand
 - Hedge Cover
 - Maximum Demand
 - Deemed (estimated) Profile

SA owned profiles reference a service agreement that is considered the owner of that data. Only SA owned profiles may reference data derivation algorithms. These algorithms are run for the owner SA.

Refer to [Interval Profile Maintenance](#) to understand how profiles are created and maintained.

Flexibility of SA / Profile Link

The flexibility of the system allows for many combinations of profiles and service agreements:

- One profile may be linked to the same service agreement serving two different roles. Using the Profile Relationship Type to define the role, one profile could be, for example, the "Maximum Demand" and the "Minimum Demand" for a service agreement. This profile may be common or may be SA owned.
- One profile may be linked to two different service agreements. This profile may be common or may be SA owned. This profile may serve the same role for two different service agreements, or it may serve two different roles.

The Link between Profile and SA is Effective Dated

An SA /Profile link is effective dated. Therefore, the data serving a given role may change over time. To be more explicit, a service agreement may have the data for Profile A serving as the Maximum Demand interval values at the beginning of the contract, then after a few months, perhaps Profile B's data may be used instead. This scenario assumes that the contract itself did not need to change.

Why would there be a need to change the profile being used for a given role (especially when the data itself changes every few minutes anyway)? There could be several reasons:

- Using the Maximum Demand example, perhaps the customer's usage profile has changed and this change warrants a different Maximum Demand curve (although, the rate does not change). A different common profile needs to be linked to the service agreement.
- Perhaps the interval size of the data for the customer has changed. If the rate linked to the customer can cater for the new interval size, a new profile with a different profile type needs to be linked to the service agreement.
- Recall that a profile's type contains the creation and validation algorithms. Perhaps algorithms needed to create or validate this profile have changed. To cater for this a new profile with a different profile type must be linked to the service agreement.

This design also applies to the link between an SA and a classic TOU map.

Note:

All algorithms that access profile and classic TOU map data must cater for the possibility of the profile or map changing during the desired period.

Creation of Profile Data through Data Derivation

As mentioned earlier, interval data linked to a profile may be interfaced to the system from an external source or it may be created by the system through a data derivation algorithm.

The Big Picture of Data Derivation

Data derivation algorithms are used when a customer's contract requires interval data that is created based on other interval data in the system.

Some examples may include:

- Adjusting measured demand to account for loss factors to produce an adjusted billable data curve
- Comparing measured data to a contract demand curve to produce an adjusted billable data curve
- Comparing measured data to a maximum demand curve to produce an excess load curve
- Aggregating raw interval data from multiple interval registers linked to the service agreement's service points
- And more...

How is this set up in the system? Using the above loss factor example, let's make the following assumptions:

- The ½ Hourly MWh curve is an SA Owned profile linked to the service agreement. Its data is interfaced into the system from an external source. Refer to [Upload Interval Data](#) for more information.
- The ½ Hourly % loss are common for a group of customers and are stored as bill factor interval values. Refer to [Bill Factor Interval Values](#) for more information.
- The Adjusted MWh curve is an SA Owned profile linked to the service agreement. Its data is created by the system through a Creation data derivation algorithm linked to the [profile type](#).

The creation algorithm (that would need to be written to handle this example) would be provided with the profile relationship type of the ½ Hourly MWh curve and the Bill Factor for the loss factors. It applies the percentage loss factor for each interval and stores the result for each interval as a new data set for the Adjusted MWh curve.

These algorithms may be executed in one of the following ways:

- Through a background process that finds every SA that has an interval profile whose profile type indicates a creation algorithm. Refer to [Process IB-SPDB - SA Interval Profile Data Creation](#) for more information.
- There is a button available on the [SA Interval Info](#) page that allows a user to execute the data derivation algorithms for a single SA.
- There is a button available on the [Account Interval Info](#) page that allows a user to execute the data derivation algorithms for all the service agreements for an Account. The service agreements are processed in the [billing processing sequence](#) order defined on their [SA type](#).

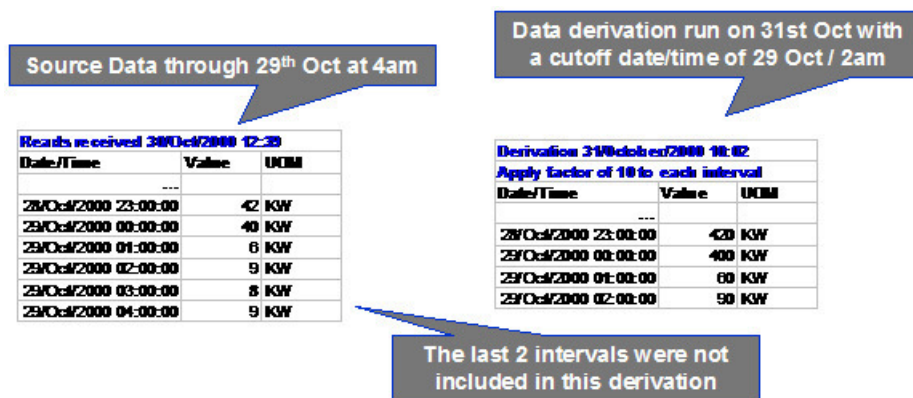

Determining What Interval Data To Derive

Preventing Gaps in Data

How do the derivation algorithms know what data needs to be derived? A simple answer is any data received since the last time data was derived should be included in the new derivation. This answer sounds good, but it's not as simple as that. Although we know the date and time of the last derivation, we don't know the date range of the data that was derived. A user may ask for data to be derived only through a certain date, even though data exists after that date. The next time data derivation runs, it may need to include the data that was after the cutoff for the previous derivation.

To illustrate this point, let's look at an example. Assume that a derivation algorithm takes a source curve and applies a value from a bill factor to arrive at the new curve. In the illustration below, data for the source curve exists up to 29 th of October 2000 at 4 a.m. When deriving new data, the user enters a cutoff date of the 29 th of October. The time used is the Cutoff Time on the service agreement, which in this case is 2 a.m. Refer to [Start and End Times for Billing](#) for more information.

The user runs the data derivation on the 31 st of October at 10:02. That date and time are the Set Date /Time for the newly created data set.

The next time data derivation runs, it is not possible for the algorithm to simply derive data that has been received since the last time data derivation was run. In the above example, only data received after the 31 st of October will be derived. However, the last two intervals for the source data received on the 30 th of October also need to be included.

The following diagram illustrates how the next derivation should behave.

| Results received 28/Oct/2000 12:39 | | |
|------------------------------------|-------|-----|
| Date/Time | Value | UOM |
| --- | | |
| 28/Oct/2000 23:00:00 | 42 | KW |
| 29/Oct/2000 00:00:00 | 40 | KW |
| 29/Oct/2000 01:00:00 | 6 | KW |
| 29/Oct/2000 02:00:00 | 9 | KW |
| 29/Oct/2000 03:00:00 | 8 | KW |
| 29/Oct/2000 04:00:00 | 9 | KW |

| Results received 30/Nov/2000 2:21 | | |
|-----------------------------------|-------|-----|
| Date/Time | Value | UOM |
| 28/Oct/2000 05:00:00 | 8 | KW |
| 28/Oct/2000 06:00:00 | 7 | KW |
| 28/Oct/2000 07:00:00 | 10 | KW |
| --- | | |
| 29/Nov/2000 01:00:00 | 6 | KW |
| 29/Nov/2000 02:00:00 | 7 | KW |
| 29/Nov/2000 03:00:00 | 7 | KW |

| Derivation 10/December/2000 1:19 | | |
|-------------------------------------|-------|-----|
| Apply factor of 10 to each interval | | |
| Date/Time | Value | UOM |
| 29/Oct/2000 03:00:00 | 80 | KW |
| 29/Oct/2000 04:00:00 | 90 | KW |
| 29/Oct/2000 05:00:00 | 80 | KW |
| 29/Oct/2000 06:00:00 | 70 | KW |
| --- | | |
| 29/Nov/2000 01:00:00 | 60 | KW |
| 29/Nov/2000 02:00:00 | 70 | KW |

Next data derivation run should include the intervals from the 'old' data set that weren't included in the last derivation

New data received later

Because users have control over what data may be derived (using the cutoff date), the algorithms cannot rely on data received since the last derivation.

To be safe and ensure that no gaps exist in the derived data, the algorithms should look for each interval from either the start of the SA or the start of the SA/Profile relationship through to the cutoff date/time to determine if new data should be derived. However, for performance reasons (and practical reasons) the algorithms supplied with the base product only look for new data to derive starting 45 days prior to the cutoff date. This is a soft parameter to the algorithms called **Number of Days to Process** and may be changed. Implementation specific algorithms may choose not to follow this example, but you must be sure to consider the performance implications.

Note:

The derivation algorithms are provided both the SA start date and cutoff time and the SA/Profile date/time. The base algorithms derive data from the SA start date/cutoff time. Implementation specific algorithms have the option of deriving data from SA/profile date/time.

Fastpath:

Refer to [interval profile type](#) for more information about the sample data derivation algorithms provided with the base product.

Using The Latest Updates to Source Data

As described in [Algorithms Find the Most Up To Date Data](#), the data derivation algorithms must also detect whether new data has been received for a given source interval that has already been used in derivation. For these cases, the more up-to-date data for the source interval should be used to re-derive the target curve.

Force Derivation of Interval Data

Derivation algorithms base their calculations on data from other profiles, classic TOU maps, registers, bill factors, contract options and so on. These may be referred to as the algorithms' source data.

Ideally, derivation algorithms should be able to detect changes made to their source data since the last derivation and re-derive values for the relevant periods if any changes are detected. Refer to [Using the Latest Updates to Source Data](#) for more information.

As long as the source data has means of recording changes (e.g. an update date/time stamped on the new records), the algorithm can detect the changes and trigger re-derivation. However, not all objects in the system have this recording mechanism, making automatic detection of changes for re-derivation impossible.

Consider the sample derivation algorithm in [Preventing Gaps in Data](#). This algorithm used a bill factor to apply a constant to the source curve to arrive at a derived curve. Imagine that the users discover that the bill factor value was incorrect and that once this value is fixed, the data needs to be re-derived. The algorithms have no way of knowing that this bill factor has changed. In such cases, the user may run derivation and specify a period for which to force derivation, so that re-derivation with new values may take place. Refer to the background processes [Process IB-SPDB - SA Interval Profile Data Creation](#) and [Process IB-STDB - SA TOU Data Creation](#) for information about running derivation through batch. Refer to [Service Agreement - Interval Info](#) for information about running derivation online.

Note:

The base derivation algorithms only support force derivation when there is source data other than interval data, such as a bill factor.

Process IB-SPDB - SA Interval Profile Data Creation

This process derives interval data for accounts in the system. Only accounts that have at least one interval service agreement with derivable profiles linked to it are processed. A 'derivable' profile is an SA Owned profile where this SA is the owner AND the profile type indicates an "Interval Data Creation" derivation algorithm. Interval data for service agreements linked to the account are derived in [billing processing sequence](#) order as defined on their [SA type](#).

Refer to [Determining What Interval Data To Derive](#) and [Start and End Times for Billing](#) for information about which records are processed by the algorithm.

For each service agreement, the interval data creation algorithms are executed in creation priority order. Refer to [Setting Up Interval Profile Types](#) for more information about defining Interval Data Creation algorithm for an interval profile type.

This process supports [Force Derivation](#) and passes the related input parameters to the data derivation algorithms.

Note:

This process is designed to run in parallel threads. Every thread processes a range of accounts.

Any errors detected during this process cause the new data set to be created in Error status and an entry to be written to the [Interval Data Exception](#) table. You can fix these errors by canceling the newly created data set and fixing the source of the problem. Refer to [How to Correct a Data Set in Error](#) for more information.

Validation of Profile Data

In addition to specifying algorithms to create data for an interval profile, you may also create algorithms to validate interval profile data. As with the creation algorithms, your validations algorithms are specified on the interval profile type. An interval profile type may specify more than one validation algorithm. If so, they are executed in priority order.

Any errors detected by the validation algorithms cause the invalid data set to be marked in Error status and an entry to be written to the [Interval Data Exception](#) table. You can fix these errors by fixing the source of the problem. Refer to [How to Correct a Data Set in Error](#) for more information.

These algorithms may be executed in one of two ways:

- Through a background process that finds every interval profile whose interval profile type specifies a validation algorithm. If multiple validation algorithms exist for a given profile type, they are executed one after the other in their predefined sequence order. Refer to [Process IPDSDVB - Interval Profile Data Validation](#) for more information.
- There is a button available on the [Interval Profile](#) page that allows a user to execute the validation algorithms for a single profile. If multiple validation algorithms exist for a given profile type, they are executed one after the other in their predefined sequence order.

Process IPDSDVB - Interval Profile Data Validation

The [IPDSSDV](#) background process is used to validate interval profile data. It processes pending interval profiles that were created up to the cutoff date/time and executes their validation algorithms, if any, defined on the profile type. The algorithms are executed in their predefined sequence order.

The standard business date is used together with the [installation base time](#) to derive the cutoff date/time that is passed to the validation algorithms. For example, if the batch business processing date is 09/08/2003 and the installation base time is 2:00AM, the cutoff date/time is calculated as 09/08/2003 02:00AM. When no business date is specified, it is set to current date.

It is important that ALL validation algorithms are provided with the same cutoff date/time as their referenced date/time. This identifies the collection of pending interval profiles to be processed as of a given date/time. This way even if a new profile is created after one validation algorithm is executed but before a subsequent validation algorithm is executed, the new profile is still not processed because it was not created by the cutoff date/time.

Refer to [Setting Up Interval Profile Types](#) for more information about defining Interval Data Validation algorithm for an interval profile type.

Note:

This process is designed to run in parallel threads. Each thread processes a range of profiles.

Fastpath:

Refer to [Validation of Profile Data](#) for more information.

Auditing Your Interval Pricing Bill Lines

Given the amount of data used to produce a bill calculation line for an interval pricing rate component, how can a customer service representative audit this bill line to understand how it was calculated? Interval pricing rate components allow you to set up an Audit Algorithm. This audit algorithm retrieves the records used to produce the bill line. As a result, the audit algorithm should take advantage of the logic used in the calculation algorithm that produced the bill line. The relevant code should be shared between the two algorithms.

Refer to [Interval Billing Calculation Details](#) to view the results of calling an audit algorithm.

Refer to [Setting Up Interval Pricing Rate Components](#) for more information related to linking an audit algorithm to your rate component.

Warning:

Snapshots of the data used to generate a bill are not taken. Rather, auditing your interval pricing bill lines rely on the interval data tables. As a result, **data records should not be changed**. To correct an interval, you should add a new interval data set to correct the interval data. Refer to [How To Correct a Data Set in Error](#) for more information.

The Big Picture of Raw Data Collection and Aggregation

The topics in this section describe the ability of the system to collect raw interval data, provide the ability to run validation algorithms on this data, and aggregate data for use on interval profiles used for billing. This functionality is sometimes referred to as "meter read pretreatment".

Some organizations use an external system to collect and aggregate the raw interval data. This information is interfaced directly to the SA interval profiles as billable data. From there, contract based adjustments may be applied.

Some organizations use Oracle Utilities Customer Care and Billing to collect and aggregate their raw interval data. This information is interfaced to interval registers linked to the service point's meter. Validation algorithms may be applied against this data to ensure that the data is valid. Interval profile creation algorithms for the SA may aggregate the raw data from the appropriate service points to prepare for billing.

Note:

If your organization uses an external system for this functionality, skip this section.

Interval Channels and Index Channels

Channel is a term often used for devices that may store data for complex metering customers. A physical channel may contain interval data or index readings:

- Index channels are a collection of time-of-use readings.
 - The information is often considered more accurate than interval data.
 - Index Channels are typically set up as a meter, where each register in the meter configuration represents a time of use code. Refer to [The Structure Of A Meter](#) for more information.
- Interval channels contain collections of interval data. This interval data follows the same logic as interval profile data. Refer to [Interval Quantities are Stored in Data Sets](#), [Fixing Errors with Complete Data Sets](#) and [Algorithms Find the Most Up To Date Data](#) for more information. An interval channel is set up as a register that is marked as "interval". Interval register data may be linked to this interval register.

Your setup of meters, meter configurations, and registers is very flexible:

- The meter in the system doesn't have to represent a physical meter.
- The meter represents a single channel or a collection of channels.
- Any of the following meter configurations are possible:
 - A single interval channel
 - Multiple interval channels
 - A collection of TOUs for an index channel
 - A combination of interval registers and TOUs for an index channel

Fastpath:

Refer to [Maintaining Meter Configurations](#) for more topics related to meter configurations.

Note:

In Oracle Utilities Customer Care and Billing, the term "channel" is only used for the Channel ID on the register, which is used as an external ID. In the system, you will use meters, meter configurations and registers to model your channels.

No special logic is required for index channels. The reads for the time of use collection for an index channel require the same logic that exists for standard non-interval registers.

Installation of Interval and Index Channels

Installing a configuration for an index or interval channel to a service point is the same procedure as installing a configuration of standard registers.

- You must define the meter configuration that is being installed.
- The installation is effective-dated. There must be a meter read on the install date.

Note that for interval registers, register reads are not allowed. However, you may create meter reads without register reads in order to install a meter configuration with interval registers on a service point.

Fastpath:

Refer to [SP/Meter Installation](#) for more information about installing meters at service points.

Validation of Register Data

You may create algorithms to validate interval register data. Your validations algorithms are specified on the interval register type. An interval register type may specify multiple validation algorithms that are executed in priority order.

Any errors detected by the validation algorithms cause an invalid data set to be marked in Error status and an entry to be written to the [Interval Register Data Exception](#) table. You can fix these errors by fixing the source of the problem. Refer to [How to Correct a Register Data Set in Error](#) for more information.

These algorithms may be executed in one of two ways:

- Through a background process that finds every interval register with an interval register type that specifies a validation algorithm. If multiple validation algorithms exist for a given interval register type, they are executed in their predefined sequence order. Refer to [Process IREGDVB - Interval Register Data Validation](#) for more information.
- There is a button available on the Meter Configuration page that allows a user to execute the validation algorithms for all the interval registers linked to the meter configuration. If multiple validation algorithms exist for a given interval register type, they are executed one after the other in their predefined sequence order. Refer to [Meter Configuration](#) for more information.

Process IREGDVB - Interval Register Data Validation

The [IREGDVB](#) background process is used to validate interval register data. It processes pending interval registers that were created up to the cutoff date/time and executes their validation algorithms, if any, defined on their register type. The algorithms are executed one after the other in their predefined sequence order.

The standard business date is used together with the [installation base time](#) to derive the cutoff date/time that is passed to the validation algorithms. For example, if the batch business processing date is 09/08/2003 and the installation base time is 2:00AM, the cutoff date/time is calculated as 09/08/2003 02:00AM. When no business date is specified, it is set to current date.

It is important that ALL validation algorithms are provided with the same cutoff date/time as their referenced date/time. This identifies the collection of pending data sets to be processed as of a given date/time. This way even if a new data set is created after one validation algorithm is executed but before a subsequent validation algorithm is executed, the new data set is still not processed because it was not created by the cutoff date/time.

Refer to [Setting Up Interval Register Types](#) for more information about defining Interval Register Data Validation algorithm for an interval register type.

Note:

This process is designed to run in parallel threads. Every thread processes a range of registers.

Fastpath:

Refer to [Validation of Register Data](#) for more information.

Processing Raw Data

The raw interval data linked to your registers is not used directly by rate algorithms. The rate algorithms only process profile data linked to the service agreement. Valid interval register data is available for use by the profile data derivation algorithms to produce billable profile data for a service agreement. For example, a profile data derivation algorithm may aggregate the register data from multiple registers to produce a new load curve.

A challenge for the aggregation algorithms is to determine which register data is applicable for a given profile. The service agreement may be linked to multiple service points, each with many different possible configurations. Because the derivation algorithm is on the interval profile type, you cannot explicitly tell the algorithm which registers to use. The following information may be useful to the algorithms to determine the appropriate registers:

- Service points linked to the service agreement. First and foremost, the algorithms restrict the selection of registers to those for the service points linked to the service agreement.
- UOM and SQI. Each interval register type indicates a unit of measure and an optional SQI that may be used by algorithms. For example, the base algorithm, which performs aggregation, finds interval registers with a UOM that matches that of the interval profile type. This algorithm also has soft parameters to indicate whether the SQI codes on the interval register type and interval profile type should match.

- If these attributes are not enough to indicate the correct registers to the algorithms, characteristics are also available for use. There are characteristics on the service point, the SA/SP and the meter that may all be used to capture information available to the processing algorithms to determine the appropriate registers.

Fastpath:

Refer to [Designing Interval Profile Types](#) for more information about the aggregation algorithm provided with the system.

Applying Adjustments To Raw Data Prior to Aggregation

It is common for a contract to require adjustments to raw data prior to aggregating the data onto a profile. For example, perhaps all the data for a given register should be adjusted by 5% based on contract requirements. These adjustments may be applicable to only certain interval registers for the contract. In addition, it is common for more than one contract to use the same register data and perhaps only certain contracts require an adjustment to that data.

To satisfy this requirement, characteristics on the SA/SP may be used to indicate adjustment factors. The appropriate derivation algorithms may then apply the adjustment factors while aggregating the data.

Note:

The aggregation algorithm provided with the system does not apply any adjustment factors.

Fastpath:

Refer to [Service Agreement - SA/SP](#) for more information about SA/SP characteristics.

Time of Use Mapping Background Topics

This section describes information related to how data is stored for classic TOU Maps and how classic TOU Maps are linked to service agreements. For information about defining time of use codes and other related topics, refer to [Time of Use Billing](#).

For information about defining time of use rate components, refer to [Designing Your Time Of Use Rate Components](#). For information about defining TOU prices and values, refer to [Bill Factor TOU Values](#).

Time Period Definitions are Stored in Data Sets

The time period definitions for a classic TOU map may have many different origins.

- It may be contract-related data that is set up at the beginning of the contract or contract year
- It may be interfaced from an external source periodically. This can occur when a customer's classic TOU map is defined dynamically based on information received from a third party.
- It may be that data needs to be overwritten for a given day. Perhaps the company has a planned interruption that changes the time period definitions for a given day. New data for the classic TOU map for that day needs to be linked to the map.

Regardless of the origin of the data, all data have similar characteristics:

- Data is received or created by the system periodically. The system stores whatever new data needs to be stored.
- The period represented by the batch of new data is variable.
- New data may be an update to previously received data.

Fastpath:

Refer to [Interval Quantities are Stored in Data Sets](#) for more information about how interval data is stored. This same model is used for TOU data. There is no difference.

Refer to [Fixing Errors with Complete Data](#) for information about how to distinguish fixing errors with complete data by creating new data sets. This same model is used for TOU data.

**Note:**

The system is able to generate data for a classic TOU map based on predefined templates. Refer to [Generating TOU data for a classic TOU Map](#) for more information.

Sharing Classic TOU Map Data

Classic TOU mapping data may be shared by more than one service agreement. There are several ways to accomplish this and your business rules will dictate the best way to do this.

Classic TOU Map Common To All SAs on the Rate

If a TOU pricing rate component on the service agreement's rate performs classic TOU mapping and/or pricing, it is possible that all service agreements for the rate use the same common classic TOU map. In this case, you indicate the classic TOU map to use directly on the rate component. In this scenario, no map information is needed for the service agreement. Refer to [Designing Your Time Of Use Rate Components](#) for more information.

Classic TOU Map Common To a Subset of Service Agreements

If not all service agreements linked to your rate use the same classic TOU map for a TOU pricing rate component, it may still be the case that a subset of those service agreements use the same classic TOU map. In this case, the appropriate classic TOU map for each service agreement must be linked to the appropriate common classic TOU map.

To set up these types of service agreements correctly, the appropriate start option should indicate the common classic TOU map to link to the SA. Refer to [Designing Your IB Start Options](#) for more information.

Classic TOU Map Owned by a Service Agreement

Some of your service agreement may require unique map data. These types of classic TOU maps are typically used for customers whose map data is determined by factors related to the specific contract. It is possible for SA owned classic TOU map types to reference [data creation](#) algorithms. This allows the classic TOU map data to be overridden or determined dynamically.

While SA Owned classic TOU maps are linked to a single "owner" SA, it's possible for this classic TOU map to be used by other service agreements (typically ones that are linked to the same account.)

To set up these types of service agreements correctly, the appropriate start option should indicate the classic TOU map type to use when creating a new SA Owned classic TOU map to link to the SA. Refer to [Designing Your IB Start Options](#) for more information.

Classic TOU Maps Linked to a Service Agreement

As mentioned above, if a service agreement's rate performs classic TOU mapping and/or pricing and the classic TOU map to use varies for different service agreements, the appropriate map must be linked to the service agreement.

There may be other reasons to link a classic TOU map to a service agreement. For example, a data derivation algorithm may require a classic TOU map for the service agreement.

The topics in this section describe other logic related to linking a classic TOU map to a service agreement.

Classic TOU Maps Serve a Role for a Service Agreement

A classic TOU map may be linked to a service agreement to serve a variety of purposes, for example:

- Rate algorithms map interval quantities in order to apply prices for each TOU.
- Data derivation algorithms compare quantities to TOU values in order to validate the data or produce a new curve.

When linking a classic TOU map to a service agreement, the role that it is serving must be indicated. The "role" is specified using a classic TOU Map Relationship Type.

This is the same model as the one used to link interval profiles to service agreements. Refer to [Interval Data Serves a Role for a Service Agreement](#) for more information.

If a TOU pricing rate component indicates a classic TOU map relationship type, it is used to find the correct classic TOU map for the service agreement for mapping the interval data. Refer to [Setting Up Classic TOU Mapping Rate Components](#) for more information.

The Link between Classic TOU Map and SA is Effective Dated

An SA /TOU Map link is effective dated. Therefore, the classic TOU map serving a given role may change over time.

This is the same model as the one used to link interval profiles to service agreements. Refer to [The Link between Profile and SA is Effective Dated](#) for more information.

Customer Specific TOU Values

As described in [Bill Factor TOU Values](#), a bill factor may define prices or values for a collection of time of use codes. A TOU bill factor may also indicate that the value can be found in a contract term. This enables you to define customer specific time-of-use prices or contract values.

The TOU Contract Values page enables you to define a set of values for a collection of time-of-use codes. The collection is effective dated. This data is available for use by rate component algorithms that apply prices for time-of-use quantities or data derivation algorithms that need contract based TOU values to perform derivation. Refer to [Service Agreement - TOU Contract Values](#) for more information about defining TOU Contract Values.

Generating Data for a Classic TOU Map

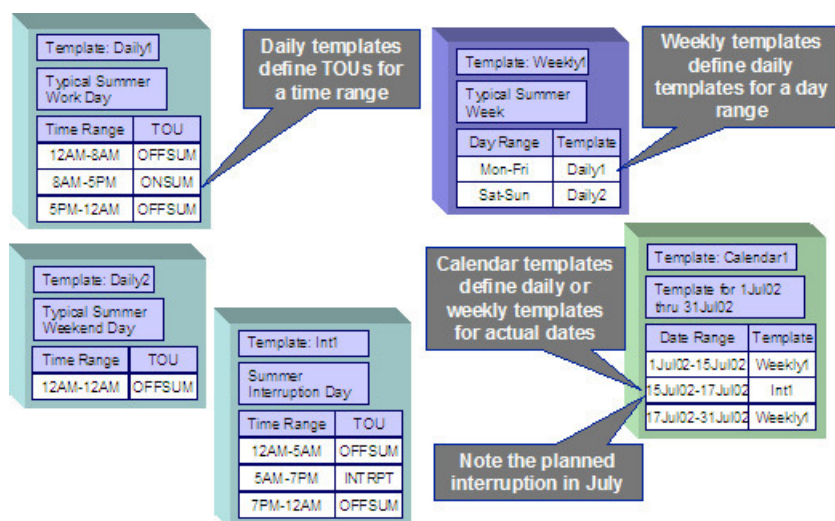

The data for a classic TOU map is a collection of date and time intervals and their corresponding time-of-use codes. Even though you may have several consecutive time periods referencing the same time-of-use code, each interval must be separately defined.

In order to facilitate the creation of data for a classic TOU map, the system enables you to define classic TOU map templates and provides you with the ability to generate data for a classic TOU map based on this template.

Actually, you may define a series of templates that work together to produce data for a classic TOU map. For example:

- Use a daily template to define time period ranges in a day with their associated TOU codes.
- Use a weekly template to define days of the week and the appropriate daily templates to use for each day.
- Use calendar template to define the weekly and daily templates applicable for actual dates in a year.

The following diagram illustrates a simple example of a collection of templates you may define for a summer period.

In the above example, a US resident may notice that no holiday is defined for the 4th of July. One would expect that if a holiday falls on a weekday, the typical weekday time period definitions may not apply.

The system is designed so that you don't have to define holidays in a classic TOU map template with their explicit dates.

- You have already defined which days of the year are holidays on the Calendar table.
- If all your holidays follow the same time period definition requirements, define a daily template that should be used for holidays.

When generating data for a classic TOU map, you are asked for:

- The appropriate calendar where your holidays are defined
- The holiday template

The TOU data generator automatically uses the holiday map for holidays defined in the calendar table.

Fastpath:

Refer to [Setting up Classic TOU Map Templates](#) for more information about defining your classic TOU map templates.

Refer to [Classic TOU Map Generation](#) for more information about generating data for a TOU map based on a template.

Automatic Creation of Classic TOU Map Data

The section [Generating Data for a Classic TOU Map](#) describes how classic TOU map templates may be set up and used to generate classic TOU map data. When defining the appropriate TOU map for a given contract, you typically generate the TOU map data at the beginning of the contract year.

However, for many contracts, you may define special situations, such as interruptions, when an override classic TOU map is applicable for a certain time period. In fact, you may have a group of customers, who are all affected by the same interruption. The system allows you to configure your interval billing options such that once your interruption period has been defined an override classic TOU map for that interruption period can be generated for all customers.

In order to generate classic TOU map data, you need to design and create an appropriate algorithm. TOU map creation algorithms are linked to the classic TOU map type. You also need to define the "special situation", for example, the interruption.

Refer to [Contract Option Background Topics](#) for more information about special events that may alter the rate calculations.

In addition, refer to [Interval Billing Examples - Override Maps](#) for an example of how to set up an interruption example.

TOU map creation algorithms may be executed in one of the following ways:

- Through a background process that finds every SA that has a TOU map with a classic TOU map type that indicates a creation algorithm. Refer to [Process IB-STDB - SA TOU Data Creation](#) for more information.
- There is a button available on the [SA Interval Info](#) page that allows a user to execute the TOU data derivation algorithms for a single SA.
- There is a button available on the [Account Interval Info](#) page that allows a user to execute the TOU data derivation algorithms for all the service agreements for an account. The service agreements are processed in the [billing processing sequence](#) order defined on their [SA type](#).

Determining What TOU Data To Derive

Refer to [Determining What Interval Data To Derive](#) for detail about ensuring that no gaps exist and ensuring that the algorithms are always using the latest data for derivation.

Note:

one difference between the base TOU creation algorithms and the base interval derivation algorithms is that the TOU creation algorithms do not use a **Number of Days to Process**. This is because the base algorithm processes contract option events and the volume of contract option events in the system is not as high as the volume processed by the interval data derivation algorithms.

Force Derivation for Classic TOU Map Data

Refer to [Force Derivation of Interval Data](#) for information on how the system may allow a user to force derivation for situations where the system may not be able to detect that source data has changed. The same logic is available for TOU map creation algorithms.

Note:

The source data for the base TOU map creation algorithms is always contract option data and as a result, there is no need to support Force Derivation in those algorithms.

Process IB-STDB - SA TOU Data Creation

This process derives classic TOU map data for accounts in the system. Only accounts that have at least one interval service agreement with derivable classic TOU maps linked to it are processed. A 'derivable' map is an SA Owned map where this SA is the owner AND the map type indicates a "TOU Data Creation" algorithm. TOU map data for service agreements linked to the Account are derived in [billing processing sequence](#) order as defined on their [SA type](#).

For each service agreement, the classic TOU Map Creation algorithms are executed in creation priority order. Refer to [Setting Up Classic TOU Map Types](#) for more information about defining a TOU Data Creation algorithm for a classic TOU map type.

This process supports [Force Derivation](#) and passes the related input parameters to the data creation algorithms.

Note:

This process is designed to run in parallel threads. Each thread processes a range of accounts.

Any errors detected during this process cause the new data set to be created in Error status and an entry to be written to the [TOU Data Exception](#) table. You can fix these errors by canceling the newly created data set and fixing the source of the problem. Refer to [How to Correct a TOU Data Set in Error](#) for more information.

Auditing Your TOU Pricing Bill Lines

Just as with interval pricing rate components, TOU pricing rate components may also use an audit algorithm to enable a user to view the details of the calculations.

Refer to [Interval Billing Calculation Details](#) to view the results of calling an audit algorithm.

Refer to [Setting Up TOU Pricing Rate Components](#) for more information related to linking an audit algorithm to your rate component.

Warning:

Snapshots of the data used to generate a bill are not taken. Rather, auditing your TOU pricing bill lines rely on the interval data and classic TOU mapping data tables. As a result, **data records should not be changed**. To correct data, you should add a new data set. Refer to [How To Correct a Data Set in Error](#) for more information.

Contract Option Background Topics

This section describes information related to contract options under which certain calculations supporting a contract's rate may be overridden or altered occasionally for specific periods of time. Also refer to [Designing Your Contract Options](#) for more information.

Overview

For some of your interval billing customers, you may define additional options under which certain calculations supporting the customer's rate may be overridden or altered occasionally for specific periods of time. Some examples of such options are:

- Special days throughout the year on which the contract's TOU map is overridden with a special predefined TOU pattern specified for that type of day
- Periods of time during which customers are required to lower their demand by a predefined contractual amount of power
- Occasional offers to pay a special price for energy falling within a specific demand range

A Contract Option Has Events

A contract option must be defined for each special option on a given rate. The contract option is linked to every service agreement eligible for this option.

The option may be related to a given service agreement or may be linked to many service agreements.

Fastpath:

Refer to [Contract Option Maintenance](#) for more information about creating contract options and refer to [Service Agreement - Contract Option](#) for more information about linking contract options to service agreements.

Each contract option contains a collection of contract option events. The events are the individual instances of the special option. Each event indicates its effective period. A given contract option may define different types of events. For example, perhaps you have several types of interruptions that should cause different overrides to occur. It is the responsibility of your data derivation algorithms and/or your rate algorithms to know how to process these events for a customer who may have contract options.

Fastpath:

Refer to [Contract Option Event Maintenance](#) for more information about creating contract option events.

The following are some examples of algorithms that may process contract option events:

- You may have a classic TOU map creation algorithm that creates override TOU map data for the period defined on a contract option event. This override map may define different time-of-use codes for a certain time period, where different prices are applicable or may alter the time period definitions for this special time periods. The standard TOU pricing rate component would then apply the appropriate prices for this override time period.
- You may have a TOU pricing rate component that only applies a charge if contract option events exist for billing period. For example, it may calculate a special charge based on whether a customer reduced their demand during a specific period.

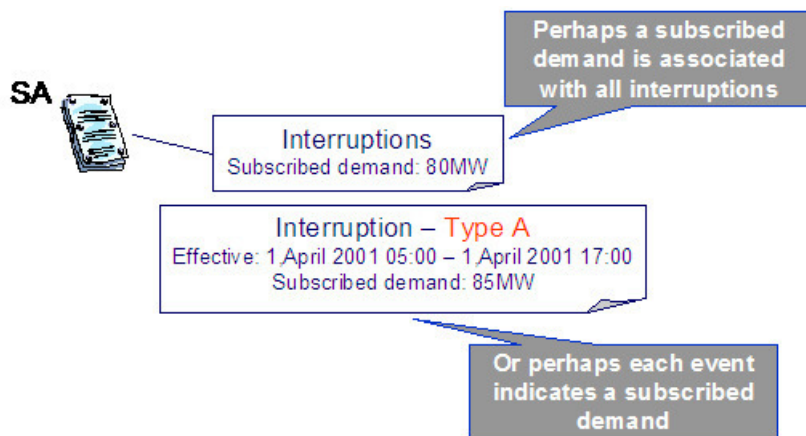

Fastpath:

For more examples, refer to [Interval Billing Examples](#).

Options and Events May Have Characteristics

It is possible that your algorithms require extra information related to a contract option or a contract option event. For example, perhaps the customer's demand during a contract option event period must be compared to a subscribed demand. Perhaps the subscribed demand is applicable to all customers linked to this contract option. Or perhaps the subscribed demand changes for each instance of the option, in other words for each event.

Characteristics are used to define this extra information. Your algorithms would then use the information in the characteristic collection for either the contract option or the contract option event during its processing.

SA May Override a Shared Event

There may be cases where an individual customer wants to override the effects of a shared contract option event. If a given contract option event is not applicable to one of the service agreements linked to the contract option, a contract option event override may be created for this service agreement. The existence of an override cancels the effects of the shared contract option event for that SA.

You may also cancel an override, which essentially reinstates the specific event for the service agreement.

Note:

Algorithms that process contract option events must process the service agreement overrides as well. This includes processing overrides that are subsequently canceled.

Fastpath:

Refer to [Service Agreement - Contract Option](#) for more information about entering contract option overrides.

Validation of Events

The system provides you with the ability to run validation algorithms to validate your events. The validation algorithms may be used, for example, to validate the characteristics linked to your events. You may define separate validation algorithms that are executed based on the status:

- Pending algorithms are executed when adding or changing a record in Pending status.
- Freeze algorithms are executed when attempting to change the status from Pending to Freeze.
- Cancel algorithms are executed when attempting to change the status from Freeze to Cancel.

**Fastpath:**

Refer to [Designing Your Contract Option Types](#) for more information about contract option event algorithms.

Maintaining Interval Data

In this section, we describe the pages that maintain interval billing and classic TOU mapping information.

Account Interval Info Maintenance

Open **Menu** > **Customer Information** > **Account Interval Information** to view interval profiles and classic TOU maps for service agreements linked to the account.

**Note:**

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

The **Account Info** displays information about the account. The **Account ID** for this account is displayed.

Use the **Derive Interval Data** button to [create profile data through data derivation](#). If clicked, the **Derive Interval Data** dialog opens.

In the resulting dialog, turn on **Force Derivation** and enter a **Force Derivation Start Date** if you want the system to re-derive data for a period that may have already been derived.

**Note:**

Not all algorithms necessarily support [force derivation](#). It depends on whether or not the algorithm can detect changes in the source data.

Enter the **Cutoff Date** to indicate date until which to generate data.

After clicking **Process**, the system processes all service agreements for the account that have an SA Owned profile where this SA is the owner AND the [profile type](#) indicates an "Interval Data Creation" derivation algorithm. Interval data for service agreements linked to the Account are derived in [billing processing sequence](#) order as defined on their [SA type](#). For each service agreement, the Interval Data Creation algorithms are executed in creation priority order as defined on their profile type.

The interval profile [tree](#) displays information about profiles linked to service agreements for this account.

- A node appears for each profile linked to more than one service agreement for the account. The profile may be common or SA owned . Expanding this node displays each service agreement linked to the shared profile.
- A node appears for each service agreement linked to the account that has interval profiles linked to it. Expanding this node displays each profile linked to the service agreement.

Use the **Derive TOU Data** button to [automatically create classic TOU map data](#). If clicked, the **Derive Interval Data** dialog opens.

In the resulting dialog, turn on **Force Derivation** and enter a **Force Derivation Start Date** if you want the system to re-derive data for a period that may have already been derived.

**Note:**

Not all algorithms necessarily support [force derivation](#). It depends on whether or not the algorithm can detect changes in the source data.

Enter the **Cutoff Date** to indicate the date until which to generate data.

After clicking **Process**, the system processes all service agreements for the account that have an SA Owned TOU map where this SA is the owner AND the [classic TOU map type](#) indicates a "TOU Data Creation" derivation algorithm. Interval data for service agreements linked to the Account are derived in [billing processing sequence](#) order as defined

on their [SA type](#). For each service agreement, the TOU Data Creation algorithms are executed in creation priority order as defined on their classic TOU map type.

The classic TOU map [tree](#) displays information about classic TOU maps linked to service agreements for this account.

- A node appears for each classic TOU map linked to more than one service agreement for the account. This classic TOU map may be common or SA owned. Expanding this node displays each service agreement linked to the shared TOU map.
- A node appears for each service agreement linked to the account that has classic TOU maps linked to it. Expanding this node displays each classic TOU map linked to the service agreement.

If a seasonal time shift record is linked to the base time zone and each time zone on the characteristic premise for each service agreement uses the same seasonal time shift record, the common **Seasonal Time Shift** for the time zones on the characteristic premises is displayed. Refer to [Time Zone and Time Changes](#) for more information.

The **Seasonal Time Shift Remark** indicates whether the data is displayed in legal time or standard time. If the seasonal time shift record on the base time zone and for the time zone for each characteristic premise linked to each SA are the same, the dates are displayed in legal time, according to this seasonal time shift record. Otherwise, the data is displayed in standard time.

Fastpath:

Refer to [Seasonal Time Shifts](#) for more information.

Interval Profile Maintenance

Use this page to view information about a profile, its data sets and its service agreements.

Interval Profile - Main

Open **Menu** > **Interval Billing** > **Interval Profile** > **Search** to maintain interval profiles.

Note:

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

The **Interval Profile Info** contains important information about the interval profile. These values only appear after the interval profile exists on the database. The **Interval Profile ID** is a system-assigned number.

Enter the **Description** of the Interval Profile.

Indicate the **Interval Profile Type** that defines this interval profile.

The **External ID** is available for cross-referencing this interval profile with an external source.

If this profile is SA Owned, the **SA ID** linked to this profile is displayed along with information about the SA.

Use the **Complete Data Sets** button if you have any pending data sets for your profile and you would like the system to complete them. When clicking this button, if the profile type contains any validation algorithms, they are executed. If no errors are detected from the profile type's validation algorithms OR if the profile type does not contain any algorithms, the pending data sets are marked as complete. Refer to [Validation of Profile Data for more information](#) about the validation algorithms.

The [tree](#) at the bottom of this page shows information about data sets linked to the profile.

- The **Pending Data Sets** node displays if any of the data sets linked to the profile are pending. Expanding this node displays each pending data set.
- The **Error Data Sets** node displays if any of the data sets linked to the profile are in error. Expanding this node displays each error data set.
- The **Data Created Through** node displays the date of the latest complete interval as of the current date. Expanding this node displays the last 10 complete data sets.

Interval Profile - Related SAs

Open **Menu** > **Interval Billing** > **Interval Profile** > **Search** and navigate to the **Related SAs** page to view service agreements to which this profile is linked.

Note:

This page is only available if the Complex Billing module is not **turned off**.

Description of Page

The **Interval Profile Info** contains important information about the interval profile. These values only appear after the interval profile exists on the database. The **Interval Profile ID** is a system-assigned number.

Note:

If the profile is linked to more than 25 service agreements, the search criteria are intentionally left blank in order to avoid retrieving all service agreements (with the resultant slow response times). You must therefore use the **SA Filter** to define the type of service agreements that should be retrieved. See the below for more information about this page's search criteria.

Use the **SA Filter** to define the service agreements to appear in the grid. The following options are available:

- **Account.** Use this option to restrict service agreements to those linked to a given **Account ID**.
- **Address.** Use this option to restrict service agreements to those linked to service points associated with a given **Address, City** and/or **Postal** code. You can specify any combination of these fields.
- **All.** Use this option if you do not want to filter service agreements.
- **Person Name.** Use this option to restrict service agreements to those whose account indicates the given **Name** as the main person.
- **SA Type.** Use this option to restrict service agreements to those linked to a given **CIS Division** and **SA Type**.

Don't forget to click the search button after changing the **SA Filter**.

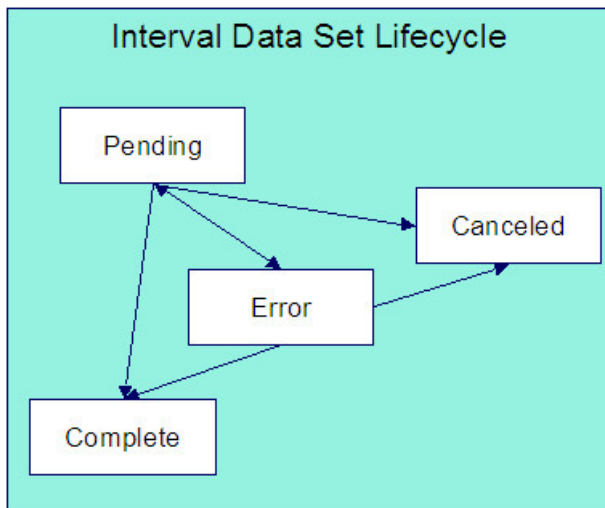

The grid that follows contains the **Accounts** and **Service Agreements** that match your search criteria.

Maintaining Interval Profile Data

In this section, we describe information related to maintaining interval data. This information includes where to maintain the data, the life cycle that this data may go through, uploading data from an external source and handling exception conditions.

Life Cycle of Interval Profile Data Sets

The following diagram shows the possible lifecycle of an interval profile data set.

Pending Use this status for data, added to the system, that requires validation to occur before it is available for further processing. Validation is handled through an algorithm linked to the profile type for this data set's profile. Refer to [Setting Up Interval Profile Types](#) for more information. When creating a data set, the system automatically sets the status to Pending when the profile type indicates a validation algorithm or if an interval profile has not been identified.

Canceled A user can cancel a Pending or Error data set if the data set should not be used for further processing. Refer to [Interval Data Maintenance](#) for more information. Additionally, algorithms may be designed to cancel data sets in certain situations.

Error A validation or derivation algorithm may set this status for a data set if it detects an error condition. Data sets in this status are also written to the [Interval Data Exception](#) table. Refer to [How To Correct a Data Set in Error](#). When a validation error has been corrected, change the status of the data set back to Pending so it will be reprocessed.

Complete Only complete data sets are used by rate application and derivation algorithms. If data being added to the system has already been validated, it may be uploaded to the system in this status. Data derivation algorithms may create a data set in Complete status or change the status of a data set to Complete if no error conditions are detected. Data validation algorithms may change the status of a data set to Complete if no error conditions are detected. When creating a data set, the system automatically sets the status to Complete when the profile type for the interval profile does not indicate a validation algorithm.

A data set is created either in Pending status or Complete status, depending on the existence of a validation algorithm on the profile type. A user can cancel a dataset. Other status changes may depend on how your validation and creation algorithms are written.

- The base validation algorithm only processes Pending data sets. As a result, a user is expected to change the status of an error data set back to pending when the error condition has been fixed. When the data is clean, the algorithm changes the status to Complete.
- The base creation algorithms automatically delete any Error data sets and start over in an attempt to produce a Complete data set. This is similar to the billing process, which deletes error bill segments and tries from the beginning to produce an error free segment. Another alternative is for a user to Cancel any data sets in Error to keep a record of the incorrect data.

For more information about data derivation and validation algorithms, refer to [Setting Up Interval Profile Types](#).

Interval Data Maintenance

The Interval Data page is used to create and maintain collections of interval data, grouped together by an interval data set, for a given interval profile. The data that is maintained here may be for a common interval profile or for an SA owned interval profile.

Open **Menu** > **Interval Billing** > **Interval Data** > **Search** to maintain interval data.

**Note:**

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

Interval Data Set is a concatenation of important information about the data set. The **Interval Data Set ID** is a system-assigned random number.

Indicate the **Interval Profile ID** to which this data set is linked.

**Note:**

It is possible that the profile cannot be identified when adding interval data. If the **Interval Profile** is not populated, the **Data Set External ID** must be populated. Refer to [Upload Interval Data](#) for more information.

The **Owner SA** indicates the SA that "owns" this data. This information is only populated for SA owned profiles. This field is useful if the data set you are viewing contains an error and the error is related to a different source profile for the service agreement. You may use the context button to quickly navigate to the service agreement to view other profiles related to the service agreement. Refer to [how to correct a data set in error](#) for more information.

The **Data Set External ID** is the external identifier of the interval profile. It may be used when a profile cannot be found for data interfaced from outside the system. Refer to [Upload Interval Data](#) for more information.

The **Set Date/Time** of the Interval Data Set represent when this collection of data was entered or received. This is considered a server date and follows the seasonal time shifting as defined on the base time zone. Refer to [Seasonal Time Shifts](#) for more information.

**Fastpath:**

Refer to [Algorithms Find the Most Up-To-Date Data](#) for more information about the Set Date /Time and its use in algorithms.

The **Data Set Type** is available for classification of the data set in some way. The value currently available with the system is No Data. Refer to [Fixing Errors with Complete Data](#) for more information about using this data set type.

**Note:**

The values for Data Set Type are customizable using the [lookup table](#). This field name is INTV_DS_TYPE_FLG.

The **Status** indicates the status of the interval profile data set. Click the **Cancel DS** button to cancel a Pending or Error data set.

**Fastpath:**

Refer to [Lifecycle of Interval Profile Data](#) for more information about interval data set status.

Use the **Revert** button to reverse the effect of a Complete data set.

**Fastpath:**

Refer to [Fixing Errors with Complete Data](#) for more information.

Use the **Start Date/Time** to indicate the starting point for the display of the interval data.

At least one interval data record must exist in the collection of interval data. For each interval data record, the **Interval Data Date/Time** and the **Interval Data** value are captured. This date is considered a logical date and follows the seasonal time shifting as defined on the interval profile type. Refer to [Seasonal Time Shifts](#) for more information.

If the data set is in Error status, a **Message** that provides the error information is displayed below the interval data collection.

If seasonal time shift records are linked to both the base time zone and the interval profile type, the **Seasonal Time Shift** associated with your interval profile type is displayed. Refer to [Setting Up Interval Profile Types](#) for more information.

Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time. If either the bill factor/characteristic or the base time zone does not indicate a seasonal time shift record, the toggle button is not visible and data is displayed and expected in standard time.

If seasonal time shift records are linked to both the base time zone and the interval profile type, the **Seasonal Time Shift Remark** indicates whether the data is displayed and should be entered in legal time or standard time. Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time. If either the interval profile type or the base time zone does not indicate a seasonal time shift record, the toggle button is not visible and data is displayed and expected in standard time.

Interval Data Query

This query shows the most recent interval profile data for a profile and a time period as of a given time.

Open **Menu > Interval Billing > Interval Data Query** to display interval data.

Note:

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

The **Interval Profile ID** is the identifier of the profile whose data should be displayed.

Use the **Start Date/Time** and **End Date/Time** if you want to limit the query to a specific time period.

Use the **Set Date/Time** to indicate the "as of what date" to use for retrieving interval data. Only data sets with a set date/time prior to this date/time are accessed.

The **Selection Type** is used to determine what data to show:

History This option displays all interval data for the profile and time period, if specified. It includes data in data sets of any status value.

Most Recent Comp. Exc. No Data This option finds the most recent interval value for each interval from completed data sets only. If the most recent interval is in a No Data data set, that interval does not appear.

Most Recent Complete Data This finds the most recent interval value for each interval from completed data sets only. If the most recent interval is in a No Data data set, that interval appears with "No Data" displayed in the **Data Set Type** column.

Fastpath:

Refer to [Fixing Errors with Complete Data](#) for more information about No Data interval data sets.

Once you have selected your criteria, use the search button to display the data. The interval data collection contains the following information:

The **Interval Data Date/Time** and **Interval Data** value for each interval is displayed. Adjacent, information about the data set to which this interval is linked is displayed, including the **Data Set Type**, **Set Date/Time** and **Interval Data Set ID**.

If seasonal time shift records are linked to both the base time zone and the interval profile type, the **Seasonal Time Shift** associated with your interval profile type is displayed.

If seasonal time shift records are linked to both the base time zone and the interval profile type, the **Seasonal Time Shift Remark** indicates whether the data is displayed and should be entered in legal time or standard time. Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time. If either the interval profile type or the base time zone do not indicate a seasonal time shift record, the toggle button is not visible and data is displayed and expected in standard time.

Upload Interval Data

The following diagram illustrates the processes involved in the uploading of interval data into the system.

The topics in this section describe how these processes work.

Process X - Populate Interval Data

Process X refers to the mechanism used by your organization to populate the Interval Data tables. Process X has the following responsibilities:

- It attempts to determine the appropriate profile to which this data belongs using the external ID. If a profile with this external ID is not found, the data set is created without being linked to a profile and the external ID is stored on the data set.
- It creates a new interval data set with the current date and time.
- If the interval data is from a different time zone, or is not in standard time for the base time zone, the time of each interval must be converted to standard time in the base time zone. Refer to [Time Zone and Time Changes](#) for more information.
- All quantities being uploaded for the same profile should be inserted into the Interval Data table and should reference the same interval data set.
- Set the status of the new data set:
 - If the data set is not linked to a profile, set the status to pending.
 - If the profile type has a validation algorithm, set the status to pending.
 - If the profile type does not have a validation algorithm, this data should be clean. Set the status to complete.
- Inserts a record in the interval data set key table.

The topics in this section describe the tables to populate.

Interval Data Set

You must create a data set for each batch of records being uploaded in the system for the same profile. The name of this table is CI_INTV_DATA_SET. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|----------|
|-------------|--------|-------|-----------|----------|

| | | | | |
|------------------|----|---|-----|--|
| INTV_DATA_SET_ID | 12 | Y | A/N | <p>This is a unique key. This key is referenced on the interval data record.</p> <p>It's suggested that this key is built as follows:</p> <ul style="list-style-type: none"> • The first five digits are the first five digits of the INTV_PF_ID • The last seven digits are randomly generated. <p>This facilitates set based processing of the data. If your process that inserts records on this table is capable of calling a routine, call ProgramCIPZKEYG passing the first five digits and it supplies a seven digit random number.</p> |
| INTV_PF_ID | 12 | N | A/N | <p>This is a foreign key reference to the interval profile to which this set is linked. It is required if an external ID is not specified.</p> |
| INTV_DS_EXT_ID | 60 | N | A/N | <p>This is the external identifier of the profile to which this data belongs. It is required if profile ID is not specified.</p> |

| | | | | |
|----------------|----|---|----------|---|
| SET_DTTM | 26 | Y | DateTime | <p>This is the date/time that the data set was received. This must be populated with the current date/time. This is considered a server date and follows the seasonal time shifting as defined on the base time zone. Refer to Seasonal Time Shifts for more information.</p> <p>Refer to Algorithms Find the Most Up-To-Date Data for information about why this date/time is important.</p> |
| SET_STATUS_FLG | 2 | Y | A/N | <p>Set this value based on whether it will be validated in the system.</p> <p>Set to P for Pending if the profile ID is blank or if the profile's profile type indicates a validation algorithm.</p> <p>Set to C for Complete if the data should not go through any further validation.</p> <p>Refer to Life Cycle of Interval Profile Data for more information</p> |

Interval Data

Each piece of interval data for the profile is stored as an Interval Data record linked to the newly created data set. The name of this table is CI_INTV_DATA. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|----------|
|-------------|--------|-------|-----------|----------|

| | | | | |
|------------------|------|---|----------|---|
| INTV_DATA_SET_ID | 12 | Y | A/N | This is a foreign key reference to the Interval Data Set that groups the interval values together. This should be your newly created ID from above. |
| INTV_DATA_DTTM | 26 | Y | DateTime | This is the date and time of the interval value. This must be stored in standard time for the base time zone. Refer to Time Zone and Time Changes for more information. |
| INTV_DATA | 18.7 | Y | N | This is the quantity for the interval. |

Interval Data Set Key

When a system-generated key value is assigned to a record, you need to also store the key value in a key table that corresponds to the record's database table. The name of this table is CI_INTV_DATA_SET_K. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|------------------|--------|-------|-----------|--|
| INTV_DATA_SET_ID | 12 | Y | A/N | This should be your newly created Interval Data Set ID from above. |
| ENV_ID | 6 | Y | N | This is the environment id defined on the installation options . |

Process IPDSIDB - Determine Profile For Profile Datasets

This process finds pending profile datasets that are not linked to a profile and attempts to determine the appropriate profile by making a match on the external ID.

Note:

. The status of the profile dataset is set to Pending or Complete by the system based on whether or not validation algorithms exist for the profile type. Refer to [Life Cycle of Interval Profile Data Sets](#) for more information.

Interval Data Exception

If a validation algorithm or data derivation algorithm finds an error with interval data, a record is written to the interval data exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, you must schedule an appropriate To Do entry creation background process. This process generates a To Do entry for every record in the interval data exception table.

The following section describes steps to take to correct the data in error.

How To Correct a Data Set in Error

A data set is in error only if an error is found by a validation algorithm or by a data derivation algorithm. Because there is no limit to the number of validation and data derivation algorithms that you create, there may be just as many ways to resolve these errors. This section describes a typical situation.

Resolving a Derivation Error

Because the derivation algorithms are creating new data sets, the error is not with the data set being created, but with source data that the algorithm is using to create the new data set.

The following describes the steps involved with fixing an error found by a creation algorithm (IPFCSACS) supplied with the system.

- Review the To Do entries generated as a result of interval data exceptions.
- The information displayed with the To Do entry provides details of the error. You may also drill down to the Data Set page to view the error.

On the Data Set page, the status is Error and the error message is displayed at the bottom. You probably have to fix a source interval data curve. This is common source of errors in *derived* data. One possible error is that data is missing from a source curve.

The following describes the steps to fix a source interval data profile:

- The error indicates that the problem is with the DEMANDKW profile relationship type. Use the context menu button adjacent to the owner SA to Go To Service Agreement. You are taken directly to the [Service Agreement Interval Info](#) page. Determine the profile associated with the DEMANDKW relationship type.
- Choose **Go To Interval Data** from the context menu for the appropriate Interval Profile ID and find the data set with the missing interval. Verify all the missing intervals that need to be fixed. (Note that the error message only reports the first missing interval it finds. There may be more.)
- Once you have determined the missing intervals, create a new data set for the profile, and enter the missing interval data.

Warning:

Existing completed data records should not be changed. If an existing data record is incorrect, you should always add a new data set, with the current date and time, and enter the corrected value for the interval. This is important because the interval data records are the audit records for an existing bill. Refer to [Auditing Your Interval Pricing Bill Lines](#) for more information.

- Once you have filled in the missing intervals, you may navigate back to the [Service Agreement Interval Info](#) page to run the data derivation again. (Note, you may also wait for the [SA Interval Profile Creation](#) background process to run.)
- When the Data Derivation is finished, view the [Interval Data](#) page for the profile with the derived data. You should notice that your Error data set is no longer there.

Resolving a Validation Error

The validation algorithms are validating data in existing data sets. The data set in error is marked and the chances are great that the error is with this data.

The following describes the steps involved with fixing an error found by the validation algorithm (IPFVDS-SMP) supplied with the system.

- Review the To Do entries generated as a result of interval data exceptions.

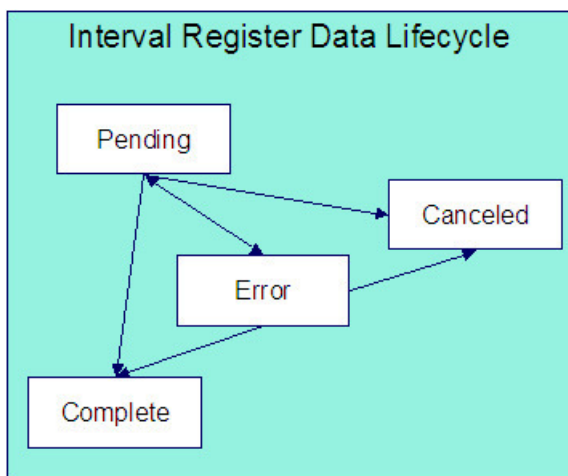

- The information displayed with the To Do entry provides details of the error. Drill down to the detail of the record on the [Interval Data](#).
- Fix the error and change the status of the data set to Pending . The next time the validation algorithm runs, it revalidates this data.

Maintaining Interval Register Data

In this section, we describe information related to maintaining interval register data. This information includes where to maintain the data, the life cycle that this data may go through, uploading data from an external source, and handling exception conditions.

Life Cycle of Interval Register Data Sets

The following diagram shows the possible lifecycle of an interval register data set.

Pending Use this status for data, added to the system, that requires validation to occur before it is available for further processing. Validation is handled through an algorithm linked to the interval register type for this data set's register. Refer to [Setting Up Interval Register Types](#) for more information. When creating a data set, the system automatically sets the status to Pending when the interval register type indicates a validation algorithm.

Canceled A user can cancel a Pending or Error data set if the data set should not be used for further processing. Refer to [Interval Register Data Maintenance](#) for more information. Additionally, algorithms may be designed to cancel data sets in certain situations.

Error A validation algorithm may set this status for a data set if it detects an error condition. Data sets in error are also written to the [Interval Register Data Exception](#) table. Refer to [How To Correct a Register Data Set in Error](#). When a validation error has been corrected, change the status of the data set back to Pending so it will be reprocessed.

Complete Only complete data sets are used by derivation algorithms. If data being added to the system has already been validated, it may be uploaded to the system in this status. Validation algorithms may change the status of a data set to Complete if no error conditions are detected. When data sets are created, their status is set to Complete if the interval register type does not indicate a validation algorithm. For more information about validation algorithms, refer to [Setting Up Interval Register Types](#).

Interval Register Data Maintenance

The Interval Register Data page is used to create and maintain collections of interval register data, grouped together by a data set, for a given interval register.

Open **Menu** > **Interval Billing** > **Interval Register Data** > **Search** to maintain interval register data.

**Note:**

This page is only available if the Meter Data Management module is not [turned off](#).

Description of Page

Register Data Set is a concatenation of important information about the data set. The **Register Data Set ID** is a system-assigned random number.

Indicate the **Register ID** to which this data set is linked.

**Note:**

It is possible that the register cannot be identified when adding interval register data. If the **Register ID** is not populated, the **Data Set External ID** must be populated. Refer to [Upload Interval Register Data](#) for more information.

The **Data Set External ID** is the external identifier of the interval register. It will correspond to the channel ID on the interval register. It may be used when a register cannot be found for data interfaced from outside the system. Refer to [Upload Interval Register Data](#) for more information.

The **Set Date/Time** of the Register Data Set represent when this collection of data was entered or received. This is considered a server date and follows the seasonal time shifting as defined on the base time zone. Refer to [Seasonal Time Shifts](#) for more information.

**Fastpath:**

Refer to [Algorithms Find the Most Up-To-Date Data](#) for more information about the Set Date /Time and its use in algorithms.

The **Data Set Type** is available for classification of the data set in some way. The values currently available with the system are:

No Data Refer to [Fixing Errors with Complete Data](#) for more information about using this data set type.

Estimation Use this value if the data set contains estimated values based on a validation algorithm. Refer to the IRVA-CLN algorithm for an example of an algorithm that creates estimated interval register values.

**Note:**

The values for Data Set Type are customizable using the [lookup table](#). This field name is REG_DS_TYPE_FLG.

The **Status** indicates the status of the interval profile data set. Click **Cancel DS** to cancel a Pending or Error data set.

**Fastpath:**

Refer to [Lifecycle of Interval Register Data](#) for more information about interval data set status.

Use the **Revert** button to reverse the effect of a Complete data set.

**Fastpath:**

Refer to [Fixing Errors with Complete Data](#) for more information.

Use the **Start Date/Time** to indicate the starting point for the display of the interval data.

At least one interval data record must exist in the collection of interval data. For each interval data record, the **Interval Register Date/Time** and the **Interval Register Data** value are captured. This date is considered a logical date and follows the seasonal time shifting as defined on the interval register type. Refer to [Seasonal Time Shifts](#) for more information.

If the data set is in Error status, a **Message** that provides the error information is displayed below the interval data collection.

If seasonal time shift records are linked to both the base time zone and the interval register type, the **Seasonal Time Shift** associated with your interval register type is displayed. Refer to [Setting Up Interval Register Types](#) for more information.

If seasonal time shift records are linked to both the base time zone and the interval register type, the **Seasonal Time Shift Remark** indicates whether the data is displayed and should be entered in legal time or standard time. Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time. If either the interval register type or the base time zone do not indicate a seasonal time shift record, the toggle button is not visible and data is displayed and expected in standard time.

Interval Register Data Query

This query shows the most recent interval register data for a register and a time period as of a given time.

Open **Menu > Interval Billing > Interval Register Data Query** to display interval register data.

Note:

This page is only available if the Meter Data Management module is not [turned off](#).

Description of Page

The **Register ID** is the identifier of the register whose data should be displayed.

Use the **Start Date/Time** and **End Date/Time** if you want to limit the query to a specific time period.

Use the **Set Date/Time** to indicate the "as of what date" to use for retrieving interval data. Only data sets with a set date/time prior to this date/time are accessed.

The **Selection Type** is used to determine what data to show:

History This option displays all interval data for the register and time period, if specified. It includes data in data sets of any status value.

Most Recent Comp. Exc. No Data This option finds the most recent interval value for each interval from completed data sets only. If the most recent interval is in a No Data data set, that interval does not appear.

Most Recent Complete Data This finds the most recent interval value for each interval from completed data sets only. If the most recent interval is in a No Data data set, that interval appears with "No Data" displayed in the **Data Set Type** column.

Fastpath:

Refer to [Fixing Errors with Complete Data](#) for more information about No Data interval data sets.

Once you have selected your criteria, use the search button to display the data. The interval data collection contains the following information:

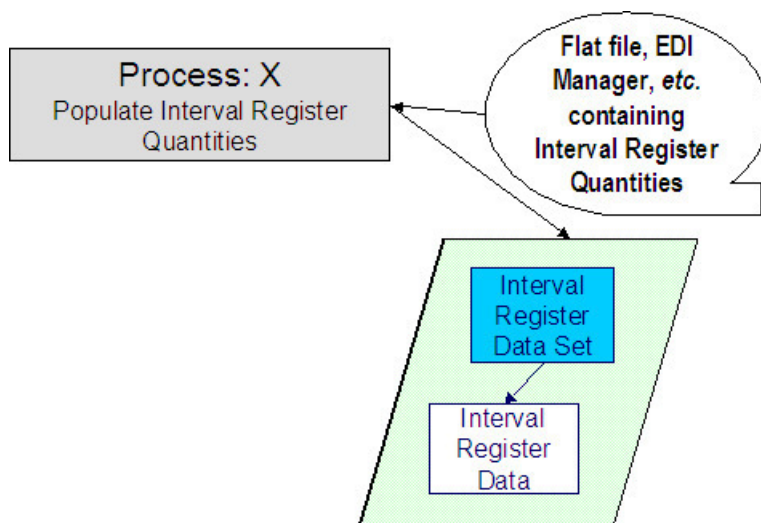

The **Interval Register Date/Time** and **Interval Register Data** value for each interval is displayed. Information about the data set to which this interval is linked is displayed, including the **Data Set Type**, **Set Date/Time** and **Register Data Set ID**.

If seasonal time shift records are linked to both the base time zone and the interval register type, the **Seasonal Time Shift** associated with your interval register type is displayed.

If seasonal time shift records are linked to both the base time zone and the interval register type, the **Seasonal Time Shift Remark** indicates whether the data is displayed and should be entered in legal time or standard time. Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time. If either the interval register type or the base time zone do not indicate a seasonal time shift record, the toggle button is not visible and data is displayed and expected in standard time.

Upload Interval Register Data

The following diagram illustrates the processes involved in the uploading of interval register data into the system.

The topics in this section describe how these processes work.

Process X - Populate Interval Register Data

Process X refers to the mechanism used by your organization to populate the Interval Register Data tables. Process X has the following responsibilities:

- It attempts to determine the appropriate Register to which this data belongs using the channel ID. If a register with this channel ID is not found, the data set is created without being linked to a register and the channel ID is stored as the external ID on the data set.
- It creates a new Register Data Set with the current date and time.
- If the interval data is from a different time zone or is not in standard time for the base time zone, the time of each interval must be converted to standard time in the base time zone. Refer to [Time Zone and Time Changes](#) for more information.
- All quantities being uploaded for the same register should be inserted into the interval register data table and should reference the same register data set.
- Set the status of the new data set:
 - If the data set is not linked to a register, set the status to pending.
 - If the register type has a validation algorithm, set the status to pending.
 - If the register type does not have a validation algorithm, this data should be clean. Set the status to complete.
- Inserts a record in the register data set key table.

The topics in this section describe the tables to populate.

Register Data Set

You must create a data set for each batch of records being uploaded in the system for the same register. The name of this table is CI_REG_DATA_SET. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|----------|
|-------------|--------|-------|-----------|----------|

| | | | | |
|-----------------|----|---|-----|---|
| REG_DATA_SET_ID | 12 | Y | A/N | <p>This is a unique key. This key is referenced on the register data record.</p> <p>It's suggested that this key is built as follows:</p> <ul style="list-style-type: none"> • The first five digits are the first five digits of the REG_ID. • The last seven digits are randomly generated. <p>This facilitates set based processing of the data. If your process that inserts records on this table is capable of calling a routine, call ProgramCIPZKEYG passing the first five digits and it supplies a seven-digit random number.</p> |
| REG_ID | 10 | N | A/N | <p>This is a foreign key reference to the interval register to which this set is linked. It is required if an external ID is not specified.</p> |
| REG_DS_EXT_ID | 60 | N | A/N | <p>This is the external identifier of the register to which this data belongs. It should correspond to the channel ID of its register. It is required if register ID is not specified.</p> |

| | | | | |
|-------------------|----|---|----------|---|
| SET_DTTM | 26 | Y | DateTime | <p>This is the date/time that the data set was received. This must be populated with the current date/time. This is considered a server date and follows the seasonal time shifting as defined on the base time zone. Refer to Seasonal Time Shifts for more information.</p> <p>Refer to Algorithms Find the Most Up-To-Date Data for information about why this date/time is important.</p> |
| REG_DS_STATUS_FLG | 2 | Y | A/N | <p>Set this value based on whether it will be validated in the system.</p> <p>Set to P for Pending if the register ID is blank or if the register's register type indicates a validation algorithm.</p> <p>Set to C for Complete if the data will not go through any further validation.</p> <p>Refer to Life Cycle of Interval Register Data for more information</p> |

Register Data

Each piece of interval data for the register will be stored as an Interval Register Data record linked to the newly created data set. The name of this table is CI_REG_DATA. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|----------|
|-------------|--------|-------|-----------|----------|

| | | | | |
|-----------------|------|---|----------|--|
| REG_DATA_SET_ID | 12 | Y | A/N | This is a foreign key reference to the Register Data Set that groups the interval values together. This should be your newly created ID from above. |
| REG_DATA_DTTM | 26 | Y | DateTime | This is the date and time of the register data. This must be stored in standard time for the base time zone. Refer to Time Zone and Time Changes for more information. |
| INTV_REG_DATA | 18.7 | Y | N | This is the quantity for the interval. |

Register Data Set Key

When a system-generated key value is assigned to a record, you need to also store the key value in a key table that corresponds to the record's database table. The name of this table is CI_REG_DATA_SET_K. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-----------------|--------|-------|-----------|--|
| REG_DATA_SET_ID | 12 | Y | A/N | This should be your newly created Register Data Set ID from above. |
| ENV_ID | 6 | Y | N | This is the environment id defined on the installation options . |

Process IREGIDB - Determine Register For Register Datasets

This process finds pending register datasets that are not linked to a register and attempts to determine the appropriate register by making a match on the external ID of the data set to the channel ID for the register.

Note:

The status of the register dataset is set to Pending or Complete by the system, based on whether or not validation algorithms exist for the register type. Refer to [Life Cycle of Interval Register Data Sets](#) for more information.

Interval Register Data Exception

If a validation algorithm finds an error with interval register data, a record is written to the interval register data exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, you must schedule an appropriate To Do entry creation background process. This process generates a To Do entry for every record in the interval register data exception table.

The following section describes steps to take to correct the data in error.

How To Correct a Register Data Set in Error

The validation algorithms are validating data in existing data sets. The following describes the steps involved with fixing an error found by the validation algorithm (IRGVDS-SMP) supplied with the system.

- Review the To Do entries generated as a result of interval register data exceptions.
- The information displayed with the To Do entry provides details of the error. You may also drill down to the Data Set page to view the error.
- Fix the error and change the status of the data set to Pending. The next time the validation algorithm runs, it revalidates this data.

Classic TOU Map Maintenance

The topics in this section describe the pages related to maintaining a classic TOU map.

Classic TOU Map - Main

The classic TOU Map page is used to create and maintain Time of Use Maps. Open this page using **Menu > Interval Billing > TOU Map > Search**.

Note:

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

The **TOU Map Info** contains important information about the classic TOU map. These values only appear after the classic TOU map exists on the database. The **TOU Map ID** is a system-assigned random number.

Enter the **Description** of the classic TOU Map.

Indicate the classic **TOU Map Type** that defines this TOU map.

The **External ID** is available for cross-referencing this TOU map with an external source.

If this map is SA Owned, the **SA ID** linked to this map is displayed along with information about the SA.

Use the **Generate** button to generate data for this TOU map based on a classic TOU map template. Refer to [Classic TOU Map - Generate](#) for more information.

The [tree](#) at the bottom of this page shows information about data sets linked to the classic TOU map.

- The **Error Data Sets** node displays if any of the data sets linked to the TOU map are in Error. Expanding this node displays each error data set.
- The **Data Created Through** node displays the date of the latest complete interval as of the current date. Expanding this node displays the last 10 Complete data sets.

Classic TOU Map - Generate

The classic **TOU Map Template** dialog opens when you click **Generate** on the classic TOU map page:

Description of Page

Indicate the classic **TOU Map Template** that you want the system to use as your template for the new data.

The **Set Date/Time** is used for the set date/time on the newly created data set.

Indicate the **Data Set Type**, if applicable.

Indicate the first TOU interval to create by entering the **Start Date/Time** to use for creating the TOU data. Enter either the **End Date/Time** or a value in **Recurring Patterns** to indicate how much data the system should generate.

The holiday fields indicate if and how the system should handle holidays differently from standard days.

Holiday Template This is the daily template to use for all holiday days in the period, instead of the classic TOU map template entered above. Notice that a single daily Holiday template is used for the period you're generating data for. In other words, the system assumes all holiday days to have the same TOU pattern, i.e. template, throughout the period. If you need to use different TOU patterns for different holiday days you would need to generate data in several steps.

Holiday Shift in Minutes If the time period covered by a holiday is not 12AM to 12AM, indicate the number of minutes, positive or negative, to shift the holiday. For example, if the holiday is considered 7pm on the eve of the holiday until 7pm on the day of the holiday, enter -300 (i.e. 5 hours) for the shift in minutes.

Calendar This is the [Calendar](#) where the holidays applicable for this time period are defined.

When you click the **Generate** button, the system creates a new classic TOU map data set for this classic TOU map based on the information provided.

The **Seasonal Time Shift** associated with the classic TOU map type is displayed.

In the **Seasonal Time Shift Remark**, you are reminded that the system expects that the values you enter for the date and time are in local legal time as defined by your classic TOU map type.

Note:

The times on the classic TOU map components are in legal time. During this generation process the system converts the time definitions into standard time, taking daylight savings into account. Time shifting is based upon the Seasonal Time Shift defined on the template's classic TOU map type. Refer to [Time Zone and Time Changes](#) for more information.

Classic TOU Map - Related SAs

Open **Menu > Interval Billing > TOU Map > Search** and navigate to the **Related SAs** page to view service agreements that reference the classic TOU map.

Note:

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

The **TOU Map Info** contains important information about the TOU map. These values only appear after the classic TOU map exists on the database. The **TOU Map ID** is a system-assigned random number.

Note:

If the map is linked to more than 25 service agreements, the search criteria are intentionally left blank in order to avoid retrieving all service agreements (with the resultant slow response times). You must therefore use the **SA Filter** to define the type of service agreements that should be retrieved. See below for more information about this page's search criteria.

Use the **SA Filter** to define the service agreements to appear in the grid. The following options are available:

- **Account.** Use this option to restrict service agreements to those linked to a given **Account ID**.
- **Address.** Use this option to restrict service agreements to those linked to service points associated with a given **Address, City** and/or **Postal** code. You can specify any combination of these fields.
- **All.** Use this option if you do not want to filter service agreements.

- **Person Name.** Use this option to restrict service agreements to those linked to accounts that indicate the given **Name** as the main person.
- **SA Type.** Use this option to restrict service agreements to those linked to a given **CIS Division** and **SA Type**.

Don't forget to click the search button after changing the **SA Filter**.

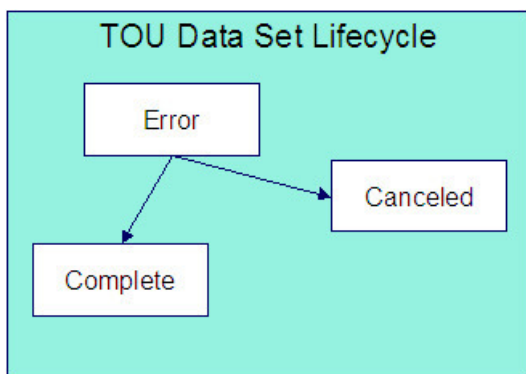

The grid that follows contains the **Accounts** and **Service Agreements** that match your search criteria.

Maintaining Classic TOU Map Data

In this section, we describe information related to maintaining time of use data. This information includes where to maintain the data, the life cycle that this data may go through, uploading data from an external source, and handling exception conditions.

Life Cycle of TOU Data Sets

The following diagram shows the possible lifecycle of a TOU data set.

Error A creation algorithm may set this status for a data set if it detects an error condition. Data sets in this status are also written to the [TOU Data Exception](#) table. Refer to [How To Correct a TOU Data Set in Error](#).

Canceled A user can cancel an Error data set if the data set should not be used for further processing. Refer to [TOU Data Maintenance](#) for more information. Additionally, algorithms may be designed to cancel data sets in certain situations.

Complete Only complete data sets are used by rate application and derivation algorithms. Data creation algorithms may create a data set in Complete status or change the status of a data set to Complete if no error conditions are detected. Data sets created online are set to Complete.

A user can only change the status of a data set to Canceled. All other state transitions are done by an algorithm. For more information about data creation algorithms, refer to [Setting Up Classic TOU Map Types](#).

Note:

Creation algorithms may be written to automatically delete any Error data sets and start over in an attempt to produce a Complete data set. This is similar to the billing process, which deletes error bill segments and tries from the beginning to produce an error free segment. Another alternative is to Cancel any data sets in Error rather than deleting them.

TOU Data Maintenance

The TOU Data page is used to create and maintain collections of time period definitions, grouped together by a data set, for a given classic TOU Map. Open **Menu > Interval Billing > TOU Data > Search** to maintain TOU data.

Note:

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

TOU Data Set is a concatenation of important information about the data set. The **TOU Data Set ID** is a system-assigned random number.

Indicate the **TOU Map ID** to which this data set is linked.

The **Owner SA** indicates the SA that "owns" this data. This information is only populated for SA owned TOU maps. This field is useful if the data set you are viewing contains an error and the error is related to a different source data linked to the service agreement. You may use the context button to quickly navigate to the service agreement to view other interval entities related to the service agreement. Refer to [how to correct a TOU data set in error](#) for more information.

The **Set Date/Time** of the TOU Data Set represent when this collection of data was entered or received. This is considered a server date and follows the seasonal time shifting as defined on the base time zone. Refer to [Seasonal Time Shifts](#) for more information.

Fastpath:

Refer to [Algorithms Find the Most Up-To-Date Data](#) for more information about the Set Date/Time and its use in algorithms.

The **Data Set Type** is available for classification of the data set in some way. The value currently available with the system is No Data. Refer to [Fixing Errors with Complete Data](#) for more information about using this data set type.

Note:

The values for Data Set Type are customizable using the [lookup table](#). This field name is TOU_DS_TYPE_FLG.

The **Status** indicates the status of the TOU data set. Click **Cancel DS** to cancel an Error data set.

Fastpath:

Refer to [Lifecycle of TOU Data](#) for more information about interval data set status.

Use the **Revert** button to reverse the effect of a Complete data set.

Fastpath:

Refer to [Fixing Errors with Complete Data](#) for more information.

Use the **Start Date/Time** to indicate the starting point for the display of the interval data.

At least one TOU data record must exist in the collection of TOU time period definitions. For each TOU data record, the **TOU Data Date/Time** and the **Time of Use** code are captured. This date is considered a logical date and follows the seasonal time shifting as defined on the classic TOU map type. Refer to [Seasonal Time Shifts](#) for more information.

If the data set is in Error status, a **Message** that provides the error information is displayed below the TOU data collection.

If seasonal time shift records are linked to both the base time zone and the classic TOU map type, the **Seasonal Time Shift** associated with your classic TOU map type is displayed. Refer to [Setting Up Classic TOU Map Types](#) for more information.

If seasonal time shift records are linked to both the base time zone and the classic TOU map type, the **Seasonal Time Shift Remark** indicates whether the data is displayed and should be entered in legal time or standard time. Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time. If either the classic TOU map type or the base time zone do not indicate a seasonal time shift record, the toggle button is not visible and data is displayed and expected in standard time.

TOU Data Query

This query shows the most recent interval data for a classic TOU Map and a time period as of a given time.

Open **Menu** > **Interval Billing** > **TOU Data Query** to display TOU map data.

Note:

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

The **TOU Map ID** is the identifier of the TOU map whose data should be displayed.

Use the **Start Date/Time** and **End Date/Time** if you want to limit the query to a specific time period.

Use the **Set Date/Time** to indicate the "as of what date" to use for retrieving interval data. Only data sets with a set date/time prior to this date/time will be accessed.

The **Selection Type** is used to determine what data to show:

History This option displays all TOU map data for the classic TOU map and time period, if specified. It includes data in data sets of any status value.

Most Recent Comp. Exc. No Data This option finds the most recent interval value for each interval from completed data sets only. If the most recent interval is in a No Data data set, that interval does not appear.

Most Recent Complete Data This finds the most recent interval value for each interval from completed data sets only. If the most recent interval is in a No Data data set, that interval appears with "No Data" displayed in the **Data Set Type** column.

Fastpath:

Refer to [Fixing Errors with Complete Data](#) for more information about No Data data sets.

Once you have selected your criteria, use the search button to display the data. The TOU map data collection contains the following information:

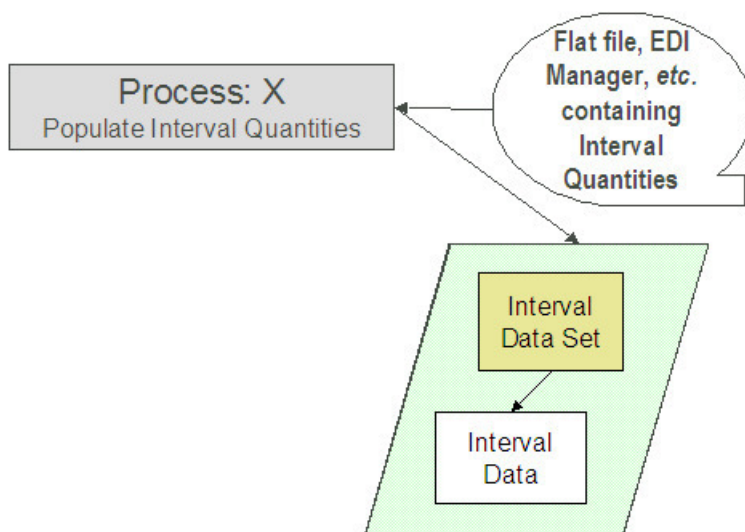

The **TOU Data Date/Time** and **Time of Use** code for each interval is displayed. Information about the data set to which this interval is linked is displayed, including the **Data Set Type**, **Set Date/Time** and **TOU Data Set ID**.

If seasonal time shift records are linked to both the base time zone and the classic TOU map type, the **Seasonal Time Shift** associated with your classic TOU map type is displayed.

If seasonal time shift records are linked to both the base time zone and the classic TOU map type, the **Seasonal Time Shift Remark** indicates whether the data is displayed and should be entered in legal time or standard time. Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time. If either the classic TOU map type or the base time zone do not indicate a seasonal time shift record, the toggle button is not visible and data is displayed and expected in standard time.

Upload Classic TOU Map Data

The following diagram illustrates the processes involved in the uploading of classic TOU map data into the system.

The topics in this section describe how these processes work.

Process X - Populate Classic TOU Map Data

Process X refers to the mechanism used by your organization to populate the classic TOU Map Data tables. Process X has the following responsibilities:

- It determines the appropriate classic TOU map to which this data belongs. (Recall that the classic TOU map can hold an external ID.)
- It creates a new TOU data set with the current date and time.
- If the classic TOU map data is from a different time zone or is not in standard time for the base time zone, the time of each interval is converted to standard time in the base time zone. Refer to [Time Zone and Time Changes](#) for more information.
- All quantities being uploaded for the same classic TOU map should be inserted into the TOU map data table and should reference the same TOU map data set.
- Inserts a record in the TOU data set key table.

The topics in this section describe the tables to populate.

TOU Data Set

You must create a data set for each batch of records being uploaded in the system for the same classic TOU Map. The name of this table is CI_TOU_DATA_SET. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|----------|
|-------------|--------|-------|-----------|----------|

| | | | | |
|-----------------|----|---|-----|--|
| TOU_DATA_SET_ID | 12 | Y | A/N | <p>This is a unique key. This key is referenced on the TOU Data record.</p> <p>It's suggested that this key is built as follows:</p> <ul style="list-style-type: none"> • The first five digits are the first five digits of the TOU MAP_ID. • The last seven digits are randomly generated. <p>This facilitates set based processing of the data. If your process that inserts records on this table is capable of calling a routine, call ProgramCIPZKEYG passing the first five digits and it supplies a seven-digit random number.</p> |
| TOU_MAP_ID | 12 | Y | A/N | <p>This is a foreign key reference to the classic TOU map to which this set is linked.</p> <p>Refer to Classic TOU Map Maintenance for more information.</p> |

| | | | | |
|----------|----|---|----------|---|
| SET_DTTM | 26 | Y | DateTime | <p>This is the date/time that the data set was received. This must be populated with the current date/time. This is considered a server date and follows the seasonal time shifting as defined on the base time zone. Refer to Seasonal Time Shifts for more information.</p> <p>Refer to Algorithms Find the Most Up-To-Date Data for information about why this date/time is important.</p> |
|----------|----|---|----------|---|

TOU Data

Each time period definition for the classic TOU map will be stored as a TOU Data record linked to the newly created data set. The name of this table is CI_TOU_DATA. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-----------------|--------|-------|-----------|--|
| TOU_DATA_SET_ID | 12 | Y | A/N | This is a foreign key reference to the TOU Data Set that groups the TOU definitions together. This should be your newly created ID from above. |
| TOU_DATA_DTTM | 26 | Y | DateTime | This is the date and time of the time period definition. This must be stored relative to the base time zone. Refer to Time Zone and Time Changes for more information. |
| TOU_CD | 30 | Y | A/N | This is the TOU code that this time period shall be mapped to. |

TOU Data Set Key

When a system-generated key value is assigned to a record, you need to also store the key value in a key table that corresponds to the record's database table. The name of this table is CI_TOU_DATA_SET_K. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-----------------|--------|-------|-----------|--|
| TOU_DATA_SET_ID | 12 | Y | A/N | This should be your newly created TOU Data Set ID from above. |
| ENV_ID | 6 | Y | N | This is the environment id defined on the installation options . |

TOU Data Exception

If a derivation algorithm finds an error while creating TOU data, a record is written to the TOU data exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, you must schedule an appropriate To Do entry creation background process. This process generates a To Do entry for every record in the TOU data exception table.

The following section describes steps to take to correct the data in error.

How To Correct a TOU Data Set in Error

Because derivation algorithms are creating new data sets, the error is not with the data set being created, but with source data that the algorithm is using to create the new data set.

The following describes the steps involved with fixing an error found by a creation algorithm (ITMCCOPT) supplied with the system. This algorithm attempts to create TOU map data based on a classic TOU map template and contract option event information.

- Review the To Do entries generated as a result of TOU data exceptions.
- The information displayed with the To Do entry provides details of the error. Drill down to view more details on the [TOU Data](#) page.

On the TOU data page, the status is Error and the error message is displayed at the bottom. In this scenario, the time period covered by the contract event does not overlap with the time period covered by the override classic TOU map template. This is a shared contract option, but this particular event does not apply to this service agreement. The suggested solution for this case is to cancel the TOU data set in error and to create an override event for the service agreement.

- Cancel the TOU data set record in error.
- Use the context menu button adjacent to the owner SA to **Go To Service Agreement**. You are taken to the interval info tab on the service agreement page.
- Navigate to the [Service Agreement - Contract Option](#) page and add an override for this event.

The next time the creation algorithm runs, it detects the override event and it does not attempt to create TOU data for this scenario.

Contract Option Maintenance

Contract options are used to define special rate options applicable to a customer or a group of customers.

Contract Option - Main

Open **Menu** > **Customer Information** > **Contract Option** > **Search** to maintain contract options data.

Note:

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

The **Contract Option Info** displays important information about the contract option. The **Contract Option ID** is a system-assigned random number.

Indicate the **Contract Option Type** for this contract option along with a **Description**.

If this contract option is linked to only one service agreement, indicate the **Create For SA ID**.

The characteristic collection is used to indicate additional information related to your contract option.

Note:

You can only choose characteristic types defined as permissible on the contract option record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

To modify a characteristic, move to a field and change its value. To add a new characteristic, click + to insert a row then fill in the information for each field. The following fields display:

Effective Date Define the date on which the characteristic becomes effective.

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Contract Option - Related SAs

Open **Menu** > **Customer Information** > **Contract Option** > **Search** and navigate to the **Related SAs** page to view service agreements that reference the contract option.

Note:

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

The **Contract Option Info** displays important information about the contract option. The **Contract Option ID** is a system-assigned random number.

Note:

If the contract option is linked to more than 25 service agreements, the search criteria are intentionally left blank in order to avoid retrieving all service agreements (with the resultant slow response times). You must therefore use the **SA Filter** to define the type of service agreements that should be retrieved. See below for more information about this page's search criteria.

Use the **SA Filter** to define the service agreements to appear in the grid. The following options are available:

- **Account.** Use this option to restrict service agreements to those linked to a given **Account ID**.
- **Address.** Use this option to restrict service agreements to those linked to service points associated with a given **Address, City** and/or **Postal** code. You can specify any combination of these fields.
- **All.** Use this option if you do not want to filter service agreements.
- **Person Name.** Use this option to restrict service agreements to those linked to accounts that indicate the given **Name** as the main person.
- **SA Type.** Use this option to restrict service agreements to those linked to a given **CIS Division** and **SA Type**.

Don't forget to click the search button after changing the **SA Filter**.

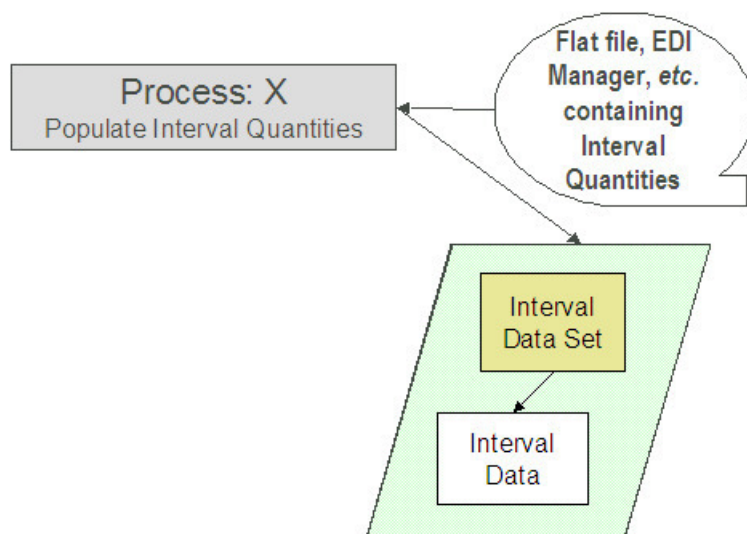

The grid that follows contains the **Accounts** and **Service Agreements** that match your search criteria.

Maintaining Contract Option Events

In this section, we describe information related to maintaining contract option events. This information includes where to maintain the data, the life cycle that this data may go through, and handling exception conditions.

Life Cycle of Contract Option Events

The following diagram shows the possible lifecycle of a contract option event.

Pending A contract option event may be created in pending status and transition to frozen to be used by processing algorithms. Events in this status may be deleted if they are incorrect.

Error A pending or frozen validation algorithm defined on the [contract option type](#) may set this status for an event if it detects an error condition. Events in this status also appear on the [Contract Option Event Exception](#) query.

Frozen Only frozen events are processed by rate algorithms and data derivation algorithms.

Canceled A frozen event may be canceled if it is incorrect.

Note:

Algorithms that process these events need to undo the effect of canceled events.

Contract Option Event Maintenance

Contract option events record the event of a contract option, including its effective period and any characteristic values related to the event. Open **Menu** > **Interval Billing** > **Contract Option Event** > **Search** to maintain event data.

Note:

This page is only available if the Complex Billing module is not [turned off](#).

Description of Page

The **Contract Option Event ID** is a system-assigned random number.

Indicate the **Contract Option ID** to which this event is linked.

Indicate the **Contract Option Event Type** for this event.

The **Start Date/Time** and **End Date/Time** of the contract option event represent when this event is effective. These are considered logical date/times and follow the seasonal time shifting as defined on the contract option type. Refer to [Seasonal Time Shifts](#) for more information.

The **Status** indicates the status of the contract option event. Use the **Freeze** button to change the status of the record from Pending to Frozen. Use the **Cancel** button to change the status of the record from Frozen to Canceled.

Note:

Any change in status causes the appropriate validation algorithm on the contract option event type, if any, to be executed.

When the pending or frozen validation algorithms find an error, the status of the record is changed to Error and an exception record is created. If the cancel validation algorithm finds an error, the error message is displayed to the user. No exception record is created.

Fastpath:

Refer to [Lifecycle of Contract Option Events](#) for more information.

The **Status Date/Time** indicates when the record's status changed to its current value. Algorithms that process these events use this information to determine whether the status change affects their processing. For example, if the status is Canceled and the status date/time is more recent than the last time the algorithm processed the events, the algorithm may need to reverse the effect of this event. This date/time is considered a server date and follows the seasonal time shifting as defined on the base time zone.

Refer to [Seasonal Time Shifts](#) for more information.

The characteristic collection is used to indicate additional information related to your contract option event.

Note:

You can only choose characteristic types defined as permissible on the contract option event record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

To modify a characteristic, move to a field and change its value. To add a new characteristic, click + to insert a row then fill in the information for each field. The following fields display:

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Contract Option Event Exception

If a validation algorithm finds an error in contract option event data, a record is written to the contract option event exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, you must schedule an appropriate To Do entry creation background process. This process generates a To Do entry for every record in the contract option event exception table.

The following section describes steps to take to correct the data in error.

How To Correct a Contract Option Event in Error

Errors in contract option events are a result of errors detected in a validation algorithm. The validation algorithms provided by the system check for overlap of other events for contract options with the same contract option type.

- Review the To Do entries generated as a result of contract option event exceptions.
- The information displayed with the To Do entry provides details of the error. Drill down to view more details on the [Contract Option Event](#) page.
- Fix the error by resolving the overlap and change the status of the data set to Pending. The next time the validation algorithm runs, it revalidates this data.

Interval Billing Calculation Details

When a bill is produced with calculation lines resulting from interval pricing rate components or TOU Pricing rate components, it's likely that a CSR may want to view the calculation detail to verify that this was done correctly.

Fastpath:

In order to view the details of the calculation of a bill, the interval pricing rate component and TOU pricing rate components must indicate an audit algorithm. Refer to [Auditing Your Interval Pricing Bill Lines](#) for more information.

Once you have a bill generated, go to **Menu > Financial > Bill Segment > Search** and navigate to the **Calc Lines** page. Locate the lines that were produced as a result of an interval pricing rate component. A drill down button appears in the first column.

When you click the drill down for a given line, you are taken to a page that shows details for the calculation of this line. If your bill line was calculated using an interval pricing rate component, you are taken to the interval pricing details page. If your bill line was calculated using a TOU pricing rate component, you are taken to the TOU pricing details page.

Interval Pricing Details - Main

To navigate to this page, you must first go to **Menu > Financial > Bill Segment > Search** and display a bill segment with interval data in its calculation lines. From the **Calc Lines** tab, you may choose to audit a bill line that is the result of an interval pricing rate component that has an audit algorithm. Choosing the drill down button for an interval pricing calculation line will bring you to the Interval Pricing - Calc Details - Main page.

Description of Page

Identifiers and descriptions are shown for the **Account**, **SA** and **Premise** linked to this bill segment.

The **Bill Seg ID**, **Bill Seg Header** and **Calc Line** identify the bill calculation line currently displayed. The **Description on Bill** displays the description of the bill line that is printed on the customer's bill.

The date and time covered by the **Consumption Period** are displayed.

Fastpath:

Refer to [Bill Period and Seasonal Time Shifts](#) for more information.

The **Quantity Billed** displays the quantity, followed by a description of the unit of measure, followed by a description of the SQI, if applicable.

The **Total Amount** of the bill line is displayed, followed by the date and time this line was **Calculated On**.

If you click **Rate Info**, a dialog opens displaying information about the rate. The information includes the rate schedule and version, the rate component sequence and description, the interval profile relationship type and bill factor information.

The **Start Date/Time** and **End Date/Time** indicate the range of the data that is currently displayed. To limit the amount of data displayed, enter a different start and end date and time and click **Zoom**. Use **Refresh** to display all the data linked to the bill segment calculation line.

The Interval Billing Graph displays three sets of data and uses color to distinguish between them. Red is used for the interval quantities. The Y-axis shows the range of values plotted under the column **UOM**. Blue is used for the prices that are coming from the interval billing factor values. The Y-axis shows the range of values plotted under the column **Price**. Green is used for the resulting calculation at each interval of quantity multiplied by price. The Y-axis shows the range of values plotted under the column **Cost**. For all three curves, the X-axis shows the date for each interval.

Controlling Which Graphs Are Displayed

All three sets of data are displayed initially, however, you may control which sets of data are displayed by clicking the **UOM**, **Price**, or **Cost** legend markers on the top of the interval graph. For example to view only the **Price** graph, click the **UOM** and **Cost** legend markers.

To redisplay the **UOM** and **Cost** graphs, click the respective legend markers again.

Drilling Down In the Graph

While the graph is displayed, you may click a group item (such as, the a date on the x-axis) to drill down into more detail. For example, clicking the group item will drill down to a small number of days.

You can display hour-by-hour information by clicking further.

At this point, if you click on one of the bars, you will be taken to the appropriate interval data set page to view the interval data itself.

Interval Pricing Details - Details

To navigate to this page, you must first go to **Menu > Financial > Bill Segment > Search** and display a bill segment with interval data in its calculation lines. From the **Calc Lines** tab, you may choose to audit a bill line that is the result of an interval pricing rate component that has an audit algorithm. Once on the **Calc Details** page, you may navigate to the **Details** tab.

Description of Page

The top section of this page is the same as the main page.

Use the **Start Date/Time** and **End Date/Time** to indicate a range of data to display.

The detailed grid displays the **Date/Time** for each interval and the **Quantity**, **Price** and resulting **Amount**. Use the context menu button at the right of the amount column to navigate to either the Interval Value page or the Interval Data page to view the source data.

Below the grid, the **Total Billable SQ** and the **Total Amount** for the bill segment calculation line are displayed.

The **Seasonal Time Shift Remark** indicates whether the data is displayed in legal time or standard time. If the seasonal time shift record on the interval profile type of the first profile matches the seasonal time shift record on the bill factor/characteristic for the price, the intervals are displayed in legal time, according to this seasonal time shift record. Otherwise, the data is displayed in standard time.

Fastpath:

Refer to [Seasonal Time Shifts](#) for more information.

Interval Pricing Details - SA Information

To navigate to this page, you must first go to **Menu > Financial > Bill Segment > Search** and display a bill segment with interval data in its calculation lines. From the **Calc Lines** tab, you may choose to audit a bill line that is the result of an interval pricing rate component that has an audit algorithm. Once on the **Calc Details** page, you may navigate to the **SA Information** tab.

Description of Page

The top section of this page is the same as the main page.

The tree structure on this page shows the profiles found for this service agreement and interval profile relationship type for the time period.

TOU Pricing Calc Details - Main

To navigate to this page, you must first go to **Menu > Financial > Bill Segment > Search** and display a bill segment with TOU pricing data in its calculation lines. From the **Calc Lines** tab, you may choose to audit a bill line

that is the result of a TOU pricing rate component that has an audit algorithm. Choosing the drill down button for a TOU pricing calculation line takes you to the TOU Pricing Calc Details - Main page.

Description of Page

Refer to [Interval Pricing Details - Main](#) for information about the information displayed in the top portion of the page. The one difference with the information displayed on this page is that the **Quantity Billed** includes the description of the time-of-use code along with the UOM and SQL.

The TOU Consumption Graph displays in Red the interval quantities that were mapped to the time-of-use code represented by the line. The Y-axis shows the range of values plotted under the column **UOM**. The X-axis shows the date for each interval.

Fastpath:

Refer to [Interval Pricing Details - Main](#) for information about drilling down into the graph.

TOU Pricing Calc Details - Details

To navigate to this page, you must first go to **Menu > Financial > Bill Segment > Search** and display a bill segment with TOU data in its calculation lines. From the **Calc Lines** tab, you may choose to audit a bill line that is the result of a TOU pricing rate component that has an audit algorithm. Once on the **Calc Details** page, you may navigate to the **Details** tab.

Description of Page

The top section of this page is the same as the main page.

Use the **Start Date/Time** and **End Date/Time** to indicate a range of data to display.

The detailed grid displays the **Date/Time** and the **Quantity** for each interval that was mapped to the time of use code associated with this bill line. Use the context menu button at the right of the amount column to navigate to either the Interval Data page or the TOU Data page to view the source data.

The **Seasonal Time Shift Remark** indicates whether the data is displayed in legal time or standard time. If the seasonal time shift record on the interval profile type of the first profile matches the seasonal time shift record on the classic TOU map type of the first classic TOU map for the period, the intervals are displayed in legal time, according to this seasonal time shift record. Otherwise, the data is displayed in standard time.

Fastpath:

Refer to [Seasonal Time Shifts](#) for more information.

TOU Pricing Calc Details - SA Information

To navigate to this page, you must first go to **Menu > Financial > Bill Segment > Search** and display a bill segment with TOU data in its calculation lines. From the **Calc Lines** tab, you may choose to audit a bill line that is the result of a TOU pricing rate component that has an audit algorithm. Once on the **Calc Details** page, you may navigate to the **SA Information** tab.

Description of Page

The top section of this page is the same as the main page.

This page displays two tree structures. The first tree structure shows the interval profiles found for this SA and interval profile relationship type for this time period. The second tree structure is only visible if the rate component references a classic TOU map relationship type. It shows the classic TOU maps found for this SA and classic TOU map relationship type for this time period.

Interval Billing Examples

How to Link Common Profiles to a Service Agreement

The system automatically links common profiles to your service agreement if you set up the appropriate start options for your service agreement type. You may also link common profiles to your service agreement manually:

- Create the profile (refer to [Interval Profile Maintenance](#) for more information).
- Go to the [Service Agreement - Interval Info](#) tab to link this profile to your service agreement.
- Choose the appropriate profile relationship type for this SA/Profile link. This profile relationship type may be the link to a rate component if this profile is getting billed.
- Indicate the Interval Profile ID that you want to link to the service agreement.
- Save your record.

How to Link SA Owned Profiles to a Service Agreement

For The SA That Is The Owner

If this service agreement is the owner SA, the system automatically creates SA owned profiles for your service agreement if you set up the appropriate start options for your service agreement type. You may also create SA owned profiles for your service agreement manually:

- Create the profile (refer to [Interval Profile Maintenance](#) for more information). Be sure to choose your Service Agreement ID when creating the profile.

Note:

If you are on the [Service Agreement Interval Info](#) page, you may navigate to Interval Profile page by choosing Go To Interval Profile +. This brings your service agreement ID to the interval profile page and populates the service agreement field.

- Go to the [Service Agreement - Interval Info](#) tab to link this profile to your service agreement.
- Choose the appropriate Profile Relationship Type for this SA/Profile link. This Profile Relationship Type may be the link to a Rate Component if this profile is getting billed.
- Indicate the Interval Profile ID that you want to link to the service agreement.
- Save your record.

For The SA That Is Not The Owner

This assumes that the profile already exists and is linked to the owner SA. If not, follow the steps above.

- Go to the [Service Agreement - Interval Info](#) tab to link this profile to your service agreement.
- Choose the appropriate Profile Relationship Type for this SA/Profile link. This Profile Relationship Type may be the link to a Rate Component if this profile is getting billed.
- Indicate the Interval Profile ID that you want to link to the service agreement.
- Save your record.

Hedge Cover

Assume your organization has some interval rates with the following conditions. The customer will pay for an agreed upon amount of usage at a fixed price. We will call this amount of usage the hedge cover. It is also known as a "reference curve". If actual usage falls above the hedge cover, the customer pays the difference at the market price. If the actual usage falls below the hedge cover, the customer receives a credit for the difference at the market price.

In this example, we assume that the actual usage, the hedge cover, the strike price and the market price are all interval curves with the same interval size.

Hedge Cover - Bill Factors

Strike Price

Set up a bill factor for the Strike Price. On the bill factor indicate that it:

- Has a bill factor type of Interval.
- Uses an appropriate characteristic. For the purposes of this example, let's assume that the strike price does not vary by any characteristic and set the value to N/A.
- Has a value type of Unit Rate.
- Should generate an error if it finds no value.

Set up characteristics for the Strike Price bill factor. On the characteristic indicate:

- Minutes Per Interval of 30 minutes.
- External ID, if applicable, for use by an interface that populates the interval data.

Populate the interval value sets and interval values for the Strike Price bill factor. These values will probably be determined at the time the contract is negotiated. However, they will probably not be entered manually. Rather, your implementers provide an interface that populates this data from an external source. Refer to [Upload Interval Values](#) for information about how this interface should work.

Market Price

Set up a bill factor for the Market Price. On the bill factor indicate that it:

- Has a bill factor type of Interval.
- Uses an appropriate characteristic. For the purposes of this example, let's assume that the market price does not vary by any characteristic and set the value to N/A.
- Has a value type of Unit Rate.
- Should generate an error if it finds no value.

Set up characteristics for the Market Price bill factor. On the characteristic indicate:

- Minutes Per Interval of 30 minutes.
- External ID for use by the interface that populates the interval data.

Set up the interface that periodically populates the interval value sets and interval values for the Market Price bill factor. These values are received from an external source and are uploaded via an interface provided by the implementers. Refer to [Upload Interval Values](#) for information about how this interface should work.

Hedge Cover - Profile Relationship Types

Set up Profile Relationship Types for the following interval profile curves:

- Hedge Cover (HEDGE)
- Measured usage (MEASUSAGE)
- Difference between Measured and Hedge (OVRUNDHDG)

Later we will populate the valid profile types for each relationship type.

Hedge Cover - Profile Types

Create Profile Types

Set up a Profile Type HEDGE30 for the Hedge Cover, with the following attributes:

- Subtype is Common
- Minutes Per Interval is 30 minutes
- Specify an appropriate UOM/SQI

Set up a Profile Type MEAS30 for the Measured Usage, with the following attributes:

- Subtype is SA Owned
- Minutes Per Interval is 30 minutes
- Specify an appropriate UOM/SQI

Set up a Profile Type OVRUND30 for the Difference between Measured and Hedge, with the following attributes:

- Subtype is SA Owned
- Minutes Per Interval is 30 minutes
- Specify an appropriate UOM/SQI
- Profile Algorithm Type is Creation with an appropriate creation algorithm. The algorithm type IPFCSACS (supplied with the product) adds or subtracts two curves. The new algorithm should set up the two source Relationship Type parameters as HEDGE and MEASUSAGE and should indicate " - " for the Add/Subtract parameter.

Update Profile Relationship Types

Now that you have created profile types, go back to each profile relationship type and link the appropriate profile type as valid.

Hedge Cover - Rate Schedule and Rate Components

Create a Rate Schedule for your rate.

For the rate components, let's assume the charges are as follows:

- A bill line with the charges for the hedge cover at the strike price
- A bill line showing the measured usage over the hedge cover at the market price
- A bill line showing the measured usage under the hedge cover at the market price

Note that this rate may contain other charges that are not illustrated here.

The above line items require algorithms to perform the interval pricing calculations. The product is shipped with the RCIPRS algorithm type, which applies an interval pricing curve to an interval profile curve assuming that the interval size is the same.

| Seq # | RC Type | Description | Profile Relationship Type | Algorithm | Bill Factor |
|-------|------------------|---|---------------------------|---|--------------|
| 10 | Interval Pricing | Hedge cover at the strike price | HEDGE | Algorithm to apply prices to an interval profile curve | Strike Price |
| 20 | Interval Pricing | Measured usage over hedge at market price | OVRUNDHDG | Algorithm that applies prices to positive values in an interval profile curve (data does not need to be continuous) | Market Price |

| | | | | | |
|----|------------------|--|-----------|---|--------------|
| 30 | Interval Pricing | Measured usage under hedge at market price | OVRUNDHDG | Algorithm that applies prices to negative values in an interval profile curve (data does not need to be continuous) | Market Price |
|----|------------------|--|-----------|---|--------------|

Hedge Cover - Common Profile

Create the common profile that contains the hedge cover data. On the common profile, populate:

- Interval profile type of HEDGE30
- External ID, if applicable, for use by an interface that populates the interval data.

Populate the interval profile sets and interval profile data for the hedge cover. These values are probably determined at the time the contract is negotiated. However, they will probably not be entered manually. Rather, your implementers provide an interface that populates this data from an external source. Refer to [Upload Interval Data](#) for information about how this interface should work.

Hedge Cover - SA Type

Determine the SA Type that is used by customers who opt for the hedge cover rate. It may be necessary to set up a new SA type. The SA type chosen must include the following:

- The rate defined above must be linked to the SA type as one of the valid rates.
- The three profile relationship types defined above must be linked to the SA type as valid profile relationship types.

Hedge Cover - Start Option

Create a start option for your SA type. It should set up the hedge cover scenario for a CSR.

- Set the rate for this start option to the hedge cover rate
- Set the default interval profile information as shown in the table below

| Profile Relationship Type | Profile Type | Profile |
|---------------------------|--------------|--|
| HEDGE | | Link the profile created above for the hedge cover |
| OVRUNDHDG | OVRUND30 | |
| MEASUSAGE | MEAS30 | |

Hedge Cover - Service Agreements

When starting service for a customer, choose the appropriate SA Type and start option. Upon creation of the SA, the following occurs:

- The appropriate rate is linked.
- The common profile created above is linked to the SA.
- Two new SA owned profiles are created for the SA using the profile types defined in the start option for measured usage and amount over /under the hedge.

Hedge Cover - Typical Business Flow

Once all the control table data is set and a customer's service agreement has been activated, here is what typically happens in the course of a month:

- Market prices are received periodically and interfaced into the system.
- The customer's measured data is received periodically and interfaced into the system.
- The data derivation background process runs periodically and creates new "over under hedge" data.
- When billing executes, it bills the hedge cover and "over under hedge" data according to the rate algorithms.

Tunnel Option

Let's build on the hedge example. For this example, rather than comparing the measured usage to a single reference curve, the usage will be compared to a range of values at each interval to see if it falls within the range or outside the range. This is sometimes known as a "tunnel" option or a hedge option with "flex" parameters.

Assume that the interval rate for this option has the following conditions.

- For each interval, if the measured usage falls WITHIN the tunnel, the measured amount will be priced at a fixed price.
- For each interval, if the measured usage falls BELOW the LOW tunnel value, the customer will pay the low tunnel value at the fixed price AND will receive a credit for the difference between the low value and the measured amount at a market price.
- For each interval, if the measured usage falls ABOVE the HIGH tunnel value, the customer will pay the high tunnel value at the fixed price AND will pay for the measured amount over the high tunnel value at a market price.

Before we start looking at the data setup, let's talk about how the "tunnel" will be defined. In most cases, each customer does NOT have their own high and low tunnel curves defined. Instead, customer has a "reference curve" (also called "hedge cover") and the high and low values are defined as standard values for your company. These are percentages.

In this example, we assume that the actual usage, the hedge cover, the strike price and the market price are all interval curves with the same interval size.

Tunnel Option - Bill Factors

Prices

This example uses the same bill factors for prices as the simple Hedge Cover example. It has a Strike Price bill factor and a Market price bill factor. Refer to [Hedge Cover - Bill Factors](#) for more information.

Tunnel Percentages

We will also use bill factors to define the tunnel percentages. The easiest thing to do is create a separate bill factor for the High Tunnel Percentage and the Low Tunnel Percentage. These will be simple bill factors with a characteristic of N/A.

Tunnel Option - Profile Relationship Types

This scenario is similar to the simple Hedge Cover scenario. We still need Profile Relationship Types for the following interval profile curves:

- Hedge Cover (HEDGE)
- Measured usage (MEASUSAGE)

However, instead of a curve that contains the difference between Measured and Hedge, we need the following profile relationship types:

- Amount of Measured Usage that falls within the Tunnel (INTUNNEL)
- Amount of Measured Usage that does not fall within the Tunnel (OUTTUNNEL)

Later we will populate the valid profile types for each relationship type.

Tunnel Option - Profile Types

Create Profile Types

This example will use the HEDGE30 and MEAS30 Profile Types that were created for the simple Hedge Cover example.

Instead of the profile type for the Difference between Measured and Hedge, this example needs the following profile types.

Set up a Profile Type INTUN30 for the Amount of Measured Usage that Falls Within the Tunnel, with the following attributes:

- Subtype is SA Owned
- Minutes Per Interval is 30 minutes
- Specify an appropriate UOM/SQI
- Profile Algorithm Type is Creation with an appropriate creation algorithm. A new algorithm type will need to be created by the implementers. See [Tunnel Option - Data Derivation Algorithm](#) for information about this algorithm.

Set up a Profile Type OUTTUN30 for the Amount of Measured Usage that Falls Outside the Tunnel, with the following attributes:

- Subtype is SA Owned
- Minutes Per Interval is 30 minutes
- Specify an appropriate UOM/SQI

Note:

Although this is a derived curve, it does not have its own data derivation algorithm. Instead, the algorithm linked to the INTUN30 profile type populates this curve because the calculations for both derived curves can be done with one algorithm.

Update Profile Relationship Types

Now that you have created profile types, go back to each profile relationship type and link the appropriate profile type as valid.

Tunnel Option - Data Derivation Algorithm

It will perform the following functionality:

- It should define two parameters for the source curves, one for the profile relationship type representing the hedge cover (or "reference curve") and one for the profile relationship type representing the measured usage.
- It should define two parameters for the bill factors for the high and low tunnel percentages.
- It should define a parameter for the profile relationship type for the destination curve of the data that falls outside the tunnel.
- This algorithm retrieves the hedge cover data. For each interval, it calculates the tunnel by applying the high and low tunnel percentages to the hedge cover value for that interval. It then compares the measured data for that interval.
- If the measured data falls within the tunnel, it populates the "Within Tunnel" curve with the measured value. (The "within tunnel" curve is the one with a profile type that contains this algorithm.)
- If the measured data falls below the tunnel, it populates the "Within Tunnel" curve with the low tunnel value and populates the "Outside the Tunnel" curve (based on the parameter passed in to this algorithm) with the difference between the low tunnel value and the measured usage.

- If the measured data falls above the tunnel, it populates the "Within Tunnel" curve with the high tunnel value and populates the "Outside the Tunnel" curve with the difference between the measured usage and the high tunnel value.

Tunnel Option - Rate Schedule and Rate Components

Create a rate schedule for your rate.

For the rate components, let's assume the charges are as follows:

- A bill line with the charges for the "within the tunnel" data at the strike price
- A bill line with the charges for the "outside the tunnel" data at the market price

Note that this rate may contain other charges that are not illustrated here.

The above line items require algorithms to perform the interval pricing calculations. The product is shipped with the RCIPRS algorithm type, which applies an interval pricing curve to an interval profile curve, assuming that the interval size is the same.

| Seq # | RC Type | Description | Profile Relationship Type | Algorithm | Bill Factor |
|-------|------------------|-------------------------------------|---------------------------|--|--------------|
| 10 | Interval Pricing | Within Tunnel data at strike price | INTUNNEL | Algorithm to apply prices to an interval profile curve | Strike Price |
| 20 | Interval Pricing | Outside Tunnel data at market price | OUTTUNNEL | Algorithm that applies prices to an interval profile curve (data does not need to be continuous) | Market Price |

Tunnel Option - Common Profile

Create the common profile that contains the hedge cover data. If applicable, the curve created in the Hedge Cover example may be reused. Otherwise, refer to [Hedge Cover - Common Profile](#) for information on how to create a common profile.

Tunnel Option - SA Type

Determine the SA type that is used by customers who opt for the tunnel rate. It is possible that the SA type used in the simple Hedge Cover example may be reused. Or it is possible that you want to set up a new SA type.

The SA type chosen must include the following:

- The rate defined above must be linked to the SA type as one of the valid rates.
- The four profile relationship types defined above must be linked to the SA type as valid profile relationship types. (If you reuse the same SA type from the Hedge Cover example, only the two new profile relationship types, INTUNNEL and OUTTUNNEL, need to be linked at this time.)

Tunnel Option - Start Option

Create a new start option for your SA type that sets up the tunnel option scenario for a CSR.

- Set the rate for this start option to the hedge cover with tunnel option rate.
- Set the default interval profile information as shown in the table below.

| Profile Relationship Type | Profile Type | Profile |
|---------------------------|--------------|--|
| HEDGE | | Link the profile created above for the hedge cover |
| MEASUSAGE | MEAS30 | |
| INTUNNEL | INTUN30 | |
| OUTTUNNEL | OUTTUN30 | |

Tunnel Option - Service Agreements

When starting service for a customer, choose the appropriate SA type and start option. Upon creation of the SA, the following occurs:

- The appropriate rate is linked.
- The common profile created above is linked to the SA.
- Three new SA owned profiles are created for the SA using the profile types defined in the start option for measured usage, inside tunnel and outside tunnel.

Tunnel Option - Typical Business Flow

Once all the control table data is set and a customer's service agreement has been activated, here is what typically happens in the course of a month:

- Market prices are received periodically and interfaced into the system.
- The customer's measured data is received periodically and interfaced into the system.
- The data derivation background process runs periodically and creates new "within tunnel" and "outside tunnel" data.
- When billing executes, it bills the "within tunnel" data and "outside tunnel" data according to the rate algorithms.

Override Maps

Assume that you have contracts with customers where the standard classic TOU map is overridden on certain days, for example, for interruptions. The customer is informed of these interruptions ahead of time so that they can plan their usage accordingly. Let's assume that the price for usage during these interruption days is more than the standard TOU Price.

Let's assume that the contract identifies the following time period definitions

| Time Period Name | TOU Code | Description | Price |
|------------------|----------|---|----------|
| On Peak, Summer | ONSUM | The TOU for the standard map for May through September, inclusive for the times 08:00 through 16:59 | \$0.0488 |

| | | | |
|------------------------|--------|---|----------|
| Off Peak, Summer | OFFSUM | The TOU for the standard map for May through September, inclusive for the times 00:00 through 07:59 and 17:00 through 23:59 | \$0.0391 |
| On Peak, Winter | ONWIN | The TOU for the standard map for October through April, inclusive for the times 08:00 through 16:59 | \$0.0421 |
| Off Peak, Winter | OFFWIN | The TOU for the standard map for October through April, inclusive for the times 00:00 through 07:59 and 17:00 through 23:59 | \$0.0347 |
| Interruption, On Peak | ONOVR | The TOU for the interruption period. This is not season dependant and covers the times 07:00 through 17:59. | \$0.0504 |
| Interruption, Off Peak | OFFOVR | The TOU for the interruption period. This is not season dependant and covers the times 00:00 through 06:59 and 18:00 through 23:59. | \$0.0418 |

As you can see, the contract is set up to designate that on these special interruption days, the definition of on peak changes to include two extra hours, and the price per TOU is higher than on the standard days.

Override Maps - TOU Codes and TOU Group

You need to create TOU codes for all the TOUs defined above. Once these are defined, you need to set up a TOU group and link all the above TOUs to this group. For this example, let's call the TOU Group INTERRUPT.

Override Maps - Rates and Bill Factors

You need to set up your rate schedule and bill factors needed to handle the TOU pricing for all the TOUs in your TOU group, including the prices for the override TOUs. Refer to [Designing Your Time Of Use Rate Components](#) for more information.

Override Maps - Profile Relationship Type and Profile Type

You need to set up a profile relationship type and a profile type for your measured usage. Let's assume that we have the same control data as that which was used in the hedge cover example.

Override Maps - Contract Option Types and Contract Option Event Types

You need to define a contract option type and event types for the interruption periods.

Create a Contract Option Type for the interruptions. Call it INTERRUPT. This contract option type has no special characteristic values.

Create a Contract Option Event Type to define the possible type of interruption events. In this example, let's assume that there is only one type of interruption. Call the event type INTERRUPT. This contract option event type has no special characteristic values.

Override Maps - Map Relationship Type and Map Type

You need to define a map relationship type and map type for classic TOU map.

For this example, create a generic Map Relationship Type of MEASUSAGE.

Create a map type that is used for customers using the contract defined above with possible overrides. Call it INTRPT30. Define the other attributes as follows:

- TOU Group is INTERRUPT
- Minutes Per Interval is 30 minutes
- Algorithm Type is Creation with an appropriate creation algorithm. A new algorithm type needs to be created by the implementers. Refer to [Override Maps - TOU Data Creation Algorithm](#) for information about this algorithm.

Once you have created the map type, go back to the map relationship type and update its valid map types list to include the new map type.

Override Maps - Classic TOU Map Templates

Create a series of classic TOU map templates for the standard time periods and create a special classic TOU map template to use for the interruptions.

Override Maps - SA Characteristic

The classic TOU map creation algorithm needs to know the correct classic TOU map template to use to generate TOU data when the interruption occurs. Our algorithm assumes that the classic TOU map template is defined as a characteristic on the service agreement.

Create a foreign key reference for the classic TOU map template.

Create a new Char type with the following attributes:

- Type is FK Reference
- FK reference code is the one created above for classic TOU map template
- Char Entity is Service Agreement

Override Maps - TOU Data Creation Algorithm

The classic TOU map creation algorithm needs to know the correct classic TOU map template to use to generate TOU data when the interruption occurs. Our algorithm assumes that the classic TOU map template is defined as a characteristic on the service agreement.

This algorithm performs the following:

- It should define a parameter of Contract Option Type to indicate the type of contract options whose events should trigger an override interruption classic TOU map. It should also define a parameter of Char Type that indicates the characteristic type used for classic TOU map templates.
- It looks for frozen contract option events for the input Contract Option Type effective during the creation time period.
- It also looks for canceled contract option events and attempt to undo their effect.

- It finds a characteristic on the service agreement, whose type matches the input Char Type parameter. It verifies that this is a valid classic TOU map template.
- It generates a new data set for the classic TOU map for the time period defined by the contract option events using the classic TOU map template.

Override Maps - SA Type

Determine the SA type that is used by customers with this option. It may be necessary to set up a new SA type. The SA type chosen must include the following:

- The rate defined above must be linked to the SA type as one of the valid rates.
- The MEASUSAGE profile relationship type defined above must be linked to the SA type as a valid profile relationship type.
- The MEASUSAGE map relationship type defined above must be linked to the SA type as a valid map relationship type.
- The INTERRUPT contract option type defined above must be linked to the SA type as a valid contract option type.

Override Maps - Start Option

Create a start option for your SA type that sets up the override map scenario for a CSR.

- Set the rate for this start option to the appropriate rate.
- In the characteristics collection, indicate the Char Type you defined for classic TOU map templates and choose the interruptions classic TOU map template that you created.
- Set the default interval profile, map and contract option information as shown in the tables below:

| Profile Relationship Type | Profile Type | Profile |
|---------------------------|--------------|---------|
| MEASUSAGE | MEAS30 | |

| Map Relationship Type | TOU Map Type, Classic | TOU Map, Classic |
|-----------------------|-----------------------|------------------|
| MEASUSAGE | INTRPT30 | |

| Contract Option Type | Contract Option |
|----------------------|-----------------|
| INTERRUPT | |

Note:

In this option, there are no common profiles or maps.

Override Maps - Service Agreements

When starting service for a customer, choose the appropriate SA type and start option. Upon creation of the SA, the following occurs:

- The appropriate rate is linked.
- The classic TOU map template for interruptions is linked as a characteristic to the service agreement.
- A new SA Owned profile is created for the SA, using the profile type defined in the start option for measured usage.

- A new SA Owned classic TOU map is created for the SA, using the map type defined in the start option.
- A new SA specific contract option is created for the SA, using the contract option type defined in the start option for interruptions.

Override Maps - Classic TOU Map Data

The standard classic TOU map data must be set up at the beginning of the contract period. A user should go to the [Classic TOU Map Maintenance](#) page and use the **Generate** button to indicate the appropriate classic TOU map templates to use for the standard data.

Override Maps - Typical Business Flow

Once all the control table data is set and the customer's service agreement has been activated and the standard classic TOU map data for the customer has been generated, here is what typically happens in the course of a month:

- The customer's measured data is received periodically and interfaced into the system.
- If any special override days occur, a new contract option event is created for the contract option.
- The classic TOU map creation algorithm runs periodically and it generates new TOU data sets with the TOU Codes and time period definitions as defined above for the interruption days.
- When billing executes, the TOU Mapping, done during rate application, obtains the most up to date classic TOU map data for each interval. This way, if any special interruption data exists, the measured usage for that day is mapped correctly into the interruption TOUs. Otherwise, the data is mapped to the standard TOUs.
- The correct prices for each time of use period are applied.

To Do Processing

There are numerous events that trigger the creation of email-like messages describing work that requires human attention. For example, if a bill segment has an error, a message is created to highlight such. We refer to each message as a **To Do Entry**. In this section, we describe how to view, manage and work To Do entries.

Fastpath: We recommend familiarizing yourself with the topics described in [The Big Picture of To Do Lists](#) to fully appreciate how To Do entries are managed by the system.

Understanding To Do Processing

The topics in this section provide background information on To Do processing functionality.

To Do Role

Each To Do entry is assigned a specific To Do Role. The role defines the users who may work on the entry. The permissible roles that may be assigned to a To Do entry are defined on the entry's To Do type. One or more users within a role may be designated as a supervisor, who is allowed to assign To Do entries to other people. Supervisors are determined through application security access.

Refer to [To Do Entries Reference A Role](#) to learn more about role assignment.

After an entry is created, its role may be changed to any role defined as valid for the entry's To Do type. Manual changes of a To Do entry's role are recorded on the [To Do entry log](#).

To Do Priority

A To Do entry is associated with a priority level representing its processing order compared to other entries. Refer to [The Priority Of A To Do Entry](#) for more information on how an entry's priority is initially assigned and how it may be automatically updated by the system.

A user may manually override a To Do entry's priority at any time. Once overridden, automatic recalculation of the priority is no longer performed so as not to override the value explicitly set by the user. Manual overrides of a To Do entry's priority are recorded on the [To Do entry log](#).

Note: Only users that are currently **Assigned** to a To Do entry or ones that are valid for the role of an **Open** To Do entry may manually change the priority.

Work Distribution

This topic goes over the various possible actions a user can take to adjust what role or what user is associated with a To Do entry while it is in a non-complete state.

Adjusting the Role

A To Do entry must always reference a role. When a To Do entry are created in the **Open** state and is associated with a [role](#). The following points highlight ways to adjust the role associated with a To Do entry.

- A user viewing a record on the [To Do Entry](#) page may use the Forward or Send Back action to change the role.
- A supervisor using the [To Do Search](#) page may assign a user not linked to the current role. In this case, the system will update the role to one valid for the assignee.

Assigning a To Do to a User

There are several ways to **Assign** a To Do entry to a user:

- The [To Do Management](#) portal provides many filters and viewing options to review To Do entries for a give To Do Type. In addition, it displays a rich amount of detail for the resulting To Do entries, helping users to make decisions. Users may use this page to assign work to themselves and supervisors may use this to assign work to others.
- A supervisor can use the [Supervisor Functions](#) pages to review, assign and reassign To Dos to users.
- A user viewing an entry on the [To Do Entry](#) page may use the Forward to a User or the Send Back action to assign the entry to a different user.
- A user may use the [To Do list](#) pages to review and assign To Dos to themselves.
- All of the above assignment functions may also be performed using the [To Do Search](#) page.

The system can also be configured to dynamically assign the highest priority work to users on demand whenever they are available for fixing errors.

Note: Assignment on demand is in a plug-in. You can customize the next assignment plug-in on the [installation options](#) to follow your organization's work distribution rules. The product provides an algorithm out of the box (**F1-NEXT-TDNS**) that can assign work solely based on priority. Another algorithm (**F1-NEXT-TDSK**) may be used to only consider To Do entries the user has the proper [skills](#) to resolve. Your implementation may provide a different algorithm based on your own business rules.

One of the main benefits of the assignment on demand approach is that work is allocated real-time based on most current information such as skills, priority, user availability, etc. This also means that work remains unassigned until a user is actually going to work on it making it available to any qualified user.

Assignment "on demand" is possible from the [Current To Do](#) zone on the sidebar. Refer to this zone to learn about all the functions it provides.

Reopening / Unassigning a To Do

It is possible to transition a To Do entry from **Assigned** back to **Open**.

- A user viewing a record assigned to them on the [To Do Entry](#) page may use the Forward to a role action to move the entry back to **Open**.
- The **Unassign** button on the [To Do Management](#) portal or the **Reopen** button on the [To Do Search](#) page causes the To Do entry to go back to **Open**.

Working On A To Do

The To Do entry you are actively working on is your **In Progress** To Do entry. This To Do entry is visible in the [Current To Do](#) zone. Refer to that zone's help topic for all the features enabled on that zone.

Important: The information here assumes that you have configured the system to use the ability to have a substatus of Assigned, which includes the **In Progress** value. If you are not taking advantage of the substatus, then see below for information about how the functionality described here works differently.

If you don't currently have an **In Progress** To Do entry, there are several ways to choose a To Do and indicate that you want to start working on it. Doing so proactively populates the To Do into the Current To Do zone and navigates you to the related object (or if the To Do type is configured to launch a script, the script is launched).

If your organization's practice is to assign work to users up front, then a typical approach is that you would start by reviewing a list of entries assigned to you using one of the base pages and indicate that you want to work on an entry in the list. Or your organization may allow you to review To Do entries that are open and in a role that you are in. In some pages, there is a way for you to enable a list of To Do Entries that you can work through without needing to return to the query page to get the next entry.

The following points highlight the available base pages and their supported functionality.

- **To Do Management** allows you to use filters to view a list of entries assigned to you or that are open. Click the Work List icon in the Action column to populate the **Work List** zone in the sidebar with the results of the search. Click the **Work** button to choose the To Do entry you wish to start with. This drills you into the related object and populates the Current To Do zone with this To Do. It marks the To Do **In Progress**. (If the To Do entry was not already assigned to you, it will first assign it to you). Use the entries in the Work List zone to subsequently work on other To Do entries.
- If you are viewing a record on **To Do Entry** on page 1100 that you are allowed to work on, click the **Work** button to indicate that you want to start working on the record. This drills you into the related object and populates the Current To Do zone with this To Do. It marks the To Do **In Progress**. (If the To Do entry was not already assigned to you, it will first assign it to you).
- **To Do List** allows you to start working on a To Do by clicking the entry's message description link. It marks the To Do **In Progress**. (If the To Do entry was not already assigned to you, it will first assign it to you). Any other To Do entries that were in that results list on that page become an internal work list and the **Previous** button and **Next** button are enabled in the Current To Do zone to work through that list. Note that clicking the next or previous button does not automatically assign the entry to you. Use the **Start Progress** button on the Current To Do zone to change the status. If you don't start progress, it means the To Do in this zone is not your current In Progress to do entry. It remains in this zone until you perform another action to populate a different To Do in this zone. If you open another browser window, the Current To Do zone will not have this same To Do entry populated.
- **To Do Search** allows you to drill into the details of a To Do by clicking the entry's message description link, but it does not automatically assign it to you or update it to **In Progress**. You can click **Start Progress** on the Current To Do zone once it's populated. Any other To Do entries that were in that results list on that page become an internal work list and the **Previous** button and **Next** button are enabled in the Current To Do zone to work through that list. As with the first To Do selected, the subsequent To Do entries will not be assigned to you or progress started automatically.

Note: The To Do Search works differently than other pages in that you can drill in on a To Do entry and push the details into the Current To Do zone even if the To Do entry is assigned to someone else or if you are not allowed to work on that To Do. If you have an **In Progress** To Do entry and use the To Do Search to drill in on a different To Do Entry that doesn't get assigned to you, that To Do is now the one in the Current To Do zone and remains there until you do something else to refresh the data in that zone. If you open another browser window, the Current To Do zone will not have this same To Do entry populated.

Refer to **Current To Do** for more information about actions available to update To Do entries that you are working on.

Additionally, you may have the option to click on the **Assign me a To Do** button on the Current To Do zone to request your next task. The returned To Do entry automatically becomes the your **In Progress** To Do. This does not enable any work list functionality.

Note: If you do already have an **In Progress** To Do and you perform one of the above actions that results in a different To Do to become **In Progress**, the To Do entry that was already **In Progress** is updated to **On Hold**.

Important: If your implementation is not taking advantage of the substatus as described in [The Lifecycle Of A To Do Entry](#), then the system doesn't have a persistent way of marking which To Do entry is the one you are working on. You may still perform any of the steps described above to make the To Do entry your 'current'

To Do. If any of the above steps indicate that the To Do will be assigned to you, that action still occurs, but the To Do entry is not moved to 'in progress'. The To Do entry is only considered the 'current To Do' for your current session. If a different session is opened, you must perform the explicit action again to make the To Do the 'current To Do' for that session.

To Do Characteristics

Characteristics are used to associated related information to a To Do entry. Refer to [Linking Additional Information to a To Do Entry](#) for more information.

Several pages in the system allow you to view a To Do entry's characteristic values and / or search for To Do entries by their characteristics.

- The [To Do Management](#) portal includes up to five filters to search for To Do entries by a characteristic value. In addition, the search results display all the current characteristics as name / value pairs.
- The [To Do Entry](#) includes a zone to display any existing characteristics. In addition, if a user is allowed to modify a To Do Entry, the edit dialogue allows a user to add or change characteristics. Note that for manual [To Do types](#), the valid characteristic types are driven by the To Do type. For automated To Do types, if valid To Do characteristic types are configured on the To Do type, only those are available. Otherwise, any valid To Do characteristic type may be linked.
- The [To Do Search](#) allows includes a single characteristic type / value filter.

Related To Do Entries

A user working on a To Do may want to know of other To Dos that may be related to the same problem. If they can be worked by the same user they may get resolved faster. It seems almost impossible to programmatically determine whether two To Dos really stem from the same problem. The user should therefore be presented with a list of potentially related To Dos from which they can select the truly relevant ones.

A To Do entry is considered potentially related to a given To Do if they reference a common entity via a characteristic. For example, if a given To Do references a certain account then any To Do referencing that same account is considered related to it.

Note: The common entity is any characteristic value linked to the To Do entry where the characteristic type is a **Foreign Key** and the main table of the foreign key is classified as a **Master** or **Transaction** table.

There are various places where the user is informed as to whether or not the current To Do Entry is related to other To Do Entries.

- To Do entry maintenance displays in insight indicating the number of related To Do Entries for the current To Do. In addition, a Related To Do Entries zone shows information about each related To Do.
- The [Current To Do](#) zone includes related To Do information and actions.
- The [To Do Management](#) query includes a count of related To Do entries.
- The [To Do Search](#) page supports a **Related To Do filter** that lists all related To Do entries for a given entry.

Complete A To Do

After you finish working on an entry, you can mark it as **Complete**. At this point, you may want to review potentially [related](#) To Do entries and complete those that have been addressed by resolving the problem associated with the current entry.

When you complete a To Do, a [log entry](#) is created that indicates when the To Do was completed and by whom.

There are multiple ways in which you can complete a To Do.

- The [To Do Management](#) page provides many filters in addition to To Do Type. One or more entries may be completed in this page.
- Use the [To Do Entry](#) page to complete a single To Do Entry. The user may also choose to add comments when completing a To Do on this page.
- You may use the [Current To Do](#) zone to complete the current entry you are working on and/or all [related](#) entries assigned to you.
- The [To Do List](#) page allows you to complete one or more selected entries of a specific To Do Type.

- The [To Do Search](#) page allows you to search for To Do entries using various search criteria and complete selected ones.

Note: It is possible for the system to automatically mark an entry as **Complete**. Refer to [The Lifecycle Of A To Do Entry](#) for more information.

Log Entry Events

Any user may add a **User Details** log entry to any To Do at any time (even after it's completed). Refer to [To Do Entry](#) page for more information.

The [To Do Management](#) portal also allows users to add a **User Details** log entry to one or more selected entries.

In addition, there are several log entries created automatically by the system. The log includes a status column, which captures the status of the To Do at the time of log. If the To Do entry is **Assigned** and its substatus **In Progress** or **On Hold**, the log captures the substatus value, otherwise it captures the status value.

The following table contains the list of all possible log events.

| Event | Log Type | Log Status | Content of Details | Content of Assigned To (on To Do entry and To Do Log) | Log User ID | Contents of Sent By (on To Do entry) |
|--|-----------|------------|------------------------------------|---|------------------------------------|--------------------------------------|
| A To Do is created (by the system or by a user) | Created | Open | | | ID of user who created the To Do | |
| A To Do is created (by the system or by a user) in Assigned status | Created | Assigned | | User ID of user who was assigned this To Do | ID of user who created the To Do | Creating user's ID |
| A To Do is completed (by the system or by a user) | Completed | Complete | | | ID of user who completed the To Do | |
| A user takes an open To Do | Assigned | Assigned | Selected by user | Assigned To User ID | Assigned To User ID | ID of user who assigned the To Do |
| A supervisor assigns a To Do to a user (also happens if they reassign) | Assigned | Assigned | Assigned to user | Assigned To User ID | ID of user who assigned the To Do | ID of user who assigned the To Do |
| A user forwards an entry to a user | Forwarded | Assigned | <i>Log details entered by user</i> | Forwarded To User ID | ID of user who forwarded the To Do | ID of user who forwarded the To Do |

| Event | Log Type | Log Status | Content of Details | Content of Assigned To (on To Do entry and To Do Log) | Log User ID | Contents of Sent By (on To Do entry) |
|---|---------------------|-------------------------|--|---|--|--------------------------------------|
| A user forwards an entry to a role | Forwarded | Open | Forwarded to role <i>Role Description (Role ID)</i> + <i>Log details entered by user</i> | | ID of user who forwarded the To Do | ID of user who forwarded the To Do |
| A user sends back a To Do | Sent back | Assigned | <i>Log details entered by user</i> | Sent Back To User ID | ID of user who sent back the To Do | ID of user who sent back the To Do |
| The status is updated (aside from the cases that have an explicit log type) | Status Updated | Current status of To Do | | User currently Assigned, if applicable | ID of the user the made the status update | |
| A user adds a log entry | User Details | Current status of To Do | <i>Log details entered by user</i> | | ID of user who added the entry | |
| A user manually overrides priority | Override Priority | Current status of To Do | Priority changed from <i>old value</i> to <i>new value</i> | Assigned To User ID | ID of user who made the change | |
| Priority is updated by a calculate priority algorithm | Calculated Priority | Current status of To Do | Priority changed from <i>old value</i> to <i>new value</i> | | ID of user that added or updated the To Do or the user associated with the Recalculate Priority batch job. | |

Managing To Do Entries

This section describes the various pages available to view and work on To Do entries.

To Do Management

The To Do Management portal provides a multi-query zone that includes a search for To Do entries using To Do Type and other To Do information. Users may search for entries using multiple criteria and perform common actions, such as assignment and completion, on selected entries.

It is intended to be used by both supervisors and non-supervisor To Do users. Supervisors are identified by their security access to the portal.

Use **Menu > To Do > To Do Management** to navigate to the portal.

To Do Information Search

This zone allows you to search for non-closed To Do entries using various attributes of the entries, and to perform actions on selected ones.

Note: Results are restricted by role. For supervisors, this search returns To Do entries that meet the search criteria and are in a role of which the supervisor is a member. For non supervisors, the search returns open To Do entries that meet the search criteria and are in a role of which the user is a member or entries currently assigned to the user. Refer to [To Do Entries Reference A Role](#) for more information about roles.

The following sections describe the features of this zone.

Search Filters

The following table describes each of the different filters supported by this zone.

| Search Filter | Description |
|----------------|--|
| To Do Type | Use this filter to restrict the search to To Do entries of a specific type. Only To Do Types where the user is a member of at least one valid role for the type will be available for selection. |
| Status | Use this filter to restrict the search to To Do entries with a status of Open , Assigned , In Progress or On Hold . If you choose Assigned, then it includes the To Do entries that are In Progress and On Hold. Note that the underlying query excludes completed To Do entries. |
| Days Old | <p>On the To Do Management portal, this option is represented by a pair of filter fields. Use these filters to restrict the search to To Do entries whose age falls within a given range in days. For example, entering values of 2 - 5 will restrict the search to entries that are greater than or equal to two days old and less than or equal to five days old.</p> <p>On the To Do Dashboard portal, this option lists the To Do Summary age ranges as set up for the user. Select a specific age range to restrict the search to To Do entries whose age falls within the given range in days.</p> |
| Assign To User | Use this filter to restrict the search to To Do entries assigned to a particular user. This filter only appears if the current user has To Do supervisor access. |
| Priority | Use this filter to restrict the search to To Do entries with a specific priority. |
| Key Value | Use this filter to restrict the search to To Do entries with a sort key value containing the entered value. |
| Message | Use this filter to restrict the search to To Do entries with a specific message. This filter appears after the To Do Type filter has been populated and shows a list of the message texts from all non closed To Do entries of the selected To Do Type. |
| Characteristic | Use these filters to restrict the search to To Do entries with a specific Characteristic Type and value. Up to five characteristic type and value pairs may be entered. For manual To Do types, the list of characteristic types will be restricted to the characteristic types defined for the To Do Type. For automated To Do Types, if valid To Do characteristic types are configured for the To Do type, only those are shown; otherwise, all valid characteristic types for the To Do Entry entity are shown. |

The system shows the total number of To Do entries displayed and the total number that satisfy your search criteria immediately below the set of results.

Note: For performance reasons, the search zone is configured to restrict the number of rows retrieved by the query. The 'Total Records' number will indicate whether there are more To Do entries that meet the criteria than can be displayed.

Search Results

The zone will display all To Do entries that meet the search criteria, up to the limit defined as a parameter to the zone. The following columns are displayed initially:

- The Action column includes the button Work. Click this button to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to [What Happens When You Work A To Do Entry](#) for more information.

Important: Automatic Assignment When you click the Work button for an open entry, the system changes the status of the entry to **Assigned / In Progress** and assigns it to you. It also causes this To Do entry to be your current To Do. Refer to [Working On A To Do](#) on page 1089 for more information.

Note: Work List. This column has a Work List icon. Clicking this icon populates the [Work List](#) zone with the results. Clicking on entries in the Work List zone performs all the logic described here when clicking the Work button for one entry. It will drill into the related object or launch a script, if configured. It will make this To Do the 'current' To Do, it will assign it to you if it is **Open** and update it to **In Progress**.

Note: Only 1 **In Progress** To Do entry. If you had a different To Do entry in progress before clicking the Work button, the other To Do entry will be put **On Hold**.

- Entries are sorted by their **Priority**. Highest in priority are listed first.
- **Days Old** is the number of days since the To Do entry was created by the system. Entries are sorted from youngest to oldest within priority.
- **Status** is the current status of the To Do entry. If the assignment substatus is populated, that value is displayed, otherwise the To Do entry status is displayed.
- **Assign To User** is the user currently assigned to the To Do entry.
- **Message** is the message associated with the To Do entry.
- **Related** displays a count of entries that are potentially related to the current entry based on having the same foreign key characteristic values. Click the hyperlink to navigate to the [To Do Search](#) page with the current entry as the Related To Do Filter value.
- **Note** displays a Comment icon  if there are either comments or a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do Entry. Click the icon to open a pop-up window which displays the To Do entry information, message, comments and logs.
- **Characteristics** displays the characteristic types and values for the entry as a concatenated string.
- **Related Entity** displays the information for the object related to this entry. The information string allows you to navigate to the page on which the entry's respective object is displayed.
- **To Do ID** is the system generated key of the entry. Click the hyperlink to navigate to the [To Do Entry](#) page to view or maintain the current entry.

Click the **Column Configuration** icon  in the zone header to show the [Column Configuration Area](#) in which additional columns can be added to the results. The additional columns include the following:

- **Create Date/Time** contains the date and time the To Do entry was created by the system.
- **Key 1** to **Key 5** contain the first five sort key values for the entry.
- **To Do Role** displays the description of the role for the To Do entry.

Actions

The zone provides the ability to perform certain actions on one or more selected To Do Entries.

Click the check box in the results list heading to select all entries displayed in the grid or click the box in a row to select a specific entry. The following actions are available:

- Use the **Update** button to open a pop-up window in which you can update the priority and/or add a **User Details log entry** to the selected To Do entries.
- Use the **Assign** button to assign a user to the selected To Do entries. Supervisors will be presented with a pop-up window in which they can choose the assignee from a list of users who are members of at least one role for the To Do Type. The user search includes information about the number of To Do entries already assigned to each user. For users without supervisor access, the current user is assumed to be the assignee and the window is not

displayed. Note that the system does not allow a non supervisor to assign themselves a To Do that is assigned to another user.

- Use the **Unassign** button to reopen the selected To Do entries and remove the assignee. Note that the system does not allow non supervisors to reopen a To Do that is assigned to another user.
- Use the **Complete** button to [complete](#) the selected To Do entries. Both supervisors and non supervisors may complete any To Do entry, including those assigned to other users.

To Do Supervisor Functions

This section describes several To Do transactions that aid supervisors in the monitoring and assignment of To Do entries.

Supervisor To Do Summary

This Supervisor To Do Summary page summarizes To Do entries by To Do Type. Only entries that are **Open** (i.e., not assigned to a specific user) or **Assigned** are summarized.

Note: Only To Do entries that are assigned to a role to which you belong are summarized on this page. Refer to [To Do Entries Reference A Role](#) for more information.

Use **Menu > To Do > Supervisor To Do Summary** to open this page.

Description of Page

This page summarizes all To Do entries that are **Open** or **Assigned**.

Note: This page does not further break down the assigned To Do entries by the substatus. Refer to [The Lifecycle Of A To Do Entry](#) for more information on the substatus values.

- **To Do Type** contains the description of the To Do type.
- **Priority** provides a total count of To Do entries of a given type by priority. For each distinct priority the description includes the priority value followed by the corresponding number of entries. If all entries are of the same priority no additional count is displayed.
- **Total** contains the total of **Open** and **Assigned** entries. The hyperlink navigates to the [Supervisor To Do Assignment](#) transaction, setting it to display all **Open** and **Assigned** entries for the given To Do Type.
- **Open** contains the number of To Do Entries whose status is **Open**. The hyperlink navigates to the [Supervisor To Do Assignment](#) transaction, setting it to display all **Open** entries for the given To Do Type.
- **Assigned** contains the number of To Do entries whose status is **Assigned**. The hyperlink navigates to the [Supervisor To Do Assignment](#) transaction, setting it to display all **Assigned** entries for the given To Do Type.

The "age bars" that appear to the right of the totals highlight the age of the To Do entries. The colors red, yellow and green are used to highlight the relative number of old, middle-aged and new To Do entries. The age associated with each of these colors is [user-configurable](#).

Supervisor User Summary

The Supervisor User Summary page summarizes To Do entries by the user who is assigned to work on the entries. Only entries that are **Assigned** are summarized.

Note: Only To Do entries that are assigned to a role to which you belong are summarized on this page. Refer to [To Do Entries Reference A Role](#) for more information.

Use **Menu > To Do > Supervisor User Summary** to open this page.

Description of Page

This page contains a grid that displays all assigned To Do entries by User ID and To Do type. It indicates how many To Do entries of the displayed Type are assigned to the user (Assigned this Type) and how many To Do entries in total are assigned to the user (Assigned Total).

Note: This page does not further break down the To Do entries by the substatus. Refer to [The Lifecycle Of A To Do Entry](#) for more information on the substatus values.

Clicking the hyperlinks transfer you to the [Supervisor To Do Assignment](#) transaction. On this transaction, you can assign / reassign To Do entries to a specific user. The difference is that clicking the To Do Type hyperlink causes only **Open** entries to be displayed on the Assignment transaction. Clicking the count in the Assigned this Type column causes **Assigned** entries assigned to the displayed user to be shown.

Supervisor To Do Assignment

This page lists To Do entries of a given type and allows a supervisor to assign / reassign them to a designated user.

Note: Refer to the [To Do Management](#) portal for a page that provides many more filters to narrow down the results. In addition, it provides more data in the results and provides more actions for a supervisor to perform for To Do entries.

Use **Menu > To Do > Supervisor To Do Assignment** to open this page.

Description of Page

This page contains **Open** or **Assigned** To Do entries of a given type. These entries can be assigned to a specified user one-by-one or several at a time. The following points describe this functionality:

- You can select a different **To Do Type** by typing in a value or pressing the search button in the upper right corner. An **Info** description of the To Do type appears on the left.
- You can change the list of entries displayed according to their status. Select the **Filter by** status to be All (blank), **Open**, or **Assigned**.
- For **Assigned** entries, you may also **Filter by User** to limit the search to a specific user assigned to the To Do entries.
- If you want to re-sort the entries by a different value, click the search button adjacent to **Extra Information**. Each row's respective sort value is displayed in the **Extra Information** column.

Note: Extra Information. Each To Do list's default **Extra Information** is defined on the list's [To Do Type](#). Also note that each To Do list's available **Extra Information** differs.

- Click the **Select All** button to select all entries displayed in the grid. Click the **Clear All** to remove the selections in the grid.
- Use the checkbox if you want to assign specific entries.
- Entries are further sorted by their **Priority**. Highest in priority are listed first.
- **Create Date/Time** contains the date and time the To Do entry was created by the system. Click the Create Date/Time hyperlink to navigate to the To Do page where additional information is visible and where additional actions are possible.
- Click the number of **Related** entries hyperlink to navigate to the [To Do Search](#) query to list potentially related entries to the current entry.
- **Worked By** shows the user currently assigned to the To Do entry.
- **To Do Entry Status** is the current status of the To Do entry. If the assigned substatus is populated, that value is shown, otherwise the status value is shown. Refer to [The Lifecycle Of A To Do Entry](#) for more information.
- **Message** contains a description of the To Do entry. Use the message description hyperlink to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Note that clicking this action does not push the To Do Entry into the [Current To Do](#) zone and does not assign the To Do Entry to you. Refer to [Working On A To Do](#) on page 1089 for information about using that functionality.
- You can assign entries to a user:
 - Enter a user ID or search for a user using the **Assign To User** field. You can only select a user that is associated with a role that is associated with this **To Do Type**. Note that the current number of assignments is displayed adjacent.
 - Select one or more entries to assign to this user and click the **Assign** button. The entries' status becomes **Assigned**.

To Do List Functions

This section describes To Do pages that aid users in the assignment and working of entries in To Do lists.

To Do Summary

This page summarizes To Do entries that meet the following qualifications:

- The entry is **Open** and you belong to the entry's To Do role. Refer to [To Do Entries Reference A Role](#) for more information about roles.
- The entry is **Assigned** and you are the user to which it is assigned.

Use **Menu > To Do > To Do Summary** to open this page.

| Keyboard Shortcut | Alternate Shortcut |
|-------------------|--------------------|
| Alt+X | Alt+Shift+X |

Note: Refer to [Shortcut Key Summary](#) for information about the alternate shortcut.

Fastpath: Refer to [The Big Picture of To Do Lists](#) for an overview of To Do functionality.

Description of Page

This page is dedicated to a grid that summarizes the To Do entries on which you can work. The following information is displayed:

- **To Do Type** contains the description of the To Do type.
- **Priority** provides a total count of To Do entries of a given type by priority. For each distinct priority the description includes the priority value followed by the corresponding number of entries. If all entries are of the same priority no additional count is displayed.
- **Total** contains the total of **Open** and **Assigned to You** entries. The hyperlink navigates to the [To Do List](#) transaction, setting it to display all **Open** and **Assigned** entries assigned to you for the given To Do Type.
- **Open** contains the number of To Do Entries whose status is **Open**. The hyperlink navigates to the [To Do List](#) transaction, setting it to display all **Open** entries for the given To Do Type.
- **Assigned to You** contains the number of To Do entries that are assigned to you whose status is **Assigned**. The hyperlink navigates to the [To Do List](#) transaction, setting it to display all **Assigned** entries for the given To Do Type.

Note: This page does not further break down the assigned To Do entries by the substatus. Refer to [The Lifecycle Of A To Do Entry](#) for more information on the substatus values.

The "age bars" that appear to the right of the totals highlight the age of the To Do entries. The colors red, yellow and green are used to highlight the relative number of old, middle-aged and new To Do entries. The age associated with each of these colors is [user-configurable](#).

To Do List

This page lists To Do entries of a given type that are either **Open** (not assigned to a specific user) or are assigned to you.

Note: Refer to the [To Do Management](#) portal for a page that provides many more filters to narrow down the results. In addition, it provides more data in the results and allows the user to adjust the priority of To Do entries.

Note: Restricted by role. Only those entries assigned to a role to which you belong may be seen on this page. Refer to [To Do Entries Reference A Role](#) for more information.

Fastpath: We recommend familiarizing yourself with the topics described in [The Big Picture of To Do Lists](#) to fully appreciate how To Do entries are managed by the system.

Use **Menu > To Do > To Do List** to open this page.

Description of Page

This page contains a grid that summarizes the To Do entries of a given type on which you can work.

The **Info** section contains a concatenation of the **To Do Type's** description and the user's name.

The area beneath **Info** provides you with options that control which To Do entries appear and the order in which they are displayed. The following points describe the various options:

- Use **Sort By** to define how you want the To Do entries sorted. The following options are available:
 - **Assigned Date - On or After.** This option sorts the To Do entries in chronological order (based on the date the entry was assigned to you) starting from the input **Date**. If you choose this option, the system assumes you want to start from the earliest To Do entry. If you want to start from a date other than the earliest To Do entry, enter the desired **Date** and click the adjacent search button.
 - **Assigned Date - On or Before.** This option sorts the To Do entries in reverse chronological order (based on the date the entry was assigned to you) starting from the input **Date**. If you choose this option, the system assumes you want to start from the today's date. If you want to start from a date other than today's date, enter the desired **Date** and click the adjacent search button.
 - **Create Date - On or After.** This option sorts the To Do entries in chronological order (based on the date the entry was created) starting from the input **Date**. If you choose this option, the system assumes you want to start from the earliest To Do entry. If you want to start from a date other than the earliest To Do entry, enter the desired **Date** and click the adjacent search button.
 - **Create Date - On or Before.** This option sorts the To Do entries in reverse chronological order (based on the date the entry was created) starting from the input **Date**. If you choose this option, the system assumes you want to start from the today's date. If you want to start from a date other than today's date, enter the desired **Date** and click the adjacent search button.
 - **Extra Information.** This option sorts the To Do entries by the value of the **Extra Info**.
- Use **Extra Info** to choose data related to the To Do Entry that should be used to sort the To Do entries. This information is displayed in each entry's **Extra Information** column.

Note: Extra Info. Each To Do types's available **Extra Info** is defined on the [To Do Type Sort Keys](#). Also note that each To Do type's available **Extra Info** differs based on the configuration of the To Do Type.

- Use **Filter by** to restrict the To Do entries based on their status. The following options are available:
 - **All.** This option shows all entries that are **Open** or **Assigned**.
 - **Assigned.** This option shows all entries that are assigned to you.
 - **Open.** This option shows all entries that are **Open**.

The grid that follows contains the To Do entries that match your criteria. The following information appears:

- Click the **Select All** button to select all entries displayed in the grid. Click the **Clear All** button to remove the selections in the grid.
- Use the checkbox if you want to mark specific entries as **Completed** or **Assigned** using the **Complete** or **Assign** buttons at the bottom.
- A Comment icon  appears if there are comments on the To Do item and a Log Entry icon  appears if there is a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do item. This column appears if at least one To Do has either comments or a special log entry.
- Entries are further sorted by their **Priority**. Highest in priority are listed first.
- **Create Date/Time** contains the date and time the To Do entry was created by the system.
- Click the Create Date/Time hyperlink or either of the special icons to navigate to the [To Do entry](#) page.
- Click the number of **Related** entries hyperlink to navigate to the [To Do Search](#) query to list potentially related entries to the current entry.
- **Assigned Date/Time** contains the date and time the To Do entry was assigned to a user. This field is only populated on entries that are **Assigned**. If a user assigned the To Do entry, the user ID and name of the user who assigned the To Do entry are displayed beneath the Date/Time.

- **Message** contains a description of the To Do entry. Use the message description hyperlink to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to [What Happens When You Work A To Do Entry](#) for more information.

Important: Automatic Assignment When you drill into an using the message link for an open entry, the system changes the status of the entry to **Assigned / In Progress** and assigns it to you. It also causes this To Do entry to be your current To Do. Refer to [Working On A To Do](#) on page 1089 for more information.

- **To Do Entry Status** is the current status of the To Do entry. If the assigned substatus is populated, that value is shown, otherwise the status value is shown. Refer to [The Lifecycle Of A To Do Entry](#) for more information.
- **Extra Information** contains the data for the entry that corresponds to the Extra Info chosen in the sort options above.
- **To Do ID** contains the unique identifier of the To Do entry.
- If you want to mark one or more entries as **Assigned**, check the desired entries and then click the **Assign** button.
- If you want to mark one or more entries as **Completed**, check the desired entries and then click the **Complete** button. Completed entries do not appear on the To Do list (but they are retained on the database for audit purposes).

To Do Entry

Refer to [Understanding To Do Processing](#) for detailed explanations about many To Do entry features.

To view a To Do entry, use **Menu > To Do > To Do Entry > Search** . You are brought to a query portal with options for searching for a To Do Entry. Note that some query options limit the results. Refer to the inline help for more information.

Note: Restricted by role. Any user may change Comments for any To Do Entry. In addition, any user may add user Log details. However, for all other changes and actions, you may only change To Do entries that are assigned to you or ones that are **Open** and assigned to a role to which you belong. Refer to [To Do Entries Reference A Role](#) for more information about roles.

Once a To Do Entry has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The inline help provides information about several fields. The following points highlight information about some of the fields that may be visible.

If the To Do entry has non-complete [related entries](#) an insight appears indicating the number of related entries. In addition, details about the related entries are shown in the Related To Do Entries zone.

If the To Do entry was **Created By** a background process, information about that background process appears with a link allowing the user to drill into the batch run, if desired. Refer to [To Dos Created for Object-Specific Error Conditions](#) for more information.

If the To Do type is configured to [To Do Entries May Be Routed Out Of The System](#), the **Extract Info** appears. If the extract process is pending, the information indicates that. Otherwise, if it has run, information about the background process appears with a link allowing the user to drill into the batch run, if desired.

The **Characteristics** collection shows existing characteristics. This collection is maintained using the Edit action for users that are allowed to update this To Do entry. Refer to [To Do Entry Characteristics](#) for more information.

Actions

Most of the actions are self-explanatory and are related to simply updating the status value. This page has three special actions.

- Using the **Work** button causes several things to occur. You drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. If the To Do entry is Open, it gets assigned to you and the assigned substatus is set to **In Progress**, if your implementation has implemented this functionality. Refer to [What Happens When You Work A To Do Entry](#) for more information.

- Use the **Forward** to assign a To Do to another user or role. When a To Do is forwarded, a log entry indicates who forwarded the To Do, to whom it was forwarded, and the specified reason. The dialogue prompts for whether to send to a User or a Role. The search for User includes information about the number of To Do entries already assigned to this user. When choosing a User, confirm the correct Role. The Details provided are captured in the log entry.
- **Send Back** is only applicable if the **Sent By** user is populated. When a To Do is sent back, a log entry is created that indicates when the To Do was sent back and by whom. If the To Do is **Open**, this dialogue allows you to send it back to a different role. If the To Do is assigned to you, the dialogue allows you to re-assign the To Do to the person who assigned it to you. The Details provided are captured in the log entry.

Related To Do Entries

If the To Do has [related To Do entries](#), this zone appears with information about the related entries. Use this zone to perform actions on the current To Do and its related entries.

Adding a Manual To Do Entry

If your system is configured with [manual To Do types](#), you can add a To Do entry online.

Open the **Menu > To Do > To Do Entry > Add**.

You are prompted for a **To Do Type**. Only To Do types that are set up for manual usage appear in the list.

The default **To Do Type Priority** is displayed adjacent. Use **Override Priority** to override the default [priority](#) assigned by the system.

Type a **Subject** for your To Do entry. Depending on how the To Do type is set up, the subject may appear as the message in the To Do entry and To Do lists.

Enter a **Comment** to provide a longer description of and more details about the To Do entry.

Send To indicates whether the new To Do will be assigned to a **Role** (the default) or **User**.

The **Role** indicates the role to which this To Do entry will be assigned. Only users of the specified role will be able to view and work on the To Do entry. The role is defaulted from the To Do type. If you want to assign the To Do to a different role, change the specified role. You can only assign the To Do entry to one of the roles specified on the To Do type.

User appears if **Send To** is set to **User**. Use this option if you want to assign the To Do to a specific user. The user must be a member of the selected role.

If the [To Do type](#) defines valid characteristic types, the **Characteristics** collection is visible. If any of the characteristic types are flagged as Default on the To Do type, the characteristic type with its default value (if applicable) are displayed.

To Do Search

This page allows you to search for To Do entries using various search criteria, and perform various actions on selected ones. This page includes completed To Do entries in its search results, when applicable with respect to the filter criteria.

Use **Menu > To Do > To Do Search** to open this page.

Note: Refer to the [To Do Management](#) portal for a page that provides many more filters to narrow down the results. In addition, it provides more data in the results and allows the user to adjust the priority of To Do entries.

Note: No restriction by role. This page returns all To Do entries that meet the search criteria, regardless of the To Do entry's role. Using the search, a user may drill into the details of a To Do entry even if the To Do is not assigned to the user. Refer to [To Do Entries Reference A Role](#) for more information about roles.

The top half of the page is where you enter the criteria used to search for To Do entries.

CAUTION: Try to be as specific as possible when entering search criteria. Why? Because entering open-ended search criteria may have a severe impact on response times.

The following table describes each of the different search filters.

| Search Filter | Description |
|---------------|---|
| Related To Do | <p>If you're searching for potentially related entries for a given To Do entry, choose Specific To Do for the Related To Do Filter. Enter the To Do ID.</p> <p>A filter value of Not Applicable defaults.</p> |
| To Do Type | <p>If you're searching for a To Do entry and you know the value of a To Do Type linked to the To Do entry, choose Specific To Do Type for the To Do Type Filter. Enter the To Do Type.</p> <p>A filter value of All defaults.</p> |
| Char Type | <p>If you're searching for a To Do entry and you know the value of a characteristic linked to the To Do entry, choose Specific Char Type for the Char Type Filter. Enter the Characteristic Type and Characteristic Value.</p> <p>A filter value of Not Applicable defaults.</p> <p>Only characteristic types that include a characteristic entity of To Do Entry and that have been marked to allow searching by characteristic value are available.</p> |
| User | <p>Use this search method if you know the Created By User, Assigned To User or Completed By User for the To Do entry. Enter the appropriate User Id.</p> <p>A filter value of Not Applicable defaults.</p> |
| Date Range | <p>Use this field if you're searching for a To Do entry and know the Date Created or Date Completed.</p> <p>A filter value of Date Created defaults. The Start Date/Time defaults to the current date, 12:00AM and the End Date/Time defaults to the current date, 11:59PM.</p> <p>If you enter a Date Range Filter of All, the system ignores this search method.</p> |
| Status | <p>Use this search method to restrict the search to To Do entries with a specific status value. You may search for To Do entries in the status of Open, Assigned or Completed. You may also perform a combination search for To Do entries that have a status value of either Open or Assigned.</p> <p>A filter value of All defaults.</p> |

Note: The system allows any combination of values. The system does not try to validate your search combinations, even if they do not make sense. For example, if you enter a **User Filter** value of **Completed By User** and a **Status Filter** value of **Open**, you will not get an error. In this case, the system will find no records that match your criteria (because To Do entries that are Open do not have a Completed By User).

The system shows the total number of To Do entries that satisfy your search results immediately below the grid.

The first group of To Do entries is displayed in the grid at the bottom of the page.

- Click the **Select All** button to select all entries displayed in the grid. Click the **Clear All** to remove the selections in the grid.
- Use the checkbox if you want to perform actions (see below) on specific entries. Only **Open** or **Assigned** entries may be selected.
- A Comment icon  appears if there are comments on the To Do item and a Log Entry icon  appears if there is a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do item. This column appears if at least one To Do item has either comments or a special log entry. Use either icon to navigate to the To Do entry page.

- Entries are sorted by their **Priority**. Highest in priority are listed first.
- **Create Date/Time** contains the date and time the To Do entry was created by the system. Use the hyperlink to navigate to the To Do entry page.
- Click the number of **Related** entries hyperlink to redisplay this page listing potentially related entries to the current entry.
- **Last Assigned Date/Time** contains the date and time the To Do entry was most recently assigned to a user, if applicable, along with the Assigned To user.
- **Message** contains a description of the To Do entry. If the To Do entry is in the status of **Open** or **Assigned**, the message description allows you to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to [What Happens When You Work A To Do Entry](#) for more information.

Note: Current To Do. Drilling into the page by clicking the Message hyperlink does not automatically assign **Open** To Do entries to the user (as the To Do List page does when clicking on the Message). But it does treat this as the user's current to do, enabling the functionality in the Current To Do zone. Refer to [Working On A To Do](#) on page 1089 for more information.

- **Status** contains the current status of the To Do entry.
- **Completion Date/Time** contains the date and time the To Do entry was completed and the user who completed the entry, if applicable.
- **To Do Type** contains a description of the To Do type for the To Do entry.

Actions

- Use the **Assign** button to assign or reassign the selected entries to a user. Enter a user ID or search for a user using the **Assign To User** field. By default this field is populated with the current user's ID. Note that the user's current number of assignments is displayed adjacent. Upon successful processing, the selected entries are assigned to the specified user and the status of **Open** entries becomes **Assigned**. Additionally, a corresponding [log entry](#) is added to each To Do.

Note: You may only assign To Do entries to yourself or to someone else if you are a valid user in the To Do entry's current role.

Note: Only users with **Supervisor Assignment** access rights may reassign entries that are not currently assigned to them.

- Use the **Reopen** button to unassign the selected entries from their users. Upon successful processing, the selected entries become **Open** and a corresponding [log entry](#) is added to each To Do.

Note: Only users with **Supervisor Assignment** access rights may unassign entries that are not currently assigned to them and the user must be a valid user in the To Do entry's current role.

- Use the **Complete** button to [complete](#) the selected entries.

To Do Dashboard

This portal provides a high level summary of open and assigned To Do entries by various criteria. It is intended to be used by both supervisors and non-supervisor To Do users. An implementation may introduce additional zones to this portal as needed.

Note: Results are restricted by role. For supervisors, the charts consider To Do entries that are in a role of which the supervisor is a member. For non supervisors, the charts consider open To Do entries that are in a role of which the user is a member or entries currently assigned to the user. Refer to [To Do Entries Reference A Role](#) for more information about roles.

Use **Menu > To Do > To Do Dashboard** to navigate to the portal.

The following zones may appear as part of the portal's **Main** tab page

- **To Do Entries By Role.** This zone summarizes To Do entries by their currently assigned role.
- **To Do Entries By Status.** This zone summarizes To Do entries by their current status.
- **To Do Entries By Priority.** This zone summarizes To Do entries by their priority.

- **To Do Entries By Age.** This zone summarizes To Do entries by age based on age ranges defined for the current user.
- **To Do Entries By Type.** This zone summarizes To Do entries by their to do type.

Selecting a specific slice of data on any of these zones broadcasts its value to the other zones on the portal allowing them to filter their data accordingly. Use the **Reset** action on each zone to reset the filter set by this zone.

The following zone appears as part of the portal's **Details** tab page

- **To Do Details** This zone lists To Do entries that match various criteria and allows the user to work and manage the list.

To Do Details

This zone allows you to search for non-closed To Do entries using various attributes of the entries, and to perform actions on selected ones.

Note: Results are restricted by role. For supervisors, this search returns To Do entries that meet the search criteria and are in a role of which the supervisor is a member. For non supervisors, the search returns open To Do entries that meet the search criteria and are in a role of which the user is a member or entries currently assigned to the user. Refer to [To Do Entries Reference A Role](#) for more information about roles.

The following sections describe the features of this zone.

Search Filters

The following table describes each of the different filters supported by this zone.

| Search Filter | Description |
|----------------|---|
| To Do Type | Use this filter to restrict the search to To Do entries of a specific type. Only To Do Types where the user is a member of at least one valid role for the type will be available for selection. |
| Status | Use this filter to restrict the search to To Do entries with a status of Open , Assigned , In Progress or On Hold . If you choose Assigned, then it includes the To Do entries that are In Progress and On Hold. Note that the underlying query excludes completed To Do entries. |
| Days Old | On the To Do Management portal, this option is represented by a pair of filter fields. Use these filters to restrict the search to To Do entries whose age falls within a given range in days. For example, entering values of 2 - 5 will restrict the search to entries that are greater than or equal to two days old and less than or equal to five days old. On the To Do Dashboard portal, this option lists the To Do Summary age ranges as set up for the user. Select a specific age range to restrict the search to To Do entries whose age falls within the given range in days. |
| Assign To User | Use this filter to restrict the search to To Do entries assigned to a particular user. This filter only appears if the current user has To Do supervisor access. |
| Priority | Use this filter to restrict the search to To Do entries with a specific priority. |
| Key Value | Use this filter to restrict the search to To Do entries with a sort key value containing the entered value. |
| Message | Use this filter to restrict the search to To Do entries with a specific message. This filter appears after the To Do Type filter has been populated and shows a list of the message texts from all non closed To Do entries of the selected To Do Type. |

| Search Filter | Description |
|----------------|--|
| Characteristic | Use these filters to restrict the search to To Do entries with a specific Characteristic Type and value. Up to five characteristic type and value pairs may be entered. For manual To Do types, the list of characteristic types will be restricted to the characteristic types defined for the To Do Type. For automated To Do Types, if valid To Do characteristic types are configured for the To Do type, only those are shown; otherwise, all valid characteristic types for the To Do Entry entity are shown. |

The system shows the total number of To Do entries displayed and the total number that satisfy your search criteria immediately below the set of results.

Note: For performance reasons, the search zone is configured to restrict the number of rows retrieved by the query. The 'Total Records' number will indicate whether there are more To Do entries that meet the criteria than can be displayed.

Search Results

The zone will display all To Do entries that meet the search criteria, up to the limit defined as a parameter to the zone. The following columns are displayed initially:

- The Action column includes the button Work. Click this button to drill into the page on which the entry's respective object is displayed. If the To Do type has been configured to associate a script with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched. Refer to [What Happens When You Work A To Do Entry](#) for more information.
-  **Important: Automatic Assignment** When you click the Work button for an open entry, the system changes the status of the entry to **Assigned / In Progress** and assigns it to you. It also causes this To Do entry to be your current To Do. Refer to [Working On A To Do](#) on page 1089 for more information.
-  **Note: Work List.** This column has a Work List icon. Clicking this icon populates the [Work List](#) zone with the results. Clicking on entries in the Work List zone performs all the logic described here when clicking the Work button for one entry. It will drill into the related object or launch a script, if configured. It will make this To Do the 'current' To Do, it will assign it to you if it is **Open** and update it to **In Progress**.
-  **Note:** Only 1 **In Progress** To Do entry. If you had a different To Do entry in progress before clicking the Work button, the other To Do entry will be put **On Hold**.
- Entries are sorted by their **Priority**. Highest in priority are listed first.
- **Days Old** is the number of days since the To Do entry was created by the system. Entries are sorted from youngest to oldest within priority.
- **Status** is the current status of the To Do entry. If the assignment substatus is populated, that value is displayed, otherwise the To Do entry status is displayed.
- **Assign To User** is the user currently assigned to the To Do entry.
- **Message** is the message associated with the To Do entry.
- **Related** displays a count of entries that are potentially related to the current entry based on having the same foreign key characteristic values. Click the hyperlink to navigate to the [To Do Search](#) page with the current entry as the Related To Do Filter value.
- **Note** displays a Comment icon  if there are either comments or a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do Entry. Click the icon to open a pop-up window which displays the To Do entry information, message, comments and logs.
- **Characteristics** displays the characteristic types and values for the entry as a concatenated string.
- **Related Entity** displays the information for the object related to this entry. The information string allows you to navigate to the page on which the entry's respective object is displayed.
- **To Do ID** is the system generated key of the entry. Click the hyperlink to navigate to the [To Do Entry](#) page to view or maintain the current entry.

Click the **Column Configuration** icon  in the zone header to show the [Column Configuration Area](#) in which additional columns can be added to the results. The additional columns include the following:

- **Create Date/Time** contains the date and time the To Do entry was created by the system.
- **Key 1** to **Key 5** contain the first five sort key values for the entry.
- **To Do Role** displays the description of the role for the To Do entry.

Actions

The zone provides the ability to perform certain actions on one or more selected To Do Entries.

Click the check box in the results list heading to select all entries displayed in the grid or click the box in a row to select a specific entry. The following actions are available:

- Use the **Update** button to open a pop-up window in which you can update the priority and/or add a [User Details log entry](#) to the selected To Do entries.
- Use the **Assign** button to assign a user to the selected To Do entries. Supervisors will be presented with a pop-up window in which they can choose the assignee from a list of users who are members of at least one role for the To Do Type. The user search includes information about the number of To Do entries already assigned to each user. For users without supervisor access, the current user is assumed to be the assignee and the window is not displayed. Note that the system does not allow a non supervisor to assign themselves a To Do that is assigned to another user.
- Use the **Unassign** button to reopen the selected To Do entries and remove the assignee. Note that the system does not allow non supervisors to reopen a To Do that is assigned to another user.
- Use the **Complete** button to [complete](#) the selected To Do entries. Both supervisors and non supervisors may complete any To Do entry, including those assigned to other users.

Reports

The following section describes the functionality provided for submitting reports on-line and for viewing reports submitted through a third party reporting tool.

Fastpath: For information about this functionality, see [The Big Picture of Reports](#).

On-line Report Submission

The on-line report submission page enables you to request a specific report to be run. This is only available if your system is able to integrate with your third party reporting system on-line. The system comes configured to integrate with BI Publisher.

Report Submission - Main

This page allows you to submit a report on-line. Navigate to this page using **Menu > Tools > Report Submission..**

Description of Page

To submit a report, choose the **Report Code** for the process you wish to submit. Refer to [Defining Report Definitions](#) for information about defining reports in the system.

A description of the report is displayed.

The parameters defined for the report on the [report definition](#) page are displayed in the grid. To see a description of a parameter, use the search button adjacent to the parameter label.

Note: Default note. The default values displayed for the parameters are defined on the [report definition](#) page.

When you have entered the appropriate parameter values, click the **Submit** button to submit the report. Refer to [How To Request Reports](#) for more information.

Note: Reports submitted via the on-line report submission page are not logged in the report history repository and are therefore not visible from the [report history](#) page. Only reports submitted through your third party reporting tool's batch scheduler are logged in the report history, if supported by the tool.

Viewing Historic Reports

If your third party reporting tool stores historic copies of reports in a repository, you may configure the system to allow a user to view these historic reports on-line.

Note: This page currently does not display historical reports for BI Publisher.

Report History - Main

This page allows you to view a report stored in your third party reporting tool's report repository, if supported. Navigate to this page using **Menu > Tools > Report History**.

Description of Page

The top part of the page shows the **Report Code**, **Description** and **Long Description** for the selected report.

To select a report, search by either **Report Code** or **Description** and click the adjacent search button. The reports matching your search criteria are displayed. Choose the desired report from the selection list.

Note: Displaying Report History. When you choose a report, the system needs to interface with your reporting software to display a list of historical occurrences of this report.

Administrative User Guides

Oracle Utilities Customer Care and Billing is a customer information system designed to meet the needs of electric, gas, and water utilities, and comprises of the following key functional areas:

- **Customer Information** - Create and maintain demographic, geographic, and contract information. Start and stop customer service. Capture customer interaction.
- **Sales and Marketing** - Create and maintain initiatives, marketing campaigns, and packages that can be offered to customers. Add eligibility criteria, as necessary, in order to target specific customer segments. Create and maintain leads and orders that can market and enroll eligible customers into initiatives and packages.
- **Device Management** - Create and maintain meter and item details including installation and removal information. Generate field work to initiate meter and item tests, and record their subsequent results.
- **Field Work** - Create and maintain field work requests. Dispatch field work to appropriate parties and record their outcome.
- **Meter Reading** - Generate and download meter read routes to meter readers. Upload meter read details and track of consumption trends to highlight anomalies.
- **Billing and Statements** - Create and maintain bills. Recalculate historical bills, as needed. Consolidate financial information from multiple accounts into a single statement.
- **Rates** - Configure and maintain rates that will be used to calculate charges that appear on bills.
- **Payments** - Post and maintain customer payments. Distribute payments based on balance-forward or open-item accounting practices. Manage automatic payments, as appropriate.
- **Credit and Collections** - Monitor customer debt. Create and maintain processes to encourage customers to pay overdue debt. Create and maintain payment arrangements and pay plans. Write-off debt, if necessary.

This documentation describes the features and functionality of the Oracle Utilities Customer Care and Billing system.

Framework Administrative User Guide

The topics in this section describe how to administer the Oracle Utilities Application Framework.

General Options

This section describes control tables that are used throughout your product.

Defining Installation Options

The topics in this section describe the various installation options that control various aspects of the system.

Installation Options - Main

Select **Admin > General > Installation Options - Framework** to define system wide installation options.

Description of Page

The **Environment ID** is a unique universal identifier of this instance of the system. When the system is installed, the environment id is populated with a six digit random number. While it is highly unlikely that multiple installs of the system at a given implementation would have the same environment ID, it is the obligation of the implementers to ensure that the environment ID is unique across all installed product environments.

System Owner will be **Customer Modification**.

The **Admin Menu Order** controls how the various control tables are grouped on Admin.

- If you choose **Functional**, each control table appears under a menu item that corresponds with its functional area. Note, the [menu](#) that is used when this option is chosen is the one identified with a menu type of **Admin**.
- If you choose **Alphabetical**, each control table appears under a menu item that corresponds with its first letter, using a Roman alphabet. For example, the Language control table will appear under the L menu item entry.

Note: The **Alphabetical** option only supports the Roman alphabet. For languages that do not use the Roman alphabet, the recommendation is to configure the system for the **Functional** setting.

CAUTION: In order to improve response times, installation options are cached the first time they are used after a web server is started. If you change the Admin Menu Order and you don't want to wait for the cache to rebuild, you must clear the cached information so it will be immediately rebuilt using current information. Refer to [Caching Overview](#) for information on how to clear the system login cache (this is the cache in which installation options are stored).

The **Language** should be set to the primary language used by the installation. Note that if multiple languages are supported, each user may define their preferred language.

The **Currency Code** is the default currency code for transactions in the product.

If your product supports effective dated characteristics on any of its objects, define the date to be used as the **Characteristic Default Date** on objects without an implicit start date. The date you enter in this field will default when new characteristics are added to these objects (and the default date can be overridden by the user).

Active Owner displays the owner of newly added system data (system data is data like algorithm types, zones, To Do types, etc.). This will be **Customer Modification** unless you are working within a development region.

Country and **Time Zone** represent the default country and time zone that should be used throughout the application.

CAUTION: In most implementations, the time zone defined here matches the database time zone. However, if there is some reason that the database time zone does not match the installation time zone, an implementation may configure a setting in the properties file to automatically convert data from the database time zone to the time zone defined here when displaying dates. Note that when this property setting is defined, changes to the installation time zone will require the server and the thread pool workers to be restarted in order for the changes to take effect.

Turn on **Seasonal Time Shift** if your company requires seasonal time shift information to be defined. Note that this is currently only applicable to Oracle Customer Care and Billing > Interval Billing functionality.

Installation Options - Messages

Select **Admin > General > Installation Options - Framework** and the **Messages** tab to review or enter messages that will appear throughout the application when a given event occurs.

The **Message** collection contains messages that are used in various parts of the system. For each message, define the **Installation Message Type** and **Installation Message Text**. The following table describes the **Message Types** provided by the framework product and how they are used in the system. Your specific product may have introduced additional message types.

| Message Type | How The Message Is Used |
|----------------------------------|---|
| Company Title for Reports | This message appears as a title line on the sample reports provided with the system. Generally it is your company name. It is only used if you have installed reporting functionality and are using the sample reports (or have designed your reports to use this message). |
| Domain Name | The text entered for this message type is meant to identify the environment and can be used for logic where it is useful to indicate the environment for a user. For example, the email sent when a background process finishes includes this information, if populated. |

Installation Options - Algorithms

Select **Admin > General > Installation Options - Framework** and the **Algorithms** tab to review or enter the algorithms that should be evoked when a given event occurs.

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

CAUTION: These algorithms are typically significant processes. The absence of an algorithm might prevent the system from operating correctly.

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|----------------------------------|----------------------------|--|
| Validate Email Attachment | Optional | Algorithms of this type are used to validate the attachments for size and total count while sending attachments using the Email service. Refer to Sending Email for more information |
| Address Geocoding | Optional | Algorithms of this type use Oracle Locator to retrieve latitude and longitude coordinates using address information. |
| Attachment Malware Scan | Optional | Algorithms of this type are invoked when adding attachment content. The algorithm receives the attachment ID and is expected to use a malware scanning tool to verify the contents of the attachment. Only one algorithm is allowed. Refer to Enabling Malware Scan for more information. |
| Global Context | Optional | Algorithms of this type are called whenever the value of one of the global context fields is changed. Algorithms of this type are responsible for populating other global context values based on the new value of the field that was changed. Refer to Global Context Overview for more information. |
| Guaranteed Delivery | Optional | Algorithms of this type may be called by processes that receive incoming messages that should ‘guarantee delivery’. Refer to Guaranteed Delivery for more information. The business service F1-GuaranteedDelivery may be used to invoke this plug-in spot. |

| System Event | Optional / Required | Description |
|-------------------------------|----------------------------|--|
| Ldap Import | Optional | Algorithms of this type are called for operations on users, groups, and group memberships after they have been processed. |
| Ldap Import Preprocess | Optional | Algorithms of this type are called to preprocess data retrieved from LDAP. |
| Next To Do Assignment | Optional | This type of algorithm is used to find the next To Do entry a user should work on. It is called from the Current To Do zone when the user asks for the next assignment. |
| Reporting Tool | Optional | If your installation has integrated with a third party reporting tool, you may wish to allow your users to submit reports on-line using report submission or to review report history online. This algorithm is used by the two on-line reporting pages to properly invoke the reporting tool from within the system. |
| SMS Receive | Optional | This type of algorithm is used to provide SMS receive service. Only one algorithm of this type should be plugged in. |
| SMS Send | Optional | This type of algorithm is used to provide SMS send service. If your installation uses the base algorithm that uses BPEL, you will need to create a feature configuration with the SMS Send Configuration feature type to define your Oracle BPEL server and service call details. If your installation has integrated with a third-party SMS service, you may want to override this algorithm type with your own implementation. Only one algorithm of this type should be plugged in. |
| To Do Information | Optional | <p>We use the term To Do information to describe the basic information that appears throughout the system to describe a To Do entry.</p> <p>Plug an algorithm into this spot to override the system default "To Do information".</p> |

| | | |
|---------------------------|----------|--|
| To Do Pre-creation | Optional | These types of algorithms are called when a To Do entry is being added. Refer to Refining a To Do Entry's Details at Creation Time for more information. |
|---------------------------|----------|--|

Installation Options - Accessible Modules

Select **Admin > General > Installation Options - Framework** and the **Accessible Modules** tab to view the list of accessible modules.

Description of Page

This page displays the full list of the application's function modules. A **Turned Off** indication appears adjacent to a module that is not accessible based on your system's module configuration setup.

Fastpath: Refer to [Module Configuration](#) for more information on function modules and how to turn off modules that are not applicable to your organization.

Installation Options - Installed Products

Select **Admin > General > Installation Options - Framework** and the **Installed Products** tab to view a read only summary of the products that are installed in the application version that you are logged into.

Description of Page

The **Product Name** indicates the name of the "products" that are installed. The collection should include **Framework**, an entry for your specific product and an entry for **Customer Release**.

Release ID shows the current release of the application that is installed. This field is used by the system to ensure that the software that executes on your application server is consistent with the release level of the database.

The **Release ID Suffix**, **Build Number** and **Patch Number** further describe the details of your specific product release.

Note: If you have developed implementation-specific transactions, you can populate the release ID, release ID suffix, build number and patch number for the **Customer Release** entry to define the latest version of implementation-specific logic that has been applied to this environment. The framework provides a script (**F1CustRelM**) to allow these fields to be updated manually. In addition, the **F1-InstallationOptions** inbound web service provides operations to view and update those fields via a REST call. Alternatively, your implementation team may populate these fields as part of their upgrade scripts.

The **Product Status** is used to indicate if a product installed by default in the version you are logged into is **Active** or **Inactive**.

The **Display** column indicates the product whose name and release information should be displayed in the title bar. Only one product sets this value to **Yes**.

Owner indicates if this entry is owned by the base package or by your implementation (**Customer Modification**).

Product Type indicates if the product is a Parallel Application. A parallel application is one that is independent of, and does not conflict with, other parallel applications. Multiple parallel applications can be installed in the same database and application server.

Note: About Information. The information on this tab is used to populate the information displayed in the [About](#) window for your product.

Support For Different Languages User Language

The language English (with the locale "en") is provided by the system and all system metadata are delivered with an English description or label. The system provides support for defining other languages and supports multiple languages in a single environment. System users can use the system in their preferred language, as long as a

translation into that language has been provided. A user sees the system in the language defined on their [user record](#). If enabled, users can use the [Switch Language](#) zone to switch to another supported language real time.

Supporting a New Language

Normally, setting up the system for another language (besides the delivered English language entry) is an implementation issue, not an administrative setup issue. However, there are several online administrative features that are used to set up a new language, and these are described here.

1. **Define a language code and indicate that it is enabled.** For details on this procedure, see [Defining Languages](#).
2. **Install or confirm the existence of a language pack.** For an on-premise installation, if the product supplies a language pack with translations for the system metadata descriptions, follow the instructions for downloading the language pack and installing it into your environment. For a cloud installation, if the product supplies a language pack for a given language, no additional step is needed here. The language pack is already installed.
3. **Copy descriptions of all language-enabled tables from an existing translation (e.g., English).** The copied values act as placeholders while the strings are translated into the new language. It is necessary to do this as a first step in order to create records using the new language code created in the previous step. Language-based descriptions can be copied using a supplied batch process, **F1-LANG**. The batch copies all English labels in the system.

The batch process will also update the new language rows with the translated metadata descriptions from the language pack, if installed.

4. **Translate additional content.** Translatable descriptions and labels for implementation data may be updated / entered in the application. First the user record must be updated to reference the new language. This may be done in one of the following ways:
 - a. Switch to the new language using the [Switch Language](#) zone.
 - b. If that zone is not available, navigate to the user page, assign the new language code to your User ID, sign out, and sign back in again.

Any online functions that you access will use your new language code. You can change the language code for all users who plan to use/modify the new language.

Note: The language pack updates all language entries for base owned system data. If your implementation updates base owned labels and descriptions after applying a language pack, they will be overwritten the next time an updated language pack is applied. Note that most user facing labels and messages support defining an Override Label or Override Description. This information is not updated by the base product and should be utilized if your implementation desires a specific label or description.

Managing Multiple Languages

Once a non-English language has been set up, there are several points to note when adding or updating records that include translatable strings.

- When a new record is added through the user interface or through a REST service call or any other means that goes through the standard maintenance service, the system automatically generates entries for each supported language and copies the text of the entered description to all the generated languages.
- When the translatable string for a record is updated, only the user's language row is updated. The system does not ripple the change to other supported language entries (because it could be overriding a valid translation).
- When your system is upgraded to a new version, the new version typically includes new system data. The upgrade only includes the English language rows. Implementers should run the **F1-LANG** batch program to generate language rows for the your supported languages for this new data. If a new translation pack for your supported language is available at the time of upgrade, then running this process also applies the translated strings. (As mentioned above, for on-premise installations, you need to download and install the language pack before this step). If the language pack is not available at the time of upgrade, then the batch program should be run again when the language pack has been installed.
- New translatable objects may also be included in a patch / hot fix. In this situation, the **F1-LANG** batch program should be run after installing the patch in order to ensure there are language rows for your supported languages. Updated language packs are only provided for full release upgrades and not for hot fixes. So implementations

may need to temporarily supply translations for the new strings until you update to the next release with the next updated translation pack.

Customer Language

Your specific product may also support capturing the language of a customer. Such that correspondence sent from the product may be produced in a language set on a customer record. Refer to your specific product's documentation for more information about additional language support.

Defining Languages

Your product may support multiple languages. For example, the field labels, input text, and even outputs and reports can be configured to appear in a localized language. A language code for every potential language exists in the system to supply this information in various languages.

Select **Admin > General > Language** to define a language.

This is a standard [All-in-One portal](#).

When **Language Enable** is checked, the system adds a row for this language whenever a row is added in another language. For example, if you add a new currency code, the system will create language specific record for each language that has been enabled. You would only enable multiple languages if you have users who work in multiple languages. Languages that are configured as enabled, appear in the [Switch Language](#) zone.

Note: For on premise applications, the login page displays all the languages that are enabled, allowing the user to toggle the login instructions in that language. The list of enabled languages is captured on the server at startup time. If a new language is enabled, contact your server administrator to refresh the server in order to see the new language displayed in the login page.

The **Locale** is a string containing three portions:

- ISO language code (lower case, required)
- ISO country code (upper case, optional)
- Variant (optional).

Hyphens separate the various portions, and multiple variants are possible.

The locale along with the collator strength control how the contents of grids and search results are sorted by the Java virtual machine (JVM) on your web server: The specific JVM in use by your particular hardware/OS configuration constrains the available **Locales**. Validating the **Locale** against the JVM is outside the scope of this transaction. This means you are responsible for choosing valid **Locales**.

Additionally, external systems that communicate with the product and provide a language use a format that matches the locale. For example in the Accept-Language header for [REST web service](#) calls, a requested language is provided.

The following are examples of valid locales:

| Locale | Comments |
|------------|----------------------|
| en-US | American English |
| en-AU | Australian English |
| pt-BR | Brazilian Portuguese |
| fr-FR-EURO | European French |
| ja-JP | Japanese |

The **Collator Strength** parameter is used for the Java collation API . This parameter controls whether, for example, upper and lower-case characters are considered equivalent, or how accented characters are sorted. Valid values for collator strength are **PRIMARY**, **SECONDARY**, **TERTIARY**, and **IDENTICAL**. If you leave this field blank, Java will use its default value for the language. We'd like to stress that the impact of each value depends on the language.

Please see <https://docs.oracle.com/javase/7/docs/api/java/text/Collator.html> for more information about the collator strength for your language.

Display Order indicates if this language is written **Left to Right** or **Right to Left**.

Note that all administrative control tables and system metadata that contain language-specific columns (e.g., a description) reference a language code. In addition, other tables may reference the language as a specific column. For example, on the User record you indicate the preferred language of the user.

Defining Countries

The topics in this section describe how to maintain countries.

Country - Main

To add or review Country definitions choose **Admin > General > Country**.

The **Main** page is used to customize the fields and field descriptions that will be displayed everywhere addresses are used in the system. This ensures that the all addresses conform to the customary address format and conventions of the particular country you have defined.

Description of Page

Enter a unique **Country** and **Description** for the country.

The address fields that appear in the **Main** page are localization options that are used to customize address formats so that they conform to address requirements around the world. By indicating that an address field is **Optional**, you make that field available everywhere addresses for this country are used in the system. You can enter your own descriptions for the labels. These labels will appear wherever addresses are maintained in the system.

Note: Your specific product may also add the ability to mark an address field as **Required**. If that is available, then the product is also supplying appropriate validation in all places where a user defines an address.

Note: For any country where the **State** is enabled, the valid states for the country must be entered on the **Country - State** tab. When entering address constituents on a record that captures this detail, the value for State is verified against the data in the State table. For any country where there is a component of the address that represents a "state" but your implementation does not want to populate the valid states for that country, choose a different field such as County for this constituent (and define an appropriate label). When entering address constituents on a record that captures this detail, no validation is done for the County column.

Country - States

To maintain the states located in a country, choose **Admin > Country > Search** and navigate to the **State** page.

Description of Page

For any country where you have enabled the State switch, use the **State** collection to define the valid states in the **Country**.

- Enter the standard postal abbreviation for the **State** or province.
- Enter a **Description** for this state or province.

Defining Currency Codes

The currency page allows you to define display options related to currency codes that are used by your system. Use **Admin > General > Currency** to define the currency codes in which financial information is denominated.

This is a standard [All-in-One portal](#).

Most attributes are self explanatory.

Note: Please contact your specific product to verify whether it supports a currency with more than 2 **Decimals**.

The **External Reference** may be used to define a currency whose currency code is more than three characters. To support that type of currency, define a currency code that uniquely identifies the currency in the system and use the

external reference to define the currency code recognized by external products. Note that your specific integration with an external system where financial information is included may need to be adjusted to use the external reference instead of the system's currency code. Refer to the specific documentation for your integrations to confirm.

Defining Time Zones

The following topics describe how to design and set up time zones.

Designing Time Zones

The Time Zone entity is used to define all the time zones where your customers may operate. Each time zone should define an appropriate Time Zone Name. This is a reference to an external source that defines time zones, their relationship to Greenwich Mean Time, whether the time zone follows any shifting for summer / winter time (daylight savings time) and when this shift occurs.

The following sections describe concepts and configuration topics related to managing time zones.

Note: Oracle Utilities Customer Care and Billing - Interval Billing applications customers should consult the topic *Time Issues* (search the Help index for "time issues") for specific information relating to that product's interval billing time related functionality.

The Base Time Zone

When designing your time zones, the first thing to determine is the base time zone. You may choose the time zone where the company's main office resides. Once this is done you can link the time zone code to the installation option as the base time zone. Refer to [Installation Options - Main](#) for more information.

Note: An attribute in the system properties file may be configured to indicate that the DB session time zone should be synchronized with the value defined on the Installation Options. Refer to the *Server Administration Guide* for more information.

If your company does business beyond your main office's time zone, define the other time zones where you may have customers or other systems with which you exchange data. At this point, your specific product may include configuration tables to capture default time zones, for example based on a postal code or geographic location.

Standard vs. Legal Time

The term **Legal Time** refers to the actual clock time as may be impacted by daylight saving (also called 'local time'). This time line has a gap hour on entry to the daylight saving period and a duplicate hour on exit from it.

The term **Standard Time** refers to a time line without any daylight saving shifts applied to it. This virtual time line has no gap hour on entry to the daylight saving period nor a duplicate hour on exit, i.e. it is continuous and non-ambiguous. As a general rule, it is recommended that all time sensitive data is stored in the standard time of the base time zone as defined on the installation options. This will prevent any confusion when analyzing data and will ensure that your algorithms do not have to perform any time zone or daylight saving shifting of data that may be stored in different time zones.

Depending on your specific product, entities may have their date/time information stored in either of the following options:

- Standard time of the base time zone (also called 'physical time').
- Standard time of another time zone related to the entity's geographical location (also called 'logical time').
- Legal time of the base time zone.

The metadata definition of a [table](#) specifies whether any of its date/time fields are stored in standard time or not. While typically all date/time fields of a table that supports standard time would be stored in the same way the system allows each [field](#) to specify its own option. The metadata definition of such field specifies whether it is base time zone standard time (**Physical Standard Time**), standard time of some other time zone associated with the entity (**Logical Standard Time**) or stored in base time zone legal time (**Referenced Time Zone**).

Storage vs. Display

Regardless of the time zone option used for storing the data in standard time, all date/time information is entered and displayed on the user interface in the legal time of its respective time zone. If a field is defined to be stored in the standard time of the base or other time zone, the user interface is designed to accept the data in the legal time of the respective time zone and shift it to the standard time of the same time zone before saving the data and performs the reverse shift from standard time back to legal time before displaying the data to the user.

It is important to understand that time zone and daylight saving time conversions to and from standard time are performed behind the scenes as part of the user interface layer. Once data reaches the server it is already in its storage time option. The user should not be aware of these time conversions.

Time shifting between standard and legal times does not happen automatically. When dealing with fields stored in standard time, their data entry and display need to explicitly include time shifting features as part of their user interface and zone configuration.

Date / Time Schema Elements

When defining date / time fields in a business object schema, schema attributes can be used to define whether or not data should be stored in standard time for the base time zone or if it should be stored in the standard time of another time zone (related to the data).

By default data stored in standard time is displayed in the corresponding time zone's legal time. Additional schema attributes can be used to indicate if the display of the time should be shifted to the legal time of a different time zone. For example, if the data is stored in the base time zone but the data is related to a different time zone, the data will be shown in the time zone appropriate for the data (including the appropriate seasonal adjustment). Refer to [Schema Nodes and Attributes- Standard Time Considerations](#) for more information.

Exchanging Date / Time Information With External Systems

Date/time information should be exchanged between systems in standard XSD format as it includes a reference to the time zone of the specified time as an offset from Coordinated Universal Time (UTC). The system automatically converts date/time elements in an inbound message from XSD to internal format and vice versa for an outbound message. The latter is controlled by an explicit date/time format setting on the External System record for the outbound message type.

The offset is determined as followed and it is based on the time zone associated with the element as explicitly defined by the respective inbound or outbound schema:

- Elements defined as stored in the standard time of the base or other time zone would always have the same offset throughout the year as this time line is never shifted for daylight saving. The offset would be the standard offset of that time zone from UTC, i.e. not during daylight saving time.
- Elements stored in the legal time of the base time zone would have the standard offset of the base time zone when the date/time value is outside the daylight saving period and the shifted offset when it is inside that period of time.

User Time Zone

If your company does business in multiple time zones, the user record of each user may reference the time zone of their location. This time zone provides additional information about the location of the user and as such may be used by specific business rules that involve time zone settings.

Note: The time zone defined on the user record is not used to automatically display date/time information in the user's time zone. By default, the system displays date/time fields that are stored in standard time in the legal time of their respective time zone and not the user's time zone.

Setting Up Time Zones

Refer to [Designing Time Zones](#) for background information about defining time zones.

Open this page using **Admin > General > Time Zone > Search** .

This is a standard [All-in-One](#) portal.

Refer to the embedded help text for more information on the Time Zone attributes.

Setting Up Seasonal Time Shift

Note: The information in this topic applies only to Oracle Utilities Customer Care and Billing - Interval Billing applications.

Open **Admin > General > Seasonal Time Shift > Search** to define the seasonal time shift schedule.

Description of Page

Enter a unique **Seasonal Time Shift** code and **Description** for the seasonal time shift.

The Collection defines the **Effective Date/Time** (in standard time) that a time zone may shift in and out of standard time. If time is changed from standard time on the effective date/time, enter the **Shift in Minutes** that the time changes from standard time (usually **60**). If the time is changed back to standard time on the effective date/time, enter a **Shift in Minutes** of **0**.

Defining Geographic Types

If your company uses geographic coordinates for dispatching or geographic information system integration, you need to setup a geographic (coordinate) type for each type of geographic coordinate you capture on your premises and/or service points (geographic coordinates can be defined on both premises and service points).

Note: Product specific. There is no framework functionality that uses this information. Refer to your specific product documentation to verify how this table is used in your specific product. In addition, you can determine if this object is a foreign key on any tables specific to your product. Navigate to the Table page in the application, search for and select the Geographic Type table and use the Relationships tab to view this information.

To define geographic types, open **Admin > Geographic > Geographic Type**.

This is a standard [All-in-One portal](#).

The **Validation Format Algorithm**, if specified, is used to validate that the geographic location entered on the premise and/or service point for the geographic type is in the format as defined in the algorithm. If you require validation, you must set up this [algorithm](#) in the system.

Defining Work Calendar

This portal is used to view and maintain information about a work calendar. Work calendars are used to ensure system-calculated dates fall on a workday.

You can access the portal from **Admin > General > Work Calendar**. You are brought to a query portal with options for searching for a specific calendar. Once a calendar has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones will appear as part of the portal's **Main** tab page

- **Work Calendar.** This zone provides information about the selected calendar.
- **Work Calendar Holidays.** This zone lists the holidays observed by your organization for this calendar. Use the zone actions to add, maintain or duplicate a work holiday entry.

Defining Display Profiles

When you set up your users, you reference a display profile. A user's display profile controls how dates, times, and numbers displayed. Choose **Admin > General > Display Profile > Search** to maintain display profiles.

Description of Page

Enter a unique **Display Profile** and **Description** to identify the profile.

Enter a **Date Format**. This affects how users view dates and how entered dates are parsed. The following table highlights standard supported date mnemonics and what is displayed at runtime.

| Mnemonic | Comments |
|-------------|--|
| dd | Day of the month. |
| d | Day of the month, suppressing the leading 0. |
| MM | Month number. |
| M | Month number, suppressing the leading 0. |
| yyyy | The 4-digit year. |
| yy | The 2-digit year. |
| y | Allows entry in either 2 or 4-digit form and is displayed in 2-digit form. |

Other characters are displayed as entered. Typically, these other characters should be separators, such as "-", ".", or "/". Separators are optional; a blank space cannot be use.

Examples:

| Configuration Format | Sample Output |
|----------------------|--|
| MM-dd-yyyy | 04-09-2001 |
| d/M/yyyy | 9/4/2001 |
| yy.MM.dd | 01.04.09 |
| MM-dd-y | 04-09-01 - In this case you could also enter the date as 04-09-2001 |

Note: For centuries, the default pivot for 2-digit years is **80**. Entry of a 2-digit year greater than or equal to **80** results in the year being interpreted as 19xx. Entry of a 2-digit year less than **80** results in the year being interpreted as 20xx.

In addition, the following date localization functionality is supported. Note that in every case, the date is stored in the database using the Gregorian format. The settings below result in a conversion of the date for the user interface.

- **Hijri Dates**

Entering **iiii** for the year is interpreted as a year entered and displayed in Hijri format. For example, the Gregorian date 2014-05-30 may be entered / displayed as 1435/07/30 for a user whose display profile date format is **iiii/MM/dd**. Note that this functionality relies on date mapping to be defined in the Hijri to Gregorian Date Mapping [master configuration](#). entry. Refer to [Additional Hijri Date Configuration](#) for more information.

- **Taiwanese Dates**

Entering **tttt** for the year is interpreted as a year entered and displayed in Taiwanese format where year 1911 is considered year 0000. For example, if the Gregorian date is 01-01-2005, it is displayed as 01-01-0094 for a user whose display profile date format is **dd-mm-tttt**.

- **Japanese Dates**

There are two options available for configuring Japanese Era date support. The setting **Gyy** for the year is interpreted as a year entered and displayed using an English character for the era followed by the era number. The letter 'T' is used for dates that fall within the *Taisho* era. The letter 'S' is used for dates that fall within the *Showa* era. The letter 'H' is used for dates that fall within the *Heisei* era. The letter 'R' is used for dates that fall within the *Reiwa* era. For example, for a user whose display profile date format is **Gyy/mm/dd** the Gregorian date 2008/01/01 is shown as **H20/01/01**; the Gregorian date 1986/03/15 is shown as **S61/03/15**. The setting **GGGGyy** is interpreted as a year entered and displayed using Japanese characters for the era followed by the era number.

Japanese date limitations are as follows:

- The years 1912 through the current date are supported.

- Any functionality that displays Month and Year does not support Japanese Era dates. These dates are shown in Gregorian format.
- Graphs that display dates do not support the **GGGGyy** format.

Enter a **Time Format**. The following table highlights standard supported date mnemonics.

| Mnemonic | Comments |
|-----------|--|
| hh | The hour 1-12. |
| h | The hour 1-12, suppressing the leading 0. |
| HH | The hour 0-23. |
| H | The hour 0-23, suppressing the leading 0. |
| KK | The hour 0-11. |
| K | The hour 0-11, suppressing the leading 0. |
| kk | The hour 1-24. |
| k | The hour 1-24, suppressing the leading 0. |
| mm | Minutes. |
| m | Minutes, suppressing the leading 0. |
| ss | Seconds. |
| s | Seconds, suppressing the leading 0. |
| a | Indicates to include am or pm . This is only needed for 12 hour formats, not 24 hour formats. (hh , h , KK , K). If an am or pm is not entered, it defaults to am . |

Examples:

| Configuration Format | Sample Output |
|----------------------|------------------------------------|
| hh:mmma | 09:34PM (can be entered as 09:34p) |
| hh:mm:ss | 21:34:00 |
| h:m:s | 9:34:0 |

There are several options for displaying Numbers.

Decimal Symbol defines the separator between the integer and decimal parts of a number. Valid values are "." (a period) or "," (a comma).

Group Symbol defines the means to separate groups of bigger numbers. Valid values are as follows:

- A comma (","). Large numbers group by threes separated by a comma, for example 1,000,000.
- A period ("."). Large numbers group by threes separated by a period, for example 1.000.000.
- **None**. Large numbers do not have any separator, for example 1000000.
- **South Asian**. This option uses a comma for its separator but will group large numbers as follows: the first comma is used for the thousands separation and numbers over 9,999 are grouped with 2 units, for example 10,00,000.
- **Space**. Large numbers group by threes separated by a space, for example 1 000 000.

Negative Format defines how negative values are displayed. Valid values are **-9.9**, **(9.9)**, or **9.9-**.

Currency values can have a different **Negative Format** from other numbers. Valid values are **-S9.9**, **(S9.9)**, or **S9.9-**, where the "S" represents the currency symbol.

Additional Hijri Date Configuration

For implementations that wish to support displaying dates according to the Hijri calendar, besides appropriate configuration in the [Display Profile](#), the mapping between the Hijri dates and the Gregorian dates must be entered. This mapping is defined in the [Hijri to Gregorian Date Mapping master configuration](#) record.

The mapping record contains a collection of entries for each year in the Islamic calendar.

For each year, clicking the Expand Zone icon shows the mapping collection with the first date of each month of the Hijri calendar. The corresponding date in the Gregorian calendar should be entered for each row.

Defining Phone Types

Phone types define the format for entering and displaying phone numbers.

To add or review phone types, choose **Admin > General > Phone Type**.

This is a standard [All-in-One portal](#).

The **Phone Number Format Algorithm** for each phone type controls the format for entry and display of phone numbers.

Use **Phone Type Flag** is used to identify phone types that may have specific functionality associated with it. For example if your product had support for sending a facsimile transmittal, identify the phone type that captures a **Fax** number.

Defining Feature Configurations

Some system features are configured by populating options on a "feature configuration". Because various options throughout the system may be controlled by settings in feature configuration, this section does not document all the disparate possible options. The topics below simply describe how to use this transaction in a generic way.

For information about specific features:

- Refer to the detailed description of each option type.
- Use the index in the online help and search for 'feature configuration' to find any specific topics describing feature options in the administration guide.

You can create options to control features that you develop for your implementation. To do this:

- Review the lookup values for the lookup field **EXT_SYS_TYP_FLG**. If your new option can be logically categorized within an existing feature type, note the lookup value. If your new option warrants a new feature type, add a lookup value to this lookup field.
- Define the feature's option types. If you have identified an existing feature type to add the options to, find the lookup with the name **xxxx_OPT_TYP_FLG** where **xxxx** is the lookup value of **EXT_SYS_TYP_FLG** noted above. If you decided to create a new feature type (by adding a new lookup value to the **EXT_SYS_TYP_FLG** lookup, you must create a new lookup with the name **xxxx_OPT_TYP_FLG** where **xxxx** is the new value you defined above.
- Flush all caches.

Feature Configuration - Main

To define your feature configuration, open **Admin > General > Feature Configuration**.

Use the **Feature Configuration Query** portal to search for an existing feature configuration. Once a feature configuration is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter an easily recognizable **Feature Name** code.

Indicate the **Feature Type** for this configuration. For example, if you were setting up the options for the external messages, you'd select **External Messages**.

Note: You can add new Feature Types. Refer to the description of the page above for how you can add Feature Types to control features developed for your implementation.

Note: Multiple Feature Configurations for a Feature Type. Some Feature Types allow multiple feature configurations. The administration documentation for each feature will tell you when this is possible.

The **Options** grid allows you to configure the feature. To do this, select the **Option Type** and define its **Value**. Set the **Sequence** to **1** unless the option may have more than value. **Detailed Description** may display additional information on the option type.

Note: Each option is documented elsewhere. The administration documentation for each feature describes its options and whether an option supports multiple values. Use the index to look for 'feature configuration' to find the various types of feature options.

Note: You can add new options to base-package features. Your implementation may want to add additional options to one of the base-package's feature types. For example, your implementation may have plug-in driven logic that would benefit from a new option. To do this, display the lookup field that holds the desired feature's options. The lookup field's name is **xxxx_OPT_TYP_FLG** where **xxxx** is the identifier of the feature on the **EXT_SYS_TYP_FLG** lookup value. For example, to add new batch scheduler options, display the lookup field **BS_OPT_TYP_FLG**.

Feature Configuration - Messages

If the feature exists to interface with an external system, you can use this page to define the mapping between error and warning codes in the external system and our system.

Open this page using **Admin > General > Feature Configuration** and navigate to the **Messages** tab.

Description of Page

For each message that may be received from an external system, define the **Feature Message Category** and **Feature Message Code** to identify the message.

A corresponding message must be defined in the [system message](#) tables. For each message identify the **Message Category** and **Message Number**. For each new message, the Message Category defaults to **90000** (because an implementation's messages should be added into this category or greater so as to avoid collisions during upgrades).

Defining Master Configurations

A master configuration is an object that enables an implementation to define configuration for features in the system. It is an alternative to using feature configuration for defining options. A master configuration is defined using a business object. Typically one master configuration exists for a given business object yet some configurations may be designed to support multiple records.

Overview / Initial Setup

The product provides one or more master configuration that may be used for configuration. Some examples of base master configuration business objects are as follows

- **Hijri to Gregorian Date Mapping.** This allows an implementation that uses Hijri dates to define the mapping between those dates and Gregorian dates.
- **ILM Configuration.** For implementations that use Information Lifecycle Management, the ILM configuration record defines some parameters used by the process.
- **Migration Assistant Configuration.** For implementations that use the content migration assistant (CMA), the configuration record defines some parameters used by the process.

For a list of all the master configuration records provided by the product, navigate to the master configuration page in the application. To find help topics related to functionality controlled by the master configuration records, use the keyword 'master configuration' in the index.

Implementations may configure the business objects to limit the ones that are visible to users if desired.

- If the master configuration does not apply to your implementation, navigate to the business object for this master configuration and update the Instance Control to **Do not allow new instances**. This ensures that the business object will not be visible to any user for the implementation.

- If a given master configuration record is only relevant for certain users in the system, application security may be used to limit the records visible by a given user. By default the base delivered business objects typically reference the Master Configuration MO application service. This may be overridden to link custom application services to the master configuration BOs to provide more granular security. Users will only see the master configurations that they have security for.

Configuration

You can access the portal from the **Admin > General > Master Configuration**. You are brought to a query portal with options for searching for a master configuration business object. If a configuration has not yet been set up for the business object use the add icon to define the record. If one or more configuration records exists for the business object you may select the master configuration business object. Once selected you are brought to this portal to view the selected record.

The following zones may appear as part of the portal's **Main** tab page.

- **Master Configuration** This zone provides information about the selected master configuration record. Please see the zone's help text for information about this zone's fields.
- **Related Configurations** This zone lists additional master configuration records for the same business object, representing different parts of the same configuration. You may add additional parts from this zone. The zone is only visible when the business object is designed to support multiple configuration parts and is explicitly marked as such by the **Multiple Configurations** business option.

Security & User Options

The contents of this section describe how to maintain a user's access rights.

Application Security

The system restricts access to various components of the application using application services. The following sections provide more information about this mechanism.

Understanding Application Security

The contents of this section and supporting topics provide information about application security.

Users

Each user who is granted access to the application is stored in the User object. This object defines the attributes of the user including identifier, name, language, time zone, home page and display profile (which defines the preferred format of dates and amounts). In addition there is configuration related to using the product, including favorite links and scripts, portal preferences and valid To Do roles - controlling what types of To Do entries a user can work on. Additionally, Refer to [Users and User Groups](#) on page 19 for additional information.

Application Services

Each object in the system that may be secured is associated with an application service. For example, each page in the system defines its application service allowing you to control what users can view a given page.

An application service defines one or more Access Modes, which typically correspond to an action associated with the application service. This allows you to control users that can only view a type of record (and grant security to the Inquire access mode) and users that can perform other actions such as add, change and delete. Refer to [Secured Objects and Application Services](#) on page 22 to understand what objects are associated with an application service and the typical access modes associated with each type of secured object.

Application Services may also define additional configuration, called security types. Refer to [Field Level Security](#) for more information.

User Groups

User Groups are a mechanism for grouping users, usually around job roles. Users are attached to User Groups through a relationship that is effective-dated. This can be useful for the attachment of temporary employees such as contractors or for people who change roles regularly.

Each User Group is authorized to access appropriate Application Services and their access modes. In addition, user groups define access to the application service's security types, if applicable. Refer to [Field Level Security](#) for more information.

Users and User Groups

A user group defines the application services and access modes its users have access to. A user may be associated to more than one user group. The user groups may have overlapping security configurations and the security access for a user is the union of all security granted by all of its user groups.

A major effort for implementations is to decide how to define their user groups. User groups can be created to represent roles or other job-related categorization; or based on organizational factors; or a combination of both. Refer to [Secured Objects and Application Services](#) on page 22 for some guidelines on understanding what application services secure and tools provided to help security administrators identify what application services to grant access to.

The following sections provide additional topics related to users and user groups, including some base functionality related to these objects as well as some best practices.

Base Delivered User / User Groups

The system is delivered with a base User and one or more base User Groups. They are provided to facilitate an initial user accessing the application.

The system supplied user is **SYSUSER**. This user is delivered so that when an environment is provisioned, there is at least one user authorized to use the system. It has access to the base delivered user groups. An initial administrator can sign in as this user and proceed to create the actual users that should get access to the environment.

Important: Once appropriate users have been defined, it is recommended to update SYSUSER to set it to disabled.

All active application services that are provided by the product are linked to a base delivered user group. The supported application services delivered by Oracle Utilities Application Framework are linked to user group **ALL_SERVICES** with all their supported access modes. Other products in your application stack may include their base delivered application services in this user group. Additionally, your specific product may deliver specialized user groups that group specific application services for a given functional area. You cannot change or remove the information delivered for the base user groups. System administrators should define user groups appropriate for their business requirements.

Important: It is not recommended for any production user to have access to the base delivered user groups.

Defining a Read-Only User Group

The product does not supply a user group that is 'read only', but it is a common requirement for implementations. This section provides a guideline for creating such a user group.

1. Create the [User Group](#) with the desired name and description.
2. Navigate to the Service Manager tab. In the Add Application Service / Access Modes tab, you can use the filter to limit the results to those with Inquire access mode. Click the checkbox in the header to select all rows and click Add. You are prompted for an expiration date. Click Save. (Note that the zone has a limit to 1000 services so you may need to do this more than once to get all services added.)
3. In addition, you should give this user group access to all the access modes for the default application service: **F1-DFLT** (Default Application Service). This application service is considered one that all users should have for basic access to the system.

Template User

The system provides support for defining one or more users as a template user. There are two broad use cases for using a template user.

Inheriting Preferences or Favorites Configuration

Some implementations want all users of a certain team to have the same configuration of portal preferences and / or favorite links. This allows users in that team to have the same information in the same place on their respective displays, facilitating in helping each other with questions.

If your organization wants to implement this practice, define a template user with the desired portal preferences and / or favorite links. You may define different users with different configurations for more granularity.

For each user whose preferences or links should be taken from the template user, go to the User record via **Admin > Security > User**. If the [portal preferences](#) should be inherited from a template user, define the desired template user as the **Portals Profile User**. If the [favorite links](#) should be inherited from a template user, define the desired template user as the **Favorites Profile User**.

If applied, the specified user's portal preferences and / or favorite links will be those defined on the template user and they will be unable to customize those preferences.

Defining a Template User to help in User Creation

The user object in the product captures configuration related to many aspects of using the product. It includes application security configuration, such as its user groups; row level security configuration through its access groups; the To Do roles that define what types of To Do entries a user can work on, along with other configuration. Many users that are in a similar 'role' in the organization would have many of the same settings. As such, it may be useful for implementations to define a template user that represents a 'role' in the organization, with much of the configuration common for users in that role. When creating a new user, you can use the template user as the starting point and then duplicate that record to create the new user. Then you only need to adjust the information that is unique for the newly created user.

Many implementations provision their users first in an external identity management system and use an interface to import the user definition into the product. Refer to [Importing Security Configuration from an External Source](#) on page 25 for more information. For these interfaces, the external system may have the ability to define custom information relevant to the product's user record, but the product also supports referencing a template user so that information from the template user is copied to the new user while creating the record.

How can you refer to a template user when creating a User from an external source?

- When the new user is uploaded to the system, the interface uses the user BO **F1-IDMUser** to create the user. The BO includes a pre-processing algorithm. This algorithm looks for the existence of a template user in the schema of the new user sent as a characteristic of type **F1-TMUSR**. If such a characteristic is found, it uses that template user. If not found, the algorithm supports defining a template user as an algorithm parameter. If a template user is identified, all the information from the template user will be copied onto the new user record except for the information passed in from the external source. The template user is captured on the newly created user via a characteristic for information / audit purposes.

Note: **Bookmarks** are not included in the data that is copied from a template user.

- Once the new user is created, its configuration can now be adjusted, if applicable. Note that the template user is only a tool used when adding a user. Updates to the template user will not "ripple" to all the other users that were created based on this template.
- Not all external sources may have the ability to define a template user and send it as a characteristic or via another field. For these integrations, using a single template user on the algorithm as a parameter may be used to define basic configuration applicable to a large percentage of new users. (More information on this below). For those integrations that are able to associate a new user with a template user in the external system and provide that template user along with the new user information allows you to associate the new user with a template user that is more aligned with the user's role. Refer to [Importing Security Configuration from an External Source](#) on page 25 for more information on how each integration supports the definition of a template user.

Designing your Template Users for helping Create Users

Before configuring template users, all the administrative control tables that are part of User configuration must be defined, including time zones, display profiles, To Do roles, data access roles and user groups.

If your integration will use a single template user defined as an algorithm parameter, you need to define a template user with the basic information that is applicable to all or at least most users. See below for guidance on referencing this template user as an algorithm parameter.

If the way you create users allows you to associate the user with a more specific template user, the next step is to define the user configuration for your system users. During this exercise, you will find that you have broad categories of users. But you will also see that within a given category of user there may be variations in the user privileges and preferences. For example, perhaps there are supervisors within the Customer Service role that have more security privileges than a typical Customer Service user. In addition, there may be variations based on the attributes of the users themselves. For example, maybe your organization exists in multiple time zones and some of your workers are in one time zone and some are in the other.

At this point your security users that are designing their user provisioning procedures must decide the following:

- What information about a new user will be captured in the identity system (besides the expected information like Name, Email and the User IDs)? For example, for the case of multiple time zones, maybe the best solution is to capture the time zone when defining the user.

What information is defined on the template user and how many template users should be created to reduce the need for manual steps or additional data captured in the identity management system? In the case of multiple time zones, proliferating the template users to have one set for one time zone and another set for the other time zone may not make sense since this is one field that is different. However it may be reasonable to create additional templates in the case of striations in the levels of privileges for workers of a different category. So rather than template users for Dispatcher, Mobile Worker, System Administrator and Contractor, your organization may have template users for Dispatcher, Mobile Worker, Mobile Worker (Supervisor), System Administrator, Contractor (Short Term) and Contractor (Long Term).

What information is must be configured on the User record in the application after the user is added? If only a small number of users have a variation from other users, it may be that the easiest way to deal with those variations is to simply update those user records manually. Using the above examples:

- If your organization covers 2 time zones but only a small group of people work in one of the time zones whereas the bulk of the users are in the other time zone, the simplest procedure may be to define the template users for the main time zone and use that for the creation of all users. Then for the small group of users in the separate time zone, navigate to the User page to adjust the time zone after the record is added.
- If only a small number of Mobile Workers are supervisors with separate privileges, rather than defining a special template user for those type of workers, the simpler procedure may be to use the Mobile Worker template and then navigate to the User page to add the additional privileges to the supervisor users after the record is added.

Defining a Template User

Regardless of which use case is applicable for your organization, the procedure for defining a template user is the same.

Navigate using **Admin > Security > User**.

- Define a User ID. If you are using a template user to help create users from an external system and the external system is able to capture the template user to send in with the new user information, this is the ID that should be referenced in the external system.
- Be sure to choose a **User Type of Template User**.
- Define all the information appropriate based on the use case.
 - For template users used as a Portal Profile user, be sure to define the appropriate portal profile information.
 - For template users used as a Favorites Profile user, be sure to define the appropriate favorite links.

- For template users acting as a type of 'role' to help with creation of users, define all the information that should be copied onto a new user that references this user as its template user. (Note that **Bookmarks** are not included in the data that is copied from a template user.)

Defining a Default Template User for Integrations

Define a default template user on the algorithm the defaults data from the this user as follows.

- Navigate using **Admin > System > Algorithm**.
- Search for and select the algorithm **F1-OIMUSR** (Populate User Data from a "Template" User).
- Edit the record. Add a new row in the Algorithm Versions collection. Enter an appropriate date (later than the date of the existing entry, but on or before the current date). Populate the template user you want to use as the default.

Secured Objects and Application Services

The system restricts access to transactions or explicit services using an [application service](#). The following sections provide more information about what objects are secured, how to find out what is secured by each app service as well as additional information related to managing application services.

What is Secured by an Application Service

- The following points highlight security related to viewing and modifying individual records in the system:
 - All [maintenance objects](#) define an application service that includes the basic actions available, typically **Add, Change, Delete, and Inquire**. The base product supplies an application service for every maintenance object. Some objects that include a fixed lifecycle, may define additional access modes on the maintenance object's application service. The application service for the maintenance object is defined on its related [service program](#).
 - 
CAUTION: Important! If an application service supports actions that modify the database other than **Add, Change, and Delete**; you must provide the user with **Change** access in addition to the other access rights. Consider a maintenance object that includes access modes **Freeze, Complete and Cancel**). If you want to give a user access to any of these special actions, you must also give the user access to the **Change** action.
 - For maintenance objects whose user interface page is not portal-based, the application service also controls whether the menu entry appears. If a user doesn't have access to the maintenance object's application service, the menu item that corresponds with the application service will not be visible.
 - For portal based user interfaces, each main (stand-alone) [portal](#) defines an explicit application service with the access mode **Inquire**, allowing the user interface to be secured independently of the underlying object security. If a user doesn't have access to the portal's application service, the menu item that corresponds with the application service will not be visible. The base product supplies an application service for every portal that is accessible from the menu. Note that the application service for the portal is defined on its related [service program](#), which is derived via its navigation option and navigation key.
 - [Menu items](#) may define an application service / access mode. Typically the security supplied for portals and maintenance objects provides enough granularity to suppress menu items that a user does not have access to. In addition, by default, the system populates application services / access modes on menu items related to a BPA script. A common use case is the 'Add' menu item for maintaining an object. In this case, typically the application service for the maintenance object is used along with the **Add** access mode. Other types of BPA related menu items may have other appropriate configuration.

Clients may choose to linking an explicit application service / access mode to further suppress a menu item. For example, imagine your implementation creates a special BPA script to add a To Do Entry and would like users to use the special BPA rather than the base supplied Add dialogue for To Do Entry. The base delivered menu item for adding a To Do Entry uses the To Do Entry maintenance object application service with the Add access. Users need that security setting to be able to add a To Do Entry even from a different dialogue. To suppress the base Add dialogue, override the setting for the base supplied menu item for To Do Entry Add with a special application service and access mode. Then define a menu entry for the new special BPA for adding.

- [Zones](#) define an application service.

- For zones linked to a portal, if a user doesn't have access to the zone's application service, the zone will not be visible on the portal. In most cases the zone is delivered with the same application service as its portal. In special cases, such as the zones on the Sidebar, the product supplies separate application services for each zone allowing implementations to determine at a more granular level which users should have access to which zones.
 - For query zones that are configured on a multi-query zone, if a user doesn't have access to the zone's application service, the zone will not be visible in the dropdown on the multi-query zone. In most cases all zones in a multi-query zone define the same application service as the multi-query zone. The product may supply a special application service for one or more zones in a multi-query zone if the functionality is special to certain markets or jurisdictions and not applicable to all implementations.
 - For zones that are used by business services to perform SQL queries, the product supplies a default application service (**F1-DFLTS**). Security for these zones is not checked by the product as they are used for internal purposes.
 - For portal based pages, individual elements may be shown or hidden based on security using the **oraHasSecurity** function in a UI map's HTML or in UI Hints in a schema. Refer to [Check User's Security Access](#) for more information.
 - [Business objects](#) define an application service. If the business object defines a lifecycle, the application service must include access modes that correspond to each state. In addition, the standard maintenance object access modes of **Add**, **Change**, **Delete** and **Inquire** are included. The base product business objects are supplied with appropriate application services. In addition, implementations may override the configured application service if desired.
-  **CAUTION:** Important! If an application service supports actions that modify the database other than **Add**, **Change**, and **Delete**; you must provide the user with **Change** access in addition to the other access rights. Consider a business object that includes lifecycle states **Freeze**, **Complete** and **Cancel**. If you want to give a user access to any of these special actions, you must also give the user access to the **Change** action.
- [Batch controls](#) define an application service which provides the ability to secure submission of individual batch processes. The application service must include an access mode of **Execute**. The base product batch controls are supplied with appropriate application services. These services will typically have an ID that matches the batch control ID.
 - [Report Definition](#) records define an application service. The application service must include an access mode of **Submit / View Report**.
- The following objects are securable but are typically executed via internal processes. The security is provided to ensure that any access to the objects from an external source is secured.
 - [BPA scripts](#) may define an application service with the access mode **Execute**. The base BPA scripts are typically not configured with any application service. An implementation may define one. Note that as mentioned above, a menu item may also be configured with an application service and access mode. This allows for a BPA that is invoked via a menu entry to be secured in more than one way.
 - [Business Services](#) and [Service Scripts](#) define an application service with the access mode **Execute**. This is needed for services that may be executed from an external system, for example via an inbound web service. Base business services and service scripts that are linked to an inbound web service are configured with special application service. All other business services and service scripts are delivered with a default application service (**F1-DFLTS**), which may be overridden by an implementation.
 - Scripts may also check security within an Edit Data step type if there is some functionality that should or should not execute based on a user's security access. The Edit Data step would include a call to the business service **F1-CheckApplicationSecurity**
 - [Service Programs](#) define an application service. As mentioned above, for Portals and Maintenance Objects, their application service is taken from the related service program. In base, specific application services are released for each of these types of service programs. All other service programs are typically delivered with a default application service (**F1-DFLTS**), which may be overridden by an implementation. Note that for service programs linked to a Business Service, the application service on the business service takes precedence when invoking the business service.

Determining What an Application Service Secures

Because the product wants to provide as much granularity as possible so that implementations can have the greatest control over what users can do, there are a large number of application services provided out of the box and it can be daunting to understand who needs to have access to what application services to do their job. The product provides several online tools to help security administrators to understand what application services exist and what they are for.

- On the [application service](#) page itself, there is a Secured Objects zone that indicates all the metadata that is related to this application service. There are a small number of application services that are securing functionality that is not discoverable by the Secured Objects zone. For those services, the detailed description of the application service should indicate what it's for.
- A large percentage of security is related to a specific page in the system that is accessible via the menu. Because of the different layers of security, to be able to view a record you may need access to several application services: the one associated with the query portal, the one associated with the maintenance portal, the one associated with the maintenance object of the record and the one associated with the business object governing the record. When viewing a [menu](#), there is an Application Security tab, which allows you to review each menu line and see a list of all the application services a user may need access to for viewing or maintaining data on that related page.
- The [Application Security Query](#) portal provides various filters for viewing what objects are being secured by what services. Besides menu items, it shows batch controls, reports, web services and other functionality. In addition, it allows you to view what users and what user groups currently have access to what application services and allows you to compare the security of two users.
- The [User Group](#) portal includes several zones that help security administrators to configure security options or review security configuration. The main tab includes a zone to Add Application Services. This zone only shows application services that are not already linked and provides several ways to narrow down the list of application services. The Service Manager tab has a similar zone, but breaks down the information to a combination of application service and access mode. Finally, the Secured Components tab is similar to the Application Security Query. It allows you to query the objects secured by application services in this user group.

Application Services Introduced in a Release

When new functionality is provided that includes any object that is associated with an application service, new application services may be introduced. The product release notes indicate the new application services included in the release. In addition, the product includes a special [Entity Tag](#) that includes a list of the new application services. The tag's description uses the cloud release reference rather than the on-premise release reference to identify itself.

Field Level Security

Sometimes transaction and action security is not sufficient. There are situations where you may need to restrict access based on the values of data. For example, in Oracle Utilities Customer Care and Billing you might want to prevent certain users from completing a bill for more than \$10,000. This is referred to as "field level security".

Field level security can be complex and idiosyncratic. Implementing field level security always requires some programming by your implementation group. This programming involves the introduction of the specific field-level logic into the respective application service(s). The recommendation is to use a business object validation algorithm for checking field level security.

Note:

The check for field level security must exist in validation logic to ensure that data is not added or updated if it does not pass the field level security rules.

It is not straight forward to implement user interface changes related to field level security, such as protecting elements under certain conditions. This is because overriding the base product delivered user interface to check for implementation specific conditions is not always supported, depending on how the user interface is built, or requires a full duplication of product artifacts, which is not recommended.

The definition of a user's access rights is performed using the same transactions used to define transaction / action level security. This is achieved as follows:

- Create a [security type](#) for each type of field-level security.

- Define the various access levels for each security type. For example, assume you have some users who can complete bills for less than \$300, and other users who can complete bills for less than \$1,000, and still other users who can complete bills for any value. In this scenario, you'd need 3 access levels on this security type:
 - Level 1 (lowest): May authorize bills <= \$300
 - Level 2 (medium): May authorize bills <= \$1,000
 - Level 3 (highest): May authorize all bills
- Link this security type to each [application service](#) where this type of field level security is implemented. This linkage is performed on the [security type](#) transaction.
- Defining each [user group's](#) access level for each security type (this is done for each application service on which the security type is applicable).

Note:

Highest value grants highest security. The system expects the highest authorization level value to represent highest security level. Moreover, authorization level is an alphanumeric field so care should be taken to ensure that it's set up correctly.

Importing Security Configuration from an External Source

The product provides support for importing security information from an external source. In all cases, the product uses a special user BO **FI-IDMUser** to create the user and the recommendation is to take advantage of the [Template User](#) on page 20 functionality. More information about the out of the box support for using this feature is described in the related links.

- If your organization uses Lightweight Directory Access Protocol (LDAP), you can import your existing LDAP users and groups into the system. Once imported, all user and group functions are available. You can import a user group, or a single user. You can resynchronize your LDAP users and groups at any time.

Fastpath: For more information refer to [LDAP Integration](#).

- The system provides an integration with Oracle Identity Manager. When a user is created in the identity manager product, its information can automatically be interfaced to the product. Once the user is successfully created in the system, all functions are available.

Fastpath: For more information refer to [Oracle Identity Manager Integration](#).

- The system provides a web service with add, update and get operations that follow the System for Cross-domain Identity Management (SCIM) specification for provisioning users.

Fastpath: For more information refer to [Provision Users with SCIM Open Standard](#) on page 483.

Defining Application Services

Please refer to [Understanding Application Security](#) on page 18 for a description of how application services are used when you grant user groups access rights to transactions and the significance of an application service's access modes.

You can access the portal using **Admin > Security > Application Service**. You are brought to a query portal with options for searching for a specific application service. Once a record has been selected you are brought to the maintenance portal to view and maintain the selected record.

Note: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- The **Application Service** zone provides the information about the application service and its access modes.
- The **Secured Objects** zone displays the object (or objects) that are secured by this application service. Refer to [Secured Objects and Application Services](#) on page 22 for details about the types of objects that may be secured.

The **Application Security** tab includes zones to view and manage which user groups have access to the application service and which ones do not have access. The following zone may appear as part of this tab page:

- The **User Groups Linked** zone lists the user groups that currently have a link to the application service. Note that expired links are included when the zone is first displayed. Use the zone filters to exclude expired links and to limit the user groups shown by user ID, user group ID, and user group description.
- The **User Groups not Linked** zone lists the user groups that do not have a link to the application service. Use the zone filters to limit the user groups shown by user ID, user group ID, and user group description.

Defining Security Types

Security types are used to define the types of [field level security](#).

Note: Programming is required. You cannot have field level security without introducing programming code. Refer to [Field Level Security](#) for more information on how security types are used to define field level security.

Security Type - Main

Select **Admin > Security > Security Type** to define your security types.

Description of Page

Enter a unique **Security Type** and **Description**.

Use the **Authorization Level** grid to define the different authorization levels recognized for this security type. Enter an **Authorization Level Number** and its **Description**.

Note: Programming is required. Note that the values that you enter are not interpreted by the system itself, but by the user exit code used to implement the special security. Check with the developer of the user exit logic for the correct values. Refer to [Field Level Security](#) for more information on how security types are used to define field level security.

Use the **Application Services** grid to define the application service(s) to which this security type is applicable. If this application service is already associated with user groups, you must update each user group to define their respective security level. This is performed on the User Group portal.

Defining User Groups

A user group is a group of users who have the same degree of security access. Think of a user group as a "role"; associated with a role are:

- The users who play this role
- The application services to which the role's users have access (along with the actions they can execute for each service and their field level security authorization levels).

Refer to [Secured Objects and Application Services](#) on page 22 and [Field Level Security](#) for more information about access modes and security types.

CAUTION: Important! If an application service supports actions that modify the database other than **Add, Change, and Delete**; you must provide the user with **Change** access in addition to the other access rights. Consider a transaction that supports actions in addition to **Add, Change, and Inquire** (e.g., **Freeze, Complete, Cancel**). If you want to give a user access to any of these additional actions, you must also give the user access to the **Inquire** and **Change** actions.

This portal allows a security administrator to view and manage information about a user group.

You can access the portal from the **Admin Menu > Security > User Group**. You are brought to a query portal with options for searching for a specific user group. Once a user group has been selected you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Application services may not be changed or removed from the **ALL_SERVICES** user group. Refer to [Base Delivered User / User Groups](#) on page 19 for an explanation.

The following zones may appear as part of the portal's **Main** tab page

- **User Group.** This zone provides information about the selected user group.
- **Application Services.** This zone lists application services linked to the selected user group. You may use this zone to edit the information for an specific application service or use mass actions to remove selected services or update their effective date.
- **Add Application Services.** You may use this zone to add application services to the selected user group.

The following zones may appear as part of the portal's **Users** tab page

- **Users.** This zone lists users linked to the selected user group. You may use mass actions to remove selected users or update their effective date.
- **Add Users.** You may use this zone to add users to the selected user group.

The following zones may appear as part of the portal's **Service Manager** tab page

- **Application Service / Access Modes.** This zone lists application service and access mode combinations currently linked to the selected user group. You may use mass action to remove a selected set of records.
- **Add Application Service / Access Modes.** You may use this zone to add application service access mode records.
- **Security Type Authorization.** This zone maintains field level security for application services included in the selected user group.

The following zone may appear as part of the portal's **Secured Components** tab page

- **Application Components.** This zone allows you to review various types of application components secured by the selected user group. The query is similar to the [Application Security Query](#) restricted to the current user group.

Defining Users

The user maintenance transaction is used to define a user's user groups, data access roles, portal preferences, default values, and To Do roles. To access the user maintenance transaction, select **Admin > Security > User**.

The user maintenance transaction is the same transaction invoked when the user launches [Preferences](#) from the user menu or shortcut key.

Application Security Query

This portal allows a security administrator to review application security configurations across users, user groups and the various types of application components they secure.

While application security is configured at the granular level of an application service and its access modes, it is more intuitive to review access rights to top level broader components:

- **Menu line.** Several application services may be related to a single menu line and impact the ability to properly leverage various aspects of its functionality:
 - The application service of the transaction page or portal, which also controls the visibility of the menu line or its 'search' part when the line is composed of 'add' and 'search' items.
 - The application services associated with any zones on that portal.
 - The application service of the underlying maintenance object when applicable, which also controls the 'add' item of the menu line.
 - The application services of business objects for the underlying maintenance object.
 - The application services of portals used to maintain these business objects.
 - The application services of related portals.
 - The application services of related maintenance objects, their business objects and portals.
 - and more

You may review the list of application services associated with a menu line on the **Application Security** tab on the **Menu** portal.

- **Sidebar Zone.** This is a regular or context sensitive zone that the user has access to on the sidebar area.
- **System.** This is a Toolbar or other system wide option a user is allowed to use.
- **Batch Control.** This is a batch process a user is allowed to submit.
- **Report Definition.** This is a report a user is allowed to submit.

- **Web Service.** This is a web service a user is allowed to invoke.
- **Miscellaneous.** This is a special service that a user is allowed to invoke.
- **Internal.** This is an internal item that is secured by default but is assumed to be called in a context that does not require security check.
- **Unclassified.** Some application services may not be related to any type of application component and as such remain unclassified. For example, there are situations where previously released services are enhanced to be associated with dedicated application service in a later release. In this situation the services may retain their original or even custom application service and the new application services may appear as not associated with any component.

Refer to [Secured Objects and Application Services](#) on page 22 for details about the types of objects that may be secured.

Open this page using **Admin > Security > Application Security Query**.

Row Security

Some products allow you to limit a user's access to specific rows. For example, in Oracle Utilities Customer Care and Billing, row level security prevents users without appropriate rights from accessing specific accounts.

A combination of framework configuration and configuration in your edge product is required for row level security. The following points describe the configuration:

- For each record that should be secured, associate it with an **Access Group**. Note that if your edge product supports row level security, that product is providing a link between the secure-able record and Access Group. Your access groups may be granular and only referenced by one secured record or they may be more broad and be referenced by multiple secured records that require the same type of security restriction.
- To define which users have access to the secured records, you define a **Data Access Role**. For each data access role, define which Access Groups the role has security clearance for. An access group may be linked to one or more data access roles. In addition, define the **Users** that have access rights to these secured records. When you grant a data access role rights to an access group, you are giving all users in the data access role rights to all secured records in all the referenced access groups. A user may belong to many data access roles.

If your edge product supports row level security, it will include logic in the appropriate areas of the system to limit the secured rows that a user may view or maintain based on this configuration. For example, in Oracle Utilities Customer Care and Billing, throughout the system users are only able to view and maintain information about an account and any of its detail if the user is in a Data Access Role for the account's Access Group (or the account is not linked to an Access Group).

Fastpath: Refer to your product's documentation for more information on row level security, if applicable.

Defining Access Groups

Refer to [The Big Picture of Row Security](#) for a description of how access groups are used to restrict access to specific objects.

Access groups control which groups of users (referred to as Data Access Roles) have rights to accounts (or other objects) associated with the access group. You can access the portal using **Admin > Security > Access Group**. You are brought to a query portal with options for searching for a specific access group. Once a record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The **Access Mode** zone provides the information about the access group and its data access roles.

- The **Data Access Role** collection defines the data access roles whose users have access to the access group's secured objects. Keep in mind that when you add a **Data Access Role** to an **Access Group**, you are granting all users who belong to this role access to all of the objects linked to the access group.

Note: You can also use [Data Access Role - Access Group](#) to maintain a data access role's access groups.

- The **To Do Role Assignment** collection may be used to route To Do Entries of a given To Do Type to a specific To Do Role if the objects related to the To Do Entry are associated with the access group. Refer to [Adjusting the To Do Role](#) for more information.

Defining Data Access Roles

Fastpath: Refer to [The Big Picture of Row Security](#) for a description of how access groups are used to restrict access to specific objects.

The data access role transaction is used to define two things:

- The users who belong to the data access role.
- The access groups whose accounts (or other objects) may be accessed by these users.

Data Access Role - Main

Select **Admin > Security > Data Access Role** to define the users who belong to a data access role.

Description of Page

Enter a unique **Data Access Role** code and **Description** for the data access role.

The scroll area contains the **Users** who belong to this role. A user's data access roles play a part in determining the accounts (or other objects) whose data they can access.

To add additional users to this data access role, press the add button and specify the following:

- Enter the **User ID**. Keep in mind that when you add a **User** to a **Data Access Role**, you are granting this user access to all of the accounts (or other objects) linked to the data access role's access groups.
- Use **Expiration Date** to define when the user's membership in this data access role expires.

Note: Also maintained on the user page. You can also use [User - Access Security](#) to maintain a user's membership in data access roles.

Data Access Role - Access Group

Select **Admin > Security > Data Access Role** and navigate to the **Access Groups** tab to define the access groups whose accounts (or other objects) may be accessed by the users in this data access role.

Description of Page

Use the **Access Group** collection to define the access groups whose objects can be accessed by this role's users. Keep in mind that when you add an **Access Group** to a **Data Access Role**, you are granting all users who belong to this role access to all of the accounts (or other objects) linked to the access groups.

Note: You can also use [Access Group - Main](#) to maintain an access group's data access roles.

Data Privacy

Personally Identifiable Information (PII) is any information that identifies or could be used in combination with other information to identify an individual. Many countries have data privacy laws governing the use of such information. A key aspect of these laws is an organization's obligation to erase personal information when there is no compelling reason to retain it. This obligation can be fulfilled either by deleting data or altering the data in such a way that it is no longer possible to associate the data with the individual.

Organizations are likely to have other legal obligations that impact how long they retain personal data. For example, there could be financial audit requirements that oblige the organization to retain relevant information for a fixed number of years after termination of a contract.

Object Erasure is designed to address right to erasure issues, with a combination of configuration and processes that may be extended to implement the appropriate policies for the PII within your data.

Encryption and Masking

"Encryption" refers to encrypting data stored in the database using an encryption key. There are two different types of encryption described in the sections below. System encryption refers to columns in the system identified by the

product to use encryption. Application encryption refers to the ability for an implementation to configure fields and elements that should be encrypted in the database.

"Masking" refers to overwriting all or part of an un-encrypted field value with a masking character. For example, perhaps only the last 4 digits of a tax ID number are visible with the other digits changed to an asterisk. The system provides support for masking fields on the user interface that may be stored as plain text in the database. In addition, there are cases where encrypted fields are shown to the user interface using masked values rather than the encrypted value.

The following sections provide more information about each feature.

System Encryption

The system automatically encrypts certain fields captured in various option tables or context tables. This is mainly used for passwords. For example, passwords captured in Message Sender context or password

In addition, batch control supports configuring a security option for parameters that capture sensitive information, such as a password. Refer to [Defining Batch Controls](#) for more information.

It is also possible to enable system encryption using the characteristic type **F1-PWD**. However, the maintenance object must include specific code to enable system encryption for characteristics of this type. In Oracle Utilities Application Framework, the only maintenance object that supports this is extendable lookup. Refer to [Extendable Lookup Advanced Topics](#) for more information.

User Interface Masking

The functionality described in this section is used to take data that is stored in plain text in the database and mask the value before it is presented to a user (or an external system). This feature includes the ability to allow some users to view the data unmasked using security configuration. The system allows different masking rules to be applied to different fields. For example, a credit card number can be masked differently than a social security number.

The following topics describe how to mask field values.

Identify the Data to be Masked

Identify the data that is stored as plain text, but should be masked for display to users. For example, imagine that you have identified that Credit Card Numbers and a person's federal ID number (for example, in the United States, the Social Security Number or SSN). Each field identified may be displayed and maintained in different user interfaces throughout the system, but the masking rules for a given field are probably uniform regardless of where the data is displayed.

Primary keys cannot be masked. A field defined as a unique identifier of a row cannot be configured for masking. Masking a field that is part of the primary key causes a problem when attempting to update the record. This restriction also applies to elements that are part of a "list" in an XML column on a maintenance object. One or more elements in the list must be defined as a primary identifier of the list. Be sure that primary key elements in the list are not ones that require masking.

List members that contain different "types". Consider a page with a list that contains a person's identification numbers. You can set up the system so that a person's social security number has different masking rules than their drivers license number. If your implementation has this type of requirement, the list of masked fields should contain an entry for each masking rule.

For each field, if there are some users that may see the data unmasked on one or more of the user interfaces, then security configuration is required. If the value of a field should be masked for all users across all pages in the application, then the security configuration is not needed.

Security Configuration

Define a [security type](#) for each field with two authorization levels:

- **1** - Can only see the element masked
- **2** - Can only see the element unmasked

Link all of the security types to an [application service](#) of your choosing. We recommend linking every masking-oriented security type to a single application service (e.g., **CM_MASK**) as it makes granting access easier.

For each security type, identify which users can see its data unmasked and which users can only see its data masked. If the masked and unmasked users fit into existing user groups, no additional user groups are necessary. Otherwise, create new user groups for the masked and unmasked users.

After the user groups for each security type are defined, link each user group to the application service defined above. When a user group is linked to the application service, you will define the authorization level for each security type linked to the application service. If a user group's users should see the security type's field values unmasked, set the authorization level to 2; otherwise set it to 1.

Note: Updating masked values. The system supports allowing a user that sees a masked value to update the value. For numbers that are masked, the masked value is typically all 9s. If there is some chance that a user is allowed to update a masked number, the recommendation is that the user is configured with authorization to see the number unmasked. Otherwise, there is a corner case where the user sees the masked number and needs to update the number to a value that exactly matches the masked value. In this case, the update won't go through because the system doesn't recognize it as a change.

Note: Flush the cache. Remember that any time you change access rights you should [flush the security cache](#) (by entering flushAll.jsp on the URL of the application) if you want the change to take effect immediately.

Configure a Masking Algorithm

A data masking algorithm (using the algorithm entity value of **Feature Configuration - Data Masking**) must be created for each combination of masking rules and security type. These algorithms determine if a user has the rights to view a given field unmasked, and, if not, how the field should be masked.

The base package provides two algorithm types. Both support configuration to allow a set of users to see the data unmasked. Parameters capture the application service, security type and authorization level defined above used to evaluate this.

- **F1-MASK:** this is for masking alphanumeric data. Its parameters are designed to handle most masking needs. Parameters allow you to configure how much of the data to mask and what masking character to use. Refer to the algorithm type description for more information.
- **F1-MASKNBR:** this is for masking numbers. Refer to the algorithm type description for more information.

Determine How the Fields are Displayed

The masking configuration differs based on how a field is retrieved for access to the user interface. So for the masking of one "logical" field (like a person's SSN), there may be multiple configuration entries required to cover all the access methods. Review each user interface where a given field is displayed and create the following categories:

- The field is an element that is retrieved by invoking a business object, a business service, or a service script
- The field is stored as an ad hoc characteristic
- The field is displayed on a fixed maintenance page (and is therefore retrieved by invoking a page service)
- The field is displayed on a fixed search page (and is therefore retrieved by invoking a search service)

Create a Feature Configuration for Each Masked Element

Create a feature configuration with a Feature Type of **Data Masking**. An option entry with option type of **Field Masking** is needed for every combination of field to mask and the method used to display the data. The value will contain mnemonics that reference the appropriate data masking algorithm along with configuration that differs depending on how the field is retrieved for display as described below.

Schema Based Object Field Masking

For data that is accessed via a schema-based object call and displayed in a UI map, the field to be masked must reference a meta-data field name in its schema definition: **field="fld_name", alg="algorithm name"**

If the element references an mdField in the schema, that is the field used to identify the masking rule. If there is no mdField reference but only a mapField reference, that is the field used to identify the masking rule. For example, if you want to mask a credit card number, let's assume that field is defined in the schema is the following:

```
<creditCard mdField="CCNBR" mapField="EXT_ACCT_ID"/>
```

In this case, the option value should be **field="CCNBR", alg="algorithm name"**. An option value of **field="EXT_ACCT_ID", alg="algorithm name"** would not result in masking.

A "where" clause may also be specified. This is useful for data that resides in a list where only data of a certain type needs to be masked: **field="fld_name", alg="algorithm name", where="fld_name='value'"**

For example, person can have a collection of IDs and only IDs of type 'SSN' (social security number) should be masked. If the person data including its collection of person IDs is displayed on a UI map via a business object call, let's assume the collection is defined in the following way:

```
<personIds type="list" mapChild=CI_PER_ID">
  <isPrimaryId mapField="PRIM_SW"/>
  <idType mapField="ID_TYPE_CD"/>
  <personIdNumber mapField="PER_ID_NBR"/>
</personIds>
```

The option value may look like this: **field="PER_ID_NBR", alg="algorithm name", where="ID_TYPE_CD='SSN'"**

Please note the following important points for schema based masking:

- **Limitation of 'where' field** Although the main use of a 'where' clause for schema oriented elements is to mask certain elements in a list based on a 'type', it is also possible to mask a single field in the schema based on the value of another field. For example, imagine that a customer submits a registration form that defines an ID type and ID value. Although this data is not in a list, the implementation may still want to only mask the ID value if the ID type is "SSN". The framework is only able to mask an element in the schema based on a 'where' clause if the element in the 'where' clause is a "sibling" in the schema.
 - If the element to be masked is in a list, the element in the 'where' clause must be in the same list.
 - If an element to be masked maps to a real column in a table, the element in the 'where' clause must also map to a real column in the table.
 - If an element to be masked maps to and XML column in the table as a single element, the element in the 'where' clause must map to the same XML column as a single element.
- **Multiple feature option entries for the same field.** It's possible that different schemas in the system have a similar type of data that may be masked based on different conditions. For example, imagine that an implementation has different schemas that captured or referenced person identifiers in different ways:
 - One schema captures a single person ID without any corresponding "type" record and it should always be masked using Algorithm CM_SSN_MASK:

```
<personSSN mapXML=BO_DATA_AREA mdField=PER_ID_NBR/>
```

- One schema captures a person ID and a corresponding ID Type and it should be masked with Algorithm CM_SSN_MASK if the type is "SSN" and masked with algorithm CM_FEIN_MASK if the type is "FEIN".

```
<personIdType mapXML=BO_DATA_AREA mdField=ID_TYPE_CD/>
<personId mapXML=BO_DATA_AREA mdField=PER_ID_NBR/>
```

- One schema captures a person ID and a corresponding ID Type and it has the same masking rules as the previous schema, but a different field name is used for the ID Type code. (This scenario could happen if for example a different label is desired for ID Type on the user interface for this schema.)

```
<personIdType mapXML=BO_DATA_AREA mdField=CM_ID_TYPE/>
<personId mapXML=BO_DATA_AREA mdField=PER_ID_NBR/>
```

For this scenario, the feature options may look like this:

1. **field="PER_ID_NBR", alg="CM_SSN_MASK"**
2. **field="PER_ID_NBR", alg="CM_SSN_MASK", where="ID_TYPE_CD='SSN'"**
3. **field="PER_ID_NBR", alg="CM_FEIN_MASK", where="ID_TYPE_CD='FEIN'"**
4. **field="PER_ID_NBR", alg="CM_SSN_MASK", where="CM_ID_TYPE='SSN'"**
5. **field="PER_ID_NBR", alg="CM_FEIN_MASK", where="CM_ID_TYPE='FEIN'"**

For each schema, the system will first find whether the element applies to any masking option. It will find 5 masking options for the field PER_ID_NBR. Then it will determine if any sibling elements match the 'where' clause.

- If more than one sibling element matches a 'where' clause, a runtime error is issued. For example if a schema has an element that references "mdField=ID_TYPE_CD" and an element that references "mdField=CM_ID_TYPE", this is an error. Additionally, if multiple elements reference mdField=ID_TYPE_CD", this is an error.
- If one and only one sibling element matches a 'where' clause, the value of the element is compared to the values defined in the 'where' clause. If it finds a match on the value, the appropriate masking algorithm is applied. If no match is found (for example, the Person ID Type is "LICENSE") the element is displayed as is.
- If no sibling element matches a 'where' clause and a feature option exists with no 'where' clause (option 1 above), then the masking algorithm of the option with no 'where' clause is applied.
- **Changing the value in the 'where' clause.** If your implementation has some users that are allowed to change records where some data is masked based on a condition, it is recommended to design the user interface to reset the masked value when the value in the 'where' clause changes. For example, if a user is prevented from viewing a person's social security number, but the user is allowed to make updates to the person's record, changing the value of the Person ID Type should reset the Person ID Number. This would ensure that the user does not 'unmask' the social security number by simply changing the ID Type.

Records Maintained Using Page Maintenance

For data that is accessed via a page maintenance service call, indicate the table name and the field name where the data resides: **table="table_name", field="fld_name", alg="algorithm name"**

For example if the Person record and its collection of identifiers are displayed and maintained using page maintenance, the option value should be **table="CI_PER_ID", field="PER_ID_NBR", alg="algorithm name"**

A "where" clause may also be specified: **table="table_name", field="fld_name", where="fld_name='value'", alg="algorithm name"**

This is useful for data that resides in a child table where only data of a certain type needs to be masked. For the person ID example, **table="CI_PER_ID", field="PER_ID_NBR", alg="algorithm name", where="ID_TYPE_CD='SSN'"**

Characteristic Data

For data that is stored as a characteristic, simply indicate the characteristic type: **CHAR_TYPE_CD='char type', alg="algorithm name"**

This needs to be defined only once regardless of which characteristic entity the char type may reside on. Note that only ad-hoc characteristics are supported.

Masking Fields in Explorer Zones or Info Strings

In explorer zones data is often retrieved using SQL directly from the database. No masking is applied automatically in this case. If there is data in the explorer zone results that should be masked, the masking must be applied by calling a business service.

Similarly, an MO Info algorithm may not use BO interaction to get data. It may access data using SQL for efficiency purposes. No masking is applied when retrieving data via SQL. To apply masking to a string prior to including it in an info string, the masking must be applied by calling a business service.

The system supplies two business services to be called to determine if masking rules apply for a specific field.

- **F1-TableFieldMask.** Mask a Table field. This business service receives a table name, field name and one or more field values. If masking applies it returns the masked value.
- **F1-SchemaFieldMask.** Mask a Schema field. This business service receives a schema name and type, XPath and field value. If masking applies it returns the masked value.

Search Service Results

For data that is displayed on a 'fixed' search page, it is retrieved via a search service call. Indicate the search name and the appropriate field to mask along with the masking algorithm. For example: **search="SearchServiceName", field="PER_ID_NBR", where="ID_TYPE_CD='SSN'", alg="algorithm name"**

To find the name of the search service, launch the search in question, right click in the filter area and choose **Inspect**. Search for "serviceName". The service name is listed there. To find the field name to mask, search for "Widget Info". There should be two results found, one for the filter area and one for the results area. This results area has the text "SEARCH_RESULTS" as prefix for each field. The field names are the ones after the x\$. Do not reference the x\$ when defining the field name. Note, the "where" statement can only apply to fields that are also part of the search results.

Additional Masking Information

The following points provide additional information to assist in your masking configuration:

- If the demonstration database includes a **Data Masking** feature configuration, review the settings because it will probably contain masking rules that will match your own.
- On data input pages, a user might be able to enter or change masked data, such as a bank account number, but not be able to subsequently see what they added or changed.
- External systems can request information by performing a service call via a web service. Please keep in mind that some web service requests require data to be masked and some do not. For example, a request from an external system to synchronize person information needs the person's social security number unmasked; whereas a request from a web self service application to retrieve the same person information for display purposes needs the person's social security number masked. To implement this type of requirement, different users must be associated with each of the requests and these users must belong to separate user groups with different access rights.
- If a maintenance object (MO) contains a field that holds an XML document and a service call invokes the MO's service program directly, the system will mask individual XML elements in the field if a **Determine BO** algorithm has been plugged into the [maintenance object](#) and the element(s) in the respective BO schema have been secured as described above.

Application Encryption

The functionality described in this section allows implementations to configure fields to encrypt when storing it in the database. This functionality is mutually exclusive from the User Interface Masking functionality described in the previous section. This feature supports encrypting specific elements stored within a CLOB or XML column.

The following points highlight the features of the encryption functionality:

- The encryption key is defined using a keystore, which must be set up in order to use this functionality. For details about setting up the keystore in the system, see the Installation Guide.
- When a field is configured to be encrypted, the encrypted data is stored in a special encryption field that is not the source field (the one exposed to the user on the user interface). The source field captures the data as masked. Because a special field is required to support encryption, the product must provide support for that field to be encrypted.
- For encrypted data that must allow searching, the system supports capturing a hash value in a special field. The product must provide support for this functionality. Besides providing a special field to capture the hash value, base search functionality for that data must also cater for this configuration.
- The system supports encrypting data that is captured as an element within an XML field. If the XML field is provided in a schema owned by the product, then the product must provide specific support for the capture of the encrypted data.

The following sections provide additional information about the support for encryption provided by the framework. Refer to the security chapter of the administration guide for your particular product for more information.

Encrypting and Masking the Data

When a product enables encrypting for a given type of data, a special encryption field should be created to capture the encrypted value. Because encrypting is optional, the source field (the one exposed to the user) should not be this special encrypted field. If encryption is configured, the system will internally populate the encrypted field. The source field will be populated with asterisks by default. That way the masked data is what is shown to the user on page rather than the encrypted value.

The following points highlight how the system behaves when encryption is configured and when it is not. Assume as an example, the field is a credit card number. The user views and populates a field with the field name `CC_NBR`. The table also has a second field `ENCR_CC_NBR`. A user populates the credit card number:

- If encryption is not configured, `CC_NBR` will be updated with the entered credit card number and `ENCR_CC_NBR` will be empty. Note that in this case, an implementation may choose to configure [user interface masking](#).
- If encryption is configured, `CC_NBR` will be updated with ‘*****’ and `ENCR_CC_NBR` will contain the encrypted value. The asterisks for the standard field will fill the full field size up to 50 characters.

If for some reason the standard masking using all asterisks is not desired, the system supports supplying an explicit masking algorithm using the same Feature Configuration - Data Masking plug-in spot used for [User Interface Masking](#).

Warning: Unlike user interface masking, the masking of encrypted fields is not driven by security. The data stored in the source field for all encrypted data should be masked. Be sure not to configure security authorization logic in algorithms used for this type of masking.

Feature Option Configuration

Create a feature configuration with a Feature Type of **Encryption**. For each source field you are encrypting, enter an option with option type of **Field Encryption**. The value will contain mnemonics that reference the appropriate encryption key alias defined in the keystore along with configuration related to the field and its table location. Unlike the user interface data masking, the configuration for data encryption is related to how the data is stored rather than how it is displayed. In addition, each entry may define an explicit masking algorithm to override the default and if supported, may also define a hash field and hash alias.

For data that is stored in a specific column on a table, an explicit field to capture the encrypted value must exist. Indicate the table name, source field name and encrypted field name along with the alias: **table='table_name', field='fld_name', encryptedField='encr_fld_name', alias='alias key'**

A "where" clause may also be specified when data resides in a child table and only data of a certain type needs to be encrypted.

Example, **table='CI_PER_ID', field='PER_ID_NBR', encryptedField='ENCR_PER_ID_NBR', alias='key alias', where='ID_TYPE_CD='SSN''**

For data that is stored in an XML column in a record, the source field to be encrypted must reference a meta-data field name in its schema definition along with the element that captures the encrypted data and the alias: **field='field_name', encryptedField='encr_field_name', alias='key alias'**

The syntax for adding a reference to a masking algorithm is **maskAlg='algorithm name'** .

The syntax for adding configuration for capturing a hash value for searching purposes is **hashAlias='hashAliasKey' hashField='HASH_FLD_NAME'**.

The following is an example of configuration that uses all the possible options (specific masking algorithm, where clause and hash field support):

table='CI_PER_ID', field='PER_ID_NBR', alias='aliasKey', encryptedField='ENCR_PER_ID_NBR', hashAlias='hashAliasKey' hashField='HASH_PER_ID_NBR', where='ID_TYPE_CD=SSN', maskAlg='CM-PERIDMASK'

Searching by an Encrypted Value

If the product supports a hashed value for an encrypted field for searching purposes, the following points highlight explorer zone configuration for this purpose

- The user filter value should reference the source field and should include an additional **encrypt=** mnemonic. For example

```
type=STRING
label=PER_ID_NBR
encrypt=[CI_PER_ID, PER_ID_NBR, ID_TYPE_CD, F1]
```

Refer to [User Filters](#) for more information.

- The SQL should include the hashed value in the WHERE clause. Note that because encryption is optional, a product zone that includes searching by a field eligible for encryption will include finding a match for the filter in the source field (as plain text) or in the hashed field. For example:

```
WHERE
  [(F2) (ID.PER_ID_NBR =:F2 OR ID.HASH_PER_ID_NBR = :F2)]
```

Customizing Encryption Algorithm

Although the encryption algorithm to use with a given key can be gleaned from the key in the keystore, there is sometimes extra information associated with an algorithm that might need to be used to encrypt or decrypt data.

The system provides a feature configuration option for the **Encryption** feature type using the option type **Algorithm Info** that can be used to adjust the behavior of the encryption.

- You can modify the default mode and padding of the encryption algorithm.
- If a key will be used to digitally sign anything, the signing algorithm can also be specified for the key.

For details about the syntax, refer to the feature option type's detailed description.

The Approach to Implementing Object Erasure

This section describes the product approach to implementing object erasure for its maintenance objects (MOs).

Note: The approach outlined is intended for managing erasure of master data objects. The assumption is that Information Lifecycle Management will be used for archiving any related transactional data.

Various events in the system may signal the need to erase data at some future date. For example, closing an account may indicate the need to erase both the account and person data once there is no longer a need to maintain related financial details. There may also be events that re-establish the business relationship with a person and signal that data marked for erasure should now be retained.

The Object Erasure Schedule is used to capture key details of objects with data that needs to be erased. Records in the schedule are monitored periodically to determine if the date for erasure has been reached and if so, execute the erasure logic. The system will create and maintain records in the schedule when specific events occur for an MO that is marked for erasure.

The system provides the ability to mark an MO as eligible for erasure via a number of MO configuration entries. Included in these is an option that defines the business object for the MO's erasure schedule records. In addition to defining the erasure record elements, this BO defines the monitoring process and the specific erasure logic for the MO.

The following sections provide more information about configuring and managing object erasure.

Configuring a Maintenance Object for Erasure

There are three types of maintenance object configuration entries that define how to manage erasure:

- An option to define the business object for erasure schedule records.

- An option to define the period between the date on which the need for erasure is detected and the date on which erasure should occur. The common logic provided by the system to add or update erasure records uses this option to determine the erasure date.
- One or more entries in the MO algorithm collection for the algorithms that determine whether a record should be scheduled for erasure, according to the current state of the record, and create or update the erasure schedule entries.

Some MOs that would commonly be regarded as eligible for erasure will be installed with a base Erasure BO already configured. The expectation is that the corresponding Erasure Period option and the algorithm for the Manage Erasure Schedule plug-in spot will be set up by your implementation with the appropriate entries for your organization's business rules.

Note: The presence of an Erasure Period option is the signal to the system that your implementation has enabled an object for erasure.

It may not be necessary for all master data objects that contain personally identifiable information to manage their own erasure schedule. For example, the event which triggers erasure for a person record may also trigger the creation of erasure schedule entries for the person's other master data records. In this case, only the person maintenance object will need to be configured with a Manage Erasure algorithm (or algorithms). Refer to your product specific documentation for more information on the recommended approaches for your product's master data objects.

Manage Erasure Schedule Algorithm

Algorithms of this type are responsible for determining a record's erasure status and creating or maintaining an entry in the Object Erasure Schedule for the record. They are triggered when certain events occur in the system for maintenance objects that are eligible for erasure. Multiple algorithms can be configured for the plug-in spot.

Depending on the determination made by the algorithm (or algorithms), a number of different actions may need to be taken. For example:

- A new schedule record may need to be added
- An existing schedule record may need to be updated with a new erasure date
- A pending record may need to be discarded if erasure is no longer applicable
- A discarded record may need to be reactivated if erasure now applies again

The base business service **F1-ManageErasureSchedule** performs the common logic to handle the possible actions and is recommended for use by these types of algorithms. The service can also optionally create a log entry for information purposes. Refer to the description of the business service for full details.

In certain circumstances, if one record is scheduled for erasure, other related records may need to be evaluated. The base business service **F1-ManageErasureScheduleDriver** performs the logic to execute an MO's Manage Erasure Schedule algorithms. It can be used to manage any related records from within another algorithm.

This type of algorithm is plugged into the [Maintenance Object — Algorithm](#) collection.

Your product may supply algorithms to manage the schedule for base MOs that are regarded as eligible for erasure. If your organization has special business rules that are evaluated to determine the erasure schedule for an MO, a custom algorithm can be created and applied by the implementation team.

Monitoring the Schedule and Performing Erasure

The erasure schedule is managed using the lifecycle of the erasure record's business object. A deferred monitor process is used to periodically check for records that are due for erasure and transition them from the 'pending erasure' state to the 'erased' state. An enter plug in on the 'erased' state is responsible for performing the erasure logic.

The system provides a 'root' business object for the object erasure schedule (**F1-ErasureScheduleRoot**) which defines the lifecycle that erasure schedule business objects should follow. The system also provides a monitor process (**F1-OESMN**) which is configured on the 'pending erasure' state of the 'root' business object. This process is configured to monitor object erasure schedule records whose erasure date is on or before the batch business date.

Maintenance objects that are eligible for erasure should be configured with an erasure schedule business object that uses the ‘root’ business object as its parent. The algorithm that performs the erasure processing applicable to that maintenance object must be plugged in on the ‘erased’ state of the ‘child’ business object.

The system provides an erasure schedule business object (**F1-ErasureScheduleCommon**) which is designed to erase an object by deleting the main record and any child records. Your product may supply additional erasure schedule business objects for certain use cases. Refer to your product specific documentation for more information.

Erasing User Information By Obfuscation

Some implementations consider the base User object to have personally identifiable information. Erasing user information by deleting the records is not advisable as it can cause referential integrity problems. The recommended approach is to obfuscate the data instead.

The system provides a user erasure business object (**F1-ErasureScheduleUser**) which is designed to support obfuscating a user’s identifiable information by removing it or replacing it with a non-identifiable value if the field is required.

If the User maintenance object is configured to be eligible for erasure in your implementation, the manage erasure schedule algorithm for the record will be invoked whenever the **Enable** flag is changed for a record on the User maintenance page. The system provides a base algorithm (**F1-OBJERSUSR**) specifically for the User MO. This algorithm will add an entry to the object erasure schedule if the user record is disabled or deactivate an existing erasure schedule record if a disabled user record is enabled again.

Viewing an Object’s Erasure Status

The system provides a portal for viewing and editing an erasure schedule record. The portal is accessed from the **Object Erasure Schedule** sidebar zone. This is a context sensitive zone which only appears when accessing a record for a maintenance object that is configured to be eligible for erasure. It displays the information for the erasure schedule entry for the record in context, if applicable.

To add the zone to an eligible maintenance object:

- Navigate to [Context Sensitive Zone](#) and search for the navigation key for the maintenance object.
- Add the Object Erasure Schedule zone **F1-OBJERSCD** to that navigation key.

Viewing Erasure Configuration

The erasure configuration may be viewed in the Maintenance Object Configuration [All-in-One portal](#). It provides the ability to view the maintenance objects that are marked as eligible for erasure and maintain their erasure configuration entries in a single place.

To view a list of the eligible MOs, open **Admin > Implementation Tools > Maintenance Object Configuration**.

In the Object Erasure Configuration zone, press the edit icon to open a window in which the configuration values for that maintenance object can be changed.

Refer to [The Approach to Implementing Object Erasure](#) for an overview of object erasure configuration.

Archiving the Object Erasure Schedule

The system provides the ability to archive older records in the object erasure schedule using Information Lifecycle Management. The object erasure schedule maintenance object is configured with a base ILM eligibility algorithm and an ILM crawler batch control.

The base object erasure schedule BO is configured to set the ILM archive switch when an erasure schedule record enters a final state and to reset it if the record becomes active again.

Refer to [The Approach to Implementing Information Lifecycle Management](#) for more information on archiving functionality.

Data Redaction on Export

Personal identifiable information (PII) requires special handling when exported out of the application and written to files. Information that is encrypted at the database level remain encrypted and therefore protected when exported. With respect to non-encrypted information, the need to obfuscate it for added protection depends on how the exported

data is intended to be used. If the exported information is part of an integration flow with an external system then the data should remain unchanged. However, when exporting data from a production environment for testing purposes sensitive information should be anonymized before they can be imported to a lower environment.

The following are key aspects of this functionality:

- Redaction rules define how specific fields should be redacted when exported.
- When redaction rules exist, data redaction is performed by default by specific export tools. In absence of redaction rules, data is exported in its original form.
- Redaction rules are customer specific and may only be relevant to environments that contain sensitive data. As such, they are not released with the base product. Review your data redaction requirements and configure appropriate rules in relevant environments.
- Certain users may be allowed to export data in a non-redacted form based on application security.

The following sections provide additional information about this topic.

Redaction Rules Are Customer Specific

Redaction rules identify which fields should be redacted and how they should be anonymized. The list of fields to redact and the function to use to manipulate their values are customer specific and therefore are not released with the base product. A sample set of rules are provided as accelerator data for reference only.

It is important that you review your data redaction requirements and configure rules that reflect your business needs.

Redaction By Default

Processes that support data redaction on export do so by default when redaction rules exists. When rules are not defined, data is exported as is. Note that for this reason it is unnecessary to define such rules in lower environments that do not contain sensitive information.

Specific Export Tools Only

Data redaction is supported by the following export tools only:

- **Content Migration Assistant (CMA).** Depending on application security, a user may indicate on a specific data set export request that data should be exported in its original form.
- **General Data Export (GDE) batch processes.** A batch parameter may be used to explicitly request that data is exported in its original form. This option is also protected by application security and enforced at batch submission time.

Note: This type of process establishes a single export stream that may be sent to multiple targets. Review these integrations to ensure they do not have conflicting data redaction requirements and set the batch parameter accordingly.

Different Types of Redaction Rules

Sensitive information may reside in various types of storage fields which impact the way they are identified for redaction. You may define rules that target fields on specific tables or provide a more global rules that applies to all references of a specific field.

The application supports the following types of redaction rules:

- **Physical Field.** This type of rule applies to a value residing in a field on a specific table. An optional filter expression may be provided when only records of a certain type needs to be redacted.
- **XML Storage.** This type of rule applies a value associated with the specified field name that resides within an XML storage field on a specific table. This option also supports a filter expression.
- **Reference Field.** This type of rule applies to a value residing anywhere and associated with the specified field name. It does not include fields referenced in XML storage fields.

Redaction Function

A redaction function defines the format by which a value is anonymized. The type of function used depends on the field's data type. For example, to anonymize a numeric field the redaction function should only use numeric values etc.

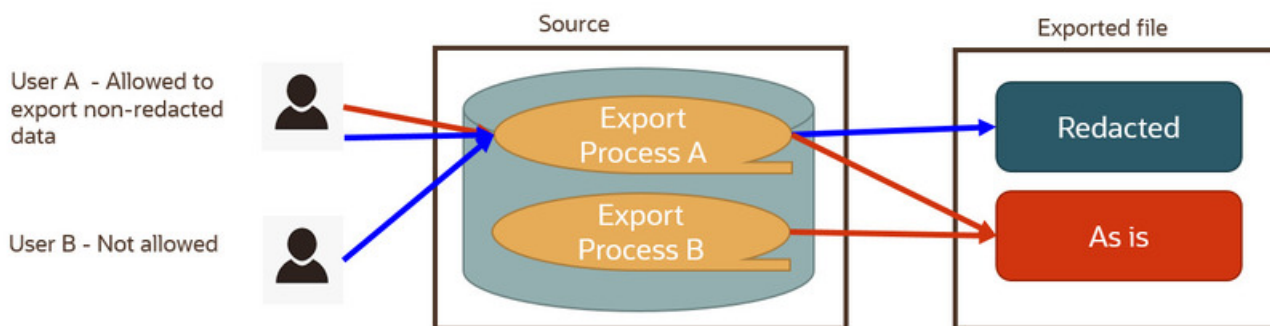

Refer to the **Redaction Function** extendable lookup for a list of available functions. The base product provides a sample of common functions but the list may be extended by your organization as needed.

Fields May Contain Sensitive Information

The field definition record includes an indication as to whether the field may contain sensitive information or not. Note that the indication does not imply that the field is actually used to capture such data but rather that it can potentially be used this way. Use this indication to review fields that may need to be associated with a redaction rule.

Exporting Non-Redacted Data Requires Security Rights

By default, the export tools redact data based on existing redaction rules. There are situations where certain users may be allowed to export data in its original form, that is, to request to not apply the redaction rules.

The following points describe the processes for exporting data:

- Some processes always export data as is, in case the target consumer needs the raw data. This is irrespective of the user requesting the export.
- Some processes perform data redaction by default and may offer an option for exporting data as is. The option to export data in its original form is secured by application security.
- In this example, process A supports data redaction by default with an option to export non-redacted data. User A has the right to export the data redacted (default) or explicitly request to export it in its original form. User B does not have the right to do so hence their export content is redacted by default.

The option to export data in its original form is associated with the **Do Not Apply Redaction Rules** access mode associated with the following relevant application services:

- For CMA, the additional access mode is associated with the migration data set export's application service. When granted, the user may select the special non-redacted export option when they create the export data set request.
- For GDE batch processes, the access mode is associated with their application service and is tied to the **Do Not Apply Redaction Rules** batch parameter they support. Only users with the proper application security can submit these batches using the special batch parameter option

Defining Redaction Rules

This portal is used to view and maintain rules that define how specific fields that containing personal information should be redacted when exported out of the application. For example, an e-mail address may be redacted by replacing some or all characters with '*'.

Refer to [Data Redaction on Export](#) for more information.

You can access the portal from the **Admin Menu > Security > Redaction Rule**. You are brought to a query portal with options for searching for a specific redaction rule. Once a redaction rule has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page

- **Redaction Rule.** This zone provides information about the selected rule.

Obfuscation Configuration

This portal is used to view and maintain all configuration options related to personal information obfuscation. It includes all masking, encryption and data redaction rules.

You can access the portal from the **Admin Menu > Security > Obfuscation Configuration**.

Refer to [Encryption and Masking](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Redaction Rules.** This zone lists all redaction rules. You may add a new rule from this zone.
- **Masking.** This zone lists masking options. You may navigate to the masking related feature configuration to review and edit these options.
- **Encryption.** This zone lists encryption options. You may navigate to the encryption related feature configuration to review and edit these options.
- **Review Fields for Redaction Rules.** This zone lists fields that may contain personal identifiable information and are not associated with a redaction rule. Review these fields and add redaction rules when applicable.

Cryptography Keys

Often when communicating information with an external system, cryptography keys are used to exchange encrypted information or confirm that the two communicating parties recognize each other and the information being provided.

The following sections include information about the functionality provided to support this type of security.

Understanding Key Rings

Cryptography keys may be used to provide a signature or credentials to a request so that the system recognizes that the request comes from a trusted party. Keys may also be used to encrypt or decrypt files shared between two parties.

The Key Ring object is provided to reference the keys that are used over time for a given business use case. Only one key or key pair may be active at any given time.

The following sections include information about the functionality provided to support different key ring classes for particular use cases.

RSA Signature Keys

RSA signature key pairs are used in the following cases:

- Certain processes in the system may need to write files to or read files from Oracle Cloud Object Storage. Cloud object storage has its own method for encrypting files, and products using the framework application do not need to define additional configuration for that. However, when communicating with cloud object storage, the application is required to provide a signature key.
Refer to [External File Storage](#) for more information about configuring the system to connect to cloud object storage.
- Customers may need the ability to authorize a customer service representative (CSR) to view the customer's account information in a customer facing portal. A signature key is required to support secure communication with the endpoint.

Refer to [User Redirection](#) for more information about configuring the system to enable this type of redirection.

The product provides an RSA Signature Key Pair business object that supports the following functions:

- Generating a key pair, public and private. The private key is stored in an appropriate "secret store" and the public key is available to copy and share with a third party.
- Viewing the public key, allowing a user to copy it to register it with cloud object storage.
- Activating the new key pair (to be done after registering the new public key).
- Inactivating an expired key.

- Key rotation. For increased security, a new key pair should be generated periodically.
- Deactivating all keys for the key ring.

OAuth Keys

The system provides support for sending messages secured by OAuth authentication. To deliver the message, the application is required to provide a client ID and secret. The OAuth secret is sensitive data and needs to be stored securely in the application. The Message Sender configuration provides the ability to store the client ID and an encrypted secret directly in the sender context. Alternatively, the sender context can refer to a key ring that stores those details. Using a key ring allows users to apply new secrets over time without having to update the affected message sender configurations.

Refer to [Message Sender - Context](#) for more information about configuring a message sender for OAuth security.

The product provides an OAuth Keys business object that supports the following functions:

- Defining the external system related to the key ring
- Adding a client ID and secret key. The secret key is stored in an appropriate "secret store".
- Key rotation. For increased security, a new secret key may be entered periodically. The new key automatically becomes the active key.

File Encryption and Signing Keys

For security, files exchanged with third parties may be encrypted, digitally signed or both. This requires the sender and recipient to maintain public/private key pairs and share public keys. The product supports the maintenance and generation of public and private keys in a format suitable for encryption using PGP standards.

The following sections provide additional information about encryption keys.

Encryption Key Pairs

Internal encryption key pairs are used in the following cases:

- Creating a digital signature for an extract file. The signature is encrypted with the private key of the key pair and decrypted by the recipient using the shared public key .
- Decrypting an import file. The expectation is that the sender has encrypted the file data using a temporary key. The temporary key is encrypted using the shared public key and decrypted using the private key.

The product provides an Encryption Key Pair business object that supports the following functions:

- Generating a key pair, public and private. The private key is stored in an appropriate "secret store" and the public key is available to copy and share with a third party. Both keys are in formats suitable for PGP encryption.
- Viewing the public key, allowing a user to copy it to register it with third parties.
- Activating the new key pair (to be done after sharing the new public key).
- Inactivating an expired key.
- Key rotation. For increased security, a new key pair should be generated periodically.
- Deactivating all keys for the key ring.

Public Encryption Keys

External public encryption keys are used in the following cases:

- Verifying the signature of an imported file. The signature is decrypted using the public key provided by the sender.
- Encrypting an extract file. The batch file adapters create a temporary key which is used to encrypt the file data. The temporary key is encrypted using the public key provided by the recipient

The product provides a Public Encryption Key business object that supports the following functions:

- Defining the external system and reference ID related to the key ring.
- Adding a public key to the key ring. The product expects the public key to be in a format suitable for PGP encryption.
- Viewing the public key.

- Inactivating an expired key.
- Key rotation. When new public keys are provided by the external system, the previously active key is set to expiring status. It may be manually inactivated after all messages using that key have been processed.
- Deactivating all keys for the key ring.

Defining Key Rings

Refer to [Understanding Key Rings](#) for an overview of key ring functionality.

To maintain the key rings applicable to your product or implementation, open **Admin > Security > Key Ring**.

This is an [All-in-One portal](#) and includes the standard List and display zones for a key ring.

The information captured on the key ring depends on the business objects supported by your product or implementation. Refer to the embedded help text for more information.

Key Zones

The key zones provide information about the keys that are associated with the key ring. The zones displayed and the available actions depend on the type of key. Refer to embedded help for more information.

Key Rotation

For internal keys, it is recommended to practice key rotation and generate new keys periodically. New key pairs are generated in the **Pending** state. The user should register the public key of the new key pair with the associated third party. Once that is done, the new key should be activated.

For external keys, new public keys are added in the **Active** state. The previously active key is set to **Expiring** and may be inactivated when no further processing needs to refer to it.

User Interface Tools

This section describes tools that impact many aspects of the user interface.

Understanding Portals and Zones

A portal is a page that is comprised of one or more information zones. The base product pages are built using either a fixed page metaphor or using portals and zones.

There are three broad classes of portals:

- **Standalone.** Standalone portals are separate pages where the main tab of the page is built using a portal. These pages are opened using any of the standard methods (e.g., by selecting a menu item, by selecting a favorite link, etc.). Additional tabs for a stand-alone portal may be included using tab page portals.
- **Tab Page.** These types of portals cannot be attached to a menu. They simply define the zones for a tab on a standalone portal.
- **Sidebar.** The sidebar portal is a special portal that appears in the [Sidebar Area](#) on the user's desktop. Its zones contain tools and information that exist on the user's desktop regardless of the transaction. There is only one sidebar portal. This portal and several zones are delivered as part of the base-package. Your implementation can add additional zones to this portal. Please contact customer support if you need to add zones to the sidebar portal.

The contents of this section describe general information about portals and zones.

Portal Page Structure

A portal page has a main tab and may have additional tabs. The page is constructed by first creating a **Standalone** portal, which is also the main portal, followed by creating a **Tab Page** portal for each additional tab and linking it to the main portal. Content is organized on each tab using independent zones.

The entire page is secured by the single application service associated with the main portal.

Portals Are Made Up of Zones

A portal is a page that contains one or more zones, and each zone contains data of some sort. All zones reference a **Zone Type**. The zone type controls the behavior of the zone and the parameters available to configure the zone.

Not All Zones Make Up Portals

Zones may or may not be associated with a portal. The following describes additional uses of zones:

- A data explorer type of zone may implement a search for an entity on an input user interface map. These zones may be referenced on a FK reference record or directly referenced on a UI map.
- A data explorer type of zone may implement a Business Service. The latter may be used for an internal process or used to build a user interface dropdown.
- A zone may be defined as a **Context Sensitive Zone** that appears on the Sidebar when a specific page or portal is in context. This type of zone is not linked to the Sidebar portal but associated with the context page or portal's navigation key.

Configuring Zones for a Portal

The portal includes configuration of how the zones should appear on the portal by default. This includes the following options, all of which may be overridden by an implementation.

- The order in which the zone should appear. An implementation may configure an override sequence to change the order zones on a base delivered portal.
- Whether the zone is visible on the portal. Zones delivered in the base product should be configured to be visible. But an implementation may override this if desired.
- Whether the zone should display initially collapsed or not. A zone's data is only retrieved when it is expanded. As such, a zone may be configured to be initially collapsed when the data is not needed very often. A user can expand the zone when the information is required. Implementations may change the collapsed setting of a base product portal / zone. Refer to [Zones May Appear Initially Collapsed When a Page Opens](#) for more information.

Flexible Layout Control

By default a zone spans the full width of the portal's display area but can be configured in a number of ways using the layout control features on the portal.

These features allow portal designers to have finer-grained control over how zones are laid out, and enables them to achieve a better user experience and a more optimal layout that reduces unused space.

The following highlight key layout control options:

- In addition to the standard half and full width options, 1/4, 3/4, 1/3 and 2/3 width options are also available.
- Better handling of zones that are dynamically hidden by a visibility script. When a zone becomes invisible its space may be reclaimed by a next zone as long as it is of same width or smaller.
- A zone may define the beginning of a new row. This indication allows for a more fixed layout that is not impacted by hidden zones. The new row indication may establish a layout of one, two or three zones displayed vertically.
- Support the following zone height options:
 - **Content (Unlimited Height)** lets the height be determined by content.
 - **Content (Limited Height)** lets the height be determined by content up to a specified maximum limit. This option may be used to achieve a more consistent portal layout, especially when a zone is rendered on long or small devices.
 - **Fixed Height** sets the zone at a specific height regardless of content.

This option too may be used to achieve a more consistent portal layout.
- When a height option is not explicitly selected, zone height is unlimited and determined by content. However, for a data explorer zone, the results grid area itself (not the entire zone) is limited by the zone parameter "height of report" (which has a default value of 50%).

User Preferences

A **Standalone** portal includes configuration to indicate whether or not the portal should appear on a user's portal preferences. The portal will not appear on the user's portal preferences if the **Show on Portal Preferences** setting is set to No. Note that an implementation may change this value for a product delivered portal. This setting is typically enabled for a portal that provides disparate information where not all zones are applicable to all users or where users may wish to adjust the order of the zones. An example of a portal enabled for portal preferences is the Sidebar portal.

The user can override zone oriented configuration for the portal:

- Which zones appear on that portal
- The order in which the zones appear
- Whether the zones should be initially collapsed when the portal opens.
- The refresh seconds. This is applicable to zones displaying data that changes often.

An implementation can optionally configure the system to define portal preferences on one or more "template" users. When a template user is linked to a "real" user, the real user's preferences are inherited from the "template" user and the "real" user cannot change their preferences. Some implementations opt to work this way to enforce a standard look and feel for users in the same business area.

Refer to [User — Portal Preferences](#) for more information about how users configure their zones.

Removing Zones From Portal

You cannot remove a base product zone from a base product portal. An implementation may override the **Display** setting to prevent a zone from displaying on the portal. In addition, you cannot remove a zone if a user has enabled it on their portal preferences. To remove a zone from the portal list, first make sure that no user has it enabled in their portal preferences.

Granting Access to A Portal

An [application service](#) is associated with each portal. A user must be granted access rights to the respective application service in order to see a portal.

When you add a new **Standalone** portal, the system automatically creates its application service behind the scenes and displays it as part of the portal definition. You'll need to use this application service to grant access to the portal. **Tab Page** portals do not have separate security access. If a user has access to the main stand-alone portal, then the user will have security access to all its tabs.

Please note the following in respect of how application security impacts a user's portals:

- A user's [Portal Preferences](#) page only shows the portals configured to show on user preferences and where they have security access.
- The system's menus only show portals to which a user has security access.
- Users can set up favorite links to all portals, but they must have security rights to the portal's application service in order to invoke the favorite link.

Granting Access to Zones

An [application service](#) is associated with each zone. A user must be granted access rights to the respective application service in order to see a zone on a portal. Refer to [The Big Picture Of Application Security](#) for information about granting users access rights to an application service.

Please note the following with respect to zone application security:

- For most base product portals, all the zones for all the portals reference the same application service that is used to grant access to the portal. In other words, if the user has access to the page, then the user has access to all the zones on all portals for the page. There may be exceptions to this rule for certain portals.
- For a base product multi-query zones, typically the individual query zones and the multi-query zone reference the same application service that is used to grant access to the main (standalone) portal for the page. However, there may be individual query zones provided with a unique application service. This may occur when the query option

is unusual and not applicable to all users or even to all implementations. If a user does not have security access to an individual query zone, that option will not be available in the dropdown.

- For base product portals that are configured to show on portal preferences, it is common that the portal contains different types of zones that may be applicable to different types of users. Typically these types of portals will deliver a unique application service for each zone so that an implementation may configure which user groups are allowed to view each zone. For these types of portals, please note the following:
 - A user's [Portal Preferences](#) page contains a row for a zone regardless of whether the user has access rights to the zone. Because of this, the system displays an indication of the user's access rights to each zone.
 - If a user's access rights to a zone are revoked, the zone will be suppressed when the user navigates to the respective portal.
 - Revoking a user's access rights does not change the user's [portal preferences](#) (i.e., a user can indicate they want to see a zone even if they don't have access to the zone - such a zone just won't appear when the respective portal appears).

Putting Portals on Menus

When you add a new **Standalone** portal, the system automatically creates its navigation option behind the scenes and displays it as part of the portal definition. You'll need to use this navigation option to add the portal to a menu or to allow any other type of navigation method to the portal.

To add a portal to a menu, you must add a [menu item](#) to the desired menu and reference the portal's navigation option on the new menu item. A portal's navigation option can appear on any number of menu items (i.e., you can create several menu items that reference the same portal).

Your users can set up their preferences to include the portal's navigation option on their [Favorite Links](#). This way, they can easily navigate to the portal without going through menus.

Portal Options

Various portal features are controlled by configuration options, such as the ability to include additional applicable actions on the portal's actions bar or the ability to include the standard information description of the maintained entity as part of the portal's title.

Note: You can add new option types. Your implementation may want to add additional portal option types. To do that, add your new values to the customizable lookup field **PORTAL_OPT_FLG**.

Setting Up Portals and Zones

The topics in this section describe how to set up portals and zones. Please refer to [The Big Picture of Portals and Zones](#) for background information.

Defining Zone Types

A Zone Types represents a particular type of zone with a specific behavior. For example, a data explorer zone type is used to select data using a specific SQL statement and display the data based on parameter configuration. The zone type defines the Java Class that controls the behavior of the zone and defines the parameters that the Java Class supports. The base product supports many zone types used to build the portal / zone user interface. Implementations may introduce their own zone types.

Note: It is not very common for an implementation to introduce their own zone types.

Select **Admin > System > Zone Type** to maintain zone types.

Description of Page

Specify an easily recognizable **Zone Type** code and **Description**. Use the **Detailed Description** to describe in detail what the zone type does.

CAUTION: When adding new zone types, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Owner indicates if this zone type is owned by the base product or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add a zone type. This information is display-only.

Java Class Name is the Java class responsible for building the zone using the parameters defined below.

Two types of parameters are specified when defining a zone type:

- Parameter values that have a **Usage** of **Zone** are defined on the zones and control the functionality of each zone governed by the zone type. A **Usage** value of **Zone - Override Allowed** indicates that an implementation may override the parameter value for a base zone.
- Parameter values that have a **Usage** of **Zone Type** are defined directly on the zone type and control how the zone type operates (e.g., the name of the XSL template, the name of the application service). A **Usage** value of **Zone Type - Override Allowed** indicates that an implementation may override the parameter value for a base zone type.

The following points describe the fields that are defined for each parameter:

- **Sequence** defines the relative position of the parameter.
- **Parameter Name** is the name of the parameter.
- **Description** is a short description that allows you to easily identify the purpose of the parameter.
- **Comments** contain information that you must know about the parameter or its implementation. For parameters with a usage of **Zone** or **Zone - Override Allowed**, this information is visible to the user when viewing or defining this parameter for a zone of this type.
- **Usage** indicates whether the parameter value is defined in a **Zone** of this type or in the **Zone Type**. **Zone - Override Allowed** and **Zone Type - Override Allowed** indicate that override values for the parameters defined in a base zone or base zone type can be entered.
- **Required** is checked to indicate that a zone must define a value for the parameter. It is not checked if a value for the parameter is optional. This field is protected if the **Usage** is **Zone Type** or **Zone Type - Override Allowed**.
- **Parameter Value** is used to define the value of zone type parameters. This field is protected if the **Usage** is **Zone** or **Zone - Override Allowed**.
- **Owner** indicates if this parameter is owned by the base product or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add a parameter. This information is display-only.

Zone Type Parameter Comments

For the product owned zone type parameters, the parameter's detailed description provides the detail needed for properly configuring the parameter. For the Action parameters (IMPLEMENTOR_ACTION_n), the parameter description is abbreviated. Additional detail about configuring this parameter may be found in the [Zone Action Parameter](#) detailed information. The same details apply.

Defining Zones

This portal is used to view and maintain the configuration of a zone. Implementations may define custom zones or override the descriptions and some parameter values for base product zones.

You can access the portal from the **Admin Menu > System > Zone**. You are brought to a query portal with options for searching for a specific zone. Once a zone record has been selected you are brought to the maintenance portal to view and maintain the selected record.

Note: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Refer to [Understanding Portals and Zones](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Zone.** This zone provides general information about the selected zone.
- **Query Options.** This zone maintains the list of query options for a Multi-Query zone. The zone is only visible for Multi-Query zones.

- **Filters.** This zone maintains various zone parameters that handle filtering options for a data explorer zone. The zone is only visible for data explorer zones.
- **General Parameters.** This zone maintains various general purpose zone parameters for a data explorer zone.
- **SQLs.** This zone maintains individual SQLs and their related parameters. The zone is only visible for data explorer zones.
- **SQL Configuration.** This zone maintains all the zone parameters related to a specific data explorer SQL. The zone is only visible when a specific SQL is broadcast from the **SQLs** zone.

The following zones may appear as part of the portal's **References** tab page

- **Zone References.** This zone list various configuration entities referencing the current zone.

Overriding Parameter Values

Implementation teams may override the value of selected types of base provided zone parameters. The override parameter value field for base owned zone parameters is only enabled when the related zone type parameter usage is **Zone - Override Allowed**.

For multi-query zones, you may use the override parameter value to add custom query options to a base product owned zone.

Overriding Zone Parameters

Implementations may override the value of a base owned zone parameter only if the zone type definition allows such override. The override parameter value is enabled for a specific base owned parameter when the related zone type parameter usage is set to **Zone - Override Allowed**.

You may use the override parameter capability to provide alternative or additional custom query options for a base owned multi-query zone.

Zone Parameter Details

For most zone parameters, the embedded help for the parameter provides the detailed information needed for configuring the parameter values. For some parameters with very detailed descriptions, the embedded help is abbreviated and more detail is provided here.

Zone Visibility Service Script

All zones support a visibility script that is used to determine if the zone should be displayed to the user or not based on conditions. The script may receive input parameters and is expected to return a Boolean value indicating if the zone should be displayed or not. The embedded help for the **Zone Visibility Service Script** parameter provides details related to the syntax.

The following table highlights some service scripts provided by the product that may be used if applicable to your zone's requirements. This is not an exhaustive list of visibility scripts. There may be others that are specific to a given zone.

| Script Code | Description | Comments |
|---------------------|--|---|
| F1-ShldShwZn | Zone Visibility - Display Zone in Portal | This script simply returns a value of 'true' and is used when the zone should always appear. |
| F1-CondShwZn | Zone Visibility - Display Zone in Portal Conditionally | This is used when the condition for showing the zone is based on the population of a context value. This is commonly used when one zone in the portal should only appear after a broadcast of a record from another zone in the portal. For an example of a zone the uses this visibility script, refer to F1-BSFTYPE . |

| Script Code | Description | Comments |
|---------------------|--------------------------------------|--|
| F1-RwCtShwZn | Zone Visibility - Based on Row Count | <p>This is used when the condition for showing the zone is based on the existence of one or more rows that can be determined using SQL. This script accepts a zone code, user filters 1 through 25 and hidden filters 1 through 10. The script returns an indication of 'true' if at least one row count is returned by the zone.</p> <p>To use this visibility script, a specific data explorer zone must be developed for the specific use case.</p> <p>For an example of a zone the uses this visibility script, refer to F1-MIGRREQEL .</p> |

SQL Statement

Data explorer zones are used to select data to display using one or more SQL statements. The SQL parameters are applicable to the following zone types

- Info Data Explorer - Single SQL (**F1-DE-SINGLE**). The parameter has the description **SQL Statement**.
- Info Data Explorer - Multiple SQLs (**F1-DE**). The parameters follow the description pattern of **SQL Statement x**.
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**). The parameters follow the description pattern of **SQL Statement x**.

Note: If your implementation has been configured to restrict the functions that may be used when defining an SQL then an error is issued at runtime if there are functions found that are not in the allowlist. The allowlist may be viewed using the **View SQL function allowlist** link in the Tips zone on the zone maintenance page.

Note: Zone SQL should take care not to use the following reserved keywords for the table alias. (For example, the table alias in this SQL is 'XX': SELECT 'X' FROM W1_ACTIVITY_TYPE XX.)

| Keyword |
|---------|
| AT |

The following table provides a list of SQL substituted keywords that may be used in the SQL Statement parameters in explorer zones. At execution time, the system determines the database and substitutes the keyword with the database specific syntax:

| Keyword | Description | Examples |
|-----------------------|--|---|
| @toCharacter() | Converts the input to Character data type. | select @toCharacter (batch_cd) as batchCode from ci_batch_ctrl |
| @toDate() | Converts the input to Date data type. | select @toDate (last_update_dttm) as lastUpdateDate from ci_batch_ctrl |
| @toNumber() | Converts the input to Number data type. | select @toNumber (next_batch_nbr) from ci_batch_ctrl |

| Keyword | Description | Examples |
|------------------------------------|---|---|
| @currentDate | Fetches the current date.  CAUTION: The Oracle functions SYSDATE and CURRENT_DATE should not be used because they do not properly cater for adjusting dates from the database time zone to the installation time zone, if needed. | select batch_cd, @currentDate as today from ci_batch_ctrl |
| @currentTimestamp | Fetches the current date / time.  CAUTION: The Oracle functions SYSTIMESTAMP and CURRENT_TIMESTAMP should not be used because they do not properly cater for adjusting the date / time from the database time zone to the installation time zone, if needed. | select batch_cd from ci_batch_ctrl where last_update_dttm > @currentTimestamp |
| @concat | Combines the result list of two or more columns. | select batch_cd @concat next_batch_nbr concatNbr from ci_batch_ctrl |
| @substr(string, start) | String is the input String that you are trying to get a substring of. Start is the position of the character for the output results. | select batch_cd batchCode from ci_batch_ctrl Result: TESTCD select @substr (batch_cd,3) batchCode from ci_batch_ctrl Result: STCD |
| @substr(string, start, end) | String is the input String that you are trying to get a substring of. Start is the position of the character for the output results. End is the number of characters required in the output from starting position. | Select batch_cd batchCode from ci_batch_ctrl Result: TESTCD select @substr (batch_cd,3,2) batchCode from ci_batch_ctrl Result: ST |
| @trim | Trims the white spaces of the output on both sides. | select @trim (batch_cd) as batchCode from ci_batch_ctrl |

The following syntax is related to ‘fuzzy’ searching. It is only applicable if Oracle DB Text is enabled and a context text index has been created. Refer to [Advanced Search Options](#) for more information.

| Keyword | Description | Examples |
|---|--|--|
| @fuzzy(string, score, numresult, 'weight') | <p>String is the input value for the search.</p> <p>Score is the degree of 'fuzziness'. Valid values are between 1 - 80. The higher the number the more precise the search. Default is 60.</p> <p>Numresults is the number of variations to consider for the string. Valid values are between 1 and 5000. Default is 100.</p> <p>Indicate 'weight' to signal that the results are returned in order of weight. Leave this setting off to indicate that the results are returned in order of score.</p> | <p>Set score to 70, number results to 6, and specify weight.</p> <pre>select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1,70, 6, 'weight')) > 0</pre> |
| @fuzzy(string) | <p>This returns a string result from the fuzzy expansion operation where the default value of 60 is assumed for the score and the default value of 100 is assumed for the numresult.</p> | <p>To use default values:</p> <pre>select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1))> 0</pre> |
| @fuzzy(string, score) | <p>This returns a string result from the fuzzy expansion operation with the score specified and the default value of 100 for the numresult.</p> | <p>Set score to 70.</p> <pre>select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1,70)) > 0</pre> |
| @fuzzy(string, score, numresult) | <p>This returns a string resulted from the fuzzy expansion operation with the similarity score and the numresults specified.</p> | <p>Set score to 70, number results to 6.</p> <pre>select user_id, last_name from sc_user where contains(last_name, @fuzzy(:F1,70, 6)) > 0</pre> |

Column Parameters

eData explorer zones are used to select data to display using one or more SQL statements. For each SQL statement, the zone may configure up to 20 Columns that contain the formatting definition for displaying the output data.

These parameters are applicable to the zone types

- Info Data Explorer - Single SQL (**F1-DE-SINGLE**). The parameters follow the description pattern of **Column x**.
- Info Data Explorer - Multiple SQLs (**F1-DE**). For this zone type, all SQLs are executed and the zone displays a union of all the results. The parameters follow the description pattern of **Column x for SQL y**. There are some mnemonics that do not make sense to differ within rows of the same column. For example, the column label. For these mnemonics, only the value in SQL 1 is considered for that column. The table below indicates which mnemonics follow this rule.
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**). For this zone type, only one SQL is executed. The **SQL y Condition** parameter may be used to control this. The system will execute the first SQL whose condition is satisfied (or with no condition populated). The parameters follow the description pattern of **Column x for SQL y**.

The following sections describe the various types of mnemonics.

Source Mnemonics

This table describe the mnemonics that control how the data in a column is derived.

| Mnemonic | Description | Valid Values | Comments |
|----------------|--|---|--|
| source= | Defines how the column's value is derived. | SQLCOL | Indicates that the source of the column's value comes from a column in the SQL statement. This type of column must also reference the sqlcol= mnemonic. |
| | | BO | Indicates that the source of the column's value comes from a business object . This type of column must also reference the bo= , input= and output= mnemonics to define how to interact with the business object. |
| | | BS | Indicates that the source of the column's value comes from a business service . This type of column must also reference the bs= , input= and output= mnemonics to define how to interact with the business service. |
| | | SS | Indicates that the source of the column's value comes from a service script . This type of column must also reference the ss= , input= and output= mnemonics to define how to interact with the service script. |
| | | FORMULA | Indicates that the source of this column's value is calculated using a formula. This type of column must also reference the formula= mnemonic. |
| | | SETFUNC | Indicates that the source of this column's value is calculated using a superset of values from the rows in the SQL statement. This type of column must also reference the setfunc= mnemonic. |
| | | ICON | Indicates that the source of this column's value is a display icon reference (meaning that an icon will be displayed in the column). This type of column must also reference the icon= mnemonic to define the icon reference. |
| | |  | Note: When using this source mnemonic, the formatting mnemonic type= is not applicable. |

| Mnemonic | Description | Valid Values | Comments |
|--------------|--|--|--|
| bo= | <p>Defines the business object to invoke when source=BO.</p> <p>This mnemonic must be used in conjunction with the input= and output= mnemonics to define how information is sent to / received from the business object.</p> | 'Business Object Code' | |
| bs= | <p>Defines the business service to invoke when source=BS.</p> <p>This mnemonic must be used in conjunction with the input= and output= mnemonics to define how information is sent to / received from the business service.</p> | 'Business Service Code' | |
| ss= | <p>Defines the service script to invoke when source=SS.</p> <p>This mnemonic must be used in conjunction with the input= and output= mnemonics to define how information is sent to / received from the service script.</p> | 'Service Script Code' | |
| icon= | <p>Defines the icon to use when source=ICON.</p> | <p>Cx</p> <p>COLUMN_NAME</p> <p>'image'</p> <p>'Display Icon Code'</p> | <p>This means the Display Icon code is defined in an earlier column. For example, define C1 if column 1 defines the icon code value.</p> <p>This means the Display Icon code was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.</p> <p>This means the image file is defined directly. For example <code>'images/treeRootObject.gif'</code>.</p> <p>This means the Display Icon code is defined directly. For example <code>'F1EDIT'</code>.</p> |

| Mnemonic | Description | Valid Values | Comments |
|-----------------|--|--|--|
| fkref= | <p>Defines the FK reference used to retrieve the column's information when source=FKREF.</p> <p>This mnemonic must be used in conjunction with the input= mnemonic to define how information is sent to the FK reference to build the information.</p> | <p>Cx</p> <p>COLUMN_NAME</p> <p>'FK Reference Code'</p> | <p>This means FK reference code is defined in an earlier column. For example, define C1 if column 1 defines the FK reference value.</p> <p>This means the FK reference was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.</p> <p>This means the FK Reference is defined directly. For example 'F1-ROLE'.</p> |
| formula= | <p>Defines the formula to use when source=FORMULA.</p> <p>Examples:</p> <ul style="list-style-type: none"> • formula=C1*.90/C2 • formula=(C1/C2)*100 | <p>The formula can contain numeric constants, operators and column references.</p> | <p>For column references, use the format Cx where x represents the column number.</p> <p>Refer to Expression Parser for information about the functions supported.</p> |
| setfunc= | <p>Defines the function to apply to the rows of a given column when source=SETFUNC.</p> | <p>function(Cx)</p> | <p>Where Cx represents a column whose rows should have the function applied and the function is one of the following:</p> <ul style="list-style-type: none"> • MAX. This derives the maximum value of all rows in the column. • MIN. This derives the minimum value of all rows in the column. • TOT. This derives the sum (total value) of all rows in the column. • ACC. This derives the cumulative total of all rows up to an including the current row. |

| Mnemonic | Description | Valid Values | Comments |
|-------------------|---|--|---|
| input= | <p>This is used to define one or more input fields and values passed to business objects, business services, service scripts, and FK references.</p> <p>The syntax is as follows: [ELEMENT_NAME=ELEMENT_REF ELEMENT_NAME=ELEMENT_REF ...]</p> <p>In other words, the list of input values is surrounded by square brackets separated by a space. Each passed value first defines the ELEMENT_NAME, which is the name of the element / field in the target. ELEMENT_REF is the value passed in. The next column indicates the possible values for ELEMENT_REF.</p> | <p>Cx</p> <p>COLUMN_NAME</p> <p>'literal value'</p> <p>userTimeZone</p> <p>installationTimeZone</p> <p>Examples:</p> <ul style="list-style-type: none"> • input=[USER_ID=C1] • input=[USER_ID=USER_ID] • input=[input/targetTimeZone=userTimeZone] | <p>Where Cx represents the value of a previous column. If the value to pass is in the first column, reference C1.</p> <p>This means the value to pass in was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.</p> <p>This means a literal value within the single quotes should be passed in.</p> <p>This means the current user's time zone should be passed in. This is typically used with the business service F1-ShiftDateTime to convert data in the storage time zone to the user's time zone for display.</p> <p>This means the installation time zone should be passed in. This is typically used with the business service F1-ShiftDateTime to convert data in the storage time zone to the installation time zone for display.</p> |
| output= | <p>This is used to define the name of the element retrieved from the business object, business service or service script used to populate this column.</p> | <p>elementName</p> | <p>Example: output=personInfo</p> |
| pagingkey= | <p>This mnemonic is only applicable when the Enable Paging parameter has been configured. It indicates that this column is one of the keys used by the SQL statement to orchestrate paging through results. This mnemonic can only be specified when the source=SQLCOL.</p> <p> Fastpath: Refer to Pagination Configuration for more information.</p> | <p>Y</p> <p>N</p> | <p>This is the default, meaning that you don't need to indicate pagingkey=N at all to indicate that the column is not one of the paging keys.</p> |

Note: If multiple columns are configured with the same source BO, BS or SS and the same input data, the system caches the output from the first call and reuses the results for subsequent columns.

Formatting Mnemonics

This table describe the mnemonics that control how a column is formatted.

Note: For the **F1-DE** zone type, zone displays the union of all the different SQLs.

| Mnemonic | Description | Valid Values | Comments |
|--------------|--|---|---|
| type= | <p>Defines how the column's value is formatted.</p> <p> Note: Icon and Foreign Key columns. The source= source mnemonic may be used to indicate a column should be derived from an icon reference or a foreign key (FK) reference. If you use either of these sources, the type= mnemonic is not relevant as either an icon or a context menu / info string will appear in the column.</p> | <p>STRING</p> <p>DATE</p> <p>TIME</p> <p>DATE/TIME</p> <p>MONEY</p> <p>NUMBER</p> | <p>Columns of this type capture a string. This is the default value.</p> <p>Columns of this type capture a date and will be displayed using the user's display profile.</p> <p>Columns of this type capture a time (in database format) and will be displayed using the user's display profile.</p> <p>Columns of this type capture a date and time (in database format) and will be displayed using the user's display profile.</p> <p>Columns of this type capture a monetary field. This type of column may also reference the cur= mnemonic. If the cur mnemonic is not specified, the currency code on the installation record is used.</p> <p>Columns of this type capture a numeric field. This type of column may also reference the dec= mnemonic.</p> |

| Mnemonic | Description | Valid Values | Comments |
|---------------|---|---|---|
| label= | <p>Defines the column's override label. The label appears in the column's heading and in the zone's drag and drop area.</p> <p>If this mnemonic is not defined, the system uses the column's default label. The source of a column's default label differs depending on the column's source. Note that some sources don't have a default value and omitting this mnemonic will result in a blank label.</p> <p> Note:</p> <p>In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will use the column definitions in SQL 1 to define the labels.</p> | <p>FIELD_NAME</p> <p>'text'</p> | <p>Enter a valid field name whose label should be used for the column label. This should always be the option used if multiple languages are needed.</p> <p>Defines the text directly.</p> |
| cur= | <p>Defines the currency code applied when type=MONEY if the installation record's currency should not be used.</p> | <p>Cx</p> <p>COLUMN_NAME</p> <p>'Currency Code'</p> | <p>This means currency code value is defined in an earlier column. For example, define C1 if column 1 defines the currency code.</p> <p>This means the currency code was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.</p> <p>This means the currency code is defined directly. For example 'USD'.</p> |

| Mnemonic | Description | Valid Values | Comments |
|--------------|--|--------------|--|
| dec= | <p>Defines the number of decimal places when type=NUMBER.</p> <p>It is optional. If provided it should be an integer. If not provided, the number of decimals will default to the number of decimal places defined on the currency code specified on the installation record.</p> | nR | <p>Where n is the number of decimal places to show. Suffixing the number of decimal places with R means that the system should round up / down. Simply specifying n (without an R) means that decimal places should be truncated. For example, entering dec=4 will display 4 decimal places and truncate the remainder.</p> <p> Note: Formatting only. This mnemonic is only used for formatting, it does not impact the precision used for subsequent calculations. For example, if a column retrieved from the database contains 6 significant digits and dec=0, the column will be shown with no decimal places (truncated), however any references to the column in subsequent calculations will use 6 decimal places. For example, if the column is referenced in a formula or set function, all 6 decimal places will be used.</p> |
| char= | This mnemonic applies special character(s) to the column's value. | 'x[]x' | <p>Where x references the literal value to display and [] defines the relative position of the characters (before or after the value).</p> <p>You need only include the [] if you want to position characters in front of the value. For example, char='%' will place a percent sign after the value. If you want to position the word 'minutes' before a value, enter char='minutes []'. If you want to output a value like BUDGET \$123.12 (YTD), enter char='BUDGET [] (YTD)'.</p> |

| Mnemonic | Description | Valid Values | Comments |
|------------------------|--|--|--|
| suppress= | <p>This is used to indicate a column should not be displayed.</p> <p>A column would be suppressed if it's only defined for use by subsequent columns, for example, if there is a formula that derives a column using two other columns. In this scenario, the columns referenced in the formula can be suppressed.</p> <p> Note: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will apply the settings for the column definitions in SQL 1 to all subsequent SQLs.</p> | <p>true</p> <p>false</p> | <p>This is the default, meaning that you don't need to indicate suppress=false at all to indicate that the field should be shown.</p> |
| suppressSearch= | <p>This is used to indicate a column should not be displayed when the zone is invoked in search mode only.</p> <p> Note: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will apply the settings for the column definitions in SQL 1 to all subsequent SQLs.</p> | <p>true</p> <p>false</p> | <p>This is the default, meaning that you don't need to indicate suppressSearch=false at all to indicate that the field should be shown.</p> |

| Mnemonic | Description | Valid Values | Comments |
|------------------------|---|--|---|
| suppressExport= | <p>This is used to indicate a column should not be downloaded when exporting.</p> <p> Note: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will apply the settings for the column definitions in SQL 1 to all subsequent SQLs.</p> | <p>true</p> <p>false</p> | <p>This is the default, meaning that you don't need to indicate suppressExport=false at all to indicate that the field should be included in a download.</p> |
| width= | <p>This is used to override the width of a column (number of pixels). The default value is the maximum width of any cell in the column.</p> | n | <p>Where n is a number between 0 and 999.</p> <p> Note: If there is no available breaking point in the data, the column will be longer than the specified number of pixels.</p> <p>The length of the column's label (which appears in the column's heading) may also make the width wider than specified.</p> <p>In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will set the width based on the column definitions in SQL 1.</p> |
| color= | <p>This is used to override the column's text color.</p> | <p>A valid HTML "named" color</p> <p>A valid RGB color model combination</p> | <p>For example color=yellow.</p> <p> Note: Refer to Color Contrast for information about the use of the HTML color 'red' and its impact on accessibility.</p> <p>For example color=#E0292F or color=#CCCCCC. Note that the # is required.</p> |
| bgcolor= | <p>This is used to override the column's background color.</p> | <p>A valid HTML "named" color</p> <p>A valid RGB color model combination</p> | <p>Similar to the color= mnemonic.</p> <p>Similar to the color= mnemonic.</p> |

| Mnemonic | Description | Valid Values | Comments |
|-------------------|---|-------------------------------|--|
| order= | Defines the column's default sort order. | ASC DESC | Indicates that the order is ascending. This is the default meaning that it is not necessary to indicate order=ASC . Indicates that the order is descending. |
| rowHeader= | Designates the column as a row header for accessibility purposes. | true | By default, the first data column of the data explorer results is identified as the row header, for accessibility tools. If the data in the first column does not uniquely identify the row, use this mnemonic to explicitly mark a different column or multiple columns as the row header.  Note: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the system will look only at the columns in SQL 1 that have this mnemonic defined and apply it to all results for those columns. |

Click Mnemonics

This table describe the mnemonics that define whether a column value may be clicked and if so, what should happen.

| Mnemonic | Description | Valid Values | Comments |
|----------------|--|---|--|
| navopt= | Defines the navigation option that references the target transaction or script when the user clicks a column. Note, this mnemonic should be used in conjunction with the context= mnemonic to define what information is sent to the navigation option's target transaction. This mnemonic is ignored if source=FKREF because the FK reference code defines the hyperlink's destination. | Cx COLUMN_NAME 'Navigation Option Code' | This means navigation option code is defined in an earlier column. For example, define C1 if column 1 defines the navigation option. This means the navigation option was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause. Example: navopt=MAIN_PORTAL This means the navigation option code is defined directly. For example navopt='userMaint' . |

| Mnemonic | Description | Valid Values | Comments |
|-----------------|--|---|--|
| context= | <p>This is used to define one or more context fields and values passed to the target navigation option to go along with the navopt= mnemonic.</p> <p>The syntax is as follows: [FIELD_NAME=FIELD_REF FIELD_NAME=FIELD_REF ...]</p> <p>In other words, the list of input values is surrounded by square brackets separated by a space. Each passed value first defines the FIELD_NAME, which is the name of the context field in the navigation option. FIELD_REF is the value passed in. The next column indicates the possible values for FIELD_REF.</p> | <p>Cx</p> <p>COLUMN_NAME</p> <p>'literal value'</p> | <p>Where Cx represents the value of a previous column. For example, if the value to pass is in the first column, reference C1.</p> <p>This means the value to pass in was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.</p> <p>This means a literal value within the single quotes should be passed in.</p> |
| bpa= | <p>Indicates that a BPA script should be executed with the user clicks the column and indicates the BPA to execute.</p> <p>Note, this mnemonic should be used in conjunction with the tempstorage= mnemonic to define the temporary storage values that will be initiated when the script is executed.</p> <p>This mnemonic is ignored if source=FKREF because the FK reference code defines the hyperlink's destination.</p> | <p>Cx</p> <p>COLUMN_NAME</p> <p>'BPA Script Code'</p> | <p>Indicates that the BPA script is defined in a previous column.</p> <p>This means the BPA script to execute was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.</p> <p>This means that the BPA script to execute is defined directly.</p> |

| Mnemonic | Description | Valid Values | Comments |
|---------------------|--|---|---|
| tempstorage= | <p>This is used to define how temporary storage variables are initiated when the bpa= mnemonic is used.</p> <p>The syntax is as follows: [FIELD_NAME=FIELD_REF FIELD_NAME=FIELD_REF ...]</p> <p>In other words, the list of input values is surrounded by square brackets separated by a space. Each passed value first defines the FIELD_NAME, which is the name of the field in temporary storage. FIELD_REF is the value passed in. The next column indicates the possible values for FIELD_REF.</p> | <p>Cx</p> <p>COLUMN_NAME</p> <p>'literal value'</p> | <p>Where Cx represents the value of a previous column. For example, if the value to pass is in the first column, reference C1.</p> <p>This means the value to pass in was retrieved by the SELECT statement. The value should match the name defined in the SELECT clause.</p> <p>This means a literal value within the single quotes should be passed in.</p> |
| list= | <p>This is used to enable work list capability for this column.</p> <p>You may optionally populate the listdesc= mnemonic to override the text that will be placed in the worklist zone.</p> | true | <p>Setting list=true will cause the work list icon to appear in the column's header. If a user clicks the column, it will populate all the rows in the output into the work list zone.</p> <p> Note: In the case of the zone type Info Data Explorer - Multiple SQLs (F1-DE), the output may be showing a union of the results of multiple SQL statements. In this case, if some of the SQL statements configure a given column with list=true, but not all, only the data in the cells for the statements that configure this mnemonic are put into the work list when the user clicks the icon. Also note that when determining which columns should have the worklist icon when building the zone, the system only looks at the configuration for the columns in SQL 1.</p> |

| Mnemonic | Description | Valid Values | Comments |
|-----------------------|---|--------------|---|
| listdesc= | This is an optional mnemonic when using the list= mnemonic. It can be used to override the text that is placed in the work list zone. | Cx | Where Cx represents the value of a previous column. For example, if the text to use is in the first column, reference C1. |
| listbroadcast= | Indicates that the broadcast information for the column is also to be made available in the work list zone. This means that the work list can be used to broadcast information to a portal in the same manner as a data explorer. | true | Use this setting to turn on the feature. |

Common Use Cases

This section provides some common configuration that can be copied and pasted for newly created zones.

| Use Case | Code Snippet |
|--|---|
| Displaying the description of a lookup value that has been retrieved in the SQL statement. The business service checks for an override label. | <pre> source=BS bs='F1-GetLookupDescription' label=FLD_NAME input=[fieldName='FLD_NAME' fieldValue=FLD_NAME] output=description </pre> |
| Display a foreign key with its information but suppressing the navigation. (This is useful when you have a foreign key that is additional information in a zone but would cause confusion to enable navigation. To display foreign key reference with its information and enabled for navigation, use the source of FKREF as described above.) | <pre> source=BS bs='F1-GetForeignKeyReference' input=[input/fkReference=FK_REF_CD input/fkValue1=BUS_OBJ_CD] output=output/infoDescription label=DESCR </pre> |
| The first example assumes that you know the FK Reference. The second example uses a business service that receives the maintenance object as input. | <pre> source=BS bs='F1-GetFKReferenceDetails' input=[input/maintenanceObject='F1-EXT LKUP' input/pkValue1=BUS_OBJ_CD input/pkValue2=C1] output=output/infoDescription label=DESCR </pre> |

| Use Case | Code Snippet |
|---|--|
| <p>Display a foreign key, including a corresponding navigation link, for generic objects that may or may not have a foreign key reference. If the FK reference exists, its information is shown, otherwise not.</p> <p>Standard foreign key services assume all rows have foreign key details. The service script F1FKInfoOpt provides the same foreign key details but does not error when foreign key details do not exist. To build the foreign key description and link, the script needs to be used twice; one column gets the navigation details and another gets the description. The latter references the navigation details column and invokes a BPA script to perform the dynamic navigation.</p> | <p>This column gets the navigation details:</p> <pre>source=SS ss='F1FKInfoOpt' input=[input/fkReference=C9 input/fkValue1=C6 input/fkValue2=C7] output=output/navigationOption suppress=true</pre> <p>This column constructs the foreign key description and link:</p> <pre>source=SS ss='F1FKInfoOpt' input=[input/fkReference=C9 input/fkValue1=C6 input/fkValue2=C7] output=output/infoDescription label=F1_APPSEC_COMP_DESCR bpa='F1AsecNav' tempstorage=[navopt=C15 pkField1=C10 pkValue1=C6 pkField2=C11 pkValue2=C7] list=true</pre> |

Zone Action

Most zone types provided by the product allow for one or more Zone Actions to be defined to appear in the zone header. An action can appear as a hyperlink, icon or button. The action can also be provided as an HTML string.

Note: Zone types also include parameters for actions defined at the zone type level using `IMPLEMENTOR_ACTION_n` (Action n) parameters. These are rarely used by the product zone types. The actions defined here override any actions defined on the zone type (if present). The details below apply to the zone type level actions as well.

A zone action is defined using the following mnemonics:

| Mnemonic | Description | Valid Values | Comments |
|--------------|--|--------------|--|
| type= | This mnemonic defines the appearance of the action in the zone header. | LINK | Indicates that the action is shown as a textual hyperlink. |
| | | ICON | Indicates that the action is shown as a graphical icon. |

| Mnemonic | Description | Valid Values | Comments |
|----------------|--|-------------------|---|
| action= | This mnemonic defines the action to take when the link/icon/button is clicked. This is ignored when the type=ASIS. | BUTTON | Indicates that the action is shown as an HTML button. |
| | | ASIS | Indicates that the parameter will provide the HTML to be used for the action. |
| | | NAVIGATION | Indicates that the action is navigation to a page. |
| navopt= | Defines the navigation option to use when the action=NAVIGATION . | SCRIPT | Indicates that the action is to run a BPA script. |
| | | 'NAV_OPT_CD' | Enter a reference to a valid navigation option in single quotes. |
| bpa= | Defines the script to run when the action=SCRIPT . | 'SCRIPT_CD' | Enter a reference to a valid BPA script in single quotes. |
| icon= | Indicates the icon to use when type=ICON . | DISP_ICON_CD | Enter a reference to a valid display icon. |
| | | 'path' | Enter an explicit path to the icon, for example 'images/gotoZone.gif'. |

| Mnemonic | Description | Valid Values | Comments |
|---------------|---|--------------|--|
| asis= | This is required when the type=ASIS . This provides the ability to precisely define the HTML you wish to have included in the header. All valid HTML is permitted including the use of "ora" css classes and JavaScript functions. | ['HTML'] | |
| label= | By default, the label or tooltip will come from the navigation option or BPA script description. Use this mnemonic to override that label. | FIELD_NAME | Enter a valid field name whose label should be used. This should always be the option used if multiple languages are needed. |
| | | 'text' | Enter the text directly in single quotes. |

| Mnemonic | Description | Valid Values | Comments |
|-------------------|---|---|--|
| sourceLoc= | <p>This mnemonic defines the source of the FIELD_NAME's value in the context mnemonic.</p> <p>If this mnemonic is left blank, the default behavior is as follows:</p> <ul style="list-style-type: none"> - The portal context is checked. - If no portal context value is found, the global context is checked. - If neither value is available, the field is ignored. | <p>G</p> <p>P</p> <p>D</p> | <p>Indicates that the field's value is retrieved from the global context.</p> <p>Indicates that the field's value is retrieved from the portal context.</p> <p>Indicates that the field's value is retrieved from the page data model.</p> |
| class= | Use this mnemonic to override the look and feel of the link / icon / button using a different CSS style. | 'className1' 'className2' | Enter one or more classes in single quotes. Multiple class names may be provided. |
| style= | Use this mnemonic to override the look and feel of the action element using the indicated css style. | Standard style= format. | All allowed css style definitions may be used. |

Examples:

- **type=BUTTON action=SCRIPT bpa='F1-SET-USER' context=[USER_ID=USER_ID] label=UPDATE_LBL**
- **type=LINK action=NAVIGATION navopt='gotoUser' context=[USER_ID=path(schema/userId)]**
- **type=ASIS asis=['Search']**

Note: If the zone type has actions defined and there is a desire to simply remove the zone type actions, the Zone Action can be set with the following configuration: **type=ASIS asis=[]**

User Filters

Data explorer zones include the ability to define User filters to allow a user to enter data to restrict the zone's rows and / or columns. The filters may be defined individually using User Filter parameters 1–25. Alternatively, a UI map may be defined for capturing filters. In this case, the map's input fields must be associated with the zone's filters by specifying the **xpath=** mnemonic on the respective User Filter parameters.

These parameters are applicable to the zone types

- Info Data Explorer - Multiple SQLs (**F1-DE**)
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**)
- Info Data Explorer - Single SQL (**F1-DE-SINGLE**)

A user filter is defined using the following mnemonics:

| Mnemonic | Description | Valid Values | Comments |
|--------------------|--|---|---|
| name= | This mnemonic is used if the zone's filter should be pre-populated with a value from global context, portal context or broadcast from another zone. | MD Field Name | |
| datasource= | This mnemonic defines the source of the filter's pre-populated value defined in the name mnemonic. If this mnemonic is left blank, the default behavior is as follows: - If the field has been broadcast from another zone, the broadcast value is used. - If no value is broadcast, the portal context is checked to determine if this field exists (if so, its value is taken). - If still no value, the global context is checked. - If still no value, no default value is shown. | G P D | Indicates that the zone should look for the filter value in global context. Indicates that the zone should look for the filter value in portal context. Indicates that the zone should look for the filter value in the page data model. |
| type= | Defines the visual metaphor used to capture the filter values. | DATE DATE/TIME STRING MONEY NUMBER | Filters of this type capture a date. Filters of this type capture a date and time. Filters of this type capture a string Filters of this type capture a monetary field. This type of filter must also reference the cur mnemonic. Filters of this type capture a numeric field. This type of filter may also reference the decimals mnemonic. |

| Mnemonic | Description | Valid Values | Comments |
|------------------|--|-------------------|--|
| | | LOOKUP | Filters of this type capture a lookup value. This type of filter must also reference the lookup mnemonic. |
| | | TABLE | Filters of this type capture an administrative table's value (code and description). This type of filter must also reference the table mnemonic. |
| | | CHARTYPE | Filters of this type capture predefined characteristic values for a characteristic type (code and description). This type of filter must also reference the chartype mnemonic. |
| | | ASIS | Filters of this type capture a list of values to be referenced within an 'IN' clause within the SQL statement. |
| label= | Defines the filter's label that appears in the zone's description bar and in the input area. | MD Field Name | Enter a valid field name whose label should be used for the filter label. This should always be the option used if multiple languages are needed. |
| | | 'text' | Defines the text directly. |
| cur= | Defines the currency code applied when type=MONEY . | Currency Code | Enter a reference to a valid currency code. |
| dec= | Defines the number of decimal places when type=NUMBER . | Valid number | It is optional. If provided it should be an integer. If not provided, the number of decimals will default to the number of decimal places defined on the currency code specified on the installation record. |
| lookup= | Defines the lookup flag whose values appear when type=LOOKUP . | Lookup Field Name | Enter a reference to a valid lookup field name. |
| table= | Defines the admin table whose values appear when type=TABLE . | Table Name | Enter a reference to a valid control table name. |
| chartype= | Defines the characteristic type code whose values appear when type=CHARTYPE . | Char Type code | Enter a reference to a valid characteristic type code. |

| Mnemonic | Description | Valid Values | Comments |
|---------------------|--|---|--|
| xpath= | This mnemonic is used in conjunction with a Filter Area UI Map. For each filter, you must specify the XPath to the corresponding UI map schema element. | XPath | The type= mnemonic must also be appropriate for the map's input field, otherwise the query's SQL could fail. |
| likeable= | This mnemonic defines if a likeable search is performed on the entered value when type=STRING . | S P PS | The query will add % to the suffix of the filter value. The query will add % to the prefix of the filter value. The query will add % to the prefix and suffix of the filter value. |
| divide= | The mnemonic controls if a divider line appears above and/or below the filter. Note, you can specify this parameter twice if you want divider lines placed above and below a filter, e.g., divide=above divide=below . | above below | This results in a divider line placed above the filter. This results in a divider line placed below the filter. |
| searchField= | This mnemonic controls the initial population of the filter when the zone is launched as a search from a UI map. | MD Field Name | Enter the field name that exactly matches the searchField name specified in the oraSearchField HTML element in the UI map. |
| encrypt= | This mnemonic defines if the user filter is encrypted and needs to be searched by hashed value. | [TBL_NAME,FLD_NAME,WHERE_FLD,WHERE_VALUE]  Note: The field name referenced here should be the source value of the field. However, the SQL should use the hashed value in its filter. | A valid table name and field name are required. The WHERE_FLD and WHERE_VALUE are optional, but if entered, both are required. Use this to only encrypt the field if another field has a certain value. The following is an example. encrypt=[CI_PERSON,PER_ID_NBR,ID_TYPE_NBR,'SSN'] . The WHERE_VALUE may also reference another filter. The following is an example. encrypt=[CI_PERSON,PER_ID_NBR,ID_TYPE_NBR,F1] . |

Examples:

- **label=F1_NBR_DAYS type=NUMBER**

- **label=F1_SHOW_ALL_REQ_FLG type=LOOKUP lookup=F1_SHOW_ALL_REQ_FLG**
- Filter value where a Filter UI Map is defined and Description is one of the filters. **type=STRING xpath=description likeable=S**
 - **type=STRING label=DESCR likeable=S divide=below**
 - **label=REQ_TYPE_CD type=TABLE table=F1_REQ_TYPE**

Hidden Filters

Data explorer zones include the ability to define Hidden filters to restrict the rows and / or columns that appear in the zone. The following are the potential sources of a hidden filter's value:

- The global area contains the fields whose values are maintained in [global context](#).
- The portal area contains the fields describing the object currently displayed in a portal.
- Other zones on a portal can broadcast information to the portal area, which can then in turn be used by the zone as a hidden filter.

These parameters are applicable to the zone types

- Info Data Explorer - Multiple SQLs (**F1-DE**)
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**)
- Info Data Explorer - Single SQL (**F1-DE-SINGLE**)

A hidden filter is defined using the following mnemonics:

| Mnemonic | Description | Valid Values | Comments |
|--------------------|--|--------------|--|
| name= | This mnemonic defines the name of the field that needs to be broadcast from other zones or populated in the portal context | FIELD_NAME | |
| datasource= | This mnemonic defines the source of the hidden filter's value. | G | Indicates that the zone should look for the filter value in global context. |
| | If this mnemonic is left blank, the default behavior is as follows: | P | Indicates that the zone should look for the filter value in portal context. |
| | - If the field has been broadcast from another zone, the broadcast value is used. | D | Indicates that the zone should look for the filter value in the page data model. |
| | - If no value is broadcast, the portal context is checked to determine if this field exists (if so, its value is taken). | | |
| | - If still no value, the global context is checked. | | |
| | - If still no value, the zone appears as per the poprule mnemonic. | | |

| Mnemonic | Description | Valid Values | Comments |
|-----------------|--|------------------|---|
| poprule= | This mnemonic controls what happens if the hidden filter is not present. | R | Indicates that a value for the filter is required. The zone will be set to the "empty state" and the "please broadcast" message will appear in the zone. This is the default value. |
| | | O | Indicates that the value is optional. If no value is required, the zone is still built without that value. |
| type= | Defines the visual metaphor used to capture the filter values. | DATE | Filters of this type capture a date. |
| | | DATE/TIME | Filters of this type capture a date and time. |
| | | STRING | Filters of this type capture a string |
| | | MONEY | Filters of this type capture a monetary field. This type of filter must also reference the cur mnemonic. |
| | | NUMBER | Filters of this type capture a numeric field. This type of filter may also reference the decimals mnemonic. |
| | | LOOKUP | Filters of this type capture a lookup value. This type of filter must also reference the lookup mnemonic. |
| | | TABLE | Filters of this type capture an administrative table's value (code and description). This type of filter must also reference the table mnemonic. |
| CHARTYPE | Filters of this type capture predefined characteristic values for a characteristic type (code and description). This type of filter must also reference the chartype mnemonic. | | |

| Mnemonic | Description | Valid Values | Comments |
|---------------------|--|---------------------|--|
| | | ASIS | Filters of this type capture a list of values to be referenced within an 'IN' clause within the SQL statement. |
| label= | Defines the filter's label that appears in the zone's description bar. | FIELD_NAME | Enter a valid field name whose label should be used. This should always be the option used if multiple languages are needed. |
| | | 'text' | Defines the text directly. |
| cur= | Defines the currency code applied when type=MONEY . | CURRENCY_CD | Enter a reference to a valid currency code. |
| dec= | Defines the number of decimal places when type=NUMBER . | N | It is optional. If provided it should be an integer. If not provided, the number of decimals will default to the number of decimal places defined on the currency code specified on the installation record. |
| lookup= | Defines the lookup flag whose values appear when type=LOOKUP . | LOOKUP_FIELD_NAME | Enter a reference to a valid lookup field name. |
| table= | Defines the admin table whose values appear when type=TABLE . | TABLE_NAME | Enter a reference to a valid admin table name. |
| chartype= | Defines the characteristic type code whose values appear when type=CHARTYPE . | CHAR_TYPE_CD | Enter a reference to a valid characteristic type code. |
| searchField= | This mnemonic controls the initial population of the filter when the zone is launched as a search from a UI map. | FIELD_NAME | Enter the field name that exactly matches the searchField name specified in the oraSearchField html element in the UI map. |

Multi-Select Action

This parameter defines an action to be included in the action area for multi-selection processing. Note that a multi-selection action can only be used if the Multi Select parameter has been set to YES, which causes a checkbox to appear on each row displayed. The action defined here will trigger against all rows selected by the user via the checkbox.

These parameters are applicable to the zone types

- Info Data Explorer - Multiple SQLs (**F1-DE**)
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**)
- Info Data Explorer - Single SQL (**F1-DE-SINGLE**)

A multi select action has the following mnemonics:

| Mnemonic | Description | Valid Values | Comments |
|-----------------|--|---|---|
| script= | This mnemonic defines the script to be invoked when the action is clicked. This is required. | SCR_CD | Enter a reference to a valid BPA script or Service Script. |
| type= | This mnemonic defines how the action should be rendered. | BUTTON LINK ICON | The action is rendered as a button. This is the default. The action is rendered as hypertext. The action is rendered as a graphic icon. For this option, the icon mnemonic is required. |
| icon= | This mnemonic defines the icon to display when type=ICON . | DISPLAY_ICON_CD | Enter a reference to a valid display icon code. |
| refresh= | This mnemonic indicates how and if a refresh should occur after the script completes. | NO ZONE PORTAL | Indicates that no refresh is performed. This is the default. Indicates that a refresh of the zone is performed. Indicates that a refresh of the entire portal is performed. |

| Mnemonic | Description/Valid Values | Comments |
|---------------|---|---|
| label= | By <code>FIELD_NAME</code> default, the button label, link text or icon tooltip will come 'text' from the script description. Use this mnemonic to override that label. | Enter a valid field name whose label should be used. This should always be the option used if multiple languages are needed. Enter the text directly in single quotes. |
| list= | When <code>listElementName</code> executing the script, the framework builds an XML list containing information from each row selected. This list must be defined in the script's schema and referenced in this mnemonic. | Enter a valid list element name from the script schema. |

| Mnemonic | Description/Valid Values | Comments |
|---|--|--|
| <p>context=[elementName1=rowData1 elementName2=rowData2]</p> | <p>This mnemonic is used to populate the list with the appropriate information from each selected row. The mnemonic supports passing multiple values.</p> <p>In each case the element in the schema list is defined first followed by an equal sign, followed by information about the data used to populate the element defined using one of the valid values defined in the next column.</p> <p>One or more values may be defined. Each context value is defined separated by spaces. The</p> <p>Cx</p> <p>Px</p> <p>COLUMN_NAME</p> <p>'constant'</p> | <p>Indicates that the element should be populated with a value in the referenced column parameter.</p> <p>Indicates that the element should be populated with a value in the referenced post processing parameter.</p> <p>Indicates that the element should be populated with a value from a column in the SQL statement.</p> <p>Indicates that the value defined in single quotes should be passed.</p> |

| Mnemonic | Description/Valid Values | Comments |
|---------------|--|--|
| class= | Use this mnemonic to override the look and feel of the action using a different CSS style. | Enter one or more classes in single quotes to be appended to the standard class(es). Multiple class names may be provided. |
| style= | Use this mnemonic to override the look and feel of the action element using the indicated css style. | All allowed css style definitions may be used. |

Data Explorer Graph Configuration

For some data explorer zones, it is more effective to display the results in a graphical form such as a pie or line chart. Visualization option parameters enable the graph configuration to be integrated with the data explorer zone that retrieves the data.

The visualization option parameters support three options:

- **Grid** - displays the data in a standard data explorer grid
- **Chart** - displays the data in the form of a chart
- **Map** - provides the ability to invoke a UI Map to display the data

Up to five visualization option parameters may be specified. One of the options must be the standard grid, allowing for a maximum of four graphical options. The zone will display icons corresponding to the visualization types to allow you to switch between the various views. These icons are presented in the same order as they are defined in the parameter list.

Note: If the only display option is a standard grid, it is not necessary to specify the grid as a visualization parameter.

Visualization option parameters are provided on the Info Data Explorer - Single SQL (**F1-DE-SINGLE**) and Info Data Explorer - Multiple SQLs (**F1-DE**) zone types.

Visualization Option Parameter Configuration

Mnemonics are used to define the attributes for an option type within the parameter value.

For a **grid**, the mnemonic is 'optiontype=GRID'. No other mnemonics are required.

For a **map**, the mnemonics are 'optiontype=MAP map=MAP_CD schemaPath=xpath', where 'MAP_CD' is the ID of the UI Map and 'xpath' is the schema path of the UI Map. In most use cases the schema elements will match

the result set from the data explorer, in which case no schemaPath mnemonic is needed. If the UI Map schema has additional elements present, the schemaPath attribute will define the group node that the data explorer information will be copied into.

For a **chart**, the option type mnemonics is 'optiontype=CHART'. This is followed by the appropriate chart configuration attributes, which are described in the section below.

Chart Configuration

The following attributes are used to configure a graphical representation of a set of data.

The '**oraChart**:' attribute defines the type of graph to display and its general configuration. The set of configuration parameters available for this attribute are as follows:

| Parameter | Values | Description |
|------------------------|-----------------------------|---|
| type: | pie | Defines the type of chart to display. |
| | stacked | Required |
| | cluster | |
| | line | |
| | area | |
| | combo | |
| | showLegend: | true false |
| legendPosition: | left | Defines where the legend should appear. |
| | right | Optional (default is right) |
| | bottom | Setting position to left or right will automatically render it vertically. |
| | top | Setting position to top or bottom will automatically render it horizontally. |
| legendBorder: | true false | Defines if the legend should display with a border around it. Optional (default is false) |
| | depth: | true false |
| animate: | true false | A value of true indicates that the graph should animate when displayed. Optional (default is true). When using large data sets, consider disabling animation. |

| Parameter | Values | Description |
|---------------------|-------------------------|---|
| dataCursor: | on off | A value of on enables hovering anywhere in the graph. Optional (default is off). It is not applicable to pie charts. |
| orientation: | horizontal | Defines the chart orientation. This only applies to bar, line, area, combo charts. E.g., oraChart="type:cluster; orientation:horizontal" , defines horizontal cluster chart. Optional (default is vertical). |

The **oraChartSeries** attribute defines the source information for the graph. Most charts support 5 of these attributes, with the following mnemonics:

- **oraChartSeries1**
- **oraChartSeries2**
- **oraChartSeries3**
- **oraChartSeries4**
- **oraChartSeries5**

Stacked charts support an unlimited number of series by continuing to add attributes **oraChartSeries6** and above, but beware of performance implications and memory limits when using an excessively high number of series. All attributes are identical in format and accept the same parameters, as described below.

Note: All the charts require **oraChartSeries1**. Stacked, Cluster and Line charts may optionally include the additional series attributes (for multiple bars/lines).

If you define multiple series, then data must be provided for all series defined. The data amounts can be 0 (zero) but they have to be present in order for the chart to display correctly.

The set of configuration parameters available for the **oraChartSeriesN** attribute are:

| Parameter | Values | Description |
|----------------|-------------------------|--|
| list: | XPath value | Defines the XPath to the list in the XML that contains the data to chart. Required only for HTML definitions in UI Maps. Data explorer values are derived from the columns for the zone. |
| amount: | Cn Pn XPath value | Defines the element containing the amount to chart. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Required |

| Parameter | Values | Description |
|----------------------|--|---|
| xaxis: | Cn Pn XPath value | Defines the element containing the x-axis data. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element is specified. Required for Stacked, Cluster, Line, Area and Combo charts. |
| xaxisFormat: | date dateTime time localDate string | Defines the x-axis data format. If it is date , dateTime or time then the value is presented in the format as defined on the user's display profile. In case of localDate or string the data is displayed as is with no special formatting. Optional (Default is date). |
| label: | Text value | Defines the label for the amount being charted. Either this setting or labelPath: must be defined. |
| labelPath: | Cn Pn XPath value | Defines the element that provides the label for the amount being charted. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Either this setting or label: must be defined. |
| currency: | A valid Currency code | Defines the currency code for the amount being charted. Optional. |
| currencyPath: | Cn Pn XPath value | Defines the element that provides the currency code for the amount being charted. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified. Optional. |

| Parameter | Values | Description |
|-----------------------|-------------------------|---|
| hoverText: | Text value | <p>Defines the hover text for the chart element.</p> <p>Optional (A default hover text is always available.) Ignored if hoverTextPath: is defined.</p> <p>The following substitution variables are available.</p> <ul style="list-style-type: none"> • \$label This will be replaced with the label text as determined by the label: or labelPath: setting. • \$amount This will be replaced with the amount text as specified by the amount: setting. • \$axis This will be replaced with the x-axis text. • \$% This will be replaced by the percentage "slice" of the pie or bar. • \$newline This will force a line break. <p>If the hover text defined contains any of the above values, they will be replaced by the equivalent text prior to being displayed.</p> <p>Example:</p> <pre data-bbox="1062 1140 1463 1226">"hoverText:\$label \$newline\$amount"</pre> |
| hoverTextPath: | Cn Pn XPath value | <p>Defines the element that provides the hover text for the chart element. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified.</p> <p>The hover text in the element can utilize all the substitution functionality described above in the hoverText: description.</p> <p>Optional.</p> |

| Parameter | Values | Description |
|--------------------|---|---|
| type: | <p>bar</p> <p>line</p> <p>area</p> | <p>This attribute is used for the combo chart type only. It defines how each series on the combo chart should be presented.</p> <p>The following example defines a combo chart where one series is rendered as bars and another one as area.</p> <pre>oraChart="type:combo;" oraChartSeries1="xaxis:C3; label:C2; amount:C1;type:bar" oraChartSeries2="xaxis:C3; label:C2; amount:C1;type:area"</pre> |
| navOpt: | A valid Navigation Option code. | <p>Defines a navigation option to be activated when the chart element is clicked.</p> <p>Optional.</p> |
| navOptPath: | <p>Cn</p> <p>Pn</p> <p>XPath value</p> | <p>Defines the element that provides the navigation option to be activated when the chart element is clicked.</p> <p>For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified.</p> <p>Optional</p> <p>Note that both navOpt: and navOptPath: may be configured. The navOptPath: navigation option is processed first. If a value is found it is used, otherwise the value in the navOpt: setting is used. This means that the chart definition can include a default navigation option and a navigation option present in the data will override it.</p> |

| Parameter | Values | Description |
|--------------------|-------------------------|--|
| key: | Cn Pn XPath value | <p>Defines the element that contains the key field data to be used in a navigation option. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified.</p> <p>This is required if either navOpt: or navOptPath: is defined.</p> <p> Note: Only one key field can be configured for a navigation option.</p> |
| script: | A BPA script name | <p>Defines a BPA script to be activated when the chart element is clicked.</p> <p>Optional</p> <p>When a script is executed, all the elements from the chart data will be made available to the script as temporary variables.</p> |
| scriptPath: | Cn Pn XPath value | <p>Defines the element that provides the BPA script to be activated when the chart element is clicked. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified.</p> <p>Optional</p> <p>Note that both script: and scriptPath: can be configured. The scriptPath: script option is processed first. If a value is found it is used, otherwise the value in the script: setting is used. This means the chart definition can include a default script and a script present in the data will override it.</p> |

| Parameter | Values | Description |
|-------------------|------------------------------|---|
| color: | HTML Color code / RGB value | <p>Optional (default colors applied)</p> <p>Defines the color for the series. The format is a valid HTML color code, e.g. green or blue. All valid color names are defined in this link: http://www.w3schools.com/html/html_colornames.asp.</p> <p>Alternatively an RGB format may be used. (00FF00 is green and 0000FF is blue)</p> <p> Note: Refer to Color Contrast for information about the use of the HTML color 'red' and its impact on accessibility.</p> |
| colorPath: | Cn Pn XPath value | <p>Defines the element containing a color for the series. For data explorers, this will be a SQL or post-processing column identifier. For HTML definitions, the XPath of the element must be specified.</p> <p>The valid formats as described in the color: setting apply.</p> <p>Optional (default colors applied)</p> |
| pieColors: | HTML color code / RGB values | <p>Defines the colors for the pie series. Any number of HTML color codes or RGB color values can be specified, separated by spaces. Examples:</p> <pre>pieColors: green blue</pre> <pre>pieColors: 00FF00 0000FF</pre> <p>Optional (default colors are applied if the series exceeds the values specified)</p> |

The **oraChartBroadcast:** attribute provides the ability to broadcast a value from a chart to the portal context. An unlimited number of fields can be broadcast, configured as name/value pairs; for example: `oraChartBroadcast="FIELD_NAME1:C1;FIELD_NAME2:C2;"` where `FIELD_NAMEn` is the name of the portal context field to be broadcast and `Cn` (or `Pn`) is the element that contains the data value to be broadcast. Broadcast is triggered by clicking on a corresponding section of the chart.

For HTML definitions in UI Maps, the syntax is `oraChartBroadcast="FIELD_NAME1:xpath1;FIELD_NAME2:xpath2;"` where 'xpathn' is the element in the list schema that contains the data value to be broadcast.

Zone Configuration Examples

Zone with a simple pie chart

In this example, the zone SQL summarizes To Do entries by Role. The column definitions are:

- C1 - role description
- C2 - count of To Do entries by role
- C3 - role ID

Visualization Option 1

This option shows To Do entries by Role as a pie chart. The role ID will be broadcast to the portal when the corresponding section of the pie chart is clicked.

```
optiontype=CHART
oraChart="type:pie;"
oraChartSeries1="labelPath:C1; amount:C2;hoverText:$label$newline$amount;"
oraChartBroadcast="ROLE_ID:C3"
```

Zone with two chart types

In this example, the zone SQL summarizes To Do entries by Priority and also calculates separate counts by To Do status within priority. The column definitions are:

- C1 - priority description
- C2 - count of To Do entries by priority
- C3 - priority flag value
- C4 - count of Open To Dos by priority
- C5 - count of Assigned To Dos by priority
- C6 - Label for the Open To Dos bar in the cluster chart
- C7 - Label for the Assigned To Dos bar in the cluster chart

Visualization Option 1

This option shows To Do entries by Priority as a pie chart. The priority value will be broadcast to the portal when the corresponding section of the pie chart is clicked.

```
optiontype=CHART
oraChart="type:pie; legendBorder:true;"
oraChartSeries1="labelPath:C1; amount:C2;hoverText:$label$newline$amount;"
oraChartBroadcast="TD_PRIORITY_FLG:C3"
```

Visualization Option 2

This option shows To Do entries by Priority as a cluster chart with two data series, one for Open To Dos and another for Assigned To Dos. The corresponding priority value will be broadcast to the portal when clicking either the Open or Assigned bar of the cluster chart.

```
optiontype=CHART oraChart="type:cluster; showLegend:true;"
oraChartSeries1="xaxis:C1; xAxisFormat:string; labelPath:C6; amount:C4;hoverText:
$label$newline$amount;"
oraChartSeries2="xaxis:C1; xAxisFormat:string; labelPath:C7; amount:C5;hoverText:
$label$newline$amount;"
oraChartBroadcast="TD_PRIORITY_FLG:C3"
```

Pagination Configuration

The various data explorer zones in the product support the ability to configure pagination so that a user can 'page through' a large set of results using "previous" and "next" buttons or links.

There are several zone parameters that are impacted when attempting to configure this functionality. The following steps highlight the configuration.

- The **Enable Pagination** parameter must be configured to define the basic setup for pagination for the zone. This parameter defines whether the "previous" and "next" actions are defined as buttons, links or icons and indicates

the location of the actions. It also allows an indication as to whether the additional rows are simply appended, rather than shown in a new "page". Refer to the parameter's embedded help for information about the specific syntax.

- It is recommended that the zone is configured with record count and page information by properly configuring the **Record Count Display** parameter. Refer to the parameter's embedded help for information about the specific syntax.
- Configure the **Number of Rows to Retrieve for SQL** parameter to define the number of records displayed per page. If this parameter is not specified the value in the **Number of Rows to Display** parameter is used.
- Configure the key that will be used for paging so that the system can keep track of the 'page break'. The data must be sorted by the paging key; as a result, the decision for identifying the paging key must take into account the design for the zone and the data being displayed. In addition, the paging key must be unique to ensure that the page breaks occur correctly. See below for configuration examples.
 - The **SQL Statement** must include additional clauses **PAGENEXT** and **PAGEPREV** based on the paging key. In addition, as mentioned above, the paging key must be used in the ORDER BY clause.
 - The **SQL Column** parameters must define the paging key mnemonic to be used in conjunction with the SQL statement paging clauses.
 - It is recommended to configure the **SQL Display Column** parameter to show the data in the same order as the ORDER BY clause.

The following zone types support this capability:

- Info Data Explorer - Single SQL (**F1-DE-SINGLE**).
- Info Data Explorer - Multiple SQLs (**F1-DE**). Note that zones of this type support a union of the results of all the SQL statements. As a result, pagination may only be enabled for zones of this type if a single SQL is used. The system is not able to keep track of the pagination across disparate SQL statements.
- Query Data Explorer - Multiple SQLs (**F1-DE-QUERY**).
- Multi Query Data Explorer (**F1-DE-MULQRY**). Zones of this type do not include configuration for SQL statements or column display. However, they do include configuration for the **Enable Pagination**. This parameter must be configured in order for pagination on the individual zones to work.

Note:

Zones used for a Business Service. Note that pagination is ignored when invoking a data explorer zone via a business service. In this scenario, the zone will return the first "chunk" of rows as defined by the Number of Rows parameters.

Zones with data visualization options. Pagination is not supported for zones that define visualization options to show data in a graphical form.

Examples

Simple Paging Key

In this example, the Extendable Lookup Value is defined as Column 1 (C1) and is marked as the paging key. This field is unique for the table and works well as a simple paging key.

```
SELECT A.F1_EXT_LOOKUP_VALUE,A.BUS_OBJ_CD
FROM
  F1_EXT_LOOKUP_VAL A,
  F1_EXT_LOOKUP_VAL_L B
WHERE
A.BUS_OBJ_CD = :H1
AND A.BUS_OBJ_CD = B.BUS_OBJ_CD
AND A.F1_EXT_LOOKUP_VALUE = B.F1_EXT_LOOKUP_VALUE
AND B.LANGUAGE_CD = :LANGUAGE
[ (F1) AND UPPER(A.F1_EXT_LOOKUP_VALUE) like UPPER(:F1) ]
[ (F2) AND ((UPPER(B.DESCR_OVRD) like UPPER(:F2))
OR (B.DESCR_OVRD = ' ' AND UPPER(B.DESCR) like UPPER(:F2))) ]
[ (PAGENEXT) AND A.F1_EXT_LOOKUP_VALUE > :C1 ]
```

```
[ (PAGEPREV) AND A.F1_EXT_LOOKUP_VALUE < :C1]
ORDER BY A.F1_EXT_LOOKUP_VALUE
```

Complex Paging Key

Most queries however do not sort by a unique value. In this case, the paging key needs to be set based on the sorting of the query and should include a unique field, such as the primary key, as the last paging key. In this example, the query is showing results sorted by To Do Type, Role and User. All fields, including the To Do Entry ID (the primary key) are marked as paging keys.

```
SELECT TD_TYPE_CD, ROLE_ID, ASSIGNED_TO, ASSIGNED_DTTM, TD_PRIORITY_FLG, TD_ENTRY_ID
FROM CI_TD_ENTRY
WHERE
ENTRY_STATUS_FLG IN ('O', 'W')
[ (F1) and TD_TYPE_CD = :F1]
[ (F2) AND ASSIGNED_TO = :F2]
[ (F3) AND ROLE_ID = :F3]
[ (PAGENEXT) and ((TD_TYPE_CD>:C1) or (TD_TYPE_CD=:C1 and ROLE_ID>:C2) or (TD_TYPE_CD=:C1
and ASSIGNED_TO>:C3) or (TD_TYPE_CD=:C1 and ROLE_ID=:C2 and ASSIGNED_TO=:C3 AND TD_ENTRY_ID>:C4)
[ (PAGEPREV) and ((TD_TYPE_CD<:C1) or (TD_TYPE_CD=:C1 and ROLE_ID<:C2) or (TD_TYPE_CD=:C1
and ASSIGNED_TO<:C3) or (TD_TYPE_CD=:C1 and ROLE_ID=:C2 and ASSIGNED_TO=:C3 AND TD_ENTRY_ID<:C4)
ORDER BY TD_TYPE_CD, ROLE_ID, ASSIGNED_TO, TD_ENTRY_ID
```

Use Data Explorer for Derived Data

There are times when a design warrants displaying data in a data explorer zone that is not accessible via SQL. For example, perhaps the data is from another system and it requires a web service call. The [JMS Message Browser](#) is another example.

The product provides functionality in the data explorer that allows you to call a script after the user filters are populated but before the SQL is executed. The script can retrieve the data as appropriate, store the data in table format so that the SQL can retrieve the data from the table.

The following points provide more detail:

- Create a service script that retrieves the data as needed. This script should store the retrieved data in a temporary table.
 - The product provides a table that may be used. It is called F1_GENERIC_GTT (Generic Global Temporary Table). There is a business service — Create Global Temporary Table Records (**F1-InsertGTTRecords**) that the service script may call to insert the records.
 - Note that if the data is accessed via a web service call, it may be appropriate to execute the web service in a separate session using the business service F1-ExecuteScriptInNewSession to trap errors that may be issued by the web service call and provide a better error.
- In the data explorer zone use this service script in the zone's pre-processing script parameter. If any user or hidden filters should be passed into the script, the parameter supports mnemonics for this purpose. Refer to the parameter's embedded help for the supported syntax.
- The SQL for the data explorer should access the temporary table that was populated by the service script.

Configuring Timeline Zones

This topic highlights information related to configuring a [timeline zone](#). The zone type is **F1-TIMELINE**. A timeline zone contains one or more "lines" where each line shows when significant events have occurred. The output of each line is driven by an algorithm configured on a timeline zone. Each algorithm is responsible for retrieving a single type of data. For example, one algorithm may retrieve bills for an account in a given time period whereas another algorithm may retrieve payments for that account for the same time period.

The algorithms to configure for a timeline zone use the **Zone - Timeline** plug-in spot. Please note the following details about the behavior for algorithms for this plug-in spot.

- The timeline algorithm receives all the global context values currently populated. In addition, it receives a start and end date from the zone, based on the time period chosen by the user, along with the maximum number of

events that can be reasonably displayed for the chosen time period. The algorithm should use this information to retrieve data for a given type of transaction related to one or more of the input context values for the provided time period.

- For each event found, the algorithm returns information about the event along with many options that assist the user in getting more detail about each event or acting on an event.
 - Event date
 - Primary key of the record (key / value pairs)
 - FK Reference. With this information, the timeline zone will display the appropriate info string to display in the zone's info area when clicking on the event. In addition, the FK reference identifies the appropriate navigation option to use when a user clicks the info string hypertext to view the record on its maintenance page.
 - Background Color and Text Color to use for the event. (Obsolete). This information is no longer used by the timeline zone and will be ignored.
 - Icon use for the event. (Obsolete). This information is no longer used by the timeline zone and will be ignored.
 - [BPA script](#) to launch when a user clicks on an event. (Optional). The algorithm may return one or more BPA scripts that a user may launch to act on an event. For example, for an event that has a status of **Error**, perhaps a BPA is provided to walk a user through resolving the error.

When a script is initiated from a timeline, the system puts the prime key of the event into a field in the page data model. The name of the field is the column name(s) of the event's prime key. For example, when a script associated with a payment event is kicked off, the system populates a field called PAY_ID with the prime-key of the selected payment.

Note that your specific edge application may supply algorithm types for a timeline zone as part of the base product. Although algorithm types may be provided, typically the product does not deliver algorithms because the parameters for the algorithms are driven by a particular implementation's business rules and preferences. As a result, the product will also not deliver pre-configured timeline zones. Please refer to your edge application's documentation for more information about what timeline algorithm types are delivered, if any and recommendations for configuration.

Defining Context-Sensitive Zones

A context-sensitive zone allows you to associate a zone with a specific user-interface transaction. A context-sensitive zone appears at the top of the Sidebar when a user accesses a page for which the zone is specified as the context. For example, when viewing a business object, additional zones are visible that are specific to the business object page.

CAUTION: Make sure that the zone is appropriate for the transaction on which you are specifying it. For example, if your zone requires a business object ID as one of its keys, it should not be displayed on the To Do entry transaction.

Select **Admin > Context Sensitive Zone** to maintain context-sensitive zones.

Description of Page

The **Navigation Key** is a unique identifier of a tab page within the system. **Owner** indicates if this navigation key is owned by the base product or by your implementation (**Customer Modification**).

CAUTION: Important! When introducing a new context sensitive zone, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The grid contains the list of context-sensitive zones and the sequence in which they appear in the sidebar for the selected navigation key. The grid contains the following fields:

- **Zone** is the name of the zone to display in the Sidebar.
- **Sequence** is the sequence in which the zone is displayed (if multiple context-sensitive zones are defined).
- **Owner** indicates if this context sensitive zone is owned by the base product or by your implementation (**Customer Modification**).

Where Used

A context-sensitive zone displays at the top of the Sidebar whenever a user accesses the transaction for with the zone is specified.

Defining Portals

This portal is used to view and maintain the configuration of portals. An implementation may define their own portals or may override some of the settings for base product provided portals.

You can access the portal from the **Admin Menu > System > Portal**. You are brought to a query portal with options for searching for a specific record. Once a portal record has been selected you are brought to the maintenance portal to view and maintain the selected record.

Note: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Refer to [Understanding Portals and Zones](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Portal.** This zone provides information about the selected portal definition.
- **Options.** This zone lists various configuration options for the selected portal record.
- **Tabs.** This zone lists other tab portals if any are configured for a standalone portal. This zone is only visible when such tabs exist for the current standalone portal.
- **Context Sensitive Zones.** This zone lists context sensitive zones that appear on the sidebar when this portal is displayed. This zone is only visible when such zones exist for the current standalone portal.

Defining Menu Options

This portal is used to define / change any menu in the system. You can access the portal from the **Admin Menu > System > Menu**. You are brought to a query portal with options for searching for a specific menu. Once a menu has been selected you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Updating menus requires technical knowledge of the system. This is an implementation and delivery issue and should not be attempted if you do not have previous experience with menus.

Note: Security and menus. Refer to [Secured Objects and Application Services](#) on page 22 for a discussion of how application security can prevent menu items (or an entire menu) from appearing.

Note: Module configuration and menus. Your [module configuration](#) can prevent menu items (or an entire menu) from appearing.

The following zones may appear as part of the portal's **Main** tab page:

- **Menu.** This zone provides information about the selected menu.
- **Menu Lines.** This zone lists the menu's lines and supports actions to add, edit and delete lines. You may also broadcast a line to review more information about its items configuration.
- **Menu Line Items.** This zone lists item information for a selected menu line.

Application security information for the menu can be reviewed and managed from the **Application Security** tab. The following zones may appear as part of this tab page:

- **Menu Lines.** This zone lists the menu's lines. Broadcast a line to review its application security information.
- **Menu Line Security.** This zone lists application services related to the selected menu line. You may use this zone to review and configure security access for the selected menu line and a specific user group.
- **Menu Line Security Details.** This zone lists the entities secured by a selected application service.

The following zone may appear as part of the portal's **References** tab page:

- **Menu References.** This zone lists entities that reference the selected menu.

The following sections provides more information.

Menu Types

The following types of menus are supported:

- **Admin** is one of the menus that appears in the Application Toolbar. It is a special type of menu because [admin menu](#) items can be grouped alphabetically or by functional group. Refer to the description of Admin Menu Order on [Installation Options - Framework](#) for more information about admin menu options.
- **Main** is another menu that appears in the Application Toolbar that is simply titled *Menu*.
- **Submenu** defines a menu group that appears when an Application Toolbar menu is selected. for the Admin menu, this is only visible when it's organized functionally.
- **Context** refers to a [context menu](#).
- **Page Action Menu** defines buttons that appear in the [Page Title Area](#).
- **User Menu** refers to the menu items that appear on the [user menu](#); for example, User Preferences.

Extending Product Owned Menus

An implementation may choose to add custom menu lines along with its menu item (or items) to a base product owned menu.

Overriding Menu Lines Sequence

An implementation may override the sequence of a base product owned menu line. Also note that the sequence is defined on the menu line language table, allowing for different orders to be used for different languages (or to let the menu be sorted alphabetically in one language and in a specified order in a different one).

Menu Information is Cached

Use the **Flush Menu** button to flush the cached menu items so you can see any modified or newly created menus. Refer to [Caching Overview](#) for more information.

Defining Navigation Keys

Each location to which a user can navigate (e.g., transactions, tab pages, tab menus, online help links, etc.) is identified by a navigation key. A navigation key is a logical identifier for a URL.

Navigation Key Types

There are three types of navigation keys:

- **System navigation keys** define locations where the target for the navigation is a transaction or portal within the system. The navigation keys define the program component that identifies the page to navigate to.
- **External navigation keys** define a URL that identifies the target location. External URLs can be specified as relative to the product web server or fully qualified. External navigation keys always launch in a new instance of a browser window. Examples of external navigation keys include application viewer links and URLs to external systems.
- **Help navigation keys** define an online help topic that identifies the specific page within the online help to launch. Help navigation keys may be related to a program component when the help is related to a specific page in system.

Navigation Key vs Navigation Option

The system has two entities that work in conjunction with each other to specify how navigation works:

- [Navigation Key](#) defines a unique location to which a user can navigate. For example, each page in the system has a unique navigation key. Navigation keys can also define locations that are "outside" of the system. For example, you can create a navigation key that references an external URL. Think of a navigation key as defining "where to go".
- [Navigation Option](#) defines how a page is opened when a user wants to navigate someplace. For example, you might have a navigation key that identifies a specific page. This navigation key can then be referenced on two navigation options; the first navigation option may allow users to navigate to the page with no context included, while the second navigates to the page with context data provided to automatically display information related to that context.

- Please note that a wide variety of options can be defined on a navigation option. In addition to defining if data is passed to the page, it could also define search options. In addition, there are some navigation options that do not reference a navigation key but rather refer to a BPA script that should be launched.

The Flexibility of Navigation Keys

Navigation keys provide a great deal of functionality to your users. Use navigation keys to:

- Allow users to navigate to new pages or search programs
- Allow users to transfer to an external system or web page. After setting up this data, your users may be able to access this external URL from a menu, a context menu, their favorite links, etc. Refer to [Linking to External Locations](#) for more information.

Refer to the Tool Suite Guide for more information on developing program components.

Note: Replacing Base-Package Pages or Searches. If your new page or search has been designed to replace a module in the base-package, the navigation key must indicate that it is [overriding an existing navigation key](#).

Linking to External Locations

If you want to include links to external systems or locations from within the system, you need to:

- Define a [navigation key](#) that specifies the URL of the location. For example, define an external navigation key that as a URL of <http://www.oracle.com/>.
- Define a [navigation option](#) that specifies from where in the system a user can go to your external location. For example, define a navigation option with a usage of **Favorites** or with a usage of **Menu**. Your navigation option points to the navigation key you defined above.
- Add your navigation option to the appropriate location within the system. For example, have users add the navigation option to their [Favorite Links](#) or add the navigation option as an item on a [menu](#).

Overriding Navigation Keys

Your implementation may choose to design a program component (e.g., a maintenance transaction or search page) to replace a component provided by the system. When doing this, the new navigation key must indicate that it is overriding the system navigation key. As a result, any menu entry or navigation options that reference this overridden navigation key automatically navigates to the custom component.

For example, if you have a custom On-line Batch Submission page and would like users to use this page rather than the one provided by the system, setting up an override navigation key ensures that if a user chooses to navigate to the On-line Batch Submission from Menu or a context menu, the user is brought to the custom On-line Batch Submission page.

To create an override navigation key, you need to:

- Define a [navigation key](#) using an appropriate [naming convention](#).
- If the Navigation Key Type of the navigation key being overridden is **External**, specify a Navigation Key Type of **Override (Other)** and define the appropriate URL Component.
- If the Navigation Key Type of navigation key being overridden is **System**, specify a Navigation Key Type of **Override (System)** and populate the Program Component ID with your custom program component ID.
- Specify the navigation key that you are overriding in the **Overridden Navigation Key** field.

Refer to the Tool Suite Guide for more information about developing your own program components.

Maintaining Navigation Keys

Select **Admin > System > Navigation Key** to maintain navigation keys.

Use the **Navigation Key Query** portal to search for an existing navigation key. Once a navigation key is selected, you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Important! When introducing a new navigation key, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Description of Page

The **Navigation Key** is a unique name of the navigation key for internal use.

Owner indicates if this navigation key is owned by the base product or by your implementation (**Customer Modification**). This information is display-only.

Navigation Key Type includes the following possible values:

- **External** indicates that the location is specified in the **URL Component** field.
- **Help** indicates that the navigation key is used to launch online help where the specific help topic is defined in the **URL Component** field.
- **Override (Other)** indicates that the navigation key overrides another navigation key of type **External** or **Help**. For this option, the name of the navigation key being overridden is populated in the **Overridden Navigation Key** field.
- **Override (System)** indicates that the navigation key overrides a system navigation key. For this option, the name of the navigation key being overridden is populated in the **Overridden Navigation Key** field.
- **System** indicates that the navigation key refers to a transaction in the system identified by its program component.

Fastpath: Refer to [Navigation Key Types](#) for more information about navigation key types.

Fastpath: Refer to [Overriding Navigation Keys](#) for more information about settings required to override a system navigation key.

Program Component ID is the name of the program component identified by the key (for system navigation keys). The program component ID can also be used to specify the transaction with which an online help link is associated.

Overridden Navigation Key is the name of the navigation key that the current navigation key is overriding (if **Override (Other)** or **Override (System)** is selected for the **Navigation Key Type**). Refer to [Overriding Navigation Keys](#) for more information.

URL Component is the specific URL or portion of the URL for the navigation key (external and help navigation keys only). The URL can be relative to the product web server or fully qualified.

Open Window Options allows you to specify options (e.g., width and height) for opening a browser window for an external navigation key. (External navigation keys always launch in a new browser window.) You can use any valid features available in the `Window.open()` JavaScript method. The string should be formatted the same way that it would be for the features argument (e.g., `height=600,width=800,resizable=yes,scrollbars=yes,toolbar=no`). Refer to a JavaScript reference book for a complete list of available features.

Application Service is the application service that is used to secure access to transactions associated with **External** navigation keys. If a user has access to the specified application service, the user can navigate to the URL defined on the navigation key. Refer to [The Big Picture of Application Security](#) for more information.

The grid displays menu items that reference the navigation key (actually, it shows menu items that reference navigations options that, in turn, reference the navigation key).

Defining Navigation Options

Every time a user navigates to a transaction, the system retrieves a navigation option to determine which transaction should open. For example:

- A navigation option is associated with every menu item. When a user selects a menu item, the system retrieves the related navigation option to determine which transaction to open.
- A navigation option is associated with every [favorite link](#). When a user selects a favorite link, the system retrieves the related navigation option to determine which transaction to open.
- A navigation option is associated with every node in the various trees. When a user clicks a node in a tree, the system retrieves the related navigation option to determine which transaction to open.
- Etc.

Many navigation options are shipped with the base product and cannot be modified as these options support core functionality. As part of your implementation, you may add additional navigation options to support your specific business processes.

Navigation options may also be used to launch a BPA script.

The topics in this section describe how to maintain navigation options.

CAUTION: In order to improve response times, navigation options are cached the first time they are used after a web server is started. If you change a navigation option and you don't want to wait for the cache to rebuild, you must clear the cached information so it will be immediately rebuilt using current information. A special button has been provided on the Main tab of the navigation option transaction that performs this function. Please refer to [Caching Overview](#) for information on the various caches.

Navigation Option - Main

Select **Admin > System > Navigation Option** to maintain a navigation option.

Use the **Navigation Option Query** portal to search for an existing navigation option. Once a navigation option is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter a unique **Navigation Option** code and **Description**.

CAUTION: When introducing a new navigation option, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The **Flush System Login Info** button is used to flush the cached navigation options so you can use any modified navigation options. Refer to [Caching Overview](#) for more information.

Owner indicates if this navigation option is owned by the base product or by your implementation (**Customer Modification**). This field is display-only. The system sets the owner to **Customer Modification** when you add a navigation option.

Note: You may not change navigation options that are owned by the base product.

Use **Navigation Option Type** to define if the navigation option navigates to a **Transaction**, launches a **BPA Script** or opens an **Attachment**.

Note: The **Attachment** option type is only applicable to navigation options that are used to launch a file attached to a record in the Attachment maintenance object.

For navigation option types of **script**, indicate the **Script** to launch. You can use the **Context Fields** at the bottom of the page if you want to transfer the contents of specific fields to temporary storage variables available to the script. The script engine creates temporary storage variables with names that match the Context Field names.

For navigation option types of **transaction**, define the **Target Transaction** (navigation key) and optionally a specific **Tab Page** (also a navigation key) if a specific tab on the transaction (other than the Main tab) should be opened when navigating to that transaction.

Note: Finding transaction navigation keys. When populating the **Target Transaction** and **Tab Page** you are populating an appropriate navigation key. Because the system has a large number of transactions, we recommend using the "%" metaphor when you search for the transaction identifier. For example, if you want to find the currency maintenance transaction, enter "%currency" in the search criteria.

The additional information depends on whether the target transaction is a fixed page or a portal-based page:

- For portal-based pages:
 - **Navigation Mode** is not applicable and should just be set to **Add Mode**.
 - If navigating to a query portal, by default the query portal will open with the default search option defined. If the navigation should open a different search option, define the **Multi-Query Zone** for that query portal and indicate the **Sub-Query Zone** to open by default. Note that for this configuration, it is common to define **Context Fields** to pre-populate search criteria in the target query zone. When using this configuration, be sure that the target query zone's [user filters](#) are defined to populate data from context.
- For fixed pages:
 - **Navigation Mode** indicates if the **Target Transaction** should be opened in **Add Mode** or **Change Mode**.

- **Add Mode** should be used if the option is used to navigate to a transaction ready to add a new object. You can use the **Context Fields** at the bottom of the page if you want to transfer the contents of specific fields to the transaction when it opens.
- **Change Mode** is only applicable for fixed pages and should be used if the option is used to navigate to a transaction ready to update an object. You have two ways to define the object to be changed:
 - Define the name of the fields that make up the unique identifier of the object in the **Context Fields** (and make sure to turn on **Key Field** for each such field).
 - Define the **Search Transaction** (navigation key) if you want to open a search window to retrieve an object before the target transaction opens. Select the appropriate **Search Type** to define which search method should be used. The options in the drop down correspond with the sections in the search (where **Main** is the first section, **Alternate** is the 2nd section, **Alternate 2** is the 3rd section, etc.). You should execute the search window in order to determine what each section does.

When you select a **Search Type**, define appropriate **Context Fields** so that the system will try to pre-populate the search transaction with these field values when the search first opens. Keep in mind that if a search is populated with field values the search is automatically triggered and, if only one object is found that matches the search criteria, it is selected and the search window closes.

- **Search Group** is only visible if the **Development Tools** module is **not turned off**. It is used to define the correlation between fields on the search page and the tab page. You can view a tab page's **Search Groups** by viewing the HTML source and scanning for **allFieldPairs**.

The **Go To Tooltip** is used to specify the label associated with the tool tip that appears when hovering over a **Go To** object. Refer to the **Usage** grid below.

The **Usage** grid defines the objects on which this navigation option is used:

- Choose **Favorites** if the navigation option can be used as a [favorite link](#).
- Choose **Menus** if the navigation option can be used as a user's [home page](#) or as a menu or context menu item.
- Choose **Script** if the navigation option can be used in a [script](#).
- Choose **Foreign Key** if the navigation option can be used as a [foreign key reference](#).
- Choose **Go To** if the navigation option can be used as a "go to" destination ("go to" destinations are used on Go To buttons, tree nodes, and hyperlinks).
- If your product supports marketing campaigns, you can choose **Campaign** if the navigation option can be used as a "post completion" transaction on a campaign. For more information refer to that product's documentation for campaigns.

The **Context Fields** grid contains the names of the fields whose contents will be passed to the **Target Transaction** or **Script** or used to launch an **Attachment**. The system retrieves the values of these fields from the "current" page and transfers them to the target transaction or to the script's temporary storage. Turn on **Key Field** for each context field that makes up the unique identifier when navigating to a transaction in **Change Mode**.

Note: For an **Attachment**, the grid should contain the Attachment ID.

Note: Navigating from a Menu. The standard followed for many base main **menu** navigation options for fixed transactions is that navigation options launched from the Menu dropdown are configured with no context.

Navigation Option - Tree

This page contains a tree that shows how a navigation option is used. Select **Admin > System > Navigation Option** and navigate to the **Tree** tab to view this page.

Description of Page

The tree shows every menu item, favorite link, and tree node that references the navigation option. This information is provided to make you aware of the ramifications of changing a navigation option.

Understanding System Messages

All error, warning and informational messages that are displayed in the system are maintained on the message table. Every message is identified by a combination of two fields:

- **Message category number.** Think of a message category as a library of messages related to a given functional area. For example, there is a message category for billing messages and another one for payment messages.
- **Message number.** A unique number identifies each message within a category.

Every message has two components: a brief text message and a long description.

The brief message text supports the %n notation within the message text to cause field values to be substituted into a message. For example, the message text "Unable to assign To Do Entry (%1). It is already assigned to another User (%2)" will have the values of 2 fields merged into it before it is displayed to the user (%1 is the To Do Entry ID, %2 is the current assigned user).

Note: You cannot change the product's text. If the message is "owned" by the product, you cannot change the product's message or detailed description. If you want your users to see a different message or detailed description other than that supplied by the product, enter your desired verbiage in the corresponding override fields (and flush the [cache](#)).

Defining System Messages

This portal is used to search for message categories and messages that appear throughout the system. An implementation may introduce messages used in custom processes or may choose to override the text for messages delivered by the product.

You can access the portal from the **Admin Menu > System > Message**. You are brought to a query portal with options for searching for a specific message category or a message. Once a record has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Understanding System Messages](#) on page 98 for more information.

Defining Message Categories

This portal is used to view and maintain a message category and its messages.

CAUTION: Message category 80000 or greater must be used to define new messages introduced for a specific implementation of the system. Changes to other Message Text will be overwritten when you next upgrade. If you want to make a change to a Message, drill down on the message and populate the Override Message Text. Note that even for message categories 80000 and higher, message numbers lower than 1000 are reserved for common base product messages.

You can access the portal from the **Admin Menu > System > Message**. You are brought to a query portal with options for searching for a specific message category or a specific message. Once a message category has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Understanding System Messages](#) on page 98 for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Message Category.** This zone provides information about the selected message category.
- **Messages.** This zone lists and maintains messages for the selected category.

Defining Messages

This portal is used to view and maintain a specific message. An implementation may introduce messages used in custom processes or may choose to override the text for messages delivered by the product.

CAUTION: Message category 80000 or greater must be used to define new messages introduced for a specific implementation of the system. Changes to other Message Text will be overwritten when you next upgrade. If you want to make a change to a Message, drill down on the message and populate the Override Message Text. Note that even for message categories 80000 and higher, message numbers lower than 1000 are reserved for common base product messages.

You can access the portal from the **Admin Menu > System > Message**. You are brought to a query portal with options for searching for a specific message category or a specific message. Once a message has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Understanding System Messages](#) on page 98 for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Message**. This zone provides information about the selected message.

Understanding Unified Search

Depending on your product, the toolbar search box may support a product specific search for business entities in addition to the standard search for menu items. For example, the search may support a query of business entities by their name, address, contact details etc. The unified search feature is a simplified version of your product's main search, that allows the user to lookup up records using free form search text or hint codes. For more complex queries, the user may navigate to the corresponding advanced search portal.

The configuration of a unified search option includes the following items:

- A **search service script** that implements the data query and defines the supported **filters**. The application service associated with this script is used to secure the unified search option.
- **Search filter rules** and **hints** for the supported filters. These rules are used to parse the text entered by the user to determine whether it qualifies as a valid filter value.
- The **advanced search** portal to use for more complex queries.

The unified search box interacts with a unified search option implementation as follows:

- As the user types free form text in the search box, the application uses the **search filter rules** and **hints** to parse the entered text and translate it to corresponding query filters.
- The **search service script** is then called to query for entities that match these filters and present the results.
- Selecting a result record navigates to the corresponding portal.
- Selecting the **Advanced Search** link in the search box navigates to the general query portal associated with the unified search option.

If a unified search option is not enabled for your product or the user does not have security access to it then the search box may only be used for searching the menu.

The following sections describe various aspects related to the configuration of a unified search option.

The Search Script Controls Everything

A unified search is implemented as a single service script that controls the following:

- **Filters**. The script determines which filters are supported and how they are applied to return results efficiently. Each filter name must be a valid **Field** record.
- **Results**. The script returns a list of business entities that matches the query filters provided by the user, along with the navigation information needed to drill in to a selected record in the list.
- **Application security**. Only users that have access to the script's application service may use the unified search associated with the search script.
- **Override Advance Search**. The script may override the advanced search portal configured for the search option.

When the search box component initializes, the script is called once in **Prepare Search Details** mode to return the list of supported filter names. In this mode the script does not perform any query.

As the user types in text in the search box, the search box component analyzes the entered text to derive query filters and calls the search script in **Perform Search** mode to return matching results.

The search box component is designed to support any type of unified search implementation and as such, the interaction between the user interface component and the search script is generic. Filters are defined as name / value pairs and results for each matched entity includes details like primary, secondary and tertiary description lines, along with a line that describes the matching text for entry.

Note: If your organization needs to implement a custom unified search script, it is strongly recommended that you follow the base product's implementation of such scripts as a reference.

Filter Rules and Hints

A unified search is designed to support a predefined set of filters for querying data. For example, searching customers by their address, name, identifiers; or searching locations by address or name etc. Each filter is uniquely identified by a **Field** name as declared by the search service script.

As the user types in free text in the search box, the application applies parsing rules to determine whether the text may be used as the value of one or more filters supported by the unified search. For example, if the user types in the text "ave", parsing rules may determine that it can be used to filter results by a person's name or address but not their email address.

Each parsing rule, defined in the **Search Filter Rule extendable lookup**, associates a filter's field name with a regular expression. Multiple filter rules defined for the same filter name are processed in execution order sequence and it is enough for one rule to return a match for the search text to be used as the value for the specific filter.

Alternatively, the user may use an explicit hint code to identify the filter they would like to use followed by the filter value. For example, an address filter may be associated with the hint "ad:" allowing the user to enter "ad: main" to look up records by address.

Each hint, defined in the **Search Filter Hint extendable lookup**, associates a filter's field name with a hint code.

Note that filter rules and hints are defined for a specific filter name and not a specific unified search option. The same parsing rules may be shared across searches using the same filter names. For example the parsing rule to identify an "email" filter or the "ad:" hint for an address filter are the same regardless of how these are used by a search query. These rules are automatically associated with any unified search option that uses the same filter names.

Note: You may customize the parsing rules and hints associated with a filter by inactivating the base product's extendable lookup records and introducing custom rules that match your business requirements.

Which Unified Search Option is Used?

Each unified search option is defined in the **Unified Search extendable lookup**, referencing the option's search service script and its corresponding advanced search portal. The unified search option is only enabled to users that have access to the search script's application service. When more than one unified search option is configured and enabled for a user, the application chooses the option with the highest sequence as the default option, allowing users to switch to other options they have access to.

Customizing Unified Search

You may customize the parsing rules and hints associated with base product search filters by inactivating the base product's extendable lookup records and introducing custom rules that match your business requirements.

If you need to support a search for different business entities and filters, you need to implement a custom unified search. The configuration of a unified search option involves the following high level steps:

- Design and implement a search script that supports a predefined set of filters and returns the topmost set of matching results while taking into account performance considerations.
- Design hints and filter rules as needed for each of the supported filters. Review existing hints and filter rules associated with same filter names when applicable.
- Register each hint, if any in the **Search Filter Hint** extendable lookup.
- Register each filter rule, if any in the **Search Filter Rule** extendable lookup.
- Register the search script in the **Unified Search** extendable lookup.

Trees

Many edge products and implementations make extensive use of UI tree structures to display hierarchical relationships between records in the system. The framework provides an objects to define a tree structure and the rules

on how to populate the nodes in the tree, and processes to interpret the configuration and dynamically render the tree display.

The topics in this section provide information about what is supplied in the framework. Your product may supply UI components with ready built trees for common use cases. Refer to your product documentation for more information.

Common Attributes of Trees

Your organization may have many portals and zones showing data in a hierarchical tree. Most trees in the system follow a similar pattern:

- Trees have a number of levels. There may be different types of tree nodes present in any given level; for instance a list of algorithm types for a script, followed by a list of script steps. Icons may be displayed to further identify the node's object type.
- The most common node types reference an entity within the system such as a schema, script, data area and so on. These nodes usually display the information string from the entity's FK reference and provide the ability to navigate to the entity. They may also allow the node context to be broadcast to other zones in the portal.
- In addition to the ability to navigate to the associated entity, many node types provide a context menu with further navigation paths.
- Some nodes are simply informational and are used to group a set of child nodes below a type or category. For example, the business object Options tree groups the option value nodes below summary nodes that describe the option type.

Each tree defines the nodes that make up the tree and the parent/child relationship between those nodes. A tree node defines which of the common attributes are applicable to the node and the algorithms responsible for retrieving the node data and, optionally, determining the node information to be displayed.

Populate Node Algorithm

A tree node displays a combination of the attributes listed above, typically for an object in context. For a root node, the object will normally be derived from a global or portal context value, such as the current script. For each lower level node, the context is derived from the context fields of its parent row; for instance, algorithms for a specific algorithm type.

The key responsibility of the populate node algorithm is to receive the tree code, node name and the parent context value (or values), determine if there is data that should be shown for this node, and return the a list of the context fields and values applicable to each row in the node. The following highlights additional optional information that may be returned by the algorithm:

- Entity information. If the node is related to a specific entity, the maintenance object code and primary key values may be returned. These are used for determining default information for the node, including navigation details.
- A display icon value. This is used to override the icon defined on the tree node and/or the default icon for the entity as defined on the maintenance object or business object.
- An information string. This may be used to override the default information string for an entity or to display stand-alone text such as a summary or description of the child nodes to follow.
- Override broadcast details if needed for a specific node. For example, set specific broadcast field names and values when they differ from the related entity's primary keys or indicate that broadcasting is not applicable for a node instance even though broadcasting is enabled by the node's definition.

Note: The populate node algorithm is responsible for returning all the context values required to populate its child nodes. For an informational or summary node, this may require including the node's parent context fields in its own context. For example, in the script tree, the summary node describing the number of steps is followed by a list of steps for the script. The summary node populate node algorithm needs to include the script code passed in as parent context in its output context list, in order for the steps to be correctly retrieved.

Information Override Algorithm

The information override algorithm has two main purposes:

- Providing alternative information text for a tree node when the information provided isn't suitable for your implementation.
- Retrieving contextual insights related to the tree node entity, to be included in the node's information text. Only badge insight types are currently supported.
- Override broadcast details if needed for a specific node. For example, set specific broadcast field names and values when they differ from the related entity's primary keys or indicate that broadcasting is not applicable for a node instance even though broadcasting is enabled by the node's definition.

The override information algorithm receives the tree code, node name, maintenance object and prime key values for the node. The following highlights the information that may be returned by the algorithm:

- A display icon value.
- An information string. This will be used to override the default information string in the node's formatted string.
- Full node text. This will be used as the full text for the display, overriding the formatting defined on the node.
- A list of badge insight types and their context.

Note: If the information override algorithm returns insight types for the entity, it is also responsible for returning all the context values required for those insight types. Refer to [Contextual Insights](#) for more information.

Preparing a Node for Display

The following section highlights key steps in fetching a node's data and formatting it for display.

Determining Node Content

The following steps are performed to retrieve the components making up the tree node display:

- The Populate Node algorithm is called to determine all instance nodes for the tree node along with their related details.
- The Information Override algorithm is called for each node instance to allow for optional override of presentation related details.

The node display contents are determined as follows:

- The icon is determined from the following sources, in order: tree node definition, override information algorithm value, populate node algorithm value, maintenance object / business object default value.
- Broadcast usage is determined by the setting on the tree node definition.
 - This setting can be overridden by either the Populate Node algorithm or the Override Information algorithm (which takes precedence) to indicate that broadcasting is not applicable for a specific node instance.
 - By default the broadcast fields for a node are the primary key names of its related entity. Broadcast field names can be overridden by either the Populate Node algorithm or an Override Information algorithm where the latter takes precedence.
- The information string is determined from the following sources, in order: override information algorithm value, populate node value, maintenance object / business object information algorithm. If the string is derived from the MO/BO algorithm, the short information text is used when available else the standard information is used.
- Context menu usage is determined by the settings on the tree node definition.
- The system supports a different style for header rows, including a larger font. Header style usage is determined by the setting on the tree definition and is only applicable if the node is a root node with only one instance.

Node Text Format

The text for nodes referencing a system entity commonly includes some combination of a label, the entity key and an information string. The node configuration provides a label field and a substitution format string field which may be used to define the node text format. The format string defines which of the components should be included in the text, the order of those components and any surrounding text and HTML markups. For example, a format string of `'%label - %key - %info'` will result in a node text like the example below:

▶  Algorithm Type - F1_PROSTINFO - Process Flow Information

If the format string is blank, the default text will include ‘%info’ only. If an override information algorithm is configured that returns the full node text, the text is presented without further formatting.

Auto Expansion

If the tree node definition indicates that the node should be expanded, the system will automatically fetch and display the data for its child node. This processing continues until there are no further child nodes marked for expansion.

Base Delivered Trees

Trees are system data and your product may already deliver several trees out of the box. You may choose to customize a base delivered tree in the following ways:

- You may add your own nodes to an existing tree definition.
- You may override the information string for a node by supplying your own **Information Override** algorithm. If a base override algorithm is configured on the node, your custom algorithm should be plugged in at a higher sequence number, to take precedence over the base algorithm.

Rendering a Tree

To render a tree on the UI, you would include the ou-tree web component in a UI map that references the tree definition.

Note: Refer to [Include a Web Component](#) for more information.

Defining Trees

This portal is used to view and maintain information about a tree definition. Trees are commonly used to display hierarchical relationships between objects in the system. Refer to [Trees](#) for background information about defining trees.

You can access the portal from **Admin > System > Tree**. You are brought to a query portal with options for searching for a specific tree definition. Once a tree has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones will appear as part of the portal's **Main** tab page

- **Tree.** This zone provides information about the selected tree.
- **Tree Nodes.** This zone lists the nodes for this tree in hierarchical order. Use the zone actions to add or maintain a node in the tree.
- **Tree Node.** This zone displays the details for a tree node. It is only visible if a tree node name has been broadcast from the Tree Nodes zone.

Contextual Insights

Contextual Insights provide a powerful way to surface focused intelligence and alerts to users in the context of the core screens for any applications built on Oracle Utilities Application Framework. There are multiple options for the visual patterns when surfacing Contextual Insights and the actions that can be performed by users are easily configurable as well. The subsequent topics provide detail about the Insight Type and Insight Group objects that are used to configure the information that may then be displayed in appropriate screens.

Insight Types

The insight type object contains all the detailed configuration for displaying one or more alerts, or important information for a record in context. The following sections provide more information about all the configuration managed by the insight type.

Insight Algorithm

Each insight type is used to display some information, typically related to an object in context. It is the responsibility of the insight type algorithm to receive the context value (or values), determine if there is information that should be shown for this context, return the text to display.

The following highlights additional optional information that may be returned by the algorithm:

- A secondary message. This is only applicable to some visual structures where more than one line of information may be displayed.
- A severity value. This is used to override the visual display configuration if different emphasis should be used for different severity values. Refer to [Override Configuration](#) for more information.
- Entity information. If the insight is related to a specific entity, the maintenance object code and primary key values may be returned. This is useful if the insight type configures a BPA or user action algorithms that may perform logic for this entity.
- Navigation and User Action information. This is only applicable to visual structures that support user actions. The algorithm must return the list of all the actions that should be made visible on the insight. If the action includes navigation, the algorithm should return the navigation option and navigation context key and value pairs. Additionally, there is configuration for each action that must be defined. Refer to [User Actions](#) for more information.

Each algorithm can return multiple insights, if applicable. For example, if the insight is about To Do entries related to the object being displayed, you could design your insight algorithm to return a single insight summarizing all the To Do related information. Or you could choose to return separate insights based on To Do information so that you provide more granular information and customize actions or navigation based on the different conditions. For example, if there are To Do Entries that the current user may perform actions on and others that current user cannot update, the algorithm could return two separate insights: one with actions and one without.

Note: Preview mode. The insight type maintenance page includes an Insight Preview section that shows the output from the insight algorithm when invoked with an insight mode of "Preview". Every algorithm should include logic that returns appropriate text when called in this mode so that something is displayed in that section.

Visual Structures

Each insight type defines a visual structure which dictates what kind of information may be shown. The system has some fixed layout expectations for each visual structure type. The insight type configuration is used to provide the source for the possible layout.

Note: All the insights use color options as part of their configuration. Refer to [Color Option](#) for more information.

Badge Insight

The simplest visual structure is the badge. It is used to display a single line of quick text with a solid background (for visibility) that is meant to alert the user to important summary information or attributes.

 3 Related To Dos

Inline Insight

The inline insight defines an icon and a single message. This is meant to be more descriptive than a badge. For this type of insight, a default light background is used so the recommendation is to select a color option for both the text and the icon that has only a foreground color defined or has a light background color.

 3 Related To Dos

List Insight

The list insight are intended to exist in a list of insights for the object. It defines an icon and can support two lines of text. In addition, this type of insight supports buttons or user actions. Refer to [User Actions](#) for more information. Note that for a list insight, if there is one valid action or 2 valid actions, the action buttons are shown. If there are three or more valid actions, one action is shown and then an 'Other Actions' button is visible. Clicking this shows the other available actions.

Note that the background color for the insight is used as the color for the full insight snippet. The text and the icon are shown on this background. The icon's background color is ignored.

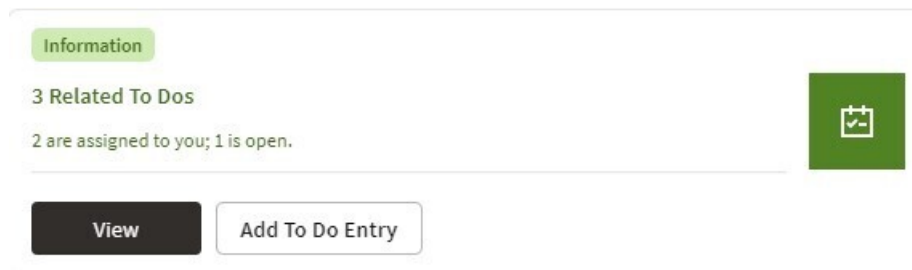

Card

The card insight is the most information rich, with up to two lines of text, [user actions](#), a large icon to call attention and header text. The header text is chosen from a dropdown list of valid options. The product provides out of the box header text of "Information", "Warning" and "Error". Implementations may add additional values to this using the lookup field `HEADER_CAT_FLG`.

Please note the following about the treatment of the various components of the card insight:

- The header text is rendered like a badge insight.
- For the message text displayed in the card, the background color is ignored so a color option with no background color or a light background color should be chosen.
- For the icon, the background color is used to create a square area for display and the icon is rendered in the foreground color.

Override Configuration

Each insight supports default visual setting for the various components of the insight. This includes the color option for the applicable components along with icons and header text, where applicable. In each case, override visual settings may be defined for a given severity number.

For example imagine the algorithm for a badge insight that returns a message with the count of related To Do entries uses a different color option if there are more than 10 related records. To do this, the algorithm can return a severity number and then the configuration user can define the override color option for this severity number.

User Actions

The list and card insights support the definition of user actions that may be presented as buttons when displaying the insight. The actions may do one or more of the following:

- Perform algorithm logic. One or more user action algorithms may be associated with an action button. This should be used to perform server logic that does not require any user interaction. For example, you can provide an action to update the status of a record related to the insight. These algorithms are configured on the Insight Type.

- Navigate to another page. For this type of action, the insight algorithm must provide the navigation context and the navigation option to launch when clicking the button. It's possible to configure navigation and configure user action algorithms. In that case the algorithms are run first and then the navigation occurs.
- Launch a BPA. This is used if there is user interaction needed to perform additional logic and / or if there is conditional navigation such that the logic is needed before navigating. It's possible to configure a BPA and configure user action algorithms. In that case the algorithms are run first and then the BPA is launched. If the insight algorithm also provides navigation for this action, it is ignored in favor of the BPA. The BPA is configured on the Insight Type.

The list of valid actions to display at run time must be returned by the insight algorithm. This allows for the algorithm to have control over which actions to display, in case there are some actions that are conditional. In addition, each possible button requires configuration related to what text should display and the style of the button.

Button Text

The button text to display is chosen from a button text lookup. The lookup name is **INSIGHT_ACT_FLD_FLG**. Implementations may add additional values to this lookup to include new button text. In addition, if you would like to change button text on any product delivered button, you can override the lookup value description.

Action Class

Each action button defines an action class. Any action configured with the action class value of **Positive** value is shown first and is styled differently for emphasis. Other action class values are for information purposes.

Base Delivered Insight Types

Insight types are system data and your product may already deliver several insight types out of the box. You may choose to include one or more insight types in an [Insight Group](#).

Rendering an Insight

To render an insight for an insight type, you would include the ou-insights web component in a UI map that references this insight type. This is how the Insight Preview section of the insight type maintenance page renders the preview.

Note: Refer to [Include a Web Component](#) for more information.

Defining Insight Types

The insight type entity is used to define the configuration of a specific type of alert to display extra information related to one or more records in context. Refer to [Insight Types](#) for a detailed description of the supported functionality.

To view or maintain insight types, open **Admin > General > Insight Type**.

This is a standard [All-in-One portal](#).

The information captured on the insight type depends on the record's business object. Refer to the embedded help text for more information.

Related Insight Groups

If there are any insight groups that reference this insight type, the **Related Insight Groups** zone displays the linked insight groups.

Insight Groups

An insight group may be used to include several [insight types](#) together onto a single map. When defining an insight group, you configure the visual structures that the insight group should include. Only insight types for the configured visual structure are available.

Insight Class

Each insight group must reference a unique insight class. The insight class is defined using a lookup. The lookup field is **INSIGHT_CLASS_FLG**. Your product may already deliver base values for insight class. To display insights in a user interface your UI map would include the ou-insights web component. This component includes syntax to reference an insight class and the logic will find the insight group for that class and render all the insight types linked to that group.

Because the insight class is used as the reference in the web component rather than the insight group, it allows your product to supply base logic to show insight group information in a base delivered user interface. The base logic defines an insight class in base and references it on a base UI map. Your implementation can then define the insight group for this insight class and choose the insight types that should be rendered in that map. Refer to your specific product documentation to find out if there are any base delivered insight classes.

If your implementation identifies a new use case where one or more insight types should be displayed, once the insight types are configured, do the following:

- Define a new Insight Class lookup value.
- Define an Insight Group that references this insight class and configure the appropriate insight types.
- Include the appropriate [web component](#) in the map for your user interface where you wish to display this information.

Defining Insight Groups

The insight group entity allows implementations to define multiple related insight types that should be displayed together in a given user interface map or zone. Refer to [Insight Groups](#) for an overview of insight group configuration and functionality.

To view or maintain insight groups, open **Admin > General > Insight Group**.

This is a standard [All-in-One portal](#).

The information captured on the insight group depends on the record's business object. Refer to the embedded help text for more information.

Related Insight Types

The **Related Insight Types** zone displays all the insight types that are currently linked to the group. The Edit link in the zone header allows you to add or remove insight types. Only insight types that reference one of the **Valid Visual Structures** may be selected.

Color Configuration

The topics in this section describe some options for configuring colors to be used in displaying information in the user interface.

Defining Colors

The system provides the [extendable lookup](#) Color (**F1-Color**) to define valid colors to be used in the system. The base colors provided are ones related to the standard color palette used in Oracle products.

At this time, zones and UI maps that define specific colors do not support any syntax to reference a color extendable lookup. In the meantime, colors applied at the zone or map level can still reference HTML colors or reference hex codes directly.

Color Options

The color option entity is used to define a combination of colors to be used in user interface components. The system provides a standard set of color options used for contextual insights.

To view or maintain color options, open **Admin > System > Color Option**.

This is a standard [All-in-One portal](#).

The information captured on the color option depends on the record's business object. Refer to the embedded help text for more information.

Defining Display Icons

Icons are used to assist users in identifying different types of objects or instructions. A limited number of control tables allow administrative users to select an icon when they are configuring the system. Select **Admin > System > Display Icon** to maintain the population of icons available for selection. You are brought to a query portal with options for searching for a specific display icon. Once a display icon has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The latest standard is to use Scalable Vector Graphic (SVG) icons. For these types of icons, the Icon Type is **Variable (SVG)**. The product also supports icons in the .gif or .png format. For these types of icons, the Icon Type defines a pixel size.

URL describes where the icon is located (folder) and the icon name (file name).

Note that there is a standard folder structure for delivered assets such as images. The structure is **{DefaultWebApp}/ {owner}/assets/images|svgs/**

- {Owner} - this is the owner of the icon. The /**cm** folder is used for custom icons.
- svgs - all images that are of type svg are in this folder.
- images - all files that have a file suffix of jpg, gif, png or other types of image formats are in this folder.

When using the above folder structure, then the URL only needs to contain the icon name (file name). The correct full URL is determined automatically at runtime. Images can optionally be placed in other folders under the DefaultWebApp. However, this is not recommended but if used, the URL must contain the full path to the icon (e.g. /cm/assets/newImages/myIcon.gif)

Custom Look and Feel Options

The default look and feel of the application can be customized via feature configuration and cascading style sheets. The base product is provided with a **Custom Look And Feel Feature Configuration** type. You may want to set up a feature configuration of this type to define style sheet and UI Map help options.

User Interface

The base product allows for the conditional inclusion of custom style sheets into the system style set. Custom styles may override any style provided by the base product. The style sheet may also include new styles for use in customer zone definitions. Use the **Style Sheet** option on the **Custom Look And Feel Feature Configuration** to define your custom style sheet.

Note: Some styles cannot change if they are part of the HTML code.

CAUTION: Implementers must ensure that the customized user interface is stable and scalable. Changing font, alignment padding, border size, and other user interface parameters may cause presentation problems, like scrollbars appearing or disappearing, cursors not working as expected, and unanticipated look and feel alterations of some layouts.

UI Map Help

A **tool tip** can be used to display additional help information to the user. This applies to section elements as well as individual elements on a map zone or UI Map. Refer to the tips context sensitive zone associated with the UI Map page for more information. The **Custom Look And Feel Feature Configuration** provides options to control the following:

- Whether UI Map Help functionality is turned on or off. By default it is turned on.
- Override the default help image with a custom image
- The location of the help image, either before or after the element.

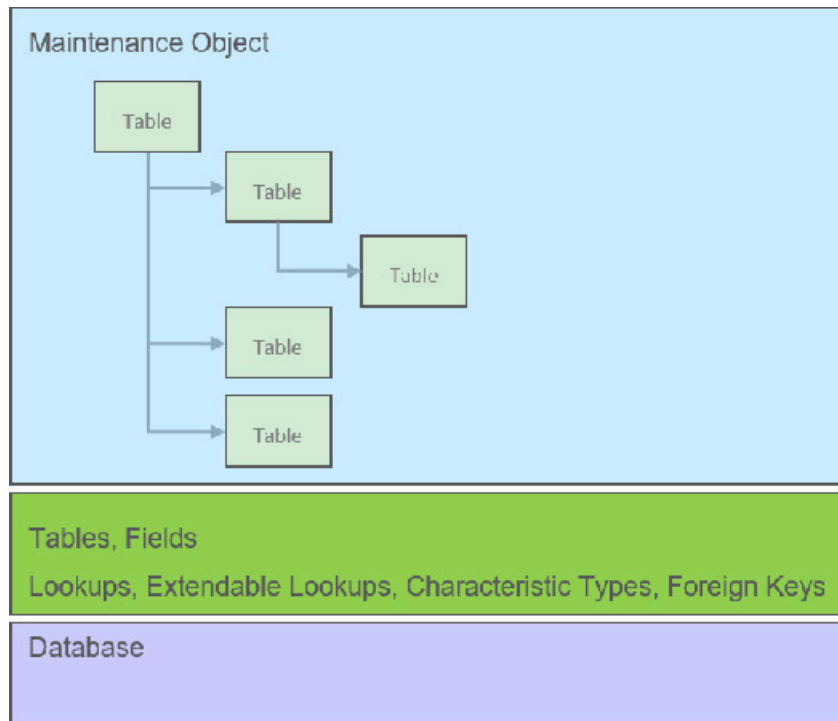

Fastpath: Refer to the feature configuration for a detailed description of each option.

Database Options

This section describes a variety of database tools that are supplied with the your product.

Understanding The Data Model

The application uses meta-data to describe its data model, from plain description of its tables and fields to more complex hierarchies of maintenance objects.

The following points briefly outline key aspects of application's data model as illustrated in this diagram:

- Table and Field records describe all the tables maintained by the application.
- Valid values for certain fields are defined using corresponding Lookup and Extendable Lookup records.
- Characteristic types may be defined to support an extension of a maintenance object via its characteristics table.
- Maintenance Objects define the physical structure of an entity. Business objects further refine maintenance objects to describe business entities. Refer to [The Big Picture of Business Objects](#) for more information.
- Foreign Key References define ways for searching and navigating to the maintenance portal of an entity.

The following sections further discusses concepts and guidelines related to the data model.

Fields

A Field definition describes the metadata needed by the application to support the capture and display of a piece of information. Fields may correspond to physical columns on database tables or represent any type of element used for calculation or presentation purposes.

The definition includes the following key details:

- Whether the field refers to a physical column on a database table or used as a work field.
- The type of data the field holds.
- The label to use when the field is presented.
- The help text to display when the user clicks on the help icon seeking additional information about this field.
- and more

The following sections further discusses concepts and guidelines related to defining fields.

Physical vs. Work Fields

A Field definition record exists for every physical column on a database table that is used by the application. Refer to [Understanding Tables](#) for more information.

A Field that does not represent a physical column on a database table is considered as work field and needs to be marked as such. Work fields are typically used as labels as well as describe internal elements used in business rules.

Data Type Information

The type of data captured by a field is defined using the following attributes:

- **Data Type** indicates the basic type of value the field holds. Valid values are **Character, Character Large Object, Date, DateTime, Number, Time, Varchar2** and **XML Type**.
- **Extended Data Type** is used to further define the type of data for certain data types. Valid values are **Currency Source, Day of Month, Duration, Money, Month of Year, Flag, Switch** and **URI**.
- **Precision** defines the length of the field. In the case of variable length fields, it is the maximum length possible. For number fields that include decimal values, the precision includes the decimal values.
- **Scale** is only applicable for number fields. It indicates the number of decimal places supported by the field.
- **Sign** is only applicable for numbers. It indicates if the data may contain positive or negative numbers.

Data Type Inheritance

A Field can be defined to inherit its data type attributes from the definition of another field. The field to inherit the attributes from is referenced as the **Base Field**. When using a base field reference, the data type attributes are defined once, on the base field, and all the fields inheriting their data type information from it are kept consistent with that definition as it may change over time. Any change of a field's data type attributes is automatically reflected on all the fields that reference it as their base field.

Data type information may either be specified directly on the field itself or by referencing a base field. The system does not support a way to partially override the base field's data type information.

It is recommended to leverage data type inheritance whenever possible, especially when the reason for creating a new field is to provide an alternate label for the original field in a certain context. In that situation the new field should reference the original field as its base field and provide the new labels and help text as needed.

Labels and Help Text

For fields that appear on a user interface, the description acts as a label to be used for presentation purposes. As per the product's multi-language support, a field is associated with a label for each of the languages enabled in the system.

A field's help text may be used to provide the user with additional information on how the field is used. When populated for a field that is visible on a user interface that supports display of embedded help, a help icon appears for the field, presenting the help text to the user when clicked.

Overriding Labels and Help Text

The label and help text provided for a product owned field may be overridden by your organization using the corresponding override fields.

The field's label and help text can be overridden for a specific table by populating the corresponding override information as part of the table / field definition. However, this override is not used in portal based user interfaces. It is only applicable if the field is displayed on fixed page user interfaces. For fixed pages, if the override label at the table / field level takes precedence over the override at the field level.

Alternate Labels

There are contexts where a separate label may be needed for the "date" and "time" parts of a date/time field. Such an example is when the field is used by the operational analytics product. For example, for a "Completion Date/ Time" field you may provide the context label "Creation Date" for the **Date** context and "Creation Time" for the **Time** context. These context labels are optional.

In the same way, date fields, time fields and date/time fields may be associated with a **Date and Time Base** context label, which is a label without a reference to the word "Date", "Time" or "Date / Time". For example, for

a "Completion Date/Time" field, the date and time base label may be "Completion". This label that can be used in combination with date or time attributes such as day, month, year, hours, minutes etc.

Overrides labels are available for these additional context labels.

Tables

A Table definition describes the metadata needed by the application to work with and access a database table or view.

The definition includes the following key details:

- The table's description in the application.
- The list of [fields](#) defined on the table and any foreign key constraints they establish with other tables.
- The table's prime key and how it is generated.
- Whether the table holds administrative, master or transactional data.
- Whether the table is released with product owned system data rows or not.
- The table's role in the conversion process.
- How should table content be upgraded.
- and more

The following sections further discusses concepts and guidelines related to defining tables.

System Tables

Tables released with rows that are owned by the base product are referred to as system tables. These tables include the **Owner** (OWNER_FLG) field to capture the owner of each row.

Refer to [System Data](#) for more information about naming conventions and standards around row record ownership.

The **Upgrade** setting on the table definition record controls what happens to the rows in a table when the system is upgraded to a new release. The most common setting allows customer owned rows to be merged with rows owned by the base product. Other settings may keep the content of the table as is, i.e. rows are not touched by the upgrade, or fully refresh the content of the table with base product rows.

Some fields on certain system owned tables are explicitly marked to allow customization. This means implementation are allowed to change these specific fields for a base owned record. Changes to the field value of one of these types of fields by an implementation are maintained when upgrading to a new version of the product.

Designated Table Roles

Some tables are designed to support the following application roles:

- **Key Tables**
 - A key table holds a copy of a table's prime key only and is only applicable to tables with system generated keys.
 - Tables with a system generated keys reference their Key Table as part of their Table definition record.
 - Records in the key table remain in the system even when the related entity is archived, preventing the same key from being allocated to a new record. Retaining the key allows the system to keep the integrity of any references that may still exist to the archived entity.
- **Language Tables**
 - To support multi-language implementations, all labels and descriptions that are presented to a user are kept in a designated language table where a row exists for each enabled language.
 - The product is released with the English content provided in the various language tables. An additional row is added to these tables for each enabled language along with the translated content for that language. Refer to [Support For Different Languages](#) for more information.
 - Tables associated with language sensitive fields reference their corresponding Language Table as part of their Table definition record.
- **Characteristics Tables**

- Many entities in the system support one or more Characteristics tables, which are used to capture additional fields for the object that are not already supported by the entity's provided attributes.
- A Characteristics table is designed to capture characteristics applicable to its specific entity only. The entity associated with a Characteristics table is referenced on the Table's definition record.
- Refer to [Setting Up Characteristic Types & Values](#) for more information.
- **Entity Log Tables**
 - Many entities in the system support the ability to capture lifecycle and other important business events on a designated log table.
 - A log table captures the event details in the form of an application message and stores any parameters for the message in a child log parameters table. All log and log parameters tables follow a predefined structure allowing them to be consistently and efficiently implemented.
 - Typically log tables do not participate in the conversion process.

Table Constraints

Foreign key relationships between tables are not enforced at the database level but rather at the application level, providing the application more flexibility around data manipulation and referential integrity.

The following types of constraints may be defined on the Table's definition record:

- **Primary Key** represents the field or set of fields that represent the unique identifier of a record stored in a table.
- **Logical Key** represents an alternate unique identifier of a record based on a different set of fields than the Primary key.
- **Foreign Key** represents a field or set of fields that specifies identifying and non-identifying relationships to other tables in the application. A foreign key constraint references the primary key constraint of another table.
- **Conditional Foreign Key** represents rare relationships between tables where a single field (or set of fields) may reference multiple primary key constraints of other tables within the application as a foreign key.

The system leverages a table's foreign key constraints information to performs referential integrity validation when rows in this table are deleted. These validations can be disabled by checking off the **Enable Referential Integrity** field on the Table definition record.

Table Indexes

The indexes delivered by the base product for a given table are visible in the index metadata. In addition, table index information may be defined as part of the cloud services support for generation of custom tables in certain use cases. Refer to the section [Generating Custom Tables](#) below for more information.

Primary Key Type

A table's primary key may be of the following types:

- **User-defined** means the user specifies the key when a record is added. This type of key is typically used for configuration and administrative tables.
- **System-generated** means a program generates a random numeric key for the record when it is added.
 - This type of table is typically associated with a key table. Refer to the **Designated Table Roles** section for more information.
 - System generated keys may be fully random or partially inherited from a parent table's key for performance reasons. Refer to the **System Generated Keys** for more information.
- **Sequential** means a sequence number is incremented whenever a record is added to the table. The next number in the sequence determines the key value.
- **Database Native Sequential Key** means a unique number is assigned using a database sequence object.
- **Other** means some other business rule allocates the table's prime-key or the prime key is made of multiple parts.

System Generated Keys

In general, randomly generated numeric system keys are used to attempt to evenly distribute records across a full range of possible IDs. Batch programs that use multiple threads will typically divide the threads using ID ranges and evenly distributed keys will help spread out the work across these threads.

If a table using a system generated key is a child of another table, the child table's key may **inherit** a portion of the random number from its parent table's key. Key inheritance for child records further extends the performance benefit. When considering partitioning, the recommendation for DBAs is to range partition data based on the primary key so that different batch threads operate on different partitions which reduces contention for hot blocks. Ideally the number of batch threads will be an exact multiple of the number of partitions. Batch programs that insert child data (for example batch Billing creation) also benefit from this design especially when the child tables are partitioned in the same way. The parent is often the driver of the batch process. If this is multi-threaded, then each thread is processing a set of parent records in a given ID range and all child records are being inserted into the same ID range.

While most entities with system generated keys either use fully random keys or partially inherited keys from a single parent, entities may be designed to implement more specific key generation rules.

When key inheritance is used, the table definition of the child table defines the following information:

- The number of most significant digits from the parent record's primary key to use as the **prefix** for the child record's key value.
- The **parent key field name** to inherit the key from. This information is provided for display and documentation purposes only and is only provided when the inheritance rule implemented by the entity may be documented this way. Typically the child key value is inherited from a single parent key but in some cases the inheritance rule may be more complex. For example, different types of records in the same child table may inherit their key from different parent key fields. In this case, multiple parent field names may be listed to describe the various inheritance options. When the rule is too complex, this information may not be provided on the table definition record.

Conversion Options

The conversion process manages the process by which master and transaction legacy data, loaded into a staging schema, is validated and assigned new system generated keys before it is copied to the production schema. Refer to [Understanding The Conversion Process](#) for more information.

The tool classifies tables into the following roles:

- Administrative tables. These only exist in the production schema. Instead of a table, a view to the production table exists in the staging schema. These views are necessary to enforce foreign key references when data is validated in the staging schema
- Convertible tables that retain their prime keys. Data conversion is supported for these tables and their prime key values remain unchanged.
- Convertible tables that require a new system generated key to be assigned. Data conversion is supported for these tables and their prime key is reassigned by the system during conversion.
- Not convertible tables. Assigning new system generated keys for a record and replacing all foreign key references it might have with the new key is a complicated process that may not be supported for all tables.

. The **Data Conversion Role** setting on the table definition record controls if / how the table is used by conversion processing.

Date/Time Configuration

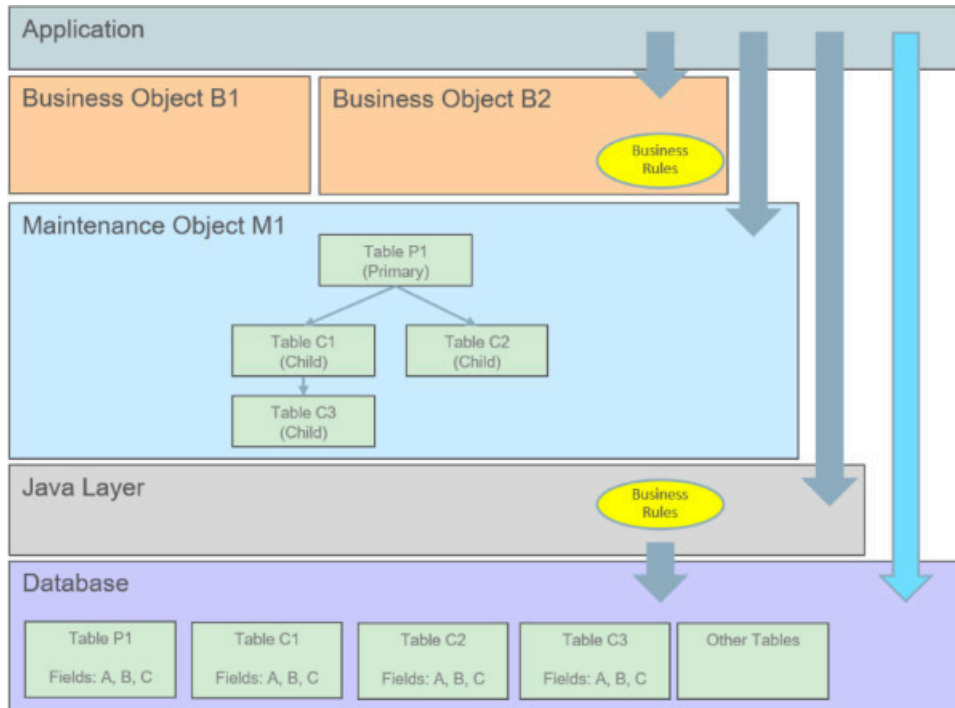

Fields capturing date/time information may be designed to store data in either local legal time or local standard time. Local legal time is captured as entered and displayed as captured in the database. It also assumes the date/time information refers to the time zone defined on the installation options. Refer to [Standard vs. Legal](#) for more information.

Generating Custom Tables

For cloud customers and for certain use cases, the product supports defining table metadata for custom tables and generating the related DDLs for that metadata in the database. For these custom tables, there is a Generation Status visible on the Table metadata that identifies where the Table is in the lifecycle for this supported feature. In addition, the index tab on the table portal is used to define custom indexes that are included in the DDL as part of this feature. If you are a cloud customer and would like more information, refer to the Cloud Services Implementation Guide.

Maintenance Objects

A maintenance object defines the configuration of a given “entity” in the system. It includes a primary table and any additional child tables that together capture the physical data for the entity. The application reads, adds, updates and deletes an entity as a single object by invoking its maintenance object service.

The following points briefly outline key aspects of application’s interaction with maintenance objects as illustrated in this diagram:

- Database tables are maintained solely via the application’s Java layer. Direct updates to a table via its Java class is not common and typically reserved to special processes.
- A maintenance object orchestrates the update to an entity’s primary table and its child tables as a single object.
- A business object defines a logical representation of an entity, including all or a subset of the maintenance object’s tables and fields.
- The more common way to maintain an entity is via its maintenance object, either directly or via one of its business objects. Most entities support the use of business objects and as such their maintenance is typically made via their business objects.
- Direct access to database tables is supported for query purposes only.

The following sections further discusses concepts and guidelines related to defining tables.

Maintaining An Entire Object

A maintenance object includes a single primary table and one or more child tables where each child table can further have nested child tables. The table structure of a maintenance object represents the scope of data that should be maintained together as a single object:

- When an object is added, data is added to each corresponding table.

- When an object is updated, data is updated in each corresponding table.
- When an object is read, data is retrieved from all the tables.
- When an object is deleted, data is deleted from all the tables.

Algorithms

Several algorithm plug-in spots are also defined on the maintenance object, allowing for business rules that govern all records for this maintenance object.

Options

The maintenance object includes options that define important information related to the maintenance object that may be accessed for logic throughout the system.

Maintenance Objects vs. Business Objects

A maintenance object defines the physical structure of an entity as stored in the database. Different business objects may be defined on top of a maintenance object to represent different types of such entity. A business object includes only the relevant information applicable to the specific type of entity as well as enforces business rules applicable only to that type.

When a maintenance object supports business object configuration, the system uses the **Determine Business Object** maintenance object algorithm to determine the identifying business object that controls a given entity's data structure and rules.

Refer to [The Big Picture of Business Objects](#) for more information.

Defining Valid Values

The product provides several options for defining valid values for a column on a table:

- Lookup
- Extendable Lookup
- Control Table

The following provides more information about the functionality of each of the options available for defining valid values for a column.

Lookup

The simplest mechanism for defining valid values for a column on a table is via the Lookup table. This is sometimes referred to as a “simple” lookup to distinguish it from an extendable lookup (described below). Using the lookup table, you can define valid values and their descriptions. When choosing a valid value that is defined by a lookup, a dropdown UI metaphor is used.

The following highlights functionality related to lookups:

- Lookups are associated with a **Field**. The field is defined as a character data type with an extended data type of **Flag**. The field's label serves as the description for the prompt to select the valid value.
- The lookup code is limited to four characters and must be all uppercase. If there is any functionality where a valid value in the application must match valid values in an external system, the lookup table may not be the appropriate choice.
- The lookup table does not support additional attributes to be defined for each value. This option is only appropriate when a simple code and description pair is needed.
- The product may also use Lookups to define valid values for functionality unrelated to a column on a table. For example, an algorithm plug-in spot may define an input parameter that supports one or more valid values. The plug-in spot may define the valid values using a lookup, allowing for a simple way to validate the value supplied when invoking the algorithm and to document the valid values.

Fastpath: For more information, refer to [Defining Lookup Options](#).

Extendable Lookup

The extendable lookup provides a way of defining valid values for a column with additional capabilities that are not supported using the Lookup table. When choosing a valid value that is defined by an extendable lookup, a dropdown UI metaphor is used.

The following highlights functionality related to extendable lookups:

- Each Extendable Lookups is defined using a business object.
- A field should be defined for the extendable lookup code. The field defines the label for the lookup code and defines the size of the lookup code. The size is determined based on the business use case. In addition, there are standard fields included in all extendable lookups, including a description, detailed description and an override description (so that implementations can override the description of base delivered values).
- The extendable lookup may define additional information for each value if warranted by the business requirement. See [Additional Attributes](#) for technical information about additional attributes.

Fastpath: For more information, refer to [Defining Extendable Lookups](#).

Control Table

There may be scenarios where a list of valid values warrants a standalone maintenance object, which is considered an administrative or control table object. When choosing a valid value that is defined by a control, either a dropdown UI metaphor or a search metaphor is used, depending on how it has been designed.

The following points highlight some reasons why this option may be chosen:

- The records require a lifecycle such that BO status is warranted.
- The additional attributes are sophisticated enough that they warrant their own column definition rather than relying on using CLOB or flattened characteristic. For example, if a list of information needs to be captured with several attributes in the list and the information in the list needs to be searchable.

In this situation, if a product has provided a control table for this type of functionality, it will be documented fully in the appropriate functional area. If an implementation determines that a custom control table is warranted, all the standard functionality for a maintenance object is required: database tables, maintenance object metadata, appropriate Java maintenance classes, portals, zones, etc. Refer to the Software Development Kit for more information. No further information is provided in this section for this option.

Characteristic Types

Many maintenance objects in the system support characteristics tables, which are used to capture additional fields for the object that are not already supported by the object's provided attributes. Each characteristic is associated with a characteristic type, which defines attributes of the field you wish to capture.

While each characteristic is stored in a separate row in the characteristic table, the user interface metaphor used to capture and display them differ based on the type of page that is used to maintain the object.

- For portal based pages, the business object drives the display and maintenance of the object. The display and maintenance of each characteristic is determined by the business object's user interface design. For these types of pages, it is recommended that characteristics are defined as flattened elements allowing the user interface to display the characteristic as if it is another field. Refer to [The Flattening Nodes and Attributes](#) for more information about flattening characteristics on a business object schema.
- There are some fixed pages in the system that do not support customization of the user interface. For these objects, the characteristics are displayed / maintained as a generic list.

The topics in this section describe various aspects of a characteristic type definition and usage.

Characteristic Value Types

Every characteristic referenced on an object references a characteristic type. The characteristic type controls the validity of the information entered by a user when they enter the characteristic's values. For example, if you have a

characteristic type on user called "skill", the information you setup on this characteristic type controls the valid values that may be specified by a user when defining another user's skill.

When you setup a characteristic type, you must classify it as one of the following categories:

- **Predefined Value.** When you setup a characteristic of this type, you define the individual valid values that may be entered by a user. A good example of such a characteristic type would be one on User to define one or more predefined skills for that user. The valid values for this characteristic type would be defined in a discreet list.
- **Ad hoc Value.** Characteristics of this type do not have their valid values defined in a discreet list because the possible values are infinite. Good examples of such a characteristic type would be ones used to define a user's birth date or their mother's maiden name. Optionally, you can plug-in an algorithm on such a characteristic type to validate the value entered by the user. For example, you can plug-in an algorithm on a characteristic type to ensure the value entered is a date.
- **Foreign Key Value.** Characteristics of this type have their valid values defined in another table. For example perhaps you want to link a user to a table where User is not already a foreign key. Valid values for this type of characteristic would be defined on the user table. Before you can create a characteristic of this type, information about the table that contains the valid values must be defined on the [foreign key reference table](#).
- **File Location.** Characteristics of this type contain a URL. The URL can point to a file or any web site. Characteristics of this type might be useful to hold references to documentation / images associated with a given entity. For example, the image of a letter sent to you by one of your customers could be referenced as a file location characteristic on a customer contact entry. When such a characteristic is defined on an entity, a button can be used to open the URL in a separate browser window.

File location characteristic values must be entered in a "non-relative" format. For example, if you want to define a characteristic value of *www.msn.com*, enter the characteristic value as `http://www.msn.com`. If you omit the `http://` prefix, the system will suffix the characteristic value to the current URL in your browser and attempt to navigate to this location when the launch button is pressed. This may or may not be the desired result.

Note:

Due to browser security restrictions, opening URLs using the file protocol ("file:///") from pages retrieved using http does not work. If the file protocol is used, the browser either does not return properly or an error is thrown (e.g., "Access Denied", which usually results from cross site scripting features added for security reasons). This issue has no known workaround. To comply with browser security standards, the recommendation is to move the target files to an FTP or HTTP server location to avoid protocols that are subject to browser security restrictions.

Also note that the functionality described in the topics for [Referencing URIs](#) do not apply to this value given that the browser is responsible for connecting to the URI and does not go via server logic.

For references to a file, the recommendation is to use the Attachment functionality to link a file to an object rather than a characteristic type of File Location. Refer to [Attachment Overview](#) for more information. The documentation related to file location remains for upgrade purposes.

Searching By Characteristic Values

For certain entities in the system that have characteristics, you may search for a record linked to a given characteristic value. The search may be done in one of the following ways:

- Some base searches provide an option to search for an object by entering Characteristic Type and Characteristic Value.
- Your implementation may define a customized search for an entity by a characteristic value for a specific characteristic type using a query data explorer.
- Your implementation may require a business service to find a record via a given characteristic value. For example, maybe an upload of user information attempts to find the user via an Employee ID, defined as a characteristic.

Not all entities that support characteristics support searching by characteristics. To confirm if a given characteristic table supports searching, verify that it includes the field `SRCH_CHAR_VAL`.

CAUTION: For ad-hoc characteristics, only the first 50 bytes are searchable. For foreign key characteristics, the search value is populated by concatenating the values of each foreign key column to a maximum of 50 bytes.

For the base searches that provide a generic option to search by characteristic type and value, you can restrict the characteristic types that can be used to search for an entity. For example, imagine you use a characteristic to define a "jurisdiction" associated with a To Do for reporting purposes. If your company operates within a very small number of jurisdictions, you wouldn't want to allow searching for a To Do by jurisdiction, as a large number of To Do entries would be returned.

A flag on the [characteristic type](#) allows an administrator to indicate if searching by this characteristic type is **allowed** or **not allowed**.

Data Typing an Ad-hoc Characteristic Value

An **Ad hoc Value** characteristic type may further restrict the data type of the captured value by referencing a Field. When populated, the system validates that the captured characteristic value complies with the data type definition of the referenced field.

Valid Characteristic Entities

Characteristics are stored in designated tables, each associated with a unique characteristic entity value referenced on the table definition record. A characteristic type record lists all the valid characteristic entities it is allowed to be captured on.

Customizing Base Owned Characteristic Types

Implementations may customize the following aspects of a base owned characteristic type:

- Extend the list of valid values for a base owned **Predefined Value** characteristic type to include additional custom values. Such extension is only supported if the characteristic type is defined with the **Custom** option turned on.
- Provide a custom algorithm to validate an **Ad hoc Value** characteristic type.
- Indicate whether characteristics of this type may be used in searches.
- Extend the list of entities associated with the characteristic type.

Foreign Key References

A Foreign Key Reference defines the necessary information needed to reference an entity in a certain table.

You need to set up this control table if you need to validate a foreign key value against a corresponding table. For example, if a schema element is associated with an FK Reference the system validates the element's value against the corresponding table. Refer to [Configuration Tools](#) to learn more about schema-based objects. Another example is characteristics whose valid values are defined in another table (i.e., you use "foreign key reference" characteristic types). Refer to [Characteristic Types](#) for a description of characteristics of this type.

A FK Reference is used not just for validation purposes. It also used to display the standard information description of the reference entity as well as provide navigation information to its maintenance transaction. Info descriptions appear throughout the UI, for example, whenever an account is displayed on a page, a description of the account appears. The product provides base product FK references for many of its entities as they are used for validation and display of elements in both fixed page user interfaces as well as portal based user interfaces.

An implementation may also see the need to define a foreign key reference. The following points describe what you should know before you can setup a foreign key reference for a table.

- The physical name of the table. Typically this is the primary table of a maintenance object.
- The program used by default to construct the referenced entity's info description.
- The transaction used to maintain the referenced entity. This is where the user navigates to when using the "go to" button or hyperlink associated with the entity.
- The name of the search page or zone used to look for a valid entity.

The topics in this section describe various aspects of a foreign key reference definition and usage.

Information Description Is Dynamically Derived

Typically a FK Reference is defined for a maintenance object's primary table. In this case the system dynamically derives the standard information associated with a specific referenced entity as follows:

- Attempt to determine the business object associated with the referenced entity. Refer to the [Determine BO](#) maintenance object algorithm system event for more information. If a business object has been determined, the system lets the business object's [Information](#) plug-in, if any, format the description.
- If a business object has not been determined or the business object has no such plug-in, the system lets the maintenance object's [information](#) plug-in, if any, format the description.
- If the maintenance object has no such plug-in, the system uses the info program specified on the FK Reference to format the information.

Note: Technical note. The class that returns the information displayed adjacent to the referenced entity is generated specifically for use as an info routine. Please speak to your support group if you need to generate such a class.

Note: Generic routine. The system provides a generic information routine that returns the description of control table objects from its associated language table. By "control table" we mean a table with an associated language table that contains a **DESCR** field. Refer to [Defining Table Options](#) for more information on tables and fields. The java class is `com.splwg.base.domain.common.foreignKeyReference.DescriptionRetriever`.

Navigation Information Is Dynamically Derived

Typically a FK Reference is defined for a maintenance object's primary table. In this case the system dynamically derives the actual transaction to navigate to for a given referenced entity as follows:

- Attempt to determine the business object associated with the referenced entity. Refer to the [Determine BO](#) maintenance object algorithm system event for more information. If a business object has been determined, use the maintenance portal defined as its **Portal Navigation Option** business object option.
- If a business object has not been determined or the business object defines no such option, the system uses the transaction specified on the FK Reference.

Search Options

The product provides two main metaphors for implementing a user interface. For input fields that are foreign keys, search options are dependent on the metaphor used by the page in question.

- A [portal based](#) user interface is a more flexible user interface where an implementation has more options for customizing the look and feel. The base product uses UI maps or automatic UI rendering to display input fields. Elements that are foreign keys may display a search icon if the FK reference defines a Search Zone.
 - **Note: Defining search zones directly.** It's possible for elements on a UI map to define a specific search zone directly in the HTML, rather than using the search zone defined on an FK reference. Refer to the UI map tips for more information on implementing searches using zones.
- A [fixed maintenance page](#) user interface is a page supplied by the base product where only minor enhancements, if any, can be introduced by implementations. The foreign key reference may be used in one of two ways.
 - The based product may use an FK reference to define a base element on one of these pages. If a search is available for such elements, the FK reference's Search Navigation Key is used to implement the search.
 - Entities that support characteristics typically include a generic characteristic collection UI metaphor on these types of pages. In this metaphor, a foreign key characteristic displays a search icon if the FK Reference has configured a Search Navigation Key.

Note: Not every FK reference provided with the product is configured with a search option. This may be the case if the base delivered pages use a dropdown for this foreign key rather than a search. In addition, base provided FK references that do provide a search may not be configured with both search options. It means that if linking this type of object as a characteristic, the search may not be available if the appropriate search is not configured.

Defining Tables

This portal is used to view and maintain information about an application table.

You can access the portal from the **Admin Menu > Database > Table**. You are brought to a query portal with options for searching for a specific table. Once a table has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Tables](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Table.** This zone provides information about the selected table.
- **Fields.** This zone lists all fields of the selected table and provides various actions to maintain this information.

The following zones may appear as part of the portal's **Relationship** tab page

- **Entity Relationship Diagram.** This zone provides a visual representation of the table's relationship to other tables in the application's data model.

The following zones may appear as part of the portal's **Constraints** tab page

- **Table Constraints.** This zone lists the various key constraints defined for the selected table and provides various actions to maintain this information.
- **Referred By Constraints.** This zone lists all tables referring to the selected table via foreign key constraints.

Refer to [Tables](#) for more information.

The following zones may appear as part of the portal's **Indexes** tab page

- **Table Indexes.** This zone lists the indexes defined for the selected table and provides various actions to maintain this information.

Refer to [Tables](#) for more information.

Defining Fields

This portal is used to view and maintain information about a field. For product owned fields, you may use this portal to override the label of a field on the various pages in the system.

You can access the portal from the **Admin Menu > Database > Field**. You are brought to a query portal with options for searching for a specific field. Once a field has been selected you are brought to the maintenance portal to view and maintain the selected record.

Note: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Refer to [Fields](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Field.** This zone provides information about the selected field.
- **Tables Using Field.** This zone lists tables referencing the field. It is not visible for work fields.
- **Lookup Values.** This zone lists and maintains valid values for the selected lookup field. The zone is only visible when the selected field is a lookup field.

The following zone may appear as part of the portal's **References** tab page

- **Field References.** This zone list various configuration entities referencing the current field.

Defining Maintenance Objects

A maintenance object defines the configuration of a given “entity” in the system. It includes the definition of the tables that together capture the physical data for the entity. In addition, the maintenance object includes options that define important information related to the maintenance object that may be accessed for logic throughout the system. Several algorithm plug-in spots are also defined on the maintenance object, allowing for business rules that govern all records for this maintenance object.

Many maintenance objects in the system support the use of business objects to further define configuration and business rules for a given record. Refer to [Maintenance Objects](#) for more information.

Maintenance Object - Main

Navigate to **Admin > Database > Maintenance Object** to view information about a maintenance object.

Use the **Maintenance Object Query** portal to search for an existing maintenance object. Once a maintenance object is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Most maintenance objects are provided with the base package. An implementation can introduce custom maintenance objects when needed. Most fields may not be changed if owned by the base package.

Enter a unique **Maintenance Object** name and **Description**. **Owner** indicates if this business object is owned by the base package or by your implementation (**Customer Modification**).

Important: If you introduce a new maintenance object, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Service Name is the name of the internal service associated with the maintenance object.

The grid displays the following for each table defined under the maintenance object:

- **Table** is the name of a given table maintained as part of the maintenance object.
- **Table Role** defines the table's place in the maintenance object hierarchy. Only one **Primary** table may be specified within a maintenance object, but the maintenance object may contain many **Child** tables.
- **Parent Constraint ID** specifies the [constraint](#) used to link the table to its parent table within the maintenance object table hierarchy.
- **Owner** indicates if this is owned by the base package or by your implementation (**Customer Modification**).

Maintenance Object - Options

Use this page to maintain a maintenance object's options. Open this page using **Admin > Database > Maintenance Object** and then navigate to the **Options** tab.

Description of Page

The options grid allows you to configure the maintenance object to support extensible options.

Select the **Option Type** drop-down to define its **Value**. **Detailed Description** may display additional information on the option type.

Set the **Sequence** to **1** unless the option can have more than one value.

Owner indicates if this is owned by the base package or by your implementation (**Customer Modification**).

Note: You can add new option types. Your implementation may want to add additional maintenance option types. For example, your implementation may have plug-in driven logic that would benefit from a new type of option. To do that, add your new values to the customizable lookup field **MAINT_OBJ_OPT_FLG**.

Maintenance Object - Algorithms

Use this page to maintain a maintenance object's algorithms. Open this page using **Admin > Database > Maintenance Object** and then navigate to the **Algorithms** tab.

Description of Page

The **Algorithms** grid contains algorithms that control important functions for instances of this maintenance object. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

- If the algorithm is implemented as a script, a link to the **Script** is provided. Refer to [Plug-in Scripts](#) for more information.
- **Owner** indicates if this is owned by the base package or by your implementation (**Customer Modification**).

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|------------------------|----------------------------|---|
| Audit | Optional | Algorithms of this type are called to notify of any changes to the maintenance object's set of tables. These algorithms are invoked just before the commit at the end of a logical transaction. The system keeps track of what records are added or changed in the course of a transaction and all MO audit algorithms are executed in order of when each record was first added or updated. |
| Determine BO | Optional | <p>Algorithm of this type is used to determine the Business Object associated with an instance of the maintenance object. It is necessary to plug in such an algorithm on a Maintenance Object to enable the business object rules functionality.</p> <p>The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number.</p> |
| ILM Eligibility | Optional | <p>Algorithms of this type are used for maintenance objects that are enabled for object erasure for Information Lifecycle Management. They are used to review records that have reached the maximum retention days and evaluate if they are ready to be archived.</p> <p>The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number.</p> |

| System Event | Optional / Required | Description |
|--------------------------------|---------------------|--|
| Information | Optional | <p>We use the term "Maintenance Object Information" to describe the basic information that appears throughout the system to describe an instance of the maintenance object. The data that appears in this information description is constructed using this algorithm.</p> <p>The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number.</p> |
| Manage Erasure Schedule | Optional | <p>Algorithms of this type are used for maintenance objects that are enabled for object erasure, which is a measure to protect Data Privacy. They are triggered when certain system events occur for those objects. The algorithms are used to determine if the record needs to be scheduled for erasure and, if so, create or maintain an entry for the record in the Object Erasure Schedule.</p> |
| Revision Control | Optional | <p>An algorithm of this type is used to enforce revision control rules when an object is added, changed, or deleted. The maintenance object service calls the plug-in once before the object is processed and once more after applying all business object rules. This allows revision rules to take place in proper revision timings.</p> |
| Transition | Optional | <p>The system calls algorithms of this type upon each successful state transition of a business object as well as when it is first created. These are typically used to record the transition on the maintenance object's log.</p> <p>Note that most base maintenance objects are already shipped with an automatic logging of state transitions. In this case you may use these algorithms to override the base logging functionality with your own. Refer to State Transitions are Audited for more information.</p> |

| System Event | Optional / Required | Description |
|-------------------------|---------------------|--|
| Transition Error | Optional | <p>The system calls this type of algorithm when a state transition fails and the business object should be saved in its latest successful state. The algorithm is responsible for logging the transition error somewhere, typically on the maintenance object's log.</p> <p>Notice that in this case, the caller does NOT get an error back but rather the call ends successfully and the exception is recorded somewhere, as per the plug-in logic.</p> <p>The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number.</p> |

Note: You can inactivate algorithms on Maintenance Objects. Your implementation may want to inactivate one or more algorithms plugged into the base maintenance object. To do that, go to the options grid on Maintenance Object - Options and add a new option, setting the option type to **Inactive Algorithm** and setting the option value to the algorithm code.

Maintenance Object - Maintenance Object Tree

You can navigate to the **Maintenance Object Tree** to see an overview of the tables and table relationships associated with the maintenance objects.

Description of Page

This page is dedicated to a [tree](#) that shows the maintenance object's tables as well as [business objects](#), if you have defined any. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Defining Lookups

Lookup fields may be used to define valid values for a column in a table or for other types of values like parameters to an algorithm. This portal is used to view and maintain information about a lookup field and its values. Note that all lookup information is also maintained as part of the corresponding Field portal.

You can access the portal from the **Admin Menu > Database > Lookup**. You are brought to a query portal with options for searching for a specific lookup field. Once a field has been selected you are brought to the maintenance portal to view and maintain the selected record.

Fastpath: Refer to [Defining Valid Values](#) for some background information.

Note: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Lookup.** This zone provides information about the selected lookup field.
- **Lookup Values.** This zone lists and maintains valid values for the selected lookup field.

The base product provides many different lookup fields and their values as part of the product. The following points highlight some functionality related to base-package lookups.

- Fields that are owned by the product will typically provide base lookup values. Implementations are not permitted to remove base delivered lookup values. Implementations may be able to add custom values to base owned lookups. This is controlled with the Custom switch on lookup.
 - When the custom switch is unchecked, it means that there is functionality controlled by the base values and an implementation may not extend or customize this functionality. An example of this type of lookup is the Data Type field on the [Field](#) table. The system supports a distinct list of data types and an implementation may not add additional values.
 - When the custom switch is checked, it means that there is base functionality supplied for the base values but that an implementation can extend the functionality by supplying their own values. An example of this type of lookup is the Access Mode on [Application Service](#). The product provides many values for the access mode lookup, representing various actions a user may perform. Implementations may add their own values to this lookup. Documentation should indicate when functionality may be extended and should highlight the lookup value that can be extended.

CAUTION: Important! If you introduce new lookup values, you must prefix the lookup value code with **X** or **Y**. If you do not do this, there is a possibility that a future release of the application could introduce a new lookup value with the name you allocated.

- There may be some scenarios where the product supplies a base field and base lookup field with no base lookup values supplied. This occurs when the product doesn't have any base functionality driven by the lookup values. Typically this type of lookup is for information or categorization purposes. The configuration guide for the functional area associated with the lookup should include a configuration step regarding defining values for this type of lookup.
- The description of base delivered values may be overridden by an implementation.

An implementation may also identify the need for defining a new lookup field with its values.

Defining Extendable Lookups

Extendable lookups are a way of defining valid values that are more sophisticated than simple lookups.

Fastpath: Refer to [Defining Valid Values](#) for some background information.

The base product provides extendable lookups as part of the product. The following points highlight some functionality related to base-package extendable lookups.

- The base product may supply base extendable lookup values. Implementations are not permitted to remove base delivered extendable lookup values. It is also possible that implementations may be able to add custom values to base owned lookups. If an implementation is not permitted to add lookup values to the base extendable lookup, the extendable lookup's business object will include validation to prevent this. There is no equivalent of the Custom switch that is on the [lookup](#) field.
- There may be some scenarios where the product supplies a base extendable lookup with no base lookup values supplied. This occurs when the product doesn't have any base functionality driven by the extendable lookup values. The configuration guide for the functional area associated with the extendable lookup should include a configuration step regarding defining values for this type of extendable lookup.
- The description of base delivered values may be overridden by an implementation.

Open this page using **Admin > General > Extendable Lookup**.

You are brought to the **Extendable Lookup Query** where you need to search for the extendable lookup object (i.e., its business object).

Once you have found the appropriate extendable lookup, select the value and you are brought to a standard [All-in-One](#) portal that lists the existing lookup values for the extendable lookup. The standard actions for an All-in-One portal are available here.

Extendable Lookup Advanced Topics

This section provides some addition technical information about extendable lookup attributes

Defining Additional Attributes

The product provides a few different ways to define additional values for an extendable lookup. Some of the methods are only relevant for base delivered lookup values as they may impact whether or not an implementation can update the values.

The following table highlights the options available and some summary information about what the option provides.

| Option | Brief Description | Extendable Lookup Value Searchable by this Attribute? | Base Delivered Value Modifiable? |
|-------------------------------------|---|---|----------------------------------|
| Element mapped to BO_DATA_AREA | The element is mapped to a CLOB field that allows for base delivered values to be modified. | No | Yes |
| Element mapped to BASE_BO_DATA_AREA | The element is mapped to a CLOB field that does not allow for base delivered values to be modified. | No | No |
| Flattened characteristic | The element is defined using the flattened characteristic mechanism. | Yes | No |

The following points highlight information from the table above:

- The decision of defining an additional attribute using a CLOB mapping or a flattened characteristic will depend on whether the functionality expects that the lookup value is known when the attribute is needed (in which case a CLOB mapping is appropriate) or if the functionality expects to determine the lookup value based on the attribute (in which case, a flattened characteristic is appropriate).
- When the base product defines an extendable lookup with additional attributes and intends to provide base extendable lookup values, it needs to determine whether or not implementations may update the additional attribute or not.
 - If no and the value is mapped to a CLOB, it will map the value to the BASE_BO_DATA_AREA column. This means that implementations will receive an owner mismatch error when attempting to change the value. In addition, upgrading to a new release will replace the value with the base value.
 - If yes and the value is mapped to a CLOB, it will map the value to the BO_DATA_AREA column. This means that implementations will be able to change the value for a base owned record. In addition, upgrading to a new release will not make any changes to the value.
 - For values mapped to a characteristic, the product does not support an implementation changing the value of a base delivered record. If the product would like to support an implementation overriding this type of value, the business object will need to be designed with a corresponding "override" element (also a flattened characteristic), similar to how the product supplies an Override Description field to support an implementation overriding the base product delivered description for a base value. This element will not be delivered with any value and will allow an implementation to populate that value.

Note: Note that in this situation, the product functionality that uses this value must cater for the override value.

- All of this detail is only relevant for base provided extendable lookup values. If an implementation adds custom values for a base supplied extendable lookup, all the additional attributes may be populated as appropriate.
- If an implementation defines a custom extendable lookup business object and wants to define an additional attribute using a CLOB, it doesn't matter which CLOB column is used. Both BO_DATA_AREA and BASE_BO_DATA_AREA provide the same functionality for custom business objects.

Capturing a Password

If an extendable lookup includes configuration of a password for some functionality, the system supports automatic encryption of the password value if the schema maps the password to a characteristic using the characteristic type **F1-PWD**.

Defining Characteristic Types

This portal is used to view and maintain characteristic types. An implementation may define their own characteristic types or override some of the settings for base product provided characteristic types.

You can access the portal from the **Admin Menu > General > Characteristic Type**. You are brought to a query portal with options for searching for a specific record. Once a characteristic type record has been selected you are brought to the maintenance portal to view and maintain the selected record.

Note: When introducing a new record, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Refer to [Characteristic Types](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Characteristic Type.** This zone provides information about the selected characteristic type.
- **Characteristic Values.** This zone is visible for pre-defined characteristic types and shows the existing values (if applicable) with action buttons. It also allows you to add new values. Note that you may only add values to a product owned characteristic type if the Custom switch is checked.

Defining Foreign Key References

The topics in this section describe the transaction that allows you to define foreign key references.

Refer to [Foreign Key References](#) for more information.

To setup a foreign key reference, open **Admin > Database > FK Reference**.

Use the **Foreign Key Reference Query** portal to search for an existing foreign key reference. Once a foreign key reference is selected, you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Important! If you introduce a new foreign key reference, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Description of Page

Enter an easily recognizable **FK** (foreign key) **Reference** code and **Description** for the record.

Enter the name of the **Table** whose primary key is referenced. After selecting a **Table**, the columns in the table's primary key are displayed adjacent to **Table PK Sequence**.

Use **Navigation Option** to define the page to which the user will be transferred when they press the go to button or hyperlink associated with the referenced entity. Refer to [Navigation Information Is Dynamically Derived](#) for more information on how this is used.

The **Info Program Type** indicates whether the default program that returns the standard information description is **Java** or **Java (Converted)**, meaning it was converted into Java.

Note: **Java (Converted)** program types are not applicable to all products.

Use **Info Program Name** to enter the Java class / program name.

Refer to [Information Description Is Dynamically Derived](#) for more information on the info program is used.

View the source. If the program is shipped with the base package, you can use the adjacent button to display the source code of this program in the [Javadocs](#) viewer.

Use **Context Menu Name** to specify the context menu that appears to the left of the value.

Note: Context Menu Name is not applicable to user interface elements displaying a generic collection using a foreign key characteristic type. It is only applicable for pages utilizing the foreign key compound element type for fixed page user interface and for data displayed in a portal based user interface where the foreign key reference is defined as an attribute for an element. Report parameters that reference foreign key characteristics are an example of a user interface where a context menu is not displayed even if the foreign key reference defines one.

Use **Search Zone** to define the search zone that opens when a user searches for valid values when the foreign key reference is configured as an input field on a portal based page. Refer to [Search Options](#) for more information.

Use **Search Navigation Key** to define the search page that will be opened when a user searches for valid values on a user interface that is a fixed page. Refer to [Search Options](#) for more information.

Use **Search Type** to define the default set of search criteria used by the **Search Navigation Key's** search page.

Use **Search Tooltip** to define a label that describes the **Search Navigation Key's** search page.

Note: Search Type and Search Tooltip. These attributes are only applicable to user interface elements utilizing the foreign key compound element type on fixed page user interfaces. Report parameters that reference foreign key characteristics are an example of a user interface where this information is not used even if the foreign key reference defines them.

Audit Trails

The topics in this section describe one way of auditing changes in the system. Note that this technique has limitations and may not be the best option for all situations.

- This functionality is configured at the table and field level. Many base maintenance objects use an XML or CLOB field to capture one or more elements using XML format, configured using a BO schema. This auditing technique is not able to capture changes to individual elements. It can only capture overall changes to the single field. The BO Audit plug-in is a better option for auditing changes to individual elements with the CLOB / XML field.
- The base table provided for supporting audits limits the field size of the before and after values to 254 bytes.
- Auditing is captured for each field. In some cases it is preferred to capture a before and after image for several fields at once. For example, if an address is changed, it's more user friendly to capture the before and after for the full address rather than the individual address components. The BO Audit plug-in allows for capturing a single audit record for multiple elements rather than granular changes for each element.

The subsequent topics highlight how to enable auditing for fields, and describe the auditing queries that you can use to view audit records.

Captured Information

When auditing is enabled for a field, the following information is recorded when the field is changed, added and/or deleted (depending on the actions that you are auditing for that field):

- User ID
- Date and time
- Table name
- Row's prime key value
- Field name
- Before image (blank when a row is added)
- After image (blank when a row is deleted)
- Row action (add, change, delete)

How Auditing Works

You enable auditing on a table in the table's meta-data by specifying the name of the table in which to insert the audit information (the audit table) and the name of the program responsible for inserting the data (the audit trail insert program). Then you define the fields you want to audit by turning on each field's audit switch in the table's field meta-data. You can audit fields for delete, insert and update actions.

Once auditing is enabled for fields in a table, the respective row maintenance program for the table assembles the list of changed fields and calls the audit trail insert program. If any of the changed fields are marked for audit, the audit program inserts audit rows into the audit table.

Note: Customizing Audit Information. You may want to maintain audit information other than what is described in [Captured Information](#) or you may want to maintain it in a different format. For example, you may want to maintain audit information for an entire row instead of a field. If so, your implementation team can use the base audit program and base audit tables as examples when creating your own audit trail insert program and audit table structures.

The Audit Trail File

Audit log records are inserted in the audit tables you define. The base product contains a single such table (called **CI_AUDIT**). However, the base audit insert program is designed to allow you to use multiple audit tables.

If you want to segregate audit information into multiple tables, you must create these tables. Use the following guidelines when creating new audit tables (that use the base delivered audit insert program):

- The new audit tables must look identical to the base table (**CI_AUDIT**).
- The new tables must be prefixed with **CM** (e.g., **CM_AUDIT_A**, **CM_AUDIT_B**, etc.). An appropriate java table name must be defined and an `*_impl.java` program for that java table name must be defined.
- The name of the new table must be referenced on the various tables whose changes should be logged in the new table.

Note: It's important to note if you use your own tables (as opposed to using the base package table called **CI_AUDIT**), the SQL used to insert and access audit trail records in the base delivered audit program is dynamic. Otherwise, if the base package's table is used, the SQL is static.

How To Enable Auditing

Enabling audits is a two-step process:

- First, you must turn on auditing for a table by specifying an audit table and an audit trail insert program.
- Second, you must specify the fields and actions to be audited for the table.

The following topics describe this process.

Turn On Auditing For a Table

In order to tell the system which fields to audit, you must know the name of the table on which the field is located. You must specify the audit table and the audit trail insert program for a table in the table's meta-data.

Note: Most of the system's table names are fairly intuitive. For example, the user table is called **SC_USER**, the navigation option table is called **CI_NAV_OPT**, etc. If you cannot find the table using the search facility on the [Table](#) portal, please contact customer support.

To enable auditing for a table:

- Navigate to the [Table](#) portal and find the table associated with the field(s) for which you want to capture audit information.
- Specify the name of the **Audit Table**.

Note: Specifying the Audit Table. You can use the audit table that comes supplied with the base package (**CI_AUDIT**) to audit multiple tables and fields. All the audit logs are combined in a single table (**CI_AUDIT**). However, you can also have a separate audit table for each audited table. Refer to [The Audit Trail File](#) for more information.

- Specify the name of the **Audit Program**. The product provides two programs. **com.splwg.base.domain.common.audit.DefaultTableAuditor** is a standard table audit program. In addition **com.splwg.base.domain.common.audit.ModifiedTableAuditor** is supplied as an alternative. This program does not audit inserts or deletes of empty string data.

CAUTION: By default, none of a table's fields are marked for audit. Even though you have enabled auditing for a table, you must still specify the fields and actions on those fields to be audited (see below).

Specify The Fields and Actions To Be Audited

The system only audits actions (insert, update and delete) made to fields that you want audited.

To specify the fields and actions to be audited:

- Navigate to the [Table](#) portal for a table on which you have enabled auditing.
- For each field you want to audit, specify the actions you want to audit by turning on the **Audit Delete**, **Audit Insert** and **Audit Update** switches as appropriate.

Note: You can also turn on the audit switches using the Field zone at the bottom of the [Table](#) portal.

CAUTION: Audit Program Caching! The audit program from the table meta-data is read into a program cache on the application server whenever the date changes or when the server starts. If you implement new auditing on a table, your audit trail does not become effective until this program cache is reloaded. In other words, new audits on tables where the audit program was not previously specified do not become effective until the next day (or the next restart of the application server). However, if you change the fields to be audited for a table where the audit program is already in the cache, your changes are effective immediately.

Audit Queries

There are two queries that can be used to access the audit information.

Audit Query by User

This transaction is used to view changes made by a user that are stored on a given [Audit Trail File](#).

CAUTION: The system only audits changes that you've told it to audit. Refer to [The Big Picture Of Audit Trails](#) for more information.

Navigate to this page by selecting **Admin > Database > Audit Query By User**.

Description of Page

To use this transaction:

- Enter the **User ID** of the user whose changes you wish to view.
- Enter the name of the table on which the audit trail information is stored in **Audit Table**. Refer to [The Audit Trail File](#) for more information about this field.

Note: Default Note. If only one audit table is used to store audit trail information, that table is defaulted.

- Specify a date and time range in **Created between** to restrict the records that result from the query.

Note: Default Note. The current date is defaulted.

- Click the search button to display all changes recorded on a specific audit table associated with a given user.

Information on this query is initially displayed in reverse chronological order.

The following information is displayed in the grid:

- **Row Creation Date** is the date and time that the change was made.
- **Audited Table Name** contains the name of the table whose contents were changed.
- **Primary Key** is the prime key of the row in the **Audited Table** whose contents were changed.
- **Audited Field Name** is the name of the field that was changed.
- **Audit Action** indicates whether the row action was **Add**, **Change** or **Delete**.
- **Field Value Before Update** contains the content of the field before the change. This column is blank if information was **Added**.
- **Field Value After Update** contains the content of the field after the change. This column is blank if information was **Deleted**.

Audit Query by Table / Field / Key

This transaction is used to view audited changes made to a given table.

CAUTION: The system only audits changes that you've told it to audit. Refer to [The Big Picture Of Audit Trails](#) for more information.

This transaction can be used in several different ways:

- You can view all audited changes to a table. To do this, enter the **Audited Table Name** and leave the other input fields blank.
- You can view all audited changes to a given row in a table (e.g., all changes made to a given user). To do this, enter the **Audited Table Name** and row's prime key (the row's prime key is entered in the field(s) beneath **Audited Field Name**).
- You can view all audited changes to a given field in a table (e.g., all changes made to all customers' rates). To do this, enter the **Audited Table Name** and the **Audited Field Name**.
- You can view all audited changes to a given field on a specific row. To do this, enter the **Audited Table Name**, the **Audited Field Name**, and row's prime key (the row's prime key is entered in the field(s) beneath **Audited Field Name**).

Navigate to this page by selecting **Admin > Database > Audit Query By Table/Field/Key**.

Description of Page

To use this transaction:

- Enter the name of the table whose changes you wish to view in **Audited Table Name**.
- If you wish to restrict the audit trail to changes made to a specific field, enter the **Audited Field Name**.
- If you wish to restrict the audit trail to changes made to a given row, enter the row's prime key (the row's prime key is entered in the field(s) beneath **Audited Field Name**). These fields are dynamic based on the **Audited Table Name**.
- Specify a date and time range in **Created between** to restrict the records that result from the query.

Note: The current date is defaulted.

- Click the search button to display all changes made to this data.

Information on this query is initially displayed in reverse chronological order by field.

The following information is displayed in the grid:

- **Create Date/Time** is the date / time that the change was made.
- **User Name** is the name of the person who changed the information.
- **Primary Key** is the prime key of the row in the **Audited Table** whose contents were changed.
- **Audited Field Name** is the name of the field that was changed.
- **Audit Action** indicates whether the row action was **Add**, **Change** or **Delete**.
- **Value Before Update** contains the content of the field before the change. This column is blank if information was **Added**.
- **Value After Update** contains the content of the field after the change. This column is blank if information was **Deleted**.

Bundling

The topics in this section describe the bundling features in the application.

About Bundling

Bundling is the process of grouping entities for export or import from one environment to another.

For example, you might export a set of business objects and service scripts from a development environment and import them into a QA environment for testing. The group of entities is referred to as a bundle. You create export bundles in the source environment; you create import bundles in the target environment.

Working with bundles involves the following tasks:

- Configuring entities for bundling if they are not preconfigured
- Creating an export bundle, which contains a list of entities to be exported from the source environment
- Creating an import bundle to import those entities to the target environment
- Applying the import bundle, which adds or updates the bundled entities to the target environment

Sequencing of Objects in a Bundle

Bundle entities are added or updated to the target environment in the sequence defined in the bundle

Typically, the sequence of entities does not matter. However, sequence is important in the following situations:

- Entities that are referenced as foreign keys should be at the top of the sequence, before the entities that reference them. Specify zones last, as they typically contain numerous foreign key references.
- When importing a business object, specify the business object first, then its plug-in scripts, then the algorithms that reference the scripts, and then the algorithm types that reference the algorithms.
- When importing a portal and its zones, specify the portal first and then its zones.
- When importing a multi-query zone, specify the referenced zones first and then the multi-query zone.
- Always specify algorithms types before algorithms.

You can specify the sequence when you define the export bundle or when you import the bundle to the target environment.

Recursive Key References

Recursive foreign keys result when one object has a foreign key reference to another object that in turn has a foreign key reference to the first object.

For example, a zone has foreign keys to its portals, which have foreign keys to their zones. If the objects you want to bundle have recursive relationships, you must create a 'bundling add' business object that has only the minimal number of elements needed to add the entity. A bundling add business object for a zone contains only the zone code and description, with no references to its portals. In the same way, a bundling add business object for a portal defines only its code and description.

When you apply the bundle, the system initially adds the maintenance object based on the elements defined in the bundling add business object. Before committing the bundle, the system updates the maintenance object with the complete set of elements based on its physical business object.

Note that use of the bundling add BO also benefits records that have optional foreign keys or foreign keys that are part of a child table. That way the person creating the bundle does not have to worry about the sequence of the records. For example, an FK Reference may optionally reference a zone for searching. If a new FK Reference and its search zone are bundled together to copy to another region, the bundling add BO for FK Reference (which doesn't include the Zone) ensures that the FK reference could be added before the zone without getting any validation errors.

Owner Flags on Bundled Entities

The owner flag of the entities in an import bundle must match the owner flag of the target environment.

If you need to import objects that your source environment does not own, you must replace the owner flag in the import bundle with the owner flag of the target environment.

Configuring Maintenance Objects for Bundling

Most base package meta-data objects are pre-configured to support bundling. All other objects must be manually configured.

If a base package maintenance object is pre-configured for bundling, the **Eligible For Bundling** option will be set to "Y" on the Options tab for the maintenance object.

To configure other objects for bundling, review the configuration tasks below and complete all those that apply:

| Configuration Task | Scope of Task |
|---|--|
| Make maintenance objects eligible for bundling | All objects to be included in the bundle. |
| Add a foreign key reference | All objects to be included in the bundle. |
| Create a physical business object | All objects to be included in the bundle. |
| Create a bundling add business object | Only needed if there are objects with recursive or optional foreign key references . |
| Add the Current Bundle zone | Perform this step for any object where you want the Current Bundle zone to appear on the sidebar when on the maintenance page for this maintenance object. This is not required by the bundling process. |
| Create a custom Entity Search zone and add it to the Bundle Export portal | Perform this step if you would like the object to be listed in the Entity Search zone in the Bundle Export portal. This is not required by the bundling process. |

Making Maintenance Objects Eligible for Bundling

The "Eligible For Bundling" maintenance object option must be set to "Y" for all bundled objects. Go to the [Maintenance Object](#) page and search for the maintenance object. On the Options tab, add a new option with the type **Eligible For Bundling**. Set the value to "Y" and click **Save**. This configuration must be in both the source environment and the target environment.

Adding a Foreign Key Reference

Foreign key references are used for many purposes and most maintenance objects should have them anyway. Check the Maintenance Object options to see if there is an entry for the **Foreign Key Reference** option. If one is not configured, navigate to [FK Reference](#) and set up a foreign key reference for the primary table of the maintenance object. Configure that new FK reference on the maintenance object using an option.

Creating a Physical Business Object

If the maintenance object does not already have a Physical BO configured, one must be created to support using it in a bundle. Refer to [Creating a Physical Business Object](#) for more information.

Creating a Bundling Add Business Object

If the objects to be bundled have recursive foreign key references, optional foreign key references or child tables that include foreign key references, create a bundling add business object to avoid problems with referential integrity.

1. Navigate to [Business Object](#) and add a business object for the maintenance object. Do not fill in any of the UI oriented configuration.
2. The business object is created with a schema that looks like the physical structure of the maintenance object.
3. Remove all child tables and all elements that are not required.
4. Save the business object.
5. Navigate to [Maintenance Object](#) and search for the maintenance object you want to bundle.
6. On the **Option** tab, add a new option with the type **Bundling Add BO**. The value is the name of the bundling add business object you just created.

Adding the Current Bundle Zone

If you want the Current Bundle zone to appear on the sidebar when the a user is on the maintenance page for the maintenance object, you must add the Current Bundle zone as a context-sensitive zone for the maintenance page's navigation key.

1. Navigate to [Context Sensitive Zone](#) and search for the navigation key for the maintenance page of this object.

2. Add the Current Bundle zone F1-BNDLCTXT, to that navigation key.

Adding a Customized Entity Search Query Zone to the Bundle Export Portal

If you want the maintenance object to be searchable in the Bundle Export portal in the Entity Search zone, you must first create an entity-specific query zone to search for the maintenance object. Then you must create a customized entity search zone that references this new query zone. Finally, you must add the customized entity search zone to the Bundle Export portal.

Note that not all base product entities that are eligible for bundling have a search configured for this zone. There is a limit to the number of searches that may be listed here. The base product has provided searches for only the most common objects that are bundled.

Create an entity-specific query zone to search for the maintenance object:

1. Navigate to [Zone](#) and search for one of the base query zones, such as the Algorithm Search zone F1-BNALGS.
2. Click the **Duplicate** button in the record actions section.
3. Enter a name and description for the new zone.
4. Click **Save**.
5. Customize the details of the parameters for your maintenance object.

Create a customized entity search zone. This step only needs to be done once. If you already have a customized search zone in the Bundle Export portal, skip this step.

1. Navigate to [Zone](#) and search for the F1-BNDLENTQ Entity Search zone.
2. Duplicate this zone.
3. Remove any references to base query zones.

Add the new entity-specific query zone to the customized entity search zone:

1. Locate the customized entity search zone for your Bundle Export portal. This is the zone created in the previous step.
2. Add the name of the query zone you created in the first step to the list of Query Zones.

Add the customized entity search zone to the Bundle Export portal. This step needs to be done only once.

1. Navigate to [Portal](#) and search for the Bundle Export portal, F1BNDLEM.
2. In the zone list, add the entity search zone you created above. (Add the new zone after the base entity search zone).
3. Save the portal.

Working with Bundles

Use the Bundle Export portal to create an export bundle. The export bundle contains a list of entities to be exported from the source environment. When you are ready to import the objects, use the Bundle Import portal to import the objects to the target environment.

Creating Export Bundles

An export bundle contains a list of entities that can be imported into another environment.

To create an export bundle:

1. Log on to the source environment from which objects will be exported.
2. Select **Admin > Implementation Tools > Bundle Export > Add**.
3. Complete the fields in the Main section to define the bundle's basic properties.

Note: You can use the Entities section to add bundle entities now, or save the bundle and then add entities as described in step 5.

4. Click **Save** to exit the Edit dialog. The export bundle status is set to Pending.
5. While an export bundle is in Pending state, use any of the following methods to add entities to the bundle:

- a) Use the **Entity Search** zone on the Bundle Export portal to search for entities and add them to the bundle. If an entity is already in the bundle, you can remove it.
 - b) To import entities from a .CSV file, click **Edit** on the Bundle Export portal, and then click **CSV File to Upload**. Specify the file name and location of the .CSV file containing the list of entities. Click **Submit** to upload the file, and then click **Save** to save the changes.
 - c) Use the **Current Bundle** zone in the sidebar of the entity you want to add. (All entities that are configured to support bundling display a Current Bundle zone). This zone displays a list of all pending export bundles to which you can add the entity.
 - d) When you check an entity into revision control, specify the export bundle on the **Revision Info** dialog.
6. When you have added all entities, click **Bundle** in the Bundle Actions zone on the Bundle Export portal. The export bundle state is set to Bundled and the Bundle Details zone displays the XML representation of every entity in the bundle.

Note: The owner flags of the entities in the bundle must match the owner flag of the bundle itself. If the owner flags do not match, the system displays a warning message. Click **OK** to continue or **Cancel** to abort the bundle. If you click OK, you will need to resolve the owner flag discrepancy before you import the bundle to the target environment.

7. Copy the XML from the **Bundle Detail** zone to the clipboard (or to a text file). You can now create an import bundle and apply it to the target environment.

Note: If you need to make additional changes to the bundle, you must change the bundle state by selecting the **Back to Pending** button in the **Bundle Actions** zone.

Creating and Applying Import Bundles

Import bundles define a group of entities to be added or updated in the target environment.

Before you create an import bundle, you must have already created an export bundle, added entities, and set the bundle's state to Bundled.

To create an import bundle and apply it to the target environment:

1. If you have not already copied the XML from the export bundle, do so now:
 - a) Select **Admin > Implementation Tools > Bundle Export** and search for the bundle.
 - b) Copy the XML from the **Bundle Detail** zone to the clipboard (or to a text file).
2. Log on to the target environment.
3. Select **Admin > Implementation Tools > Bundle Import > Add**.
4. In the **Bundle Actions** zone, click **Edit XML**.
5. Paste the contents of the clipboard (or text file if you created one) into the **Bundle Detail** zone.
6. Make any necessary changes to the XML and click **Save**. The status of the import bundle is set to Pending.

Note: Use caution when editing the XML to avoid validation errors.

7. To remove entities from the import bundle or change their sequence, click **Edit**. Enter your changes and click **Save** to exit the Edit dialog.
8. When you are ready to apply the bundle, click **Apply**. The import bundle state is set to Applied and the entities are added or updated in the target environment.

Editing Export Bundles

You can add or remove entities from an export bundle when it is in Pending state. You can also change the sequence of entities.

To edit to an export bundle that has already been bundled, you must change the bundle state by selecting the **Back to Pending** button on the Bundle Export portal.

To edit a pending export bundle:

1. Open the bundle in edit mode.

2. Click **Edit** on the Export Bundle portal.
3. Make any necessary changes on the edit dialog and then click **Save**.

Editing Import Bundles

You can remove entities from an import when it is in Pending state. You can also change the sequence of entities and edit the generated XML.

To edit a pending import bundle:

1. Open the bundle in edit mode.
2. To edit the XML snapshot, click **Edit XML**. Edit the XML code as needed, then click **Save**.

Note: Use caution when editing the XML to avoid validation errors.

3. To remove entities or change their sequence, click **Edit**. Make any necessary changes and click **Save**.

Revision Control

The topics in this section describe the revision control features in the application.

About Revision Control

Revision control is a tool provided for the development phase of a project to allow a user to check out an object that is being worked on. In addition, it captures the version of the maintenance object when users check in an update, maintaining a history of the changes to the object.

If revision control is enabled for an object you must check out the object to change it. While the object is checked out no one else can work on it. You can revert all changes made since checking out an object, reinstate an older version of an object, recover a deleted object, and force a check in of an object if someone else has it checked out.

Note: Revision control does not keep your work separate from the environment. Because the metadata for maintenance objects is in the central database, any changes you make to an object while it is checked out will be visible to others and may impact their work.

Many of the maintenance objects used as configuration tools are already configured for revision control, but it is turned off by default. For example, business objects, algorithms, data areas, UI maps, and scripts are pre-configured for revision control.

Turning On Revision Control

Revision control is turned off by default for maintenance objects that are configured for revision control.

To turn on revision control:

1. Add the base package **Checked Out** zone to the Sidebar portal.
 - a) Navigate to [Portal](#).
 - b) Search for the portal CI_DASHBOARD.
 - c) In the zone list for the **Sidebar** portal, add the zone F1-USRCHKOUT.
2. Set up application security.

For users to have access to revision control, they must belong to a user group that has access to the application service F1-OBJREVBOAS.
3. Add the revision control algorithm to the maintenance object that you want to have revision control.

This step must be repeated for each maintenance object that you want to have revision control.

 - a) Go to the [Maintenance Object](#) page and search for the maintenance object that you want to have revision control.
 - b) On the **Algorithms** tab of the maintenance object, add the revision control algorithm F1-REVCTL.

Configuring Maintenance Objects for Revision Control

Most configuration tool maintenance objects are pre-configured for revision control. You can configure other maintenance objects for revision control, as well.

To configure other objects for revision control:

1. Create a physical business object for the maintenance object. Refer to [Creating a Physical Business Object](#) for more information.
2. Add a foreign key reference to the maintenance object so that the standard information string is displayed. Foreign key references are used for many purposes and most maintenance objects should have them anyway. Check the Maintenance Object options to see if there is an entry for the **Foreign Key Reference** option. If one is not configured, navigate to [FK Reference](#) and set up a foreign key reference for the primary table of the maintenance object. Configure that new FK reference on the maintenance object using an option.
3. Add the **Revision Control** zone to the maintenance object.
 - a) Navigate to [Context Sensitive Zone](#) and search for the navigation key for the maintenance object.
 - b) Add the Revision Control zone, F1-OBJREVCTL, to that navigation key.
4. Add the revision control algorithm to the maintenance object.
 - a) Go to the [Maintenance Object](#) page and search for the maintenance object that you want to have revision control.
 - b) On the **Algorithms** tab of the maintenance object, add the revision control algorithm F1-REVCTL.

Working with the Revision Control Zones

You use two zones in the sidebar to work with revision controlled objects when revision control is turned on.

The **Revision Control** zone gives you several options for managing the revision of the currently displayed object. This zone also shows when the object was last revised and by whom. This information is linked to the **Revision Control Search** portal which lists all of the versions of the object.

Using the Revision Control zone you can:

- Check out an object in order to change it.
- Check in an object so others will be able to work on it.
- Revert the object back to where it was at the last checkout.
- Force a check in of an object that is checked out by someone else. You need special access rights to force a check in.
- Delete an object.

The **Checked Out** zone lists all of the objects that you currently have checked out. Clicking on an object listed in this zone will take you to the page for that object. The zone is collapsed if you have no objects checked out.

See [Revision Control Search](#) for more information about Check In, Force Check In, and Check Out one or more records simultaneously.

Checking Out an Object

You must check out a revision controlled object in order to change it.

An object must have revision control turned on before you can check it out.

Note: When you first create or update an object a dialog box informs you that the object is under revision control. You can select **OK** to check out the object and save your changes, or **Cancel** to stop the update.

1. Go to the object that you want to work on.
2. Select **Check Out** in the **Revision Control** sidebar zone.

Checking In an Object

You must check in a revision controlled object in order to create a new version of it. Checking in an object also allows others to check it out.

1. Select a link in the **Checked Out** sidebar zone to go to the object that you want to check in.
2. Select **Check In** in the **Revision Control** sidebar zone.
3. Provide details about the version:
 - In the **External References** field state the bug number, enhancement number, or a reason for the revision.

- In the **Detailed Description** field provide additional details regarding the revision.
- In the **Keep Checked Out** box specify if you want to keep the object checked out. If you keep the object checked out then your revision is a new version that you can restore later.
- In the **Add To Bundle** box specify if the object belongs to a bundle.

4. Select **OK** to check in the object.

Reverting Changes

Reverting changes will undo any changes you made since you checked out an object.

To revert changes:

1. Go to the object that you want to revert.
2. Select **Revert** in the **Revision Control** sidebar zone.
3. In the confirmation dialog box select **OK** to confirm the action or **Cancel** to return to the object page.

Once reverted, the object can be checked out by another user.

Forcing a Check In or Restore

You can force a check in if an object is checked out by another user and that person is not available to check it in.

You must have proper access rights to force a check in or restore.

To force a check in or restore:

1. Go to the object that is checked out by another user.
2. Select **Force Check In** or **Force Restore** in the Revision Control zone.

The **Force Check In** option is the same as a regular check in. The **Force Restore** option checks in the object and restores it to the previously checked in version.

Deleting an Object

If revision control is turned on for an object, you must use the **Revision Control** zone to delete it.

The object must be checked in before it can be deleted.

To delete a revision controlled object:

1. Go to the object that you want to delete.
2. Select **Delete** in the **Revision Control** zone.
3. Provide details regarding the deletion.
4. Select **OK** to delete the object.

The system creates a revision record before the object is deleted so that the deleted object can be restored.

Restoring an Object

You can restore an older version of either a current object or a deleted object.

An object must be checked in before an older version can be restored.

To restore an object:

1. Go to the **Revision History** portal for the object.
 - If the object was deleted you must search for it by going to **Admin > Implementation Tools > Revision Control**.
2. Select the desired entity by clicking the hyperlink in the **Details** column.
3. Locate the row in the version history that has the version that you want to restore and click **Restore**.
4. In the confirmation dialog box select **OK** to confirm the action or **Cancel** to return to the object page.

Working with the Revision Control Portal

The **Revision Control** portal lists information about each version of a revision controlled object.

You can navigate to the **Revision Control** portal from either a link in the **Revision Control** sidebar zone or by going to **Revision Control** portal through **Admin**.

If you want to find the Revision History entry for an earlier version or deleted object, you must search for the object using the **Revision Control Search** portal. Once you select the desired entry, you can restore a previous version of the object clicking **Restore** in the row for the version that you want to restore. You can also see the details of each version by clicking the broadcast icon for that version.

See [Working with Revision Control Zones](#) for more information about tasks that can be performed through Revision Control.

Revision Control Search

The **Revision Control Search** portal allows users to search for entities that have a revision history. The **Search By** dropdown provides additional functionality so that users can search for revisions that are associated to theirs or other's user ID. Users can also **Check In**, **Force Check In**, or **Check Out** one or more entities through this portal.

Zone Options

- **Revision History Search** allows the user to query for revised entities based on a combination of criteria.
 - In the **User ID** field, enter the user ID that is associated with a revision.
 - In the **External Reference** field, enter an ID from an external system and is associated with a revision.
 - In the **Maintenance Object** dropdown menu, select the Maintenance Object that is associated with a revision. The options in this list are populated by the Maintenance Objects that are active to track revision.
 - In the **Key 1**, **Key 2**, **Key 3**, **Key 4**, **Key 5** fields, enter the primary identifier(s) for the revised entity. Typically, the entity only requires a single key, but some entities require more than one (for example, Oracle Utilities Customer Care and Billing SA Type require CIS Division and SA Type).
 - In the **Status** dropdown menu, select the entity status for your search.
- **Check In** allows the user to search for entities currently checked out to the logged in user ID and a combination of criteria. Once the search results are returned, the user has the option to select one or more entities and check them in.
 - In the **Maintenance Object** dropdown menu, select the Maintenance Object that is associated with a revision. The options in this list are populated by the Maintenance Objects that are active to track revision.
 - In the **Key** field, enter the primary identifier(s) for the revised entity.
- **Force Check In** allows the user to search for entities that are currently checked out by other user IDs (excluding the logged in user ID) based on a combination of criteria. Once the search results are returned, the user has the option to select one or more entities and check them in.
 - In the **Checked Out By User** field, enter the user ID that has the entity in a Checked Out status.
 - In the **Maintenance Object** dropdown menu, select the Maintenance Object that is associated with a revision. The options in this list are populated by the Maintenance Objects that are active to track revision.
 - In the **Key** field, enter the primary identifier(s) for the revised entity.
- **Check Out** allows the user to search for entities currently checked in user ID and a combination of criteria. Once the search results are returned, the user has the option to select one or more entities and check them out.
 - In the **Maintenance Object** dropdown menu, select the Maintenance Object that is associated with a revision. The options in this list are populated by the Maintenance Objects that are active to track revision.
 - In the **Key** field, enter the primary identifier(s) for the revised entity.

Please see [Working with Revision Control Zones](#) for more information about working with individual entities.

Information Lifecycle Management

Information Lifecycle Management (ILM) is designed to address data management issues, with a combination of processes and policies so that the appropriate solution can be applied to each phase of the data's lifecycle.

Data lifecycle typically refers to the fact that the most recent data is active in the system. As time progresses, the same data becomes old and unused. Older data becomes overhead to the application not only in terms of storage, but also in terms of performance. This older data's impact can be reduced by using advanced compression techniques, and can be put into slower and cheaper storage media. Depending on how often it's accessed, it can be removed from the system

to make an overall savings of cost and performance. The target tables for ILM are transactional tables that have the potential to grow and become voluminous over time.

The Approach to Implementing Information Lifecycle Management

This section describes the product approach to implementing ILM for its maintenance objects (MOs).

Note: The term archiving is used to cover any of the possible steps an implementation may take in their data management strategy, including compression, moving to cheaper storage, and removing the data altogether.

Age is the starting point of the ILM product implementation for some of its high volume data. In general "old" records are considered eligible to be archived. In the product solution, maintenance objects (MOs) that are enabled for ILM have an ILM Date on the primary table and the date is typically set to the record's creation date. (An MO may have special business rules for setting this date, in which case, a different date may be used to set the initial ILM Date). For implementations that want to use ILM to manage the records in the MO, the ILM date is used for defining partitions for the primary table.

There are cases where a record's age is not the only factor in determining whether or not it is eligible to be archived. There may be some MOs where an old record is still 'in progress' or 'active' and should not be archived. There may be other MOs where certain records should never be archived. To evaluate archive eligibility using information other than the ILM Date, the ILM enabled MOs include an ILM Archive switch that is used to explicitly mark records that have been evaluated and should be archived. This allows DBAs to monitor partitions based on age and the value of this switch to evaluate data that may be ready to be archived.

Evaluating records to determine their archive eligibility should still occur on "old" records. The expectation is that a large percentage of the old records will be eligible for archiving. The small number that may be ineligible could be updated with a more recent ILM date. This may cause the records to move into a different partition and can delay any further evaluation of those records until more time has passed.

For each MO enabled for ILM, the product provides a batch process to review "old" records and an ILM eligibility algorithm that contains business logic to evaluate the record and mark it eligible for archiving or not. The following sections provide more information about the batch process and algorithm functionality.

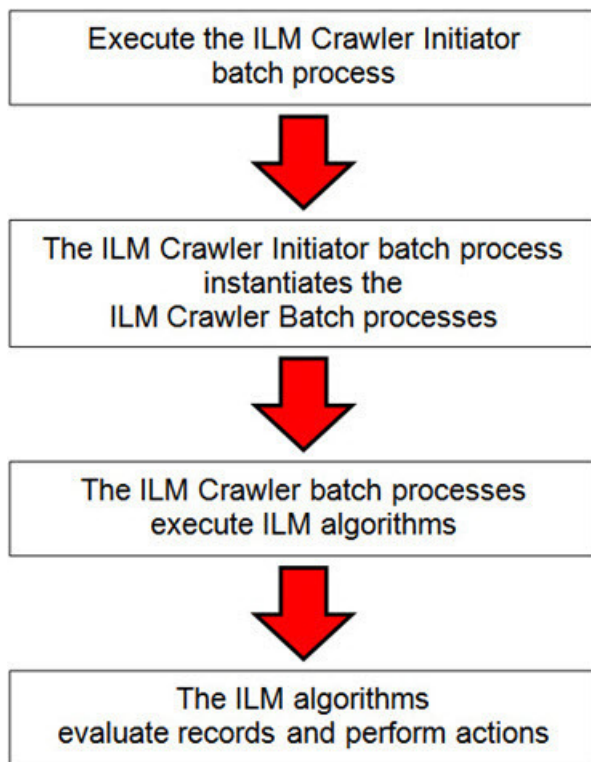

Batch Processes

There are two main types of batch processes that manage data for ILM in the application: ILM Crawler Initiator and individual ILM Crawlers (one for each MO that is configured for ILM).

- **ILM Crawler Initiator: (F1-ILMIN)** - The ILM Crawler Initiator is a *driver* batch process that starts the individual ILM Crawler batch control as defined by the MO's options.

Restartable: In case of server failure, the ILM Crawler Initiator process can be restarted, which will also restart the ILM Crawler processes.

- **ILM Crawler:** Each maintenance object that is configured for ILM defines an ILM Crawler. These are *child* batch processes that can be started either by the ILM Crawler Initiator or by a standalone batch submission.

The ILM Crawler batch process selects records whose retention period has elapsed and invokes the MO's ILM eligibility algorithm to determine if the record is ready to be archived or not. The ILM eligibility algorithm is responsible for setting the record's ILM archive switch to 'Y' and updating the ILM date, if necessary.

The retention period defines the period that records are considered active. It spans the system date and cutoff date (calculated as system date - retention days).

The retention days of an MO is derived as follows:

- If the ILM Retention Days MO option is defined, that is used.
- Otherwise, the Default Retention Days from the ILM Master Configuration record is used.

An error is issued if no retention period is found.

The crawler calculates the cutoff date and selects all records whose ILM archive switch is 'N' and whose ILM date is prior to the cutoff date. Each record returned is subject to ILM eligibility.

If the Override Cutoff Date parameter is supplied, it will be used instead of the calculated cutoff date. An error is issued if the override cutoff date is later than the calculated cutoff date. This parameter is useful if an object has many years of historic data eligible for archiving. Setting this parameter allows for widening the retention period and therefore limiting the process to a shorter period for initial processing.

Note: ILM Crawler batch processes are designed not to interfere with current online or batch processing. Because of this, these batch processes can run throughout the day.

Note: Before passing the cut-off date to the algorithm, the ILM crawler ensures that the number of days calculated (System Date – override cut-off date) is more than the retention period specified in the MO option or the Master Configuration. If the number of days calculated is **less than** the retention period specified on the MO option or the Master Configuration, then it throws an error.

Eligibility Algorithm

Algorithms are triggered by the ILM batch crawler for the maintenance object. The key responsibility of the ILM algorithm is to determine whether a record can be marked as ready to be archived or not. If a record is determined to be ready for archive, the algorithm should set the ILM Archive switch to Y. If not, the algorithm leaves the switch

set to N and may decide to update the ILM Date to something more recent (like the System Date) to ensure that the record does not get evaluated again until the future.

This algorithm is plugged into the [Maintenance Object — Algorithm](#) collection.

Oracle Utilities Application Framework provides the algorithm **ILM Eligibility Based on Status (F1-ILMELIG)** to support the ILM batch crawler. Refer to the algorithm type description for details about how this algorithm works. If a maintenance object has special business rules that are evaluated to determine the eligibility for ILM, a custom algorithm can be created and applied by the implementation team.

Enabling ILM for Supported Maintenance Objects

In order to enable ILM for one or more maintenance objects, several steps are needed in both the configuration and in the database. This section describes some configuration enabled by default and some steps that must be taken in order to fully implement ILM.

There is some configuration enabled by default, but it will not be used unless ILM is fully configured. Each maintenance object that the product has configured for ILM has the following provided out of the box:

- **Special Table Columns:** Maintenance objects that support ILM include two specific columns: ILM Archive Switch (**ILM_ARCH_SW**) and ILM Date (**ILM_DT**).
- **Crawler Batch Process:** A "crawler" batch process is provided for each maintenance object that supports ILM and it is plugged into the MO as an option. Refer to [Batch Processes](#) for more information.
- **ILM Eligibility Algorithm:** Each maintenance object that is configured for ILM defines an [eligibility algorithm](#) that executes the logic to set the ILM Archive switch appropriately. This is plugged in to the MO algorithm collection.

If an implementation decides to implement ILM, there are steps that need to be followed, which are highlighted below.

Create the Master Configuration Record

The first step when enabling ILM is to create the **ILM Configuration** [master configuration](#) record.

The master configuration for ILM Configuration defines global parameters for all ILM eligible maintenance objects. For example, the Default Retention Period. In addition, your product may implement additional configuration. Refer to the embedded help for specific details about the information supported for your product's ILM configuration.

In addition, the user interface for this master configuration record displays summary information about all the maintenance objects that are configured to use ILM.

Confirm the Maintenance Objects to Enable

In viewing the list of maintenance objects that support ILM in the ILM master configuration page, your implementation may choose to enable ILM for only a subset of the supported maintenance objects. For example, some of the maintenance objects may not be relevant for your implementation. Or perhaps, the functionality provided by the maintenance object is used, but your implementation does not expect a high volume of data.

For each maintenance object that your implementation has confirmed for ILM, the following steps should be taken:

- Determine if the maintenance object should have a different number of default retention days than the system wide value defined on the master configuration. If so, use the MO option **ILM Retention Period in Days** to enter an override option for this maintenance object.
- Review the functionality of the ILM Eligibility algorithm provided by the product for this maintenance object. Each algorithm may support additional configuration based on business needs. If your organization has special business rules that aren't satisfied by the algorithm provided by the product, a custom algorithm may be provided to override the base algorithm.

For each maintenance object that your implementation does not want to enable for ILM, inactivate the eligibility algorithm. This will ensure that the ILM Crawler Initiator background process does not submit the crawler batch job for the maintenance object in question.

- Go to the [Maintenance Object - Algorithm](#) tab for each maintenance object and take note of the **ILM Eligibility** algorithm code.
- Go to the [Maintenance Object - Option](#) tab for the same maintenance object and add an option with an option type of **Inactivate Algorithm** and the value set to the ILM eligibility algorithm noted in the previous step.

Database Administrator Tasks

In order to implement ILM for each of the maintenance objects determined above, your database administrator must perform several steps in the database for the tables related to each MO. The following points are a summary of those steps. More detail can be found in the Information Lifecycle Management section of your product's *Database Administration Guide*.

- **Initializing ILM Date:** Your existing tables that are enabled for ILM may not have the ILM Date and ILM Archive switch initialized on all existing records. When choosing to enable ILM, a first step is to initialize this data based on recommendations provided in the *Database Administration Guide*.
- **Referential Integrity:** The recommended partitioning strategy for child tables in a maintenance object is referential partitioning. In order to implement this, database referential integrity features must be enabled.
- **Partitioning:** This provides a way in which the data can segregate into multiple table partitions and will help in better management of the lifecycle of the data.

Schedule the ILM Crawler Initiator

The final step of enabling the system for ILM is to schedule the ILM crawler initiator **F1-ILMIN** regularly based on your implementation's need. It is recommended to only schedule this batch process once all the required database activities are complete.

Ongoing ILM Tasks

For an environment where ILM is enabled, besides the periodic execution of the ILM crawler batch processes to review and mark records, your database administrator has ongoing tasks.

The DBA reviews and maintains partitions and identifies partitions that may warrant some type of archiving step. The Information Lifecycle Management section of your product's *Database Administration Guide* provides more information for your DBA.

Archived Foreign Keys

If your DBA chooses to archive a partition, there may be records in the system that refer to one of the archived records as a foreign key.

When a user attempts to view a record using a hyperlink or drill down mechanism, if the implementation of the navigation uses FK Reference functionality, the system will first check if the record exists. If not, it will display a message to the user indicating that the record has been archived.

Configuration Tools

This section describes tools to facilitate detailed business configuration. The configuration tools allow you to extend both the front-end user interface as well as create and define specialized back-end services.

Business Objects

A [maintenance object](#) defines the physical tables that are used to capture all the possible details for an entity in the system. A business object is tool provided to further define business rules for a maintenance object.

This section provides an overview of business objects and describes how to maintain them.

Understanding Business Objects

The topics in this section describe background topics relevant to business objects.

What Is A Business Object?

A business object (BO) is a powerful tool used throughout the system. For many maintenance objects, a BO is a key attribute of the record used to define the data it captures, its user interface behavior and its business rules. Some business objects support the definition of a lifecycle, capturing different states that a record may go through, allowing for different business rules to be executed along the way. This type of business object is considered the “identifying” or “governing” business object. We will see later that other types of BOs exist that are different from the “identifying” business object.

The use of business objects allows for extensibility and customization of product delivered maintenance objects. There are many options to adjust the behavior of base delivered business objects. In addition, implementations may introduce their own business objects if the base product delivered objects do not meet their business needs.

Note: Not all maintenance objects in the product support business objects as a “identifying” or “governing” tool. This is the standard going forward for new maintenance objects. However, there are some maintenance objects created before this became a standard.

A Business Object Has a Schema

A business object has elements. The elements are a logical view of fields and columns in one of the maintenance object’s tables. The structure of a business object is defined using an XML schema. The main purpose of the schema is to identify all the elements from the maintenance object that are included in the business object and map them to the corresponding maintenance object fields. Every element in the BO schema must be stored somewhere in the maintenance object. The BO may not define elements that are derived.

When defining elements for the primary table or the language table (for an administrative object) there is no need to define the name of the physical table in the schema. The system infers this information. The following is a snippet of a schema:

```
<schema>
  <migrationPlan mapField="MIGR_PLAN_CD" suppress="true" isPrimeKey="true"/>
  >
    <bo mapField="BUS_OBJ_CD" fkRef="F1-BUSOB"/>
    <customizationOwner mapField="OWNER_FLG" suppress="input"/>
    <version mapField="VERSION" suppress="true"/>
    <description mapField="DESCR"/>
    <longDescription mapField="DESCRLONG"/>
    ...
  </schema>
```

Many maintenance objects have child table collections (e.g., a collection of names for a person, or a collection of persons on an account). Depending on the requirements, the business object may define the full collection such that the user will maintain the information in a grid. However, the schema also supports “flattening” records in a child table so that they can be treated as if they were singular elements. The following are examples of each:

Example of a child table. This is a snippet of the Instructions collection on the migration plan business object. You can see that the list attribute defines the child table and all elements within it map to the appropriate column in that table.

```
<migrationPlanInstruction type="list" mapChild="F1_MIGR_PLAN_INSTR">
  <migrationPlan mapField="MIGR_PLAN_CD" suppress="true"/>
  <sequence mapField="PLAN_INSTR_SEQ" suppress="true"/>
  <instructionSequence mapField="INSTR_SEQ"/>
  <instructionType mapField="INSTR_TYPE_FLG"/>
  <parentInstructionSequence mapField="PARENT_INSTR_SEQ"/>
  <businessObject mapField="BUS_OBJ_CD" fkRef="F1-BOMO"/>
  ...
</migrationPlanInstruction>
```

Example of a simple “flattened” field. The business object for Status Reason includes an element called Usage, which maps to a pre-defined characteristic of type **F1-SRUSG**. The “row” defines which child table is being flattened and the attributes of the row in that child that uniquely identify it.

```
<usage mdField="STATUS_RSN_USAGE" mapField="CHAR_VAL">
```

```

    <row mapChild="F1_BUS_OBJ_STATUS_RSN_CHAR">
      <CHAR_TYPE_CD is="F1-SRUSG"/>
      <SEQ_NUM is="1"/>
    </row>
  </usage>

```

Example of a “flattened row”. This business object for Account includes a single row for the Person collection where only the “financially responsible, main” customer is defined. The “accountPerson” attribute defines one field from that row (the Person Id) and includes the ‘flattening’ criteria in the “row” information. In addition, a second field from that same row (“accountRelType”) is defined. Instead of having to repeat the flattening criteria, the “rowRef” attribute identifies the element that includes the flattening.

```

  <accountPerson mapField="PER_ID">
    <row mapChild="CI_ACCT_PER">
      <MAIN_CUST_SW is="true"/>
      <FIN_RESP_SW default="true"/>
    </row>
  </accountPerson>
  <accountRelType mapField="ACCT_REL_TYPE_CD" rowRef="accountPerson" dataType="string" />

```

Example of a “flattened list”. The business object for Tax Bill Type includes an list of valid algorithms for “bill completion”. The Sequence and the Algorithm are presented in a list. The list element identifies the child table and the ‘rowFilter’ identifies the information about the list that is common.

```

  <taxBillCompletion type="list" mapChild="C1_TAX_BILL_TYPE_ALG">
    <rowFilter suppress="true" private="true">
      <TAX_BILL_TYPE_SEVT_FLG is="C1BC"/>
    </rowFilter>
    <sequence mapField="SEQ_NUM"/>
    <algorithm mapField="ALG_CD" fkRef="F1-ALG"/>
  </taxBillCompletion>

```

In addition, many maintenance objects support an XML structure field within the entity. These fields may be of data type CLOB or XML. One or more business object elements may be mapped to the MO’s XML structure field. These elements may be defined in different logical places in the business object schema based on what makes sense for the business rules. When updating the MO, the system builds a type of XML document that includes all the elements mapped to the XML structure and stores it in one column. The following is an example of elements mapped to an XML column:

```

  <filePath mdField="F1_FILE_PATH" mapXML="MST_CONFIG_DATA" required="true"/>
  <characterEncoding mdField="F1_CHAR_ENCODING" mapXML="MST_CONFIG_DATA"/>

```

Note: If the MO’s XML structure field is of the data type XML, the database will allow searching for records based on that data, assuming appropriate indexes are defined. If the MO’s XML structure field is of the data type CLOB, indexing or joining to elements in this column via an SQL statement is not typically supported. Note that most MOs are currently using the CLOB data type for the XML structure column, if provided.

Some business objects may have child tables that allow data to be stored in an XML structure field. The schema language supports defining elements from those fields in your schema as well.

Besides including information about the physical “mapping” of the element to its appropriate table / field location in the maintenance object, the schema supports additional syntax to provide the ability to define basic validation and data manipulation rules, including:

- Identifying the primary key of the record or the primary key of the a row in a list.
- Identifying which elements are required when adding or changing a record.
- Default values when no data is supplied on an Add.

- For elements that are lookup values, the lookup may be specified to validate that the value of the element is a valid lookup value.
- For elements that are foreign keys to another table, the FK Reference may be specified to validate the data.

The system will check the validity of the data based on the schema definition obviating the need for any special algorithm to check this validation.

In addition, the schema language may include some attributes that are used to auto-render the view of the record on the user interface, such as the **suppress** attribute. Refer to [BO Defines its User Interface](#) for more information.

Note: Refer to [Schema Syntax](#) for the complete list of the XML nodes and attributes available to you when you construct a schema.

A business object's schema may include a subset of the fields and tables defined in the maintenance object. There are two reasons for this:

- The fields or tables may not be applicable to the type of record the business object is governing. For example, a field that is specific to gas may not be included on a Device business object that is specific to electric meters.
- The information is not maintained through the business object, but rather maintained separately. For example, many BO based maintenance objects include a Log table. The records in the log table are typically not included the BO because they are viewed and maintained separately from the business object.

A Business Object May Define Business Rules

A business object may define business rules that govern the behavior of entities of this type. The following table describes supported system events that can be associated with such rules.

| System Event | Optional / Required | Description |
|--------------|---------------------|---|
| Audit | Optional | <p>Algorithms of this type may be used to audit certain changes made to business object instances.</p> <p>The system hands over to the algorithms a summary of all the elements that were changed throughout a specific call to update an object. For each element its original value before the change as well as its new value are provided.</p> <p>It is the responsibility of such algorithms to log the changes if and where appropriate, for example as a log entry in the maintenance object's log table or an entry in the business event log.</p> <p>These plug-ins are executed after all the post-processing rules are executed.</p> <p>The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.</p> <p>By default all elements of the business object are subject to auditing. You can however mark certain elements to be excluded from the auditing process using the noAudit schema attribute. Marking an element as not auditable will prevent it from ever appearing as a changed element in the business object's audit plug-in spot. In addition, if the only elements that changed in a BO are ones marked to not audit, the audit algorithm is not even called. Refer to Schema Syntax for more information on this attribute.</p> |

| System Event | Optional / Required | Description |
|------------------------|---------------------|--|
| Information | Optional | <p>We use the term "Business Object Information" to describe the basic information that appears throughout the system to describe an entity defined by the business object. The data that appears in this information description is constructed using this algorithm.</p> <p>The system invokes a single algorithm of this type. If more than one algorithm is plugged-in the system invokes the one with the greatest sequence number found on the business object closest to the current business object in the inheritance hierarchy. Refer to Business Object inheritance for more information.</p> |
| Post-Processing | Optional | <p>Algorithms of this type may be used to perform additional business logic after a business object instance has been processed.</p> <p>For example, such an algorithm may be used to create a To Do Entry or add a log record as part of the business object logical transaction. These plug-ins are executed after all the validation rules are executed.</p> <p>The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.</p> |

| System Event | Optional / Required | Description |
|-----------------------|---------------------|--|
| Pre-Processing | Optional | <p>Algorithms of this type further populates a request to maintain a business object instance right before it is processed.</p> <p>Such algorithm may be used to "massage" a business object's elements prior to any maintenance object processing. For example, although simple element-level defaulting is supported by schema attributes. you may use this type of algorithm to default element values that are more sophisticated.</p> <p>The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.</p> |
| Validation | Optional | <p>Algorithms of this type may be used to validate a business object instance when added, updated or deleted.</p> <p>Simple element-level validation is supported by schema attributes. Note that element-level validation is executed before any maintenance object processing. For more sophisticated rules you create validation algorithms and associate them with your business object. BO validation algorithms are only executed after "core validation" held in the MO is passed.</p> <p>The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to Business Object inheritance for more information.</p> |

The system applies business object rules (schema based and algorithms) whenever a business object instance is added, changed or deleted. This is only possible when the call is made via the maintenance object service. For example, when made via business object interaction ("invoke BO"), the MO's maintenance page or inbound web services that reference the BO. In addition the system must be able to [determine the identifying business object](#) associated with the actual object being processed. If the business object cannot be determined for a maintenance object instance business object rules are not applied.

Note:

Pre-Processing is special. The pre-processing algorithm plug-in spot is unique in that it only applies during a BO interaction. It is executed prior to any maintenance object processing. It means that when performing add, change or delete via the maintenance object service, the pre-processing plug-in is not executed.

CAUTION: Direct entity updates bypass business rules! As mentioned above, it is the maintenance object service layer that applies business object rules. Processes that directly update entities not via the maintenance object service bypass any business object rules you may have configured.

Fastpath: Refer to [BO Algorithm Execution Order](#) for a summary of when these algorithms are executed with respect to lifecycle algorithms.

The plug-in spots described above are available for all business objects and they are executed by the system when processing adds or updates to the business object. It is possible for a specific maintenance object to define a special plug-in spot for business objects of that MO. When this happens, the maintenance object identifies the special algorithm entity lookup value as an **MO option: Valid BO System Event**, causing the BO Algorithm collection to include that system event in its list.

A Business Object Defines its User Interface

One of the responsibilities of an identifying business object is to define its user interface rules for viewing and maintenance of its record. The standard implementation for maintaining a business object is that a [maintenance portal](#) is used to display a record. This portal includes a "map" zone that displays the information about the business object. To add or make changes to a record, the user clicks a button that launches a maintenance BPA script which displays a maintenance "map".

The display and maintenance "maps" are driven by the business object. The BO may define a full [UI map](#) where all the information is displayed based on the map's HTML. Note that for a child BO, the maps may be [inherited](#) by a parent BO (or any BO "up the chain").

The standard going forward is to use schema definition and UI Hints to define user interface behavior so that a full UI map is not needed but rather the HTML is derived. The schema language includes some basic display attributes such as **label** and **suppress**. UI hints provide many additional tags and elements that allow dynamic generation of formatted UI Maps. For more complex behavior in the user interface, for example where javascript is needed, UI map fragments may be defined within the schema via UI hints. In this way only complex UI behavior warrants small snippets of javascript and HTML. However the rendering of standard fields can be dynamically rendered. UI map fragments also allow for derived fields to be included in the user interface.

A business object schema may include [data areas](#) for segments of its schema definition to allow for reusable components. In this case the data area would also include schema attributes and UI hints for the elements that it is including.

Note: Refer to [UI Hint Syntax](#) for detailed information about the supported syntax.

As mentioned in [Business Object Inheritance](#), schemas are not inherited on a child business object. As such, when using UI hints for automatic UI rendering, the child BO must define the full schema with all the definitions. A good business object hierarchy will be designed for reuse meaning that the child BO will include the parent BO schema or alternatively, the BO schemas will include reusable data areas.

A Business Object Defines Options

A business object may be associated with configuration options that control specific features. For example, the scripts used to maintain and display a business object are defined as options. Refer to the detailed description of each option type for more information on the functionality it controls.

Note: You can add new options types. Your implementation may want to add additional option types. For example, your implementation may have plug-in driven logic that would benefit from a new option. To do that, add your new values to the customizable lookup field **BUS_OBJ_OPT_FLG**. If you add a new option type for a business option, you must update its maintenance object to declare this new option type. Otherwise, it won't appear on the option type dropdown. You do that by referencing the new option type as a **Valid BO Option Type maintenance object option**.

Some options may be defined for a specific lifecycle status. For example, marking a status specific base algorithm as inactive is defined as an option on that status definition record.

Note: You can add new options types. Your implementation may want to add additional option types. For example, your implementation may have plug-in driven logic that would benefit from a new option. To do

that, add your new values to the customizable lookup field **BO_OPT_FLG**. If you add a new option type for a status, you must update the business object's maintenance object to declare this new option type. Otherwise, it won't appear on the option type dropdown. You do that by referencing the new option type as a **Valid BO Status Option Type** [maintenance object option](#).

Invoking A Business Object

We have talked about defining a business object. This section describes how business objects are used throughout the system to view, add and update records.

- Various parameters for zones that are used to display data in the system include support for retrieving data by referencing a business object. The zone code will "invoke" the BO, meaning that the record will be retrieved using the referenced BO.
- The system's [scripting](#) language includes a step type to "invoke BO". This allows for BPA scripts, service scripts and plug-in scripts to retrieve information and add or update records using BO interaction.
- [Inbound web services](#) may reference a business object in its operations collection. This allows external systems to add or update records in our product via web service interaction.

Often when configuring a zone or writing a script, the BO to use in the "invoke BO" statement should be the identifying BO of the record. As such, often the script will include steps prior to the "invoke BO" step to "[determine the identifying BO](#) of the record" and once the identifying BO is found, the script step will invoke that BO. Note that zones and inbound web services reference a BO directly. In each case, if the BO to use should be dynamic, then the zone / inbound web service should reference a service script that can perform the steps to identify the BO and then invoke that BO.

It should be noted however that the BO used in an "invoke BO" statement (or referenced in an inbound web service) **does not have to match** the identifying BO for the record. Here are some examples of where this may be true:

- A script may only require a subset of elements for a record and not the entire record. In this case, it is better for performance purposes to define a special BO (sometimes called a "lite" BO or a "mini" BO) that only defines the needed elements. When the system retrieves the data, it will only access the tables that are included in the BO's schema definition. In addition, if there are no elements that map to an XML structure field, the system will skip any parsing of that column. Similarly, if a script is **updating** a subset of elements on a record, it may be beneficial to use a "mini" BO to do the updates.

Note: Please note the following with respect to using a mini BO. This BO is only used for its schema.

This type of BO would not define algorithms or a lifecycle. Because the BO is special, it often should not be able to be used as any record's identifying BO. To control that, these BOs are often configured to not allow new instances. Refer to [Determine the Identifying BO](#) for more information.

- The maintenance object to be added or updated in a script may not support business objects as "identifying BOs". For example, Batch Control maintenance object does not have an identifying BO. However, scripts may still wish to retrieve data (or make updates) to these types of records. An easy way to achieve that goal is to define a business object and use "invoke BO" to access the data.

Note: Not all maintenance objects support being maintained through a business object interaction. This is true in a small number of older objects where the underlying maintenance service includes additional functionality besides simply updating the database tables. These maintenance objects are identified via the [MO option BO Maintenance](#), set to N.

- Some functionality may be trying to add or update records for a maintenance object in a 'physical' manner and do not want or need to use the object's identifying BO. Or the MO may not have an identifying BO. For example, revision control takes a snapshot of a record for audit purpose and to be able to restore a previous version. In this case, the system wants to capture a full "physical" view of the record. To do this, a special "physical" BO may be created that includes all (or most of) the columns and the child tables.

Note: Like the mini BO, the physical BO would not define algorithms or a lifecycle and should not be able to be used as any record's identifying BO. To control that, these BOs are often configured to not allow new instances. Refer to [Determine the Identifying BO](#) for more information.

Note: To reiterate, the BO referenced in the "invoke BO" statement or referenced in an inbound web service does not have to match the identifying BO and does not have to be configured to "allow new instances".

Determine the Identifying BO

As mentioned in other topics, the identifying BO is the business object that governs the business rules for a record. This is the business object that the record will be validated against when any additions or changes are made to the record as long as updates are made via the maintenance service. This includes using "invoke BO" for add or update, using inbound web service interaction and for access to the maintenance page service (via an old style fixed page or via a business service).

How does the system determine the identifying BO? An algorithm plugged into the maintenance object (the **Determine BO** plug-in spot) is responsible for this. If the maintenance object is not configured with an algorithm for this plug-in spot, or no BO is found by the algorithm, no BO business rules are applied.

Most maintenance objects in the system capture the record's identifying BO directly on the record. However, it is possible to define the identifying BO somewhere else. For example, there may be some maintenance objects that are master or transaction objects with an associated "type" object where the identifying BO is defined on its "type" object. Note that the standard Determine BO algorithm plugged into most maintenance objects (**F1-STD-DTMBO - Determine Standard Business Object**) checks for these two conditions.

There may also be cases where a single identifying BO is used for all BOs for a given MO. This may be an option used for some older maintenance object created prior to the business object functionality when implementations wish to introduce custom business rules that are common for all records of that MO. The product provides a base algorithm type (**F1-MOBO - Determine Specific Business Object**) that captures the BO as a parameter.

Base Business Objects

For each maintenance object (MO) that supports an "identifying" business object, the type of business object provided by the product depends on the functionality and expected use by implementations. The following are some common patterns.

- There are MOs where the product provides base BOs that implementations may use if applicable for their business rules. In addition, it is expected that implementation will define custom BOs to support their business needs. Good examples of this type of MO are any of the various "rule" MOs. For example, calculation rule in Oracle Utilities Customer Care and Billing or the usage rule in Oracle Utilities Meter Data Management. The product provides business objects for common rules but each implementation could have special rules that they need to implement and will need to create custom business objects.
- There are MOs where the product provides base BOs that supply common behavior for an object. Implementations may find that supplied the business objects match their business requirements and use the BOs as is. It is expected, however that for many implementations, their business rules will require additional elements to be captured or have special rules to apply. In this case the base business objects may be extended. This scenario may apply to 'master' data objects in various products such as the Device or Meter.
- There are MOs where the product may deliver a base BO that is not expected to satisfy most implementations because different jurisdictions or different implementations will typically have their own rules. In this case the base delivered BO can be used as a template or starting point for custom defined BOs. Some examples of this are Rebate Claim in Oracle Utilities Customer Care and Billing.
- There are MOs where the expectation is that every implementation will have different requirements for the type of data to capture and the product will not supply base BOs that can be used as the "identifying" BO. However, it may supply a "parent" BO that defines the lifecycle and many of the business rules that it expects all records to follow. In these scenarios, the implementations will create "child" BOs that will serve as the "identifying" BOs and refer to the base "parent" BO for many of its rules through [inheritance](#). An example of this is the Activity in Oracle Utilities Mobile Workforce Management.
- There are some scenarios where the base product provides business objects and the expectation is that implementations will use the business objects as delivered with little or no customization. This is a case where the system used business objects to implement product functionality, not because there is an expectation that the implementers will extend the functionality, but because the business object model is the favored development tool even for the product. The objects delivered for Content Migration Assistant are an example.

Note: Not all maintenance objects in the product support business objects as a "identifying" or "governing" tool. This is the standard going forward for new maintenance objects. However, there are some maintenance objects created before this became a standard.

For all maintenance objects, the base product may provide additional BOs that are not meant to be "identifying" BOs, but instead are provided to support functionality to interact with the MO using the BO as a tool as described in [Invoking a BO](#).

- One or more "mini" or "lite" BOs may be supplied for a maintenance object. This may be found when the product has functionality to retrieve a subset of elements for the maintenance object via scripting or via a user interface.
- A "physical" BO may be supplied. This a BO that typically includes all tables and all fields of the maintenance object in there "physical" form. In other words, there is no "flattening" of child tables and any XML structure fields are defined as a single field. Physical BOs are used in system processing where the full record needs to be captured as is. Some functionality that uses a physical BO includes [bundling](#), [revision control](#) and the pre-compare algorithm for CMA to [adjust data prior to comparing](#). If there are any maintenance objects that do not have a base supplied physical BO, refer to [Creating a Physical Business Object](#) for steps on how to provide one.
- A "bundling add" BO may be supplied. Refer to [Recursive Key References](#) for more information as to why this type of BO may be supplied.

Business Object Inheritance

A business object may inherit business rules from another business object by referencing the latter as its parent. A child business object can also have children, and so on. A parent's rules automatically apply to all of its children (no compilation - it's immediate). A child business object can always introduce rules of its own but never remove or bypass an inherited rule.

The following is an illustration of multiple levels of business object inheritance.

Notice how the "Business Customer" business object extends its parent rules to also enforce a credit history check on all types of customers associated with its child business objects.

Most types of business object system events allows for multiple algorithms to be executed. For example, you can have multiple **Validation** algorithms defined for a business object. For these, the system executes all algorithms at all levels in the inheritance chain starting from the highest-level parent business object moving on to lower levels.

Other types of system events allows for a single algorithm to be executed. For example, you can only have one **Information** algorithm to format the standard description of a business object instance. For these, the system executes the one at the level nearest to the business object currently being processed.

Note: The parent and its children must reference the same maintenance object.

Note: Data structures are not inherited. While you can declare schemas on parent business objects, their children will not inherit them. A good practice is to design child business object schemas to **include** their parent business object's schema.

Note: User interface maps are inherited. When determining if the business object has a UI map to use for UI rendering, the system looks for display and maintenance maps linked to the BO as options. If the identifying BO does not have maps defined, the system follows "up the chain" of inheritance until it finds a

map to use. This allows for a child BO to be used to extend business rules of a parent BO but inherit its user interface behavior. Refer to [Business Object Defines its User Interface](#) for more information.

Note: Use Inheritance Wisely. While it is intellectually attractive to abstract behavior into parent BOs to avoid redundant logic and simplify maintenance, before doing this weigh the reuse benefits against the cost in transparency, as it is not easy to maintain a complex hierarchy of business objects.

Each Business Object Can Have A Different Lifecycle

Many maintenance objects have a status column that holds the business entity's current state within its lifecycle. Rules that govern lifecycle state transition (what is its initial state, when can it transition to another state, and so on.) and the behavior associated with each state are referred to as lifecycle rules. Older Maintenance Objects, such as To Do Entry, have predefined lifecycles whose rules are governed by the base-package and cannot be changed. The lifecycle of newer Maintenance Objects exists in business object meta-data and as such considered softly defined. This allows you to have completely different lifecycle rules for business objects belonging to the same maintenance object.

Here are examples of two business objects with different lifecycles that belong to the same maintenance object.

The boxes in the above diagram show the potential valid states a business entity of the above business object can be in. The lines between the boxes indicate the state transition rules. These rules govern the states it can move to while in a given state. For example, the above diagram indicates a high bill complaint that's in the **Lodged** state can be either **Canceled** or moved into the **Preliminary Investigation** state.

When you set up a business object, you define both its valid states and the state transition rules, including the label for the Action to display on a button for users that may initiate a transition. For example, the action label to transition to the 'Approved' state could be configured as 'Approve'.

Note: The status description and the action label of base delivered values may be overridden by your implementation.

Note: A Maintenance Object supports soft lifecycle rules if it is defined with a **Status Field Maintenance Object option**.

The topics that follow describe important lifecycle oriented concepts.

One Initial State and Multiple Final States

When you set up lifecycle states, you must pick one as the initial state. The initial state is the state assigned to new entities associated with the business object. For example, the above high-bill complaint business object defines an initial state of **Lodged**, whereas the literature request one defines an initial state of **Literature Sent**.

You must also define which statuses are considered to be "final". Typically when an entity reaches a "final" state, its lifecycle is considered complete and no further processing is necessary.

Note: Allowing An Entity To Be "Reopened". You can set up your state transition rules to allow a business entity to be "reopened" (i.e., to be moved from a final state to a non-final state). Neither of the above examples allows this, but it is possible if you configure your business object accordingly.

State-Specific Business Rules

For each state in a business object's lifecycle, you can define the following types of business rules.

| System Event | Optional / Required | Description |
|----------------|---------------------|---|
| Enter | Optional | Algorithms of this type apply business rules when a business object instance enters a given state. |
| Exit | Optional | Algorithms of this type apply business rules when a business object instance exits a given state. |
| Monitor | Optional | Algorithms of this type monitor a business object instance while in a given state. Typically these are used to auto-transition it to another state. |

The system invokes all algorithms of this type defined on the business object's inheritance hierarchy. Refer to [Business Object Inheritance](#) for more information.

Fastpath: Refer to [BO Algorithm Execution Order](#) for a summary of when these lifecycle algorithms are executed with respect to BO level algorithms.

Entering A State

You can define algorithms that execute before a business entity enters a given state. For example, you could develop an algorithm that requires a cancellation reason before an entity is allowed to enter the **Canceled** state.

You can also incorporate state auto-transitioning logic within this type of algorithms. Refer to [auto-transition](#) for more information.

Also note that when a record is processed by the monitor batch program, by default the BO Post Processing, BO Audit and MO Audit algorithms are not executed. However, it is possible for an enter algorithm to indicate that the other algorithms should be executed by the batch process by setting the “force post processing” indicator to true.

Exiting A State

You can define algorithms that execute when a business entity exists a given state. For example, you could develop an algorithm that clears out error messages when a given entity exits the **Error** state.

Also note that when a record is processed by the monitor batch program, by default the BO Post Processing, BO Audit and MO Audit algorithms are not executed. However, it is possible for an exit algorithm to indicate that the other algorithms should be executed by the batch process by setting the “force post processing” indicator to true.

Monitor Rules

You can define algorithms to monitor a business entity while it is in a given state. This type of logic is typically used to check if the conditions necessary to [transition](#) the entity to another state exist (and, if so, transition it). For example, transition an entity to the **Canceled** state if it's been in the **Error** state too long. Another common use is to perform ancillary work while an entity is in a given state. For example, update statistics held on the object while it's in the **Active** state.

Monitor algorithms are invoked when a business entity first enters a state and periodically after that in [batch](#). You have the option to defer the monitoring of a specific state until a specific monitoring batch job runs. You do so by associating the state with a specific monitoring process. In this case the system will only execute the monitoring rules of this state when that specific batch process runs. This is useful when processing one type of record typically creates another type of record. You may want the processing of the second set of records to be deferred to a later time.

A monitor algorithm can carry out any business logic. In addition it can optionally tell the system to do either of the following:

- Stop monitoring and transition to another state. The system will not call any further monitoring algorithm plugged in on the state and attempt to transition the entity to the requested new state.
- Stop monitoring. Same as above except that no transition takes place. You may want to use this option to prevent transitions while some condition is true.

If none of the above is requested the system keeps executing subsequent monitoring algorithms.

Also note that when a record is processed by the monitor batch program, by default the BO Post Processing, BO Audit and MO Audit algorithms are not executed. However, it is possible for a monitor algorithm to indicate that the other algorithms should be executed by the batch process by setting the “force post processing” indicator to true.

Fastpath: Refer to [Business Object - Lifecycle](#) for more information on how to set up state-specific algorithms.

Inheriting Lifecycle

If a business object references a parent business object, it always **inherits** its lifecycle from the highest-level business object in the hierarchy. In other words, only the highest-level parent business object can define the lifecycle and the valid state transitions for each state. Child business objects, in all levels, may still extend the business rules for a given state by introducing their own state-specific algorithms.

The system executes all state-specific algorithms at all levels in the inheritance chain starting from the highest-level parent business object moving on to lower levels.

Auto-Transition

In a single transition from one state to another, the system first executes the **Exit** algorithms of the current state, transitions the entity to the new state, executes the **Enter** algorithms of the new state followed by its **Monitor** algorithms. At this point if a **Monitor** algorithm determines that the entity should be further automatically transitioned to another state the remaining monitoring algorithm defined for the current state are not executed and the system initiates yet another transition cycle.

Notice that an **Enter** algorithm can also tell the system to automatically transition the entity to another state. In this case the remaining **Enter** algorithm as well as all **Monitor** algorithms defined for the current state are not executed.

The following illustration provides an example of an auto-transition chain of events.

In this example a business entity is in a Pending state. While in that state a **Monitor** algorithm determines to auto-transition it to the Denied state. At this point the following takes place:

- No further **Monitor** algorithms of the Pending state are executed
- Pending state **Exit** algorithms are executed
- The system transitions the entity to the Denied state
- Denied state **Enter** algorithms are executed. No further auto-transition is requested.
- Denied state **Monitor** algorithms are executed. No further auto-transition is requested.

Keeping An Entity In Its Last Successful State

By default, any error encountered while transitioning a business entity from one state to another rolls back all changes leaving the entity in its original state.

When applicable, the Maintenance Object can be configured to always keep an entity in its last successful state rather than rolling all the way back to the original state. This practice is often referred to as "taking save-points". In case of an error, the entity is rolled back to the last successfully entered state and the error is logged on the [maintenance object's log](#). Notice that with this approach no error is returned to the calling process, the error is just logged.

The logic to properly log the error is in a **Transition Error Maintenance Object plug-in**. The system considers a maintenance object to practice "save-points" when such an algorithm is plugged into it.

Even if the maintenance object practices "save-points", in case of an error the system will not keep an entity in the last successfully entered state if that state is either marked as [transitory](#) or one of its **Enter** algorithms has determined that the entity should proceed to a next state. The system will roll back to the first previous state that does not match these conditions.

Monitoring Batch Processes

A monitor batch process may be used to transition a business object into its next state by executing the monitor algorithms associated with the current state of the entity. The use cases for performing the monitor logic in batch are as follows:

- The record may be waiting for something else to occur before transitioning. The monitor algorithm may be coded to determine if the condition is satisfied and initiate the transition then. For example perhaps when entering a state, a field activity is generated and the record should exit the state when the field activity is complete. The monitor algorithm can check the status of the field activity.
- Perhaps a record is added or updated manually and the next step in the BO lifecycle includes a large amount of processing such that the logic should occur in batch. In this case the BO status is configured with an explicit reference to a batch control (referred to as "deferred"), which indicates to the system that the monitor algorithms should not be performed automatically (but should be deferred to batch). Later when the batch process runs, it selects all the records to process to progress the records.

Note: When a status includes a deferred batch control, it may also be configured to allow a user to manually transition the record to the next state rather than waiting for batch. When a user manually transitions a record that includes monitor algorithms, those algorithms are not executed.

- Perhaps a record is added or updated in batch, but a subsequent step in the overall lifecycle should be processed later. This may be accomplished by ensuring that the batch control linked to the state to process later does not match the batch control that added or updated the record.
- Monitor processes may also be used to periodically perform some logic related to the record without actually transitioning the record.

Note that only the parent business object may refer to a deferred monitor batch process. However, any business object in the "[inheritance](#)" chain may be configured with monitor algorithms, which will all be executed.

The base package provides a periodic monitoring batch process for each maintenance object that supports a configurable BO lifecycle. The process periodically executes the monitoring algorithms associated with the current state of an entity, excluding states explicitly referencing a deferred monitoring batch process that is for a different batch control.

A deferred monitoring process selects records whose current state references this particular batch control as their monitor process. Deferred monitor process is only needed when an object has different use cases for monitoring the same type of records with different schedules. In this case only one periodic monitor batch should be configured. Other monitors should be configured to restrict by batch control so that there is no overlap in processing.

Note: MO option configuration. The maintenance object includes options to indicate the batch controls delivered for periodic and deferred monitor batch controls.

Your business rules will dictate the execution frequency of each monitoring process and the order in which they should be scheduled. Refer to [Monitor Background Processes](#) in the background process chapter for more information about the parameters supported for this type of batch process.

Note: Updates to the business object. When the monitor algorithms indicate that the business object should transition, the monitor batch processes are responsible for ensuring the business object is transitioned appropriately and that the appropriate exit, enter and monitor algorithms are executed. Please note that the business object is not updated using a call to the maintenance object service and therefore by default the [business rules](#) plugged in to the business object are not executed. However, it is possible for an Enter algorithm, Exit algorithm or Monitor algorithm to indicate that the other algorithms should be executed by the batch process. If the "force post processing" indicator is set to true, then the batch process invokes the BO Post Processing, BO Audit and MO Audit algorithms.

Transitory States

You can define a state as **Transitory** if you do not wish the business entity to ever exist in that particular state.

The following illustrates a lifecycle with a transitory Validate state.

In this example, the business entity is saved still not validated in the Pending state. At some point, the user is ready to submit the entity for validation and transitions it into a transitory state **Validate** whose **Enter** rules contain the validation logic. The responsibility of the transitory state's **Enter** algorithms is to decide if the entity is valid or in error and then transitions it into the appropriate final state. In this scenario, you may not ever want the business entity to exist in the **Validate** state.

Let's also assume that the maintenance object in this example is practicing "[save-points](#)" and requires the entity to be kept in its last successful state. If an error were to occur during the transition from **Validate** to the next state, the system would roll back the entity back to Pending, and not **Validate** even though the entity has successfully entered the **Validate** state. Refer to the [Auto Transition](#) section for more information.

State Transitions Are Audited

Most Maintenance Objects that support soft lifecycle definition also have a log to hold significant events throughout a business entity's lifecycle. For example, log entries are created to record:

- When the business entity is created (and who created it)
- When its status changes (and who changed it)
- If a transition error occurred (and the error message)
- References to other objects created throughout the entity's lifecycle. For example, if a To Do entry is created as part of processing the entity, the To Do Entry is referenced in the log.
- Manual entries added by a user (think of these as "diary" entries)

When a business entity is first created and when it transitions into a new state the system calls **Transition** algorithm(s) plugged in on the [Maintenance Object](#) to record these events. If the maintenance object supports a log these events can be captured as log entries.

Note: Most base package maintenance objects supporting a log may already provide state transition logging as part of their core logic. In this case you only need to provide a **Transition** plug-in if you wish to override base logging logic with your own.

Required Elements Before Entering A State

You can define additional elements that are required before a business entity can enter a given state. For example, let's assume that a Cancel Reason must be defined before an object can enter the *Canceled* state. You do this by indicating that element as a **Required Element** [state-specific option](#) on the appropriate state on the business object.

Capturing a Reason for Entering a State

Some business objects support configuring certain states to allow or require a status reason when an object enters the state. The product provides a centralized status reason table that may be used to define the valid BO status reasons for various business objects and various states. The status reasons are defined using the [Status Reason](#) portal.

The following sections provide additional information about the BO status reason functionality.

Maintenance Object Must Support Status Reason

In order for a business object to use the centralized status reason table to define reasons, the maintenance object must first support the status reason. MOs that support status reason have the following characteristics:

- The primary table includes a column for Status Reason. This represents the status reason for the record's current status, if applicable.

- The log table includes a column for Status Reason. The standard logic for capturing a log record when entering a state also captures the status reason, if applicable. This allows a user to review the history of the changes in status and the status reason captured for a previous state transition, if applicable.
- The maintenance object option collection includes an option that defines the Status Reason field. This setting is a trigger for business objects of this MO to be able to configure states to allow or require status reason.

Business Object State Indicates if Reasons are Applicable

Once the MO is configured to support status reason, configuration on the business object is required to indicate the states where a reason is applicable. States may be configured to require status reasons, allow status reasons as optional or not allow status reasons. With this configuration, the framework will automatically get the list of valid reasons for a state that allows or requires them and then prompt the user for a status reason when a manual state transition occurs for that state. It also automatically triggers an error if the state requires a status reason and no reason is provided.

Note: The status reason configuration on the business object state is customizable. That means that for a product owned business object, an implementation may opt to change the delivered configuration.

Status reasons are defined for the parent (or “lifecycle”) business object. All business objects in the hierarchy of the parent business object have the same valid reasons for their states.

The status reason code must be unique for the centralized status reason table. Business object and status are required fields, so it is not possible to share a common reason code (like “Not applicable”) across multiple business objects or states. If multiple BOs / states want to support a reason “Not applicable” then each must define a unique record for it. This point should be considered when planning for your status reasons.

Override Description

The description of product owned status reasons may be overridden by your implementation.

Selectable vs. Not Selectable

When defining a status reason, you may indicate whether it’s **Selectable** or **Not Selectable**. When a manual transition is performed and a user is prompted for a status reason, only the **Selectable** reasons are presented. The **Not Selectable** reasons may be defined to support transitions that occur via algorithm processing.

Note: The Selectable setting is customizable. That means that if a product provides a base owned status reason for a business object state, an implementation may opt to change whether it is selectable or not. Careful consideration should be made before changing a base delivered status reason from **Not Selectable** to **Selectable** as this may affect base provided algorithm functionality that could be relying on the setting of **Not Selectable**.

Status Reason Business Object

The status reason maintenance object, as with many maintenance objects in the product, references a business object used to define attributes and behavior related to defining status reasons. The framework provides a business object for status reason (**F1-BOStatusReason**). For the business objects that have states that require a status reason (let’s call these “transactional BOs”), if there is some special logic required for defining the status reasons, it is possible to define a different status reason BO. In this situation, the override status reason BO to use for capturing status reasons should be defined as a BO option on the transactional BO using the **Status Reason Business Object** option type. If a transactional BO does not define any status reason BO option, then the **F1-BOStatusReason** is used when adding a status reason.

Defining a Usage

The base product status reason BO provides the ability to define a “usage” value. This is useful for algorithms that perform state transitions where a status reason is needed and where the algorithm is usable by more than one business object. In this case, the status reason to use cannot be provided as a parameter because each business object must define its own set of status reasons for each state. The Usage value can be used instead. Each business object can

configure the status reason to use in the algorithm and set the appropriate usage value. The algorithm can reference the usage value and retrieve the correct status reason to use based on the record's transactional BO.

The status reason business object provided with the framework product (**F1-BOStatusReason**) supports capturing a usage. The valid usage values are defined in the **Status Reason Usage** characteristic type.

Alternatives for Defining Reasons

There may be business objects in the system that capture reasons that are defined somewhere besides the BO status reason table. For example, some objects may have an explicit administrative table for status reasons. Some objects may use a Lookup or an Extendable Lookup to capture reasons. Refer to the business object description for information about how valid reasons are defined, if applicable.

If a business object supports a reason that is not related to a state transition (such as a creation reason), the BO status reason would not be used. One of the alternate methods for defining a reason, described above, would be used.

Opening UI Maps Before Entering A State

You can define a UI Map to capture additional elements before a business entity can enter a given state. You do this by configuring the **State Transition UI Map** [state-specific option](#) on the appropriate state on the business object.

There may be circumstances in which the status pre-processing logic can determine the value of the elements, in which case it is not necessary to invoke the map. The system provides a data area (**F1-StateTransitionCommon**) which contains a boolean element to indicate if the state transition map can be skipped. This data area can be included in your pre-processing script to allow the element to be set according to your business logic. The base maintenance script (**F1-MainProc**) references this element to determine whether to open the state transition map.

BO Algorithm Execution Summary

This table highlights the processing steps that occur when adding or changing a record that is governed by a business object.

| Invoke BO | |
|---|---|
| Event | Comments |
| BO Pre-processing algorithms executed | These algorithms are only executed when Invoke BO is used. The business object in the Invoke BO is the one whose rules are executed. |
| MO Processing | |
| Event | Comments |
| Determine if status has changed. | The system keeps a note of the new status value but initially proceeds with the old value. |
| MO Processing. | Standard MO processing, including MO validation is executed. |
| Determine BO algorithm executed. | The MO level algorithm is executed to determine the identifying BO . |
| BO Validation algorithms executed. | |
| State transition rules are performed if the status has changed. | BO Status Exit algorithms for the “old” status executed. Status updated to the new value. BO Status Enter algorithms for the “new” status executed. |

| | |
|---|--|
| | If no error — MO Transition algorithms are executed. |
| |  Fastpath: Refer to State Transitions are Audited for more information. |
| | If error and there are “save points” the MO Transition Error algorithms are executed. |
| |  Fastpath: Refer to Keeping An Entity In Its Last Successful State for more information. |
| | Otherwise, the error is reported. |
| BO Status Monitor algorithms are executed. | If the record transitions again, the prior step (State transition rule step) is repeated for the new transition. |
| BO Post-processing algorithms are executed. | |
| BO Audit algorithms are executed. | These algorithms are only executed if the system detects a change in elements that are not marked with “no audit”. |

Note: To emphasize, the steps in the MO Processing table are only executed when the maintenance object service is invoked. Any add or update initiated by an “invoke BO” statement will invoke the MO service. This is also true for web service that invoke the business object. The [Monitor Batch Process](#) does not invoke the maintenance service. By default the monitor batch process only executes the monitor algorithms and the state transition rules (if the monitor algorithms indicate that a status change should occur). However, it is possible for an Enter algorithm, Exit algorithm or Monitor algorithm to indicate that the other algorithms should be executed by the batch process. If the “force post processing” indicator is set to true, then the batch process invokes the BO Post Processing, BO Audit and MO Audit algorithms.

Note: For records that do not have a status, the state transition rules and the monitor rules are not applicable.

Granting Access To Business Objects

Every business object must reference an [application service](#). When you link a business object to an application service, you are granting all users in the group access to its instances. You can prevent users from transitioning a business object into specific states by correlating each business object status with each application service action (and then don't give the user group rights to the related action).

Fastpath: Refer to [The Big Picture Of Application Security](#) for information about granting users access rights to an application service.

The system checks if a user has access rights each time the application is invoked to add, change, delete, read, or transition a business object. However, if a business object invokes another business object, we assume that access was controlled by the initial business object invocation and we do not check access for other business objects that it invokes. In other words, access rights are only checked for the initial business object invoked in a service call.

In order to apply business object security the system must be able to determine the business object associated with the actual object being processed. To do that the Maintenance Object itself has to have a **Determine BO** algorithm [plugged in](#). If this algorithm is not plugged in or it cannot determine the BO on the MO, the system will not invoke any BO rules. If the business object cannot be determined for a maintenance object instance, business object security is not checked. In this case the system checks the user's access rights using standard maintenance object security.

Note: Parent business objects are ignored. If a child business object exists, a user need only have access to the child business object's application service (not to every application service in the business object hierarchy).

Defining Business Objects

This portal is used to view and maintain information about a business object.

You can access the portal from the **Admin Menu > System > Business Object**. You are brought to a query portal with options for searching for a specific business object. Once a business object has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Understanding Business Objects](#) for more information.

CAUTION: Important! If you introduce a new business object, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The following zones may appear as part of the portal's **Main** tab page.

- **Business Object.** This zone provides information about the selected business object.
- **Schema Editor.** This zone describes the business object's schema and supports basic edits in plain text. Refer to the **Schema** tab below for additional schema editor information.

The following zones may appear as part of the portal's **Schema** tab page.

- **Schema Editor.** This zone allows you to edit the business object's schema using the [Schema Designer](#) tool. The purpose of the schema is to describe the business object's properties and map them to corresponding maintenance object fields.

Fastpath: Refer to [Schema Syntax](#) and [UI Hint syntax](#) for a complete list of the XML nodes and attributes available to you when you construct a schema.

Tip: Click the **View Schema** hyperlink to view the business object's expanded schema definition. Doing this opens the [schema viewer](#) window.

The following zones may appear as part of the portal's **Algorithms** tab page. Refer to [A Business Object May Define Business Rules](#) on page 146 for more information.

- **Algorithms.** This zone is used to maintain the algorithms associated with the current business object.
- **Hierarchy Algorithms.** This zone displays all algorithms associated with the business object's [inheritance hierarchy](#). The zone is visible when the current business object is part of a hierarchy and such algorithms exist.

The following zones may appear as part of the portal's **Options** tab page. Refer to [A Business Object Defines Options](#) on page 150 for more information.

- **Options.** This zone is used to maintain various configuration options associated with the current business object.
- **Hierarchy Options.** This zone displays all options associated with the business object's [inheritance hierarchy](#). The zone is visible when the current business object is part of a hierarchy and such options exist.

The following zones may appear as part of the portal's **Lifecycle** tab page. This tab is only available when the maintenance object supports [lifecycle](#) definition.

- **Lifecycle.** This zone describes and maintains the current business object's lifecycle definition. Broadcast a specific status to review its complete configuration.
- **Status Details.** This zone is used to maintain basic definition information for a selected status within the current business object's lifecycle.
- **Status Algorithms.** This zone is used to maintain algorithms for a selected status within the current business object's lifecycle.
- **Status Options.** This zone is used to maintain various configuration options for a selected status within the current business object's lifecycle.
- **Hierarchy Status Algorithms.** This zone displays all algorithms associated with the business object's [inheritance hierarchy](#) for a selected status. The zone is visible when the current business object is part of a hierarchy and such algorithms exist.
- **Hierarchy Status Options.** This zone displays all options associated with the business object's [inheritance hierarchy](#) for a selected status. The zone is visible when the current business object is part of a hierarchy and such options exist.
- **Status Reasons.** This zone is used to maintain reasons for a selected status. The zone is visible when the maintenance object supports a reason field and usage of reasons is allowed by the status definition.

The following zones may appear as part of the portal's **Lifecycle View** tab page. This tab is only available when the maintenance object supports lifecycle definition.

- **Lifecycle View.** This zone provides a schematic view of the current business object's lifecycle definition. Broadcast a specific status to review its complete configuration.
- **Status Details.** This zone is used to maintain basic definition information for a selected status within the current business object's lifecycle.
- **Status Algorithms.** This zone is used to maintain algorithms for a selected status within the current business object's lifecycle.
- **Status Options.** This zone is used to maintain various configuration options for a selected status within the current business object's lifecycle.

The following zones may appear as part of the portal's **Hierarchy** tab page. This tab is only available when the current business object is part of a [hierarchy](#).

- **Business Object Hierarchy.** This zone lists the inheritance hierarchy of business objects up to and including the current business objects. The zone is visible if the current business object is not the top level business object of the hierarchy.
- **Business Object Tree.** This zone describes the entire hierarchy of the current business object.
- **Hierarchy Algorithms.** This zone lists all algorithms defined for the current business object. The zone is visible if algorithm information exists for the current business object.
- **Hierarchy Lifecycle Algorithms.** This zone lists all algorithms associated with the current business object's inheritance hierarchy. The zone is visible if the current business object is not the top level business object of the hierarchy and algorithm information exists. Refer to [Inheriting Lifecycle](#) for more information.
- **Hierarchy Options.** This zone lists all configuration options for the current business object's lifecycle. The zone is visible if options information exists for the current business object.
- **Hierarchy Lifecycle Options.** This zone displays all options associated with the current business object's inheritance hierarchy. The zone is visible if the current business object is not the top level business object of the hierarchy and options information exists. Refer to [Inheriting Lifecycle](#) for more information.

The following zones may appear as part of the portal's **References** tab page.

- **Business Object References.** This zone list various configuration entities referencing the current business object or its schema.

Actions

The page supports the following special actions:

- **Generate User Interfact Configuration Artifacts.** When creating a new business object or editing an existing one, you may request to generate the user interface configuration artifacts needed to properly maintain and display the business object on an existing portal.

For example, if a display script is needed to further prepare the business object's details for presentation then request to generate such script. You can then navigate to the script from the **User Interface Configuration** section and adjust it as needed.

- **Subclass a Business Object.** Use the **Subclass** action to create a new business object that is a child of an existing business object. The action generates the new business object's schema as inherited from the existing business object. Refer to [Business Object Inheritance](#) on page 153 for more information.

Once created, you may extend and adjust the new business object's schema and rules as needed.

- **Create an Algorithm.** Use this action, on the Algorithm tab or the Lifecycle tab for a specific status, to creates a script based algorithm related to this business object. You are prompted for information regarding the plug-in spot (BO or BO Status) and the system event, the name, description, etc. Once all the information is provided, the system creates an algorithm type, a script, an algorithm and links the algorithm to the business object. You may then navigate to the script to adjust it as needed.
- **Inactivate / Activate Base Algorithms.** You can inactivate algorithms on base Business Objects. Your implementation may want to use a business object provided by the base product, but may want to inactivate one

or more algorithms provided by the base business object. To do that, use the "Inactivate" action on the appropriate algorithm entry on the Algorithm tab. Use the "Activate" action to mark an inactive algorithm as active.

Note that these actions add and remove the "Inactive Algorithm" business option as needed.

- **View Schema.** Click the hyperlink to view the business object's expanded schema definition. Doing this opens the [schema viewer](#) window.

Advanced BO Tips and Techniques

The topics in this section describe some advanced tips and techniques for configuring business objects.

Creating a Physical Business Object

The physical business object's schema represents the complete physical structure of the maintenance object, and includes elements for all fields in the maintenance object's tables. There are several processes in the system that may use a maintenance object's physical BO.

To create a physical business object for the maintenance object:

1. Navigate to [Business Object](#) and add a business object for the maintenance object. Do not fill in any of the UI oriented configuration.
2. The business object is created with a schema that looks like the physical structure of the maintenance object.
3. Save the physical business object.
4. Navigate to [Maintenance Object](#) and search for the maintenance object.
5. On the **Option** tab, add a new option with the type **Physical Business Object**. The value is the name of the physical business you just created.

Managing To Do Entries

The product provides several base algorithm types that may be used to manage To Do entries through status changes for a given record via BO lifecycle plug-ins.

Create To Do Entry

The product supplies a BO status Enter algorithm type **Generic To Do Creation (F1-TDCREATE)** that creates a To Do entry based on parameter configuration. Refer to the algorithm type description for more information about how it determines the To Do type or To Do role and how to populate the appropriate message text onto the To Do. This algorithm may be used in conjunction with the Retry Logic (below).

If your implementation has a business rule that requires a To Do entry to be created when entering a given BO status and the logic provided by the algorithm type meets the needs of the business rule, this algorithm type may be used. Create an algorithm for the algorithm type, populate the algorithm parameters according to the business rules and plug the new algorithm into the appropriate business object status as an Enter algorithm.

Retry Logic

The algorithm type **Retry for To Dos (F1-TODORETRY)** is supplied for a special use case. It is a BO status monitor plug-in and may be used for a state that is a type of 'error' or 'waiting' state. It relies on the To Do entry creation logic to set a Retry Frequency. The algorithm transitions to the originating state to retry the logic. The idea is that the condition that caused the record to enter the 'error' or 'waiting' state may be resolved after some period of time has passed, allowing the record to progress in its lifecycle. Refer to the algorithm type description for more information about its logic.

To use this functionality, create an algorithm for this algorithm type, populate the algorithm parameters according to the business rules and plug the new algorithm into the appropriate business object status as a Monitor algorithm. The state should also have an algorithm for the **Generic To Do Creation** algorithm type plugged in as an Enter algorithm (or something equivalent) that sets the appropriate Retry Frequency.

To Do Completion

It is common that one or more To Do entries associate with a given record should be completed when exiting a state (if it is not already completed). The system supplies the algorithm type **Generic To Do Completion (F1-TODOCOMPL)** that may be used for this purpose. Note that the algorithm type functionality is not tied to any To Do creation logic. It may be used for any use case where To Do entries should be completed on exiting a state. Refer to the algorithm type description for more information about its functionality and how to prevent certain To Do entries from being automatically completed.

To use this functionality, create an algorithm for this algorithm type, populate the algorithm parameters according to the business rules and plug the new algorithm into the appropriate business object status as an Exit algorithm.

Submitting a Batch Job

The product provides a base algorithm type that submits a batch job when entering a BO state. This functionality allows for “event driven” batch submission where the event is the lifecycle transition for a certain record.

The algorithm type is **Create Batch Job Submission Entry for Batch Control (F1-SCHEDJOB)**. The batch control code is a parameter for the algorithm. Refer to the algorithm type description for more information about its logic.

To use this functionality, create an algorithm for this algorithm type, populate the algorithm parameter with the batch control that should be submitted and plug the new algorithm into the appropriate business object status as an Enter algorithm.

Defining Status Reasons

Status Reasons are used to provide more information about why a business object transitioned to a given state. The status reason table provides a centralized place where status reasons can be defined across many different business objects and states.

Note: Refer to [Defining Reasons for Entering a State](#) for overview information.

If a business object has one or more states that are configured to capture a status reason, you may configure the valid reasons by navigating to the status reason portal using **Admin > System > Status Reason**.

The topics in this section describe the base-package zones that appear on the Status Reason portal.

Business Objects with Status Reason List

This zone displays the business objects that have one or more status values that allow status reasons to be defined.

Click the broadcast icon to open other zones that contain more information about the business object’s status reasons.

Status Reasons

The **Status Reasons** zone contains a list of the existing status reasons for the broadcasted business object.

Data Areas

The data area has no business purpose other than to provide a common schema location for re-used schema structures. It exists solely to help eliminate redundant element declaration. For example, if you have multiple schemas that share a common structure, you can set up a stand-alone data area schema for the common elements and then include it in each of the other schemas.

Be aware that a stand-alone data area can hold elements that are mapped to true fields. For example, you might have 50 different types of field activities and all might share a common set of elements to identify where and when the activity should take place. It would be wise to declare the elements that are common for all in a stand-alone data area and then include it in the 50 field activity business objects.

It's strongly recommended that you take advantage of stand-alone data areas to avoid redundant data definition!

CAUTION: Dynamic inclusion! When the system renders a schema, all schemas included within it are expanded real-time. This means that any change you make to a data area will take effect immediately within all schemas it is referenced within.

**Note:**

Schema Tips. The data area page includes a special Schema Tips zone that provides a link to launch help topics related to the [Advanced Schema Topics](#) help in one click.

Data areas may be included in a business object that does not define a full UI map for display or input. Rather, it is using auto-rendering by defining UI attributes in its schema and via UI hints.

Note: View UI Rendering. A context sensitive "View UI Rendering" zone appears on this page. It may be used for a data area that is part of a business object that is using auto-rendering for the display and input maps. The buttons allow you to view the rendered UI for the segment of the schema that is defined by the data area.

Defining Data Areas

The topics in this section describe how to maintain Data Areas.

Data Area - Main

Use this page to define basic information about a data area. Open this page using **Admin > System > Data Area**.

Use the **Data Area Query** portal to search for an existing data area. Once a data area is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter a unique **Data Area** name and **Description**. Use the **Detailed Description** to describe what this data area defines in detail. **Owner** indicates if the data area is owned by the base package or by your implementation (**Customer Modification**).

CAUTION: Important! If you introduce a new data area, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Click the **View Schema** to view the data area's expanded schema definition. Doing this opens the [schema viewer](#) window.

Click the **View XSD** hyperlink to view the business object's expanded schema definition in XSD format.

To extend another data area, reference that data area in the **Extended Data Area** field. By extending a data area you can add additional elements to a base product data area.

Here's an example of an extended data area:

- The product releases with data area A, which contains elements a, b, and c.
- Your implementation creates data area CM-A, which contains element z, and references data area A as the extended data area.
- At run time, everywhere data area A is included it will contain elements a, b, c, and z.

Data Area - Schema

Use this page to maintain a Data Area's schema and to see where the data area is used in the system. Open this page using **Admin > System > Data Area** and then navigate to the **Schema** tab.

Description of Page

The contents of this section describe the zones that are available on this portal.

The **General Information** zone displays the main attributes of the data area.

The [Schema Designer](#) zone allows you to edit the data area's schema. The purpose of the schema is to describe the structure and elements of the data area.

Fastpath: Refer to [Schema Syntax](#) and [UI Hint syntax](#) for a complete list of the XML nodes and attributes available to you when you construct a schema. Also note that the **Schema Tips** zone in the sidebar provides links to launch these help topics directly.

Note: View UI Rendering. A context sensitive "View UI Rendering" zone is associated with this page. The zone is useful for data areas that are to be included in [business objects that define the user interface detail](#)

using schema attributes and UI Hints. The buttons allow you to view the automatically rendered display and input maps.

The **Schema Usage Tree** zone summarizes all cross-references to this schema. These may be other schemas, scripts, and web services. For each type of referencing entity, the **tree** displays a summary node showing a total count of referencing items. The summary node appears if at least one referencing item exists. Expand the node to list the referencing items and use their description to navigate to their corresponding pages.

Business Services

A business service is used to expose a back-end service so that it may be invoked by a script or a zone or a map to retrieve information or perform functions, depending on the related service.

As with the business object, the business service's interface to the internal service is defined using its schema. The schema maps the business service's elements to the corresponding elements in the internal service program's XML document. Just as a business object can simplify the schema of its maintenance object by only defining elements that it needs and “flattening” entries in a child collection to be defined as a singular element, a business service schema may simplify its service XML in a similar way.

Fastpath: Refer to [Schema Syntax](#) for a complete list of the XML nodes and attributes available to you when you construct a schema.

[Inbound web services](#) and [scripts](#) support interaction with business services. You can also invoke a business service from a Java class.

Service Program

This transaction defines services available in the system. These include user interface services as well as stand-alone services that perform a specific function. A service may be referenced by a business service. Use this transaction to view existing service and introduce a new stand-alone service to be made available to a Business Service.

Select **Admin > System > Service Program** to maintain service programs.

Description of Page

Service Name is the unique identifier of the service.

CAUTION: Important! When adding new service programs, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Owner indicates if this service is owned by the base package or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add a service. This information is display-only.

Description describes the service.

Application Service is the application service that is used to provide [security](#) for the service. If the service is related to a maintenance object, the access modes for the application service should be the standard **Add, Change, Delete** and **Inquire**. For other services, the application service should have the **Execute** access mode.

Service Type indicates whether the service is a **Java Based Service** or a **Java (Converted) Service**. Note that services generated to support a portal in the system will not have a service type populated.

This **Program Component** grid shows the list of program user interface components associated with the service. For a stand-alone service, this list is typically not applicable.

Defining Business Services

The topics in this section describe how to maintain business services.

Note that several context sensitive sidebar zones appear on this page and are visible on all tabs.

- **Schema Tips.** This zone provides several links to launch help topics related to valid schema syntax.
- **Generate Schema.** This zone includes a button that can be used to generate the schema based on the XML of its related Service. Once generated, adjust the schema as desired.

Business Service - Main

Use this page to define basic information about a Business Service. Open this page using **Admin > System > Business Service**

Use the **Business Service Query** portal to search for an existing business service. Once a business service is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter a unique **Business Service** name and **Description**. Use the **Detailed Description** to describe the purpose of this business service in detail. **Owner** indicates if the business service is owned by the base package or by your implementation (**Customer Modification**).

CAUTION: Important! If you introduce a new business service, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Enter the internal **Service Name** being called when this business service is invoked.

Enter the **Application Service** that is used to provide security for the business service. The application service must have an Access Mode of Execute.

Click the **View Schema** to view the business service's expanded schema definition. Doing this opens the [schema viewer](#) window.

Click the **View XSD** hyperlink to view the business object's expanded schema definition in XSD format.

Business Service - Schema

Use this page to maintain a Business Service's schema and to see where the Business Service is used in the system. Open this page using **Admin > System > Business Service** and then navigate to the **Schema** tab.

Description of Page

The contents of this section describe the zones that are available on this portal.

The **General Information** zone displays main attributes of the business service.

The [Schema Designer](#) zone allows you to edit the business service's schema. The purpose of the schema is to map the business service's elements to the corresponding fields of the back-end service program it rides on.

Note: Generating a Schema A context sensitive "Generate Schema" zone is associated with this page. The zone provides a button that allows the user to generate a basic schema that includes all the elements that are found in the XML of the BS's service.

Fastpath: Refer to [Schema Syntax](#) for a complete list of the XML nodes and attributes available to you when you construct a schema. Also note that the **Schema Tips** zone in the sidebar provides a link to launch this help topic directly.

The **Schema Usage Tree** zone summarizes all cross-references to this schema. These may be other schemas, scripts, and web services. For each type of referencing entity, the [tree](#) displays a summary node showing a total count of referencing items. The summary node appears if at least one referencing item exists. Expand the node to list the referencing items and use their description to navigate to their corresponding pages.

Useful Services and Business Services

The following section highlights some business services and services provided by the product that may be useful for implementations to use.

Data Explorer Service

The system provides a mechanism for performing an SQL select statement for use in scripting, Java plug-ins, or via a web service call. This is done by creating a zone using one of the data explorer zone types where the SQL is defined. Then, create a business service using the Data Explorer service (**FWLZDEXP**).

Note: There are numerous business services delivered with the base product that reference this service that may be used as a template.

The following points highlight how to create your own business service for this service. Note that typically a separate business service exists for each zone.

- Enter a **Business Service** code and a **Description**. It is recommended to define the business service code to match the zone code so that it's easier to manage which business service invokes which zone.
- Select the **Service Name FWLZDEXP**.
- On the **Schema** tab, under the `<schema>` node, enter mapping for the fields that are required for the Data Explorer service:
 - The **Zone** should be mapped into service field `ZONE_CD`. Define the zone code as the default value.
 - For every **user filter** defined on the zone, create a schema mapping into the service field `Fx_VALUE`, where "x" is the filter number (from the zone parameters).
 - For every **hidden filter** defined on the zone, create a mapping into the service field `Hx_VALUE`, where "x" is the filter number (from the zone parameters).
 - The search results are returned as a list by the data explorer service. Each column value is in the service field `COL_VALUE` with an appropriate sequence number (`SEQNO`). The results can be [flattened](#) based on sequence number allowing for a logical element name to be defined.
 - Another useful field is `ROW_CNT`, which provides the number of rows retrieved by your search.

The following is an example of the schema for a BS that receives a business object code and returns a list of status values and their descriptions that allow status reasons to be defined.

```
<schema>
  <zone mapField="ZONE_CD" default="F1-BOSTSLST"/>
  <bo mapField="H1_VALUE" />>
  <rowCount mapField="ROW_CNT"/>>
  <results type="list" mapList="DE">>
    <status dataType="string" mapField="COL_VALUE">
      <row mapList="DE_VAL">>
        <SEQNO is="1" />>
      </row>>
    </status>>
    <description dataType="string" mapField="COL_VALUE">
      <row mapList="DE_VAL">>
        <SEQNO is="2" />>
      </row>>
    </description>>
  </results>>
</schema>
```

Maintenance Object Log Service

Many maintenance objects support a log table that follows a pattern of column names and behavior. The system provides a service called Generic MO Log Service (**FIMOLOGP**) that may be used to perform common functions related to log entries:

- Read log entries. If you pass a certain MO, primary key and log sequence number, the service will return the details of that log entry. The product provides a generic business service that may be used for this purpose — Generic MO - Retrieve Log Details (**F1-ReadMOLog**). Alternatively, it is possible to create a business service for a given MO where the MO code is assigned to the MO element using the default syntax. This allows business functionality specific to that maintenance object to use the specific BS.
- Add log. The service may be used to add a log entry. If a user log is added, then the comments from the user are populated in the detailed description. System generated log entries typically supply a message category / message number along with other information such as the status, a specific log type and optionally a related object reference (via a characteristic). The product provides a generic business service that may be used for this purpose — Add Generic MO Log (**F1-AddMOLog**). Alternatively, it is possible to create a business service for a given MO where the MO code is assigned to the MO element using the default syntax. This allows business functionality specific to that maintenance object to use the specific BS.

Base Business Services

The following table highlights some business services provided by the product that may be useful for custom logic for an implementation.

CAUTION: This is not intended to be a complete reference of Business Services. Refer to the business service page to find all the supported business services.

Business Object Related Services

| Business Service Name | Description |
|---------------------------------------|--|
| F1-AutoTransitionBO | Performs monitoring algorithms associated with the current state of a given business object instance (which may result in subsequent state transitioning). |
| F1-CompareBusinessObjectData | Compares two versions of a given business object instance. |
| F1-DetermineBo | Determines the business object of a given instance of a maintenance object by executing the MO's Determine BO logic. |
| F1-GetRequiredFieldsForBOState | Returns the required fields for a given business object status. |
| F1-RetrieveBOOption | Returns BO option values for a given BO and option type. |
| F1-RetrieveBOStatusOption | Returns BO option values for a given BO, status and option type. |
| F1-RetrieveBOStatusOption | Retrieves a list of BOs for a given MO that are accessible for the current user. |
| F1-RetrieveBoStatusDescription | Return the description of a given BO status. |
| F1-RetrieveBusinessObjectLabel | Return the label appropriate for a given path (e.g. element) within a BO schema. |
| F1-RetrieveNextStates | Return a list of next possible states based on the input of a MO and its prime key, or a BO and one of its statuses. |

Email Related Services

| Business Service Name | Description |
|----------------------------------|---|
| F1-EmailService | Sends an email message in real time. |
| F1-RetrieveEmailAddress | Retrieves the email addresses of users belonging to a To Do Role. |
| F1-RetrieveEnvironmentURL | Retrieves the current environment URL information for the installation. |

Tools for Maps and Scripting

| Business Service Name | Description |
|---------------------------------|--|
| F1-AddWarning | This business service may be used to log a warning by providing the message details. The system gathers all the warning and displays them to the user all at once. |
| F1-CheckOnlineConnection | Check if Connection is Online or Batch. |

| Business Service Name | Description |
|--------------------------------------|--|
| F1-CheckWarning | Used to check if any warnings have been accumulated. If warnings have been accumulated, any logic that cannot be rolled back (when the warnings are shown) should not be performed. |
| F1-DateMath | Performs various date and time math calculations. Refer to the BS description for more details. |
| F1-DateTimeFormattingService | Formats a given date / time based on the user's display profile settings. |
| F1-ExecuteScriptInNewSession | Executes a Service Script in a new processing session/ transaction. |
| F1-GetFieldLabel | Retrieves the label for a given field. |
| F1-GetForeignKeyReference | Returns foreign key reference information for a given FK Reference and primary key, including info description, navigation option, and context menu. |
| F1-GetFKReferenceDetails | Returns foreign key reference information for a given MO and primary key, including FK reference code, info description, navigation option, search zone and context menu. |
| F1-GetLookupDescription | Returns lookup description for a lookup field value given the lookup field name. |
| F1-GetExtLookUpVal | Returns the list of values for a given extendable lookup BO. |
| F1-GetMonthInYearAbbreviation | Returns a 3-character month abbreviation for an input date in system format. |
| F1-NumberAmountFormatter | Formats a given amount or number based on the user's display profile settings. It also may receive input to adjust the scale and optionally apply currency settings. |
| F1-OutmsgDispatcher | Dispatches a real-time message giving the user the option of whether to persist the message on the database, and whether to trap errors that may take place during the call. Refer to Real Time Messages for more information. |
| F1-OutmsgMediator | Alternative to F1-OutmsgDispatcher and may be a better option if the sender does not require an outbound message record to be instantiated. Refer to Real Time Messages for more information. |
| F1-RethrowError | Issues an application error using the input message category / number / parameters. |
| F1-RetrieveMODescription | Retrieves the description for a maintenance object. |
| F1-ReturnMessage | Returns the expanded message given a message category, number, parameters, and parameter types. |
| F1-SavePointDispatcher | Allows for a service script to be executed where exceptions are trapped and the transaction is rolled back to a save point set before the service script execution. |

| Business Service Name | Comments |
|---------------------------------------|---|
| F1-CheckApplicationSecurity | Checks a user's security for a given application service / access mode |
| F1-CheckUserAuthorization | Determine whether a given user is authorized for access based on the input application service, security code, and authorization level. |
| F1-DetermineIfUserCanApproveTD | Determine if the current user can approve a given To Do. |

User Interface (UI) Options

Your implementation may create input forms and output maps that closely match your customer's business practice within the following user interface areas:

- Content presented in [portal zones](#). For example, a map that displays the details of a [business object](#) or any other informational content. Refer to [Map Zones](#) for more information.
- An input form presented via [Business Process Assistant \(BPA\) scripts](#) for data entry and update purposes. For example, a form that captures [business object](#) information or prompts the user for additional information related to a task they perform.
- An input form presented as a panel within a [process flow](#).

The HTML for these forms and maps may be provided using the following options:

- **UI Map.** Compose your HTML and store it as a UI map, which is a repository for an HTML document. The UI Map HTML gives you the ability to craft the display by any method that an HTML document can support, including JavaScript and full CSS functionality.
- **UI Hints.** With this technique you do not compose the HTML. Instead, the HTML is generated at run time based on a schema that describes the data being displayed and embeds user interface rendering instructions known as "UI Hints".

Understanding UI Maps

The preferred method for creating input and output HTML maps is by leveraging the schema-based HTML rendering technique known as [UI Hints](#). For more complex requirements, you may craft an HTML that closely matches your customer's business practices and capture it as a User Interface (UI) map.

The User Interface (UI) map is a repository for a single HTML document paired with an XML schema where the schema defines the data that the HTML document displays and/or modifies. The UI Map HTML gives you the ability to craft the display by any method that an html document can support, including JavaScript and full CSS functionality.

The topics in this section describe concepts and guidance relevant to UI map configuration.

Output Maps and Input Forms

UI maps are typically crafted as output tables when used in conjunction with portal zones - please refer to [Map Zones](#) for more information. When referenced within [BPA scripts](#) or [process flows](#), UI maps are typically crafted as forms for the capture and update of data.

Figure 3: Customer HTML Rendered (Output Data for Zone)

UI Map Fragments

A UI map may represent a complete HTML map or a fragment that can be embedded in a complete map.

You may use a UI map fragment in the following use cases:

- To share and reuse the same HTML/JavaScript across multiple complete UI maps. The UI map fragment is referenced as part of the HTML definition of the complete UI maps.
- To embed complex HTML/JavaScript logic as part of a map that its HTML is otherwise rendered using [UI Hints](#).
- To implement a filter map for a data explorer search zone where basic filter definition syntax does not handle your business requirements.

Configuration Tool Support

Configuration tool support for UI Maps hinges around the ability to inject and extract an XML document from the HTML. For more information on the specialized support for HTML and JavaScript functionality refer to [UI Map Attributes and Functions](#).

Ensuring Unique Element IDs for UI Maps

The following describes how to modify JavaScript code to ensure the proper rendering of unique element IDs for UI Maps.

The modification is required only for code that renders HTML using a `getElementById()` (or similar) function to generate list IDs and avoid account verification or related errors.

The following sample snippet contains the necessary modifications:

```
...
function getElementsFromList(namePrefix) {
    var ret = [];
    var elements = document.getElementsByTagName("INPUT");
    for(var i=0;i<elements.length;i++) {
        var elemID = elements[i].id;
        if((id) && (id.startsWith(namePrefix + '_'))) {
            ret.push(elements[i]);
        }
    }
    ...
    return ret;
}
```

Since IDs aren't necessarily unique in generated UI Map IDs, the code shown above ensures uniqueness at runtime by appending an underscore and row number (e.g., `myField_1`, `myField_2`) for proper handling by Framework in the rendered HTML, while still allowing you to reference the unmodified IDs contained in the generated UI Map.

A switch in the `spl.properties` file also permits you to disable the generation of unique IDs for elements in a grid (as described below), though, for standards compliance reasons, it is highly recommended that this switch be left at its default value.

```
Property Name: spl.runtime.compatibility.uiMapDisableGenerateUniqueHtmlIDs
File Name: spl.properties (under web project in FW)
Default Value: false
Accepted Values: true or false
Description: This property controls the generation of unique IDs for all input elements
a list. When this value is set to true it disables the generation of unique IDs, thus
replicating the old behavior. When this property is set to false or this property is mis-
it enables the generation of unique IDs, thus enabling the list to be standards-
compliant.
```

Understanding UI Hints

A schema may be used to describe the structure of a business object or any other XML document. When applicable, the same schema may also embed user interface (UI) "hints" that are interpreted at run time and render the HTML needed to display or maintain that document. Refer to [UI Hint Syntax](#) on page 177 for more information.

The main advantages of this technique are as follows:

- **Less error prone.** A tighter correlation between the data structure and its presentation layer keeps the latter up to date, for example:
 - Adding an element to the schema or removing an element from it result in a corresponding change to the presentation layer. Note that you can explicitly exclude elements from the presentation layer as needed.
 - The HTML widget that is most appropriate to present or input data for an element is determined by its data type as defined by the schema. For example, a date picker is used for an input date element. If the element's data type changes in the schema its presentation adjusts accordingly.
- **Faster to implement.** No HTML skills are needed. The schema definition along with its embedded UI hint instructions is used to render the HTML at run time. Eliminating the need of crafting HTML and maintaining it as a [UI Map](#) reduces implementation and maintenance costs.
- **Supports business object inheritance.** Incorporating the presentation layer into the business object schema allows each business object in a hierarchy to contribute their part to the complete HTML that displays the entity. In other words, the complete HTML used to display a subclassed business object is made of the HTML rendered by the included schema of its parent business object, followed by elements extended by the subclass.

The topics in this section describe concepts and guidance relevant to the UI Hints functionality.

Display vs. Input Modes

The same schema may be used to generate either a display version of its HTML map or an input map. In the display version, element values are presented as read-only, corresponding descriptions are shown instead of codes, and additional artifacts such as links are available for navigation to related pages. In the input version, the element is editable, using the appropriate HTML widget for its data type. For example, a foreign key element is rendered along with search components, and a date element includes a date picker widget.

The type of map generated depends on the context in which it is used:

- The display map is generated when the schema is used to present content in a [map zone](#).
- The input map is generated when the schema is used for data entry as part of a BPA script step or a process flow panel. Refer to [Generate Edit Map Statements](#) on page 298 and [process flows](#) for more information.

By default, each element in the schema is assumed to be included in both the display and input presentation maps. UI hints allow an element to be excluded from presentation altogether, included only in the display map or included only in the input map.

Not Just Business Object Schemas

While mostly used to describe the display and maintenance maps of business objects, UI Hints may also be embedded as part of other schema based objects:

- You may use a [data area](#) to describe an input form and prompt the user to fill it in using a [BPA script step](#) or a [process flow panel](#).
- You may embed UI hints in a business service or service script schema for the purpose of displaying the content prepared by the service in a portal zone. Refer to [map zones](#) for more information.
- You may embed UI hints in a service script's schema to prompt for user input before calling the script to perform a task and presenting results. Refer to [Generate Edit Map Statements](#) on page 298 for more information.

Definition Order is Presentation Order

Elements are presented in the order they are defined in the expanded schema. For example, a subclassed business object that includes its parent business object followed by extension elements is presented with the parent portion of the HTML, followed by the extension fields.

Use UI Map Fragments for Complex HTML

The following items describe basic capabilities supported by the UI Hints functionality:

- Control which elements are presented in the display and input maps.
- Provide a title for the input map.
- Introduce sections around elements by injecting start and end section instructions. The order in which the elements are defined within a section is also their presentation order.
- Basic visibility rules are supported at the element and section level.

For more complex requirements around a specific element, you may craft the necessary HTML/JavaScript for the element, capture it as a [UI Map Fragment](#), embed the fragment as part of the schema in the appropriate presentation order, and suppress the element from basic rendering for the corresponding input or display map.

Note: You may also use this technique to display elements in a different presentation location. For example, when a business object's display script needs to display additional elements that are not part of the business object's schema. In this situation, the script's schema introduces the elements as suppressed and the business object schema includes an embedded HTML UI map fragment to display them in the appropriate section. Note that this may only work when both the business object and script are owned by your organization.

Refer to [UI Hint Syntax](#) on page 177 for more information.

UI Hint Syntax

Working Examples

For working examples of uiHint functionality, refer to the following business objects:

BOs with User Assigned Keys

The following examples illustrate the patterns used to enable uiHints on an object with a user specified key.

- **F1-OutcomeStyleLookup.** This extendable lookup BO does not require state transition, but does allow duplicate and delete actions.
- **F1-ToDoSumEmailTyp.** This request type illustrates the hints required to support state transition on a display map.
- **F1-WebSvc.** This web service BO is a good example for management of complex JavaScript requirements. Both display and input maps have functionality that requires specialized javascript.

BO with System Generated Key

The following example illustrates the pattern used to enable uiHints on an object with a system generated key.

- **F1-GenericAttachment.** This attachment BO has a system assigned key, which entails the following special handling:
 - **F1-AttachmentMain.** This is the main section data area contains the elements common to all attachments, including the key, bo, and version. Because this data area is used to define the main section of the generated maps, the main section of the map can be extended by an implementation via data area extension functionality.
 - **F1-AttachmentActions.** This record actions map contains the standard actions, Edit and Delete, plus custom actions used only by attachments, View and Upload.
 - **F1-AttachmentIDFrag.** This record information map contains the primary key of the attachment.

Display Map Service Script

Display map service scripts can be fully supported via dynamic HTML generation. However, to help eliminate the need for a display service script, self-contained uiHint functionality has been developed to write the business object status and determine valid state transitions. So the two most common reasons to craft a display service script have been eliminated.

A typical reason to use a display pre-script is if you have an embedded map fragment that contains a business service schema. The display service script can be used to invoke the business service. Both the map fragment and the display service script must declare the business service schema to support this scenario.

Warning: The zone used to display the object's map must have a derivation script, like **F1-GncDsMpDZ** or **F1-GenDss**, that will invoke a display service script for the business object if it has been defined as a BO option - but not require an explicit display map BO option. In addition, the display service script's schema must be enabled for uiHint functionality - as the script's schema will be dynamically rendered by the zone - and not the BO schema.

- **F1-ExcelSpreadsheet.** This attachment BO has a display service script used to manipulate the attachment business object before displaying it:
- **F1-AttchDtlU.** This display map service script's schema has been defined with the uiHint namespace, and will have a display map generated for it.

Maintenance Pre-Processing Service Script

Maintenance pre-processing service scripts can be used with uiHints.

- **F1-ExcelSpreadsheet.** This attachment BO has a maintenance pre-processing service script used to manipulate the attachment business object before rendering the maintenance map:
- **F1-AttchPre.** This pre-processing service script's schema mimics a maintenance map schema with embedded boGroup and action elements. It will be invoked before the maintenance map is rendered.

Maintenance Post-Processing Service Script

Maintenance post-processing service scripts can be used with uiHints.

- **F1-ExcelSpreadsheet.** This attachment BO has a maintenance post-processing service script used to manipulate the attachment business object after rendering the maintenance map:
- **F1-AttchPost.** This post-processing service script's schema mimics a maintenance map schema with embedded boGroup and action elements. It will be invoked after the maintenance map is rendered.

Technical Notes

The following prerequisites are required to support dynamic HTML generation:

Schema Requirements

To support automated UI generation, the business object schema must contain the following:

- `<schema xmlns:uiHint="http://oracle.com/ouafUIHints">`. The schema node must name the uiHint namespace.
- `isPrimeKey="true"`. Every element of the business object schema that is part of the primary key must be identified.

Maintenance Script Requirements

The maintenance script for the MO must be enabled for dynamic generation.

CAUTION: The business object maintenance BPA script must be declared as an MO Option for uiHint maintenance functionality to work!

If the script performs **F1-BOProc** then it is likely no special functionality is needed. However, if the maintenance script contains its own call to **F1-GetValOpt** then the following statement is required prior to that call:

```
move 'false' to "F1-GetBOOpts/input/maintenanceMapRequired";
performScript 'F1-GetValOpt';
```

After the call to **F1-GetValOpt** the following logic must be included to dynamically declare the map schema if the business object does not have a maintenance map of its own:

```
// Perform Main Processing
if ("F1-GetBOOpts/output/maintenanceMap = $BLANK")
  declareBOWithBOGroup "$bo" as 'map_schema';
else
  declareMap "F1-GetBOOpts/output/maintenanceMap" as 'map_schema';
end-if;
```

Format an Input Map Title

Note: Throughout this topic the term "field" to refer to both the generic concept of displaying and capturing data in a 'field' as well as referring to the meta-data object supplied in the product to define **Fields**. When referring to the latter, the term "MD Field" (meta-data Field) is used.

A `uiHint` element can be used to build a title for a maintenance map. The title will only print on the maintenance map, not on the display map. It will be printed as the first line in the map, centered, with a heading style.

| Syntax | Description | Examples |
|--|--|--|
| <code><uiHint:title mdField=" "/></code> | Displays the label of a referenced MD field as the title. | <pre><schema xmlns:uiHint="http:// oracle.com/ouafUIHints"> <uiHint:title mdField="STATUS_RSN_LBL"/> ... </schema></pre> |
| <code><uiHint:title text=" "/></code> | Displays the indicated text as the title. (Do not use this mechanism when multiple languages are supported.) | <pre><schema xmlns:uiHint="http:// oracle.com/ouafUIHints"> <uiHint:title text="Status Reason"/> ... </schema></pre> |

Create a Section

The `uiHint` namespace supports the definition of a UI map section. Note that sections are currently created in generated UI Maps when the schema has a group or list node with a label or `mdField`. The functionality described here enables the creation of a section without requiring a labeled group or list node within the schema. Every section must be bounded by **startSection** and **endSection** element pair.

| Syntax | Supporting Attributes | Description |
|---|---|---|
| <code><uiHint:startSection ></code> | <code>sectionColumn="left right fullWidth float"</code> | The default is that the section will be the full width in display maps. To override that setting, specify if you want a half-width section to appear in either the left (left) or right (right) column or to float (float). Sections that are marked as 'float' will display half-width and be aligned according to whether prior sections are displayed or conditionally hidden. For example, if a left-aligned section is followed by a floating section, the floating section will appear in the right column if the left section is populated but will display in the left column if the left section is hidden / collapsed. |
| | <code>editColumn="left right fullWidth float"</code> | By default a section appears as full width in maintenance maps. To override that setting, specify if you want a half-width section to appear in either the left (left) or right (right) column or to float (float). The behavior is the analogous to the sectionColumn behavior. |
| | <code>sectionOpen="false"</code> | By default a section is open on initial display. Specify this attribute to initially display the section as closed (collapsed). |

| Syntax | Supporting Attributes | Description |
|--------|-----------------------------------|---|
| | mdField=" " | Specify the name of a MD field whose label should be used as the section heading. |
| | label=" " | Specify the explicit text to use as the section heading. |
| | visibleOn="displayMap inputMap" | By default a section appears on both the display and the input maps. Use this attribute to limit the display of the section to either the display map (displayMap) or input map (inputMap). |

The syntax for the end section attribute is `<uiHint:endSection/>`

Examples:

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  <uiHint:startSection label="Main" sectionColumn="left"/>
  ...
  <uiHint:endSection/>
</schema>
```

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  <uiHint:startSection mdField="F1-ADD-
INFO" sectionColumn="fullWidth" editColumn="float" sectionOpen="false" visibleOn="displayMap" />
  ...
  <uiHint:endSection/>
</schema>
```

Note: The sectionColumn, editColumn and sectionOpen attributes are available for group and list nodes as well.

Include a Map Fragment

You can specify a UI map fragment to inject HTML into a generated map using the **includeMap** element name. This allows for you to support more sophisticated behavior on your user interface. For any element that is included for rendering in the map fragment, be sure to suppress the element in its schema definition, otherwise HTML will automatically be generated for the element.

| Syntax | Supporting Attributes | Description |
|--|-----------------------------------|---|
| <code><uiHint:includeMap map=" " /></code> | | Specify the name of the map. |
| <code>></code> | visibleOn="displayMap inputMap" | By default the details from the map fragment appear on both the display and the input maps. Use this attribute to limit the display of the section. |

Example:

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  ...
  <uiHint:includeMap map="StandardActionButtons" visibleOn="displayMap"/>
  ...
</schema>
```

Note: Important note on the map fragment schema: If a map fragment contains a schema, then the fragment schema structure will be injected into the dynamically generated schema when the business object is rendered for input. Technically, the fragment schema will be inserted after the boGroup structure within the

map's schema. This method may be used to support the implementation of maintenance pre and post script processing for a business object and oraInvokeBS function calls within embedded JavaScript.

If JavaScript is required within an XHTML UI Map fragment, it is necessary to bound it within a `![CDATA[]]` tag to ensure a valid XML document. Note that the tags themselves may need to be commented out to promote compatibility with older browsers. For example:

```
<script type="text/javascript">
/*  */
//
//javascript
//
/* ]]&gt; */
&lt;/script&gt;</pre>
</div>
<div data-bbox="128 275 908 337" data-label="Text">
<p><b>Flush the cache:</b> For performance reasons, the Framework automatically caches business object schemas, data areas, and UI maps. When you update a business object, the cache is automatically flushed. However, if the business object includes either a data area or embedded UI map fragment, the cache must be manually flushed in order for your changes to be recognized. Refer to <a href="#">Server Cache</a> for more information.</p>
</div>
<div data-bbox="128 354 276 372" data-label="Section-Header">
<h2>Build A Dropdown</h2>
</div>
<div data-bbox="128 377 886 409" data-label="Text">
<p>Syntax is provided to build a dropdown list in an edit map. The dropdown may be built using data returned from a service script, a business service or a table.</p>
</div>
<div data-bbox="128 414 906 532" data-label="Table">
<table border="1">
<thead>
<tr>
<th>Syntax</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>uiHint:select="ss: "</td>
<td>Specify the name of the service script after the colon.</td>
</tr>
<tr>
<td>uiHint:select="bs: "</td>
<td>Specify the name of the business service after the colon.</td>
</tr>
<tr>
<td>uiHint:select="table: "</td>
<td>Specify the name of the table after the colon.</td>
</tr>
</tbody>
</table>
</div>
<div data-bbox="128 544 902 575" data-label="Text">
<p>When specifying a service script or a business service, extra mapping information is needed to pass data to and from the service.</p>
</div>
<div data-bbox="128 581 906 736" data-label="Table">
<table border="1">
<thead>
<tr>
<th>Syntax</th>
<th>Values</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td rowspan="2">uiHint:selectIn=" "</td>
<td>serviceXPath:element</td>
<td>Used to pass the value of another element into the service (mapping to the service's XPath).</td>
</tr>
<tr>
<td>serviceXPath:'Literal'</td>
<td>Used to pass a constant or literal to the service (mapping to the service's XPath).</td>
</tr>
<tr>
<td>uiHint:selectOut="valuePath:"<br/>descPath: "</td>
<td>See examples below.</td>
<td>Used to indicate which element in the service's output holds the values and which one holds the descriptions.</td>
</tr>
</tbody>
</table>
</div>
<div data-bbox="128 748 204 765" data-label="Text">
<p>Examples:</p>
</div>
<div data-bbox="138 778 936 900" data-label="Text">
<pre>&lt;schema xmlns:uiHint="http://oracle.com/ouafUIHints"&gt;
  &lt;boStatus mapField="BO_STATUS_CD" uiHint:select="bs:F1-
BOStateReasonList"
  uiHint:selectIn="boStatusBO:boStatusBO" uiHint:selectOut="valuePath:results/
status;
  descPath:results/description"/&gt;
  ...
  &lt;algorithm mdField="ALG_CD" uiHint:select="bs:F1-
RetrieveSysEvtAlgorithms"</pre>
</div>
```

```

    uiHint:selectIn="algorithmEntity:'F1AA';" uiHint:selectOut="valuePath:results/
algorithm;
    descPath:results/description"/>
    ...
    <outboundMsgType mdField="OUTMSG_TYPE_CD" required="true" fkRef="F1-
OMTYP" uiHint:select="table:F1_OUTMSG_TYPE"/>
</schema>

```

Conditionally Hide Elements

The **displayNone** attribute is used to suppress elements on the map based on conditions.

| Syntax | Values | Description |
|---------------------------------|--|--|
| <code>uiHint:displayNone</code> | <code>"XPath','value','!=' '='"</code> | Used to conditionally hide this element based on the value of another element (referenced using its XPath). Enter a value of '' to interrogate a blank value. By default the operator is '='. This may be overridden using '!='. Used to indicate a JavaScript function, which must return a Boolean. |
| | <code>"function name, true false"</code> | |

Warning:

Embedded spaces are not supported within the comma separated string values of this attribute.

This setting may be used on group nodes, list nodes, and elements - except for elements within a list. Elements within a list cannot be hidden conditionally.

The following example illustrates that two elements (currency reference and lookup) that will be hidden or displayed based on the value of the data type element. Note that this example also illustrates [Trigger Dependent Behavior](#) because the data type element's value may change and if it does, the condition for hiding the subsequent elements should be re-evaluated.

```

<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
    ...
    <dataType mdField="F1_SE_DATA_TYPE" dataType="lookup" lookup="F1_SE_DATA_TYPE"
    uiHint:dependents="currencyRef;lookup; "/>
    <currencyRef mdField="F1_SE_CURR_REF_LBL" uiHint:displayNone="'dataType','F1MO','!
='"/>
    <lookup mdField="F1_SE_LOOKUP_LBL" fkRef="F1-
LKUPF" uiHint:displayNone="'dataType','F1LP','!='"/>
    ...
</schema>

```

The following example illustrates referring to a function where the function receives parameters:

```

<uiHint:startSection mdField="F1_SE_DEFAULT_SECT"
    uiHint:displayNone="isApplicableForSchemaType(item,'F1MP'),true"/>

```

Conditionally Protect Elements

The **protect** attribute is used to protect elements on the map based on other factors.

| Syntax | Values | Description |
|-----------------|--|---|
| uiHint:protect= | "XPath','value','!=' '='" | Used to conditionally protect this element based on the value of another element (referenced using its XPath). Enter a value of '' to interrogate a blank value. By default the operator is '='. This may be overridden using '!='. |
| | "function name, true false " | Used to indicate a JavaScript function, which must return a Boolean. |
| | " action ','A' 'C','!=' '='" | Use the ' action ' setting to protect the element based on the current action. For example, certain elements may only be specified when adding a record. Any subsequent changes to the record should protect the element from being changed. When using this option, the valid values for the ' <i>value</i> ' are A (add) and C (change). |

Warning:

Embedded spaces are not supported within the comma separated string values of this attribute.

The protect UI Hint may be used on group nodes, list nodes, and elements - except for elements within a list. Elements within a list cannot be protected conditionally.

The following UI Hint will protect the statistics category when the action is 'C'.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  ...
  <statisticsCategory dataType="lookup" mapField="STAT_CATEGORY_FLG"
    lookup="STAT_CATEGORY_FLG" uiHint:protect="'action','C','='"/>
  ...
</schema>
```

Trigger Dependent Behavior

The dependents attribute is used to trigger behavior on a child element when a parent element is changed.

| Syntax | Values |
|-----------------------|---|
| uiHint:dependents=" " | A list of one or more dependent elements separated by semicolons. |

The following example illustrates that the dropdown list of one element is driven by the value of another element. In this example, when the Country changes, the list of States to choose from should change to only show the states for the indicated country.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  <country label="Country" uiHint:select="table:CI_COUNTRY" uiHint:dependents="state"/>
  <state label="State" uiHint:select="ss:CM-RetrieveCountryStates"
    uiHint:selectIn="input/
country:country;" uiHint:selectOut="valuePath:output/state/stateCode;
descPath:output/state/stateDesc"/>
  ...
</schema>
```

Note:

Dependent targets may only name elements, not group or list nodes.

Do not modify the "id" attribute value of dependent and parent element. Data population in dependent is done based on the "id" attribute value.

Control Rendering Target

By default all elements that are not suppressed are visible on both the display map and the input map. Use the **visibleOn** attribute to limit the inclusion of an element to either the display or input map.

| Syntax | Values |
|-------------------|----------------------------|
| uiHint:visibleOn= | "displayMap" "inputMap" |

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  ...
  <uiHint:includeMap map="StandardActionButtons" visibleOn="displayMap"
  ...
</schema>
```

Generate a Text Area

By default, a standard text box is rendered in an input map for any string element. If the field is larger and you wish to have a bigger text area (with a scroll bar), use the **textArea** attribute.

| Syntax |
|------------------------|
| uiHint:textArea="true" |

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  ...
  <message label="Message" uiHint:textArea="true"/>
  ...
</schema>
```

Modify FK Reference Defaults

By default, when an element with **fkRef** is displayed, an info string, context menu, navigation, and search are enabled (if the FK reference has been configured accordingly). Syntax is provided to allow you to selectively turn off any of these features.

| Syntax |
|--|
| uiHint:fkRef="info:false;context:false;navigation:false;search:false;" |

Only the feature that you wish to turn off needs to be specified. The following example illustrates turning off the navigation capability, meaning the text will not be rendered as hypertext.

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  ...
  <attachmentID fkRef="F1-
ATTCH" primeKey="true" suppress="input" uiHint:fkRef="navigation:false;"/>
  ...
</schema>
```

Fastpath: Refer to [FK Reference Formatting](#) in the UI Map Attributes section for more information on each FK reference setting.

Suppress Automatic Number Formatting

By default numeric fields (**dataType="number"**) are formatted as numbers. An attribute is provided to instead apply alphanumeric formatting.

Note: If **dataType** is not specified explicitly, it is be derived from **mdField** or **mapField**.

Syntax

```
uiHint:alphaFormat="true|false"
```

By default, its value is **false** (and therefore can be left out altogether).

Examples:

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  ...
  <numberCount mdField="" dataType="number" uiHint:alphaFormat="true"/>
  ...
</schema>
```

Auto Capitalize the Input Data

The **uiHint** provides syntax to automatically capitalize input data.

Syntax

```
uiHint:capitalize="true|false"
```

By default, its value is **false** (and therefore can be left out altogether).

```
<schema xmlns:uiHint="http://oracle.com/ouafUIHints">
  <todoTypeCd mdField="TD_TYPE_CD" uiHint:capitalize='true' isPrimeKey="true"/>
  >
</schema>
```

Note: This attribute is ignored if **uiHint:textArea="true"** is configured.

The attribute is only available in the schema designer when the **isPrimeKey** is set to **true**. The attribute may be added to any string element when using the source viewer.

Defining UI Maps

The topics in this section describe how to maintain UI Maps.

UI Map - Main

Use this page to define basic information about a user interface (UI) Map. Open this page using **Admin > System > UI Map**

Use the **UI Map Query** portal to search for an existing UI Map. Once a map is selected, you are brought to the maintenance portal to view and maintain the selected record.

Description of Page

Enter a unique **Map** name. **Owner** indicates if the UI map is owned by the base package or by your implementation (**Customer Modification**).

CAUTION: Important! If you introduce a new UI map, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Use **UI Map Type** to indicate the map type. The system recommends using a **Complete XHTML Document** (the default) or **XHTML Fragment**. The values **Complete HTML Document** and **HTML Fragment** remain for backward compatibility but are not recommended.

Enter a **Description**. Use the **Detailed Description** to describe how this map is used in detail.

Click on the **View Schema** to view the UI map's expanded schema definition. Doing this opens the [schema viewer](#) window.

Use the **Test UI Map** hyperlink to render your HTML in a test window.

Note: The **Test UI Map** hyperlink also exercises the proprietary functionality that binds an XML element with an HTML element so you can get immediate feedback on your HTML syntax.

UI Map - Schema

Use this page to maintain a UI Map's HTML and schema and to see where the UI Map is used in the system. Open this page using **Admin > System > UI Map** and then navigate to the **Schema** tab.

Description of Page

The contents of this section describe the zones that are available on this portal.

The **General Information** zone displays main attributes of the UI Map.

The **HTML Editor** zone allows you to edit the HTML document of the map.

Note: Refer to [UI Map Attributes and Functions](#) and [UI Map Standards](#) for more information about HTML definition syntax. These topics describe good ways to produce simple HTML, however, they are not an HTML reference. Note that you can use a variety of HTML editors to compose your HTML, which you can then cut and paste into your UI map.

Note: Providing Help. A **tool tip** can be used to display additional help information to the user. This applies to section elements as well as individual elements on a map. Refer to [UI Map Attributes and Functions](#) for more information on how to enable and provide UI map help.

The **Schema Designer** zone allows you to edit the data schema part of the map. The purpose of the schema is to describe the data elements being displayed by the map.

Fastpath: Refer to [Schema Syntax](#) for a complete list of the XML nodes and attributes available to you when you construct a schema. Also note that the **UI Map Tips** zone in the sidebar provides a link to launch this help topic directly.

The **Schema Usage Tree** zone summarizes all cross-references to this schema. These may be other schemas, scripts, and web services. For each type of referencing entity, the **tree** displays a summary node showing a total count of referencing items. The summary node appears if at least one referencing item exists. Expand the node to list the referencing items and use their description to navigate to their corresponding pages.

UI Map Attributes and Functions

Note: This topic uses the term "field" to refer to both the generic concept of displaying and capturing data in a 'field' as well as referring to the meta-data object supplied in the product to define **Fields**. When referring to the latter, the term "MD Field" (meta-data Field) is used and a hyperlink to the Field documentation is provided.

Bind XML to HTML

Only two different attributes are required to bind a UI Map's XML to its HTML. Both of these attributes require an XML document embedded within the HTML, where the XML is bounded by `<xml>` nodes.

Warning: You must embed a pair of `<xml></xml>` tags within your HTML document for binding to occur.

Linking a Field

| Syntax | Values | Description |
|--------------|---------------------|--|
| oraField=" " | Field element XPath | This attribute is used to link an HTML element directly with an XML element, where the XML element is defined within the UI Map's XML schema. The attribute can be used with any <i>rendering</i> HTML element, such as: , <div>, and <input>. |

- HTML for input element:

```
<html>
<body>
<table>
  <tr>
    <td>Address:</td>
    <td><input type="text" oraField="address"/></td>
  </tr>
  <tr>
    <td>City:</td>
    <td><input type="text" oraField="city"/></td>
  </tr>
  <tr>
    <td>State:</td>
    <td><input type="text" oraField="state"/></td>
  </tr>
  <tr>
    <td>Zip:</td>
    <td><input type="text" oraField="zip"/></td>
  </tr>
</table>
</body>
<xml>
  <root>
    <address>123 Main St</address>
    <city>Alameda</city>
    <state>CA</state>
    <zip>94770</zip>
  </root>
</xml>
</html>
```

Rendered HTML

Address:

City:

State:

Zip:

- HTML for span and div elements:

```
<html>
<body>

<div oraField="address"></div>
<span oraField="city"></span>
<span>,</span>
<span oraField="state"></span>
<span oraField="zip"></span>
```

```

<span oraField="country"></span>

</body>
<xml>
  <root>
    <address>123 Main St</address>
    <city>Alameda</city>
    <state>CA</state>
    <zip>94770</zip>
  </root>
</xml>
</html>

```

HTML rendered:

123 Main St
Alameda, CA 94770

Linking a List

This attribute is used to link an HTML table with an XML list, where the XML list is defined within the UI Map's XML schema. The purpose of the element is to trigger the framework to replicate the table's HTML for each occurrence of the list.

| Syntax | Values | Description |
|-------------|--------------------|--|
| oraList=" " | List element XPath | This attribute is used to link an HTML table with an XML list, where the XML list is defined within the UI Map's XML schema. The purpose of the element is to trigger the framework to replicate the table's HTML for each occurrence of the list. |

Note: The oraField attributes embedded within the list must contain XPath navigation relative to the list. See below for an example.

```

<html>
<head><title>Bind xml list element</title></head>
<body>
<table oraList="payment">
  <thead>
    <tr>
      <th><span>Pay Date</span></th>
      <th><span>Amount</span></th>
    </tr>
  </thead>
  <tr>
    <td>
      <span oraField="date" oraType="date"></span>
    </td>
    <td align="right">
      <span oraField="amount" oraType="money"></span>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <payment>
    <date>2008-01-01</date>
    <amount>44.28</amount>
  </payment>

```

```
<payment>
  <date>2008-02-01</date>
  <amount>32.87</amount>
</payment>
<payment>
  <date>2008-03-01</date>
  <amount>21.76</amount>
</payment>
</root>
</xml>
</html>
```

HTML rendered:

| Pay Date | Amount |
|-----------------|---------------|
| 01-01-2008 | \$44.28 |
| 02-01-2008 | \$32.87 |
| 03-01-2008 | \$21.76 |

Build a Dropdown List

The following attributes are provided to build an HTML 'select' element, also called a dropdown, based on various sources.

| Source | Syntax | Values | Examples |
|--------------------------------------|--|-----------------------------|--|
| Lookup | <code>oraSelect="lookup: ;"</code> | Lookup field | <pre>... <td>House Type:</td> <td> <select oraField="houseType" oraSelect="lookup:HOUSE_TYPE; "> </select> </td></pre> |
| Extendable Lookup | <code>oraSelect="lookupBO: ;"</code> | BO code | <pre>... <td>UI Device Display Type:</ td> <td> <select oraField="uiDeviceType" oraSelect="lookupBO: F1-DeviceDisplayTypes; "></ select> </td></pre> |
| Characteristic Type (pre-defined) | <code>oraSelect="charType: ;"</code> | Characteristic Type code | <pre>... <td>Usage:</td> <td> <select oraField="statusReasonUsage" oraSelect="charType:F1- SRUSG; "></select> </td> ... </pre> |
| Control Table | <code>oraSelect="table: ;"</code>  Note: This attribute only works with tables that follow the standard control table structure where there is a related language table that includes that includes the column DESCR as its description column. Use the Application Viewer data dictionary to identify tables that qualify for this functionality.  Warning: The oraSelect function will only work if less than 500 values are displayed. | Table name | <pre>... <td>Currency: </td> <td> <select oraField="currency" oraSelect="table:CI_CURRENCY_CD; "> </select> </td> ... </pre> |

| Source | Syntax | Values | Examples |
|------------------|-------------------|-----------------------|--|
| Service Script | oraSelect="ss: ;" | Service Script code | See below for additional syntax needed when using this function. |
| Business Service | oraSelect="bs: ;" | Business Service code | See below for additional syntax needed when using this function. |

When specifying a service script or a business service, extra mapping information is needed to pass data to and from the service.

| Syntax | Values | Description |
|--|--|---|
| oraSelectIn=" ;" | serviceXPath:element; serviceXPath:'Literal'; | Used to pass the value of another element into the service (mapping to the service's XPath). Used to pass a constant or literal to the service (mapping to the service's XPath). |
| oraSelectOut="valuePath: ;" descPath: " | See examples below | Used to indicate which element in the service's output holds the values and which one holds the descriptions. |

Example using a business service:

```
...
<td>External System: </td>
<td>
  <select oraField="externalSystem"
    oraSelect="bs:F1-RetrieveExternalSystems"
    oraSelectIn="outboundMsgType:boGroup/parameters/outboundMsgType;"
    oraSelectOut="valuePath:results/externalSystem;"
    descPath:results/description">
  </select>
</td>
...
```

This method for building dropdowns is often used when there is a dependency between elements and the list of valid values in a dropdown (for the child element) is based on another element in the map (the parent element). When the parent element is changed, it may be required to refresh the child element. This behavior can be implemented using the function called within an **onChange** event in the map. The syntax is **oraHandleDependentElements('dependent element')**; Multiple target elements (dependents) can be named.

The following example is related to the above business service example where the list of external systems is specific for a given outbound message type, which is passed in as input. The snippet below shows the configuration for the outbound message type element to trigger a refresh of the external system's dropdown list.

```
...
<div>
  <label oraLabel="boGroup/parameters/outboundMsgType"></label>
  <span>
    <select oraSelect="table:F1_OUTMSG_TYPE"
      oraField="boGroup/parameters/outboundMsgType"
      onChange="oraHandleDependentElements('boGroup/parameters/
externalSystem');">
    </select>
  </span>
</div>
...
```

Format Input and Output Fields

The following attributes are designed to apply data type formatting for input and output fields.

Automatic Formatting

Syntax

```
oraSchemaDataTypes="false"
```

This attribute is used to trigger automatic formatting in the rendered HTML document. The automated formatting will occur according to the data type attributes defined in the UI map's schema. For details on specific data type formatting, please refer to the oraType attribute descriptions below.

Warning: The attribute `oraSchemaDataTypes="true"` will be automatically injected into the UI map's HTML! If you do not wish to apply the schema's data types to the rendered HTML then you must specify this attribute in the body node with a value of false. The attribute `<body oraSchemaDataTypes="false">` is required to avoid automatic formatting!

- UI Map schema:

```
<schema>
  <schemaDate dataType="date"/>
  <schemaDateTime dataType="dateTime"/>
  <schemaFKRef fkRef="CI_USER"/>
  <schemaLookup dataType="lookup" lookup="ACCESS_MODE"/>
  <schemaMoney dataType="money"/>
  <schemaNumber dataType="number"/>
  <schemaTime dataType="time"/>
</schema>
```

- UI Map HTML:

```
<html>
<body oraSchemaDataTypes="true">
<table border="1" cellpadding="1" cellspacing="1">
  <tr><th>dataType</th><th>result type</th><th>input result</
th><th> display-only result</th></tr>
  <tr>
    <td rowspan="2">date (from schema)</td>
    <td>raw</td>
    <td><input oraField="schemaDate" oraType="string" /></td>
    <td><span oraField="schemaDate" oraType="string"></span></td>
  </tr>
  <tr>
    <td>rendered</td>
    <td><input oraField="schemaDate"></td>
    <td><span oraField="schemaDate"></span></td>
  </tr>
  <tr>
    <td rowspan="2">dateTime (from schema)</td>
    <td>raw</td>
    <td><input oraField="schemaDateTime" oraType="string"></td>
    <td><span oraField="schemaDateTime" oraType="string"></span></td>

| | rendered | <input type="text" value="11:45PM"/> | 11:45PM |

Date Formatting

This function is used to display a date according to the user's display profile. For input fields, the setting formats the data when the user tabs out of the field.

Syntax

```
oraType="date"
```

```

<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Date: </td>
    <td><span oraField="date" oraType="date"></span></td>
  </tr>
  <tr>
    <td>Date: </td>
    <td><input oraField="date" oraType="date"/></td>
  </tr>
</table>
</body>

```

```
<xml>
<root>
  <date>2008-12-28</date>
</root>
</xml>
</html>
```

HTML rendered.

Date: 12-28-2008

Date:

Time Formatting

This function is used to display a time according to the user's display profile. For input fields, the setting formats the data when the user tabs out of the field.

Syntax

oraType="time"

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Time: </td>
    <td><span oraField="time" oraType="time"></span></td>
  </tr>
  <tr>
    <td>Time: </td>
    <td><input oraField="time" oraType="time"/></td>
  </tr>
</table>
</body>
<xml>
<root>
  <time>00.28.54.389</time>
</root>
</xml>
</html>
```

HTML rendered.

Time: 12:28AM

Time:

Date and Time Formatting

This function is used to display a timestamp according to the user's display profile. If this function is used for an input element, it is broken into two pieces, one for **date** and one for **time**. Optionally, the time portion of the date time element can be suppressed using the attribute value 'time:suppress'.

Syntax

oraType="dateTime; time:suppress"

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
```

```

<tr>
  <td>Date time: </td>
  <td><span oraField="dateTime" oraType="dateTime"></span></td>
</tr>
<tr>
  <td>Date only: </td>
  <td><span oraField="dateTime" oraType="dateTime; time:suppress"></span></td>
</tr>
<tr>
  <td>Date time: </td>
  <td><input oraField="dateTime" oraType="dateTime"/></td>
</tr>
<tr>
  <td>Date only: </td>
  <td><input oraField="dateTime" oraType="dateTime; time:suppress"/></td>
</tr>
</table>
</body>
<xml>
<root>
  <dateTime>2009-11-01-00.28.54</dateTime>
</root>
</xml>
</html>

```

HTML rendered.

Date time: 11-01-2009 12:28AM

Date only: 11-01-2009

Date time:

Date only:

Date / Time Formatting with Standard Time

This true function is used to render a date / time element according to the daylight savings time schedule of the 'base' time zone. The 'base' time zone is specified on the Installation table and represents the database time zone. For input elements with this setting, all time entered is assumed to correspond with the daylight savings time schedule of the base time zone. If a time is entered that cannot be unambiguously translated to standard time, then the user will be required to provide a time zone label to indicate whether daylight savings time, or standard time, has been entered.

Syntax

oraType="dateTime; stdTime:true;"

```

<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Date time: </td>
    <td><span oraField="dateTime" oraType="dateTime; stdTime:true;"></span></td>
  </tr>
  <tr>
    <td>Date time: </td>
    <td><input oraField="dateTime" oraType="dateTime; stdTime:true;" /></td>
  </tr>
</table>

```

```

</body>
<xml>
<root>
  <dateTime>2009-11-01-00.28.54</dateTime>
</root>
</xml>
</html>

```

HTML rendered.

Note: The time zone label is displayed because 1:28 is ambiguous otherwise. Legally, November 1, 2009 1:28 AM occurs twice because daylight savings time (DST) is removed at 2:00 AM. With the stdTime function time zone labels are only displayed when required to clarify time overlaps.

Date time: 11-01-2009 01:28AM PDT

Date time:

HTML rendered for the following day.

Date time: 11-02-2009 12:28AM

Date time:

Date and Time Formatting with Time Zone Reference

| Syntax | Valid Values | Description |
|--|-------------------------------------|--|
| oraType="dateTime; stdTimeRef: ;" | Reference an XPath after the colon. | This function is used to render a date / time element according to the daylight savings time schedule of a time zone whose XPath is referenced. Note that the time processed is assumed to have been stored in the standard time of the referenced time zone - so only daylight savings time shifting will execute - not time zone shifting. |
| oraType="dateTime; displayRef: ;" | Reference an XPath after the colon. | This function is similar to the stdTimeRef function, except that this function will execute time zone shifting in addition to daylight savings time shifting. To use displayRef correctly, only associate it with time zone elements that have been stored in the base time zone. |

For input elements, all time entered is assumed to correspond with the daylight savings time schedule of the referenced time zone. If a time is entered that cannot be unambiguously translated to standard time, then the user will be required to provide a time zone label to indicate whether daylight savings time, or standard time, has been entered.

```

<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Date time: </td>
    <td><span oraField="dateTime" oraType="dateTime; stdTimeRef:timeZone;"></
span></td>
  </tr>
  <tr>
    <td>Date time: </td>
    <td><input oraField="dateTime" oraType="dateTime; stdTimeRef:timeZone;"
></td>
  </tr>

```

```

</table>
</body>
<xml>
<root>
  <timeZone>US-EAST</timeZone>
  <dateTime>2009-11-01-00.28.54</dateTime>
</root>
</xml>
</html>

```

HTML rendered.

Note: The time zone label is always displayed for a referenced time zone.

Date time: 11-01-2009 01:28AM EDT

Date time:

HTML rendered for the following day.

Date time: 11-02-2009 12:28AM EST

Date time:

Duration Formatting

Syntax

oraType="duration"

This function is used to display time duration. For an input element, the value entered by the user is translated from minutes to hour and minutes as appropriate. For example, an entered value of '90', is converted to '00:01:30' when tabbing out of the input field.

```

<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Duration: </td>
    <td><span oraField="duration" oraType="duration"></span></td>
  </tr>
  <tr>
    <td>Duration: </td>
    <td><input oraField="duration" oraType="duration"/></td>
  </tr>
</table>
</body>
<xml>
<root>
  <duration>90</duration>
</root>
</xml>
</html>

```

HTML rendered.

Duration: 00:01:30

Duration:

Day in Month Formatting

Syntax**oraType="dayInMonth"**

This function is used to display a concatenated day and month.

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Day In Month: </td>
    <td><span oraField="dayMonth" oraType="dayInMonth"></span></td>
  </tr>
  <tr>
    <td>Day In Month: </td>
    <td><input oraField="dayMonth" oraType="dayInMonth"/></td>
  </tr>
</table>
</body>
<xml>
<root>
  <dayMonth>0228</dayMonth>
</root>
</xml>
</html>
```

HTML rendered.

Day In Month: 02-28

Day In Month:

Month In Year Formatting

Syntax**oraType="monthInYear"**

This function is used to display a concatenated month and year.

```
<html>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Month In Year: </td>
    <td><span oraField="month" oraType="monthInYear"></span></td>
  </tr>
  <tr>
    <td>Month In Year: </td>
    <td><input oraField="month" oraType="monthInYear"/></td>
  </tr>
</table>
</body>
<xml>
<root>
  <month>200811</month>
</root>
</xml>
</html>
```

HTML rendered.

Month In Year: 11-2008

Month In Year:

Monetary Formatting

This function is used to display a number as a monetary amount. See the table for configuration options with respect to the currency. For input elements, an error is issued if a non-numeric value is entered.

| Syntax | Description |
|--|---|
| <code>oraType="money: "</code> | Directly specify a currency code after the colon. |
| <code>oraType="money;currencyRef: "</code> | Reference an XPath (after the colon) for an element that references a currency code. |
| <code>oraType="money"</code> | If no currency or currency reference is specified, the installation currency is used. |

Note: You must specify a pair of stylesheet references, `cisEnabled` and `cisDisabled`, in the map's header for right alignment. The stylesheet controls how the field will be rendered. If you want to alter the rendering you must override the `oraMoney` style.

```
<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Amount, currency specified:</td>
    <td><span oraType="money:EUR" oraField="totalAmt"></span></td>
  </tr>
  <tr>
    <td>Amount, default currency:</td>
    <td><span oraType="money" oraField="totalAmt"></span></td>
  </tr>
  <tr>
    <td>Amount, default input:</td>
    <td><input oraType="money" oraField="totalAmt"/></td>
  </tr>
  <tr>
    <td>Amount, currency reference:</td>
    <td><input oraType="money;currencyRef:cur" oraField="totalAmt"/></td>
  </tr>
</table>
</body>
<xml>
<root>
  <totalAmt>50500.09</totalAmt>
  <cur>EUR</cur>
</root>
</xml>
</html>
```

HTML rendered

| | |
|-----------------------------|---|
| Amount, currency specified: | €50500.09 |
| Amount, default currency: | \$50500.09 |
| Amount, default input: | <input type="text" value="\$50500.09"/> |
| Amount, currency reference: | <input type="text" value="€50500.09"/> |

Number Formatting

This function is used to display a number or validate an input value. For input elements, the system will return an error if a non-numeric value is entered.

Syntax

oraType="number"

Note: You must specify a pair of stylesheet references, `cisEnabled` and `cisDisabled`, in the map's header for right alignment. The stylesheet controls how the field will be rendered. If you want to alter the rendering you must override the `oraNumber` style.

```
<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Count:</td>
    <td><span oraType="number" oraField="count"></span></td>
  </tr>
  <tr>
    <td>Count, input:</td>
    <td><input oraType="number" oraField="count"/></td>
  </tr>
</table>
</body>
<xml>
<root>
  <count>989</count>
</root>
</xml>
</html>
```

HTML rendered.

Count: 989
 Count, input:

FK Reference Formatting

By default, when an element with an **fkRef** oraType is displayed, an info string, context menu, navigation, and search are enabled (if the FK reference has been configured accordingly). Syntax is provided to allow you to selectively turn off any of these features.

Note that you can enable the foreign key hyperlink separately as well, refer to [Embed Framework Navigation](#) for more information. The various attributes used to control foreign key reference functionality are as follows. Note that in every case, the default value is **true**. A value of **false** should be used to disable the feature.

Syntax

oraType="fkRef:true|false; info:true|false; context:true|false; navigation:true|false; search:true|false"

- **fkRef.** A value of 'true' enables all of the following foreign key reference processing. Use a value of 'false' to disable automatic FK Reference processing.
- **info.** A value of 'true' renders an [information string](#) on the UI map, if applicable.
- **context.** A value of 'true' renders a context menu to appear before the foreign key reference element, if applicable.
- **navigation.** A value of 'true' causes the information string to be rendered as a hyperlink, if applicable. Clicking the hyperlink [navigates](#) to the appropriate page.
- **search.** A value of 'true' displays a search icon that launches the [search zone](#) if applicable.

Note: Foreign key navigation and context menu functionality is only available for UI maps presented in a portal zone. UI Maps presented during BPA script processing cannot support navigation options. Search functionality is only available for input HTML elements.

- UI Map schema:

```
<schema>
  <bo fkRef="F1-BOMO"/>
</schema>
```

- UI Map HTML:

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Business Object</td>
    <td><span oraField="bo" oraType="fkRef:true; info:true; context:true; navigatio
span></td>
  </tr>
</table>
</body>
<xml>
<root>
  <bo>F1-COUNTRY</bo>
</root>
</xml>
</html>
```

- HTML rendered.

BUSINESS OBJECT  Country

Lookup Formatting

This function is used to display the description of a lookup value.

| Syntax | Valid Values |
|---------------------------|------------------------------------|
| oraType="lookup: " | Lookup field name after the colon. |

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Status:</td>
    <td><span oraField="status" oraType="lookup: BATCH_JOB_STAT_FLG"></
span></td>
  </tr>
</table>
</body>
```

```
<xml>
<root>
  <status>PD</status>
</root>

</html>
```

HTML rendered.

Status: Pending

Extendable Lookup Formatting

This function is used to display the description of an extendable lookup value.

| Syntax | Valid Values |
|-----------------------------|--|
| oraType="lookupBO: " | Business Object code name after the colon. |

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Value:</td>
    <td><span oraField="status" oraType="lookupBO:F1-
DeviceDisplayTypes"></span></td>
  </tr>
</table>
</body>
</html>
<xml>
<root>
  <status>oraTablet</status>
</root>
</xml>
</html>
```

HTML rendered.

Value: Tablet size

Characteristic Type Formatting

This function is used to display the description of a predefined characteristic value.

| Syntax | Valid Values |
|-----------------------------|---|
| oraType="charType: " | Characteristic Type code after the colon. |

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Skill:</td>
    <td><span oraType="charType:CM-SKILL" oraField="skill"></span></td>
  </tr>
</table>
</body>
</html>
<xml>

Skill: Quality assurance

Control Table Formatting

This function is used to display the description of a control table that has an associated language table.

| Syntax | Valid Values |
|--------------------------|-----------------------------|
| oraType="table: " | Table code after the colon. |

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Currency:</td>
    <td><span oraType="table:CI_CURRENCY_CD" oraField="curr"></span></td>
  </tr>
</table>
</body>
</html>
<xml>
<root>
  <curr>USD</curr>
</root>
</xml>
</html>
```

HTML rendered.

Currency: United States Dollars

Add / Remove Grid Formatting

| Syntax | Description |
|--------------------------------|--|
| oraType="addGridRow" | <p>The addGridRow function is used to build "insert row" dialog into the UI map.</p> <ul style="list-style-type: none"> An 'add' image is displayed. Clicking the image inserts a new row in the grid. If the list is empty, by default, an empty grid row is automatically be added. This means that the user will always see at least one grid row when this attribute is used. |
| oraType="deleteGridRow" | <p>The deleteGridRow function is used to build "delete row" dialog into the UI map.</p> <ul style="list-style-type: none"> A 'delete' image is displayed. Clicking the image removes the adjacent row from the grid. |

Note: Because add and delete dialogs are relevant only inside a table, these attributes must be specified within a <td> element.

Warning: These attributes are designed to work with the business object action of 'replace' rather than 'update'. Therefore, if the map contains a grid, the business object action of 'replace' must be used to update the business object. Refer to [BO Replace Action](#) for more information.

Example:

```
<html>
<head>
<title>Demonstrate Grid Add and Grid Delete OraTypes</title>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table oraList="listEntry">
  <thead>
    <tr>
      <th/>
      <th/>
      <th><span>Date</span></th>
      <th><span>Amount</span></th>
    </tr>
  </thead>
  <tr>
    <td oraType="addGridRow"></td>
    <td oraType="deleteGridRow"></td>
    <td>
      <input oraField="date" oraType="date"></input>
    </td>
    <td align="right">
      <input oraField="amount" oraType="money"></input>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <listEntry>
    <date>2008-01-01</date>
    <amount>44.28</amount>
  </listEntry>
  <listEntry>
    <date>2008-02-01</date>
    <amount>32.87</amount>
  </listEntry>
  <listEntry>
    <date>2008-03-01</date>
    <amount>21.76</amount>
  </listEntry>
</root>
</xml>
</html>
```

HTML rendered.

| | DATE | | AMOUNT |
|---|------------|--|---------|
| + | 01-01-2008 | | \$44.28 |
| + | 02-01-2008 | | \$32.87 |
| + | 03-01-2008 | | \$21.76 |

Unformatted Elements

This function is used to display the contents of an element that contains 'raw' data as defined for the schema element being rendered.

Syntax

oraType="raw"

- UI Map schema:

```
<schema>
  <rawStuff type="raw"/>
</schema>
```

- UI Map HTML:

```
<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Raw Stuff:</td>
    <td><span oraType="raw" oraField="rawStuff"></span></td>
  </tr>
</table>
</body>
<xml>
<root>
  <rawStuff>
    <ele1>text in element 1</ele1>
    <group1>
      <ele2>text inside element 2, group 1</ele2>
      <ele3>text inside element 3, group 1</ele3>
    </group1>
  </rawStuff>
</root>
</xml>
</html>
```

HTML rendered.

| | |
|------------|--|
| Raw Stuff: | <pre><ele1>text in element 1</ele1> <group1> <ele2>text inside element 2, group 1</ele2> <ele3>text inside element 3, group 1</ele3> </group1></pre> |
|------------|--|

String Formatting

This function is used to display the contents of an element, as XML pretty-print, when the element contains escaped XML.

Syntax

oraType="xmlString"

Note: It is not required, but the pretty print of the rendered XML is enhanced if you specify a pair of stylesheet references, `cisEnabled` and `cisDisabled`, in the map's header.

Example:

```
<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>XML Stuff:</td>
    <td><span oraType="xmlString" oraField="xmlStuff"></span></td>
  </tr>
</table>
</body>
<xml>
<root>
  <xmlStuff>
    <ele1>text in element 1</ele1>
    <group1>
      <ele2>text inside element 2, group 1</ele2>
      <ele3>text inside element 3, group 1</ele3>
    </group1>
  </xmlStuff>
</root>
</xml>
</html>
```

HTML rendered.

| | |
|-------------------|--|
| XML Stuff: | <pre><ele1>text in element 1</ele1> <group1> <ele2>text inside element 2, group 1</ele2> <ele3>text inside element 3, group 1</ele3> </group1></pre> |
|-------------------|--|

HTML rendered without `oraType="xmlString"`

| | |
|-------------------|--|
| XML Stuff: | <pre><ele1>text in element 1</ele1><group1><ele2>text inside element 2, group 1</ele2><ele3>text inside element 3, group 1</ele3></group1></pre> |
|-------------------|--|

HTML Formatting

This function is used to display the contents of an element as HTML as opposed to plain text. An element defined as `oraType="fkref"` is automatically rendered as HTML.

| |
|-----------------------------|
| Syntax |
| <code>oraType="html"</code> |

Warning:

To avoid execution of malicious HTML not all HTML tags are supported. The list of supported tags is defined in the "F1-HTMLWhiteList" managed content definition.

If unsupported HTML is detected the entire element is escaped and rendered as plain text. It is therefore recommended to properly escape any source string that contributes to the final HTML element if it is not expected to contain valid HTML. This way only the offending string is escaped and not the entire element.

If the HTML element is composed in scripting refer to the 'escape' function described in the [Edit Data Syntax](#) for more information. Use the `WebStringUtilities.asHTML` java API for escaping text composed in Java.

```
<html>
<head>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table summary="" border="0" cellpadding="1" cellspacing="1">
  <tr>
    <td>Info :</td>
    <td><span oraType="html" oraField="info"></span></td>
  </tr>
</table>
</body>
<xml>
<root>
  <info><b>text in bold</b></info>
</root>
</xml>
</html>
```

HTML rendered.

Info : **text in bold**

HTML rendered without `oraType="html"`

Info : text in bold

Display Labels

Derive Label from an Element

This attribute is used to obtain a language sensitive label for a ``, `<td>`, or `<input>` HTML element.

| Syntax | Valid Values |
|---------------------------|--|
| <code>oraLabel=" "</code> | XPath of an element in the UI map schema. The element must reference either the <code>mapField=</code> , <code>mdField=</code> , or <code>label=</code> attribute. |

Note: You can also define a field directly in your HTML for label definition, refer to [Deriving Label from a Field](#) for more information.

Note: If the schema contains multiple attributes, the `oraLabel` attribute will pick the label to render according to the following hierarchy: The `label` attribute overrides the `mdField` attribute, which in turn will override the `mapField` attribute.

- UI Map schema:

```
<schema>
  <user mapField="USER_ID"/>
  <info type="group" mapXML="CLOB">
    <city label="Metro Area"/>
    <age mdField="AGE_LBL"/>
  </info>
</schema>
```

- HTML:

```
<html>
<head><title oraMdLabel="BUS_LBL"></title></head>
<body>
<table>
  <tr>
    <td oraLabel="user"></td>
    <td><input oraField="user"/></td>
  </tr>
  <tr>
    <td oraLabel="info/city"></td>
    <td><input oraField="info/city"/></td>
  </tr>
  <tr>
    <td oraLabel="info/age"></td>
    <td><input oraField="info/age"/></td>
  </tr>
  <tr>
    <td/>
    <td><input type="button" oraMdLabel="ACCEPT_LBL"/></td>
  </tr>
</table>
</body>
<xml>
<root>
  <user>RWINSTON</user>
  <info>
    <city>Alameda</city>
    <age>32</age>
  </info>
</root>
</xml>
</html>
```

HTML rendered:

| | |
|------------|---------------------------------------|
| User | <input type="text" value="RWINSTON"/> |
| Metro Area | <input type="text" value="Alameda"/> |
| Age | <input type="text" value="32"/> |
| | <input type="button" value="Accept"/> |

Deriving Label from a Field

This attribute is used to obtain a language sensitive label for a ``, `<td>`, `<input>`, or `<title>` HTML element. The label text is derived from the field referenced.

| Syntax | Valid Values |
|-----------------------------|---------------------------------|
| <code>oraMdLabel=" "</code> | MD Field code . |

Note: You can also define labels derived from the map's schema definition, refer to [Derive Label from an Element](#) for more information.

- HTML:

```
<html>
<head><title oraMdLabel="F1_DETAILS_LBL"></title></head>
<body>
<table>
```

```

<tr>
  <td oraLabel="user"></td>
  <td><input oraField="user"/></td>
</tr>
<tr>
  <td oraLabel="info/city"></td>
  <td><input oraField="info/city"/></td>
</tr>
<tr>
  <td oraLabel="info/age"></td>
  <td><input oraField="info/age"/></td>
</tr>
<tr>
  <td/>
  <td><input type="button" oraMdLabel="ACCEPT_LBL"/></td>
</tr>
</table>
</body>
<xml>
<root>
  <user>RWINSTON</user>
  <info>
    <city>Alameda</city>
    <age>32</age>
  </info>
</root>
</xml>
</html>

```

HTML rendered:

The screenshot shows a browser window titled 'Details - Google Chrome' with the URL 'slcao351.us.oracle.com:20000/spl/usermap'. The page content includes a 'Details' section with three input fields: 'User' containing 'RWINSTON', 'Metro Area' containing 'Alameda', and 'Age' containing '32'. Below the 'Age' field is an 'Accept' button.

Enable UI Map Help

The [Display Labels](#) section describes ways to derive the label for an element using an underlying [MD Field](#). In addition, if the same MD field contains help text, the system will automatically generate a tool tip adjacent to the element label. Clicking the tool tip allows the user to view the help text.

It is possible to change the rendering of the tool tip. Refer to [Custom Look And Feel Options](#) for more information.

Search Using a Pop-Up Explorer Zone

Search Option

This attribute is used to enable search zone functionality for input HTML elements.

| Syntax | Valid Values |
|----------------------------|--------------|
| <code>oraSearch=" "</code> | Zone code. |

Note: The oraSearch attribute is similar to the oraType attribute, because it will be 'automatically' included into HTML via the oraSchemaDataTypes attribute. This means that coding the oraSearch attribute into UI Map HTML is only required if a search zone has not been specified in the schema, or in the schema element's FK reference.

- Example of defining the search in the HTML. UI Map's Schema:

```
<schema>
  <uiMap/>
</schema>
```

UI Map's HTML

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>UI Map with Search </td>
    <td><input oraField="uiMap" oraSearch="F1-UISRCH"></td>
  </tr>
</table>
</body>
<xml>
<root>
  <uiMap/>
</root>
</xml>
</html>
```

- Example of defining the search in the schema. UI Map's Schema:

```
<schema>
  <uiMap search="F1-UISRCH"/>
</schema>
```

UI Map's HTML

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>UI Map with Search </td>
    <td><input oraField="uiMap"></td>
  </tr>
</table>
</body>
<xml>
<root>
  <uiMap/>
</root>
</xml>
</html>
```

- Example where the FK reference defines the search zone. UI Map's Schema:

```
<schema>
  <uiMap fkRef="F1-UISRC"/>
</schema>
```

UI Map's HTML

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>UI Map with Search </td>
    <td><input oraField="uiMap"></td>
  </tr>
</table>
</body>
</html>
<xml>
<root>
  <uiMap/>
</root>
</xml>
</html>
```

In all cases, the HTML rendered is the same.

UI MAP WITH SEARCH 

Initializing Search Fields

This optional attribute is used to initialize search zone filters. Multiple filters may be initialized. This attribute can only be used in conjunction with the oraSearch attribute.

| Syntax | Valid Values | Field Value Options | Comments |
|--|--|---------------------|--|
| oraSearchField=" " | One or more pairs of field name and field value separated by colon. Each pair is separated by a semi-colon. | No value | If you do not specify a field value, then the value of the input element containing the oraSearchField attribute will be used. |
| oraSearchField=" fieldName:fieldValue: ..." | The field name is used to identify the zone filter to initialize when the search is launched. The field name must match the value of the searchField mnemonic specified on a search zone user filter or hidden filter parameter. | XPath 'literal' | Indicate the XPath to the schema element that contains the value to use. Indicate a literal value to supply. |

Note: If you do not specify an oraSearchField attribute and the schema element has a search enabled fkRef specified, the framework automatically builds an oraSearchField where the field name is equal to the FK reference's key (MD) [fields](#).

Warning: The pop-up explorer zone can be invoked one of two ways: By clicking on the search button, or by hitting the enter key from the field to the left of the button. If you click on the button then no search field information will be passed to the zone. Search field information is only used to initialize zone filter values when enter is pressed.

Two filter values are initialized as shown in the following example:

```
<schema>
  <bo/>
  <uiMap/>
```

```

</schema>

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>UI Map with Search </td>
    <td><input oraField="uiMap" oraSearch="F1-
UISRCH" oraSearchField="MAP_CD; BUS_OBJ_CD:bo;"></td>
  </tr>
</table>
</body>
</html>
<xml>
<root>
  <bo/>
  <uiMap/>
</root>
</xml>
</html>

```

Mapping Returned Search Fields

This optional attribute is used to direct values returned by the search zone. Multiple fields may be specified. This attribute can only be used in conjunction with the oraSearch attribute.

| Syntax | Valid Values | Field Value Options | Comments |
|--|---|---------------------|--|
| oraSearchOut=" " | One or more pairs of field name and field value separated by colon. Each pair is separated by a semi-colon. | No value | If you do not specify a field value, then the input element containing the oraSearchField attribute receives the returned value. |
| oraSearchOut="field name:xpath target; ..." | The field name is used to identify the search result returned from the query zone. The field name must match the ELEMENT_NAME mnemonic defined within the explorer zone's search results parameter. | XPath | Indicate the XPath to the schema element that should receive the returned value. |

Note: If you do not specify an oraSearchOut attribute, the framework will build a default where the field name will be set equal to the oraSearchField's field name.

Two values are returned in the following example:

```

<schema>
  <bo/>
  <mo/>
</schema>

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>BO Search </td>

```

```

<td><input oraField="bo" oraSearch="Z1-
BOSRCH" oraSearchOut="BUS_OBJ_CD; MO_CD:mo;"></td>
</tr>
</table>
</body>
</xml>
<root>
  <bo/>
  <mo/>
</root>
</xml>
</html>

```

Display Errors

Display Error Variables

One of the following error variables may be displayed.

Syntax

```
oraErrorVar="ERRMSG-TEXT"
```

```
oraErrorVar="ERRMSG-LONG"
```

```
oraErrorVar="ERRMSG-CATEGORY"
```

```
oraErrorVar="ERRMSG-NUMBER"
```

```

...
<table width="100%" cellpadding="12">
  <tr class="oraErrorText">
    <td>
      <a href="" onclick="oraShowErrorAlert(); return false;">
        <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
      </a>
    </td>
  </tr>
</table>
...

```

HTML rendered

The screenshot shows a form with the following elements:

- User Id:** BOND007
- First Name:** James
- Last Name:** (empty input field)
- Error Message:** Last name required (highlighted in red)

Highlight a Field in Error

Note: For more information on throwing an error, refer to the [Terminate Statement](#) in the Edit Data Syntax.

| Syntax | Comments |
|--|--|
| <pre>oraError="automate:true false; prefix: "</pre> | Specifying automate:true automatically enables highlighting of the element in error when issuing an error. Note that true is the default and doesn't need to be specified. Specify automate:false to turn off field highlighting. |

| Syntax | Comments |
|--------|--|
| | The system uses a match on the element name referenced in the error to the element names in the UI map. If the elements in the schema are within an XPath that may not match what is referenced by the error, use prefix:XPath to specify that. |

Note: A pair of stylesheet references, `cisEnabled` and `cisDisabled`, must be specified for reference of the `oraError` style. The stylesheet controls how the field in error will be rendered. If you want to alter the rendering you must override the `oraError` style.

The following HTML example shows that the elements in the map are defined within a group called **boGroup**. The element name returned by the error will not include this group so in order for the field highlighting to work properly the **prefix:** attribute must indicate the group name.

```
<html>
<head>
  <title>User Zone Input</title>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body oraError="automate:true; prefix:boGroup">
<table width="100%" cellpadding="12">
  <tr class="oraErrorText">
    <td>
      <a href="" onclick="oraShowErrorAlert(); return false;">
        <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
      </a>
    </td>
  </tr>
</table>
<table width="100%" border="0" cellpadding="4">
  <tr style="padding-top:30px;">
    <td align="right" class="label">User Id</td>
    <td>
      <span oraField="boGroup/userId" class="normal"/>
    </td>
  </tr>
  <tr>
    <td align="right" class="label">First Name</td>
    <td>
      <input oraField="boGroup/firstName" class="normal"/>
    </td>
  </tr>
  <tr>
    <td align="right" class="label">Last Name</td>
    <td>
      <input oraField="boGroup/lastName" class="normal"/>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <boGroup>
    <userId>BOND007</userId>
    <firstName>James</firstName>
    <lastName></lastName>
  </boGroup>
</root>
</xml>
</html>
```

HTML rendered, where the error element thrown is equal to 'lastName':

Overriding the Error Element Name

In the rare occasion where the element name returned by the error doesn't match the element name in the map, you can add an explicit attribute to indicate the error element name.

| Syntax | Valid Values | Comments |
|-------------------------|----------------|--|
| oraErrorElement= | "element name" | The element name referenced here must exactly match the name of the error element assigned when the error was thrown. More than one HTML field can be referenced by the same error element name. |

Note: A pair of stylesheet references, `cisEnabled` and `cisDisabled`, must be specified for reference of the `oraError` style. The stylesheet controls how the field in error will be rendered. If you want to alter the rendering you must override the `oraError` style.

This illustrates a scenario where the element name associated with the error differs from the element name on the map.

```
<html>
<head>
  <title>User Zone Input</title>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table width="100%" cellpadding="12">
  <tr class="oraErrorText">
    <td>
      <a href="" onclick="oraShowErrorAlert(); return false;">
        <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
      </a>
    </td>
  </tr>
</table>
<table width="100%" border="0" cellpadding="4">
  <tr style="padding-top:30px;">
    <td align="right" class="label">User Id</td>
    <td>
      <span oraField="userId" class="normal"/>
    </td>
  </tr>
  <tr>
    <td align="right" class="label">First Name</td>
    <td>
      <input oraField="firstName" class="normal" oraErrorElement="firstName"/>
    </td>
  </tr>
  <tr>
    <td align="right" class="label">Last Name</td>
    <td>
```

```

        <input oraField="familyName" class="normal" oraErrorElement="lastName"/
    >
        </td>
    </tr>
</table>
</body>
</xml>
<root>
    <userId>BOND007</userId>
    <firstName>James</firstName>
    <familyName></familyName>
</root>
</xml>
</html>

```

HTML rendered.

Last Name

Display Error Pop-Up

When the error text is displayed, this function may be used to pop-up the standard error dialog (which displays more information) when a user clicks the error message.

Syntax

```
oraShowErrorAlert(); return false;
```

```

<html>
<head>
    <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
    <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table width="100%" cellpadding="12">
    <tr class="oraErrorText">
        <td>
            <a href="" onclick="oraShowErrorAlert(); return false;">
                <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span>
            </a>
        </td>
    </tr>
</table>
<table>
    <tr>
        <td >Address:</td>
        <td><input type="text" oraField="address"/></td>
    </tr>
    <tr>
        <td>City:</td>
        <td><input type="text" oraField="city"/></td>
    </tr>
    <tr>
        <td>State:</td>
        <td><input type="text" oraField="state"/></td>
    </tr>
</table>

```

```

        <td>Zip:</td>
        <td><input type="text" oraField="zip"/></td>
    </tr>
    <tr>
        <td/>
        <td style="padding-top:15px;">
            <oraInclude map="F1-SaveCancelButtons"/>
        </td>
    </tr>
</table>
</body>
</xml>
<root>
    <address>123 Main St</address>
    <city>Alameda</city>
    <state>CA</state>
    <zip>94770</zip>
</root>
</xml>
</html>

```

HTML rendered.

Standard error pop-up dialog launched via click on error message:

Fire JavaScript for Browser Events

Working with the JavaScript Framework

There are many JavaScript events that can be used within the HTML/Javascript environment. These include events such as onLoad, onBlur, onChange, etc. The UI Map Framework also makes use of some of these events. It is important that any UI Map you develop works with the framework in order to obtain consistent results (events may not always be executed in the same order at all times!).

**Warning:**

The following describes the recommended approach for safely handling loading and processing field updates in your UI Maps.

If JavaScript is required within an XHTML UI Map or fragment, it will be necessary to bound it within a `![CDATA[]]` tag to ensure a valid XML document. Note that the tags themselves may need to be commented out to promote compatibility with older browsers. For example:

```
<script type="text/javascript">
/* <![CDATA[ */

//
// javascript
//

/* ]]> */

</script>
```

Element Change Event

| Syntax | Valid Values |
|----------------------------|------------------------|
| <code>oraChange=" "</code> | A JavaScript function. |

At the time of UI Map load, if there is an event handler already attached to an HTML element, the framework removes it and attaches a combined event handler. The combined handler calls any **framework handler first** and then calls the other (custom) handlers.

Warning: Note that the function must not be used to execute logic that will modify the associated field data value again - or an endless loop will occur.

In the following example the `oraInvokeBS` function is executed when the button is clicked.

```
<html>
  <head>
    <title>oraInvokeBS test</title>
  </head>
  <body>
    <table>
      <tr>
        <td>User Id:</td>
        <td>
          <input oraField= "xmlGroup/userId"/>
          <input type="button" value="Search" oraChange="oraInvokeBS('UserSearch',
>
        </td>
      </tr>
      <tr>
        <td/>
        <td>Search Results</td>
      </tr>
      <tr>
        <td/>
        <td>
          <table oraList="xmlGroup/searchList">
            <tr>
              <td><span oraField="userId"></span>
            </td>
            </tr>
          </table>
        </td>
      </tr>
    </table>
```

```

        </td>
      </tr>
    </table>
  </body>
</xml>
<root>
  <xmlGroup>
    <userId/>
    <searchList>
      <userId></userId>
    </searchList>
  </xmlGroup>
</root>
</xml>
</html>

```

Page Load Event

| Syntax | Valid Values |
|--------------------|------------------------|
| oraLoad=" " | A JavaScript function. |

Warning: When executing oraLoad within a fragment UI map, and you need to execute a JavaScript function during page load (where the function invokes a business object, business service, or service script) you can use the special syntax "**oraLoad[\$SEQUENCEID]**". For other special syntax used for map fragments, refer to the [Construct a Portal Zone Header](#) section.

- In the following example, the [oraDisplayNone](#) function is executed during page load:

```

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td oraLoad="oraDisplayNone(item,'userId','')">User Id: </td>
    <td><span oraField="userId"></span></td>
  </tr>
</table>
</body>
</html>
<root>
  <userId>SPLAXT</userId>
</root>
</xml>
</html>

```

- HTML rendered

User Id: SPLAXT

After Page Load Event

| Syntax | Valid Values |
|------------------------|------------------------|
| oraAfterLoad="" | A JavaScript function. |

In the following example the oraGetValueFromScript function is executed after page load.

```

<div>
  <label for="boGroup_parameters_externalSystem" oraLabel="boGroup/
parameters/externalSystem">
  </label>
  <span>

```

```

        <select oraSelect="bs:F1-
RetrieveExternalSystems" class="oraInput"
        id="boGroup_parameters_externalSystem" oraField="boGroup/
parameters/externalSystem"
        oraSelectOut="valuePath:results/
externalSystem; descPath:results/description"
        oraSelectIn="outboundMsgType:boGroup/parameters/
outboundMsgType"
        oraAfterLoad
        ="oraGetValueFromScript (document.getElementById('boGroup_parameters_extern
        </select>
    </span>

</div>

```

Hide Elements

Hide Using a Function

The system provides multiple techniques for hiding an HTML element.

| Syntax | Valid Values | Comments |
|-------------------------------|---|--|
| oraDisplayNone(item); | (item, 'XPath', 'value', 'operator') | Used to hide an element based on the value of another element (referenced using its XPath). Enter a value of '' to interrogate a blank value. By default the operator is '='. This may be set instead to another operator such as '!=', '>', or '<'. |
| | (item, function name, true false) | Used to indicate a JavaScript function, which must return a Boolean. |
| oraIsSuppress="true" | | Use this option for fields that need to be hidden always and not dependent on something else. Set this attribute on the HTML element (div element). |

- Example where the User Id label is hidden when no User Id value exists.

```

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td oraLoad="oraDisplayNone(item, 'userId', '')">User Id: </td>
    <td><span oraField="userId"></span></td>
  </tr>
</table>
</body>
<xml>
<root>
  <userId></userId>
</root>
</xml>
</html>

```

- Example where the Save button is hidden when the user does not have security access to the action of change ('C') for the application service 'F1-DFLTS'.

```

<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>

```

```

    <td oraLoad="oraDisplayNone(item, oraHasSecurity('F1-
DFLTS', 'C'), false );">
      <input name="Save" type="button" onclick="oraInvokeBO('CM-
IndividualTaxpayer', null, 'replace')"/>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <userId></userId>
</root>
</xml>
</html>

```

Check User's Security Access

The system provides two functions to check a user's security access to a given application service and access mode. These are commonly used for hiding elements.

| Syntax | Parameters |
|------------------------------------|--|
| oraHasSecurity() | 'Application Service code' 'Access Mode' |
| oraHasSecurityPath('x','y') | 'Application Service XPath' 'Access Mode XPath' |

See the previous section for an example of the **oraHasSecurity** function. The following shows an example where the status button is hidden when the user does not have security access to the access mode 'ACT' of the application service 'FORMTST'.

```

<html>
<body>
<table>
  <tr>
    <td oraLoad="oraDisplayNone(item, oraHasSecurityPath('appService', 'accessMode'), fa
      <input oraField="statusLabel" type="button" onclick="oraRunScript('UpdateState', 's
    >
  </td>
</tr>
</table>
</body>
<xml>
<root>
  <status>ACTIVATE</status>
<statusLabel>Activate</statusLabel>
<appService>FORMTST</appService>
  <accessMode>ACT</accessMode>
</root>
</xml>
</html>

```

Invoke Schema Based Services

The system provides functions for invoking a business object, business service or service script.

Invoke BO Function

This function is used to perform a BO interaction directly from the UI map's HTML. It returns a 'true' or a 'false' depending on whether the invocation encounters an error.

| Syntax | Parameters | Comments |
|----------------------|---|---|
| oraInvokeBO() | 'BO Name' 'XPath' or null 'action' | Identifies a group element via XPath. If you specify the word null , then the entire embedded XML object will be passed. Indicate the action to use. Valid values are add , delete , read , update , replace , fastAdd and fastUpdate .  Fastpath: Refer to BO Actions for more information about the various BO actions. |

Example with the statement invoked in a JavaScript function.

```
function invokeBO {
    if (!oraInvokeBO('F1-User', 'xmlGroup', 'read')) {
        oraShowErrorAlert();
        return;
    }
}
```

Example with the statement invoked within onClick.

```
<input type="button" class="oraButton" oraMdLabel="DISPLAY_LBL" onClick="oraInvokeBO('F1-User');"/>
```

Invoke BS Function

This function is used to perform a business service interaction directly from the UI map's HTML. It returns a 'true' or a 'false' depending on whether the invocation encounters an error.

| Syntax | Parameters | Comments |
|----------------------|---|---|
| oraInvokeBS() | 'BS Name' 'XPath' or null | Identifies a group element via XPath. If you specify the word null , then the entire embedded XML object will be passed. |

Example with the statement coded within a JavaScript function.

```
function invokeBS {
    if (!oraInvokeBS('F1-UserSearch', 'xmlGroup')) {
        oraShowErrorAlert();
        return;
    }
}
```

Example with the statement invoked via onClick.

```
<input type="button" class="oraButton" oraMdLabel="DISPLAY_LBL" onClick="oraInvokeBS('RetrieveInfo');"/>
```

Invoke SS Function

This function is used to perform a service script interaction directly from the UI map's HTML. It returns a 'true' or a 'false' depending on whether the invocation encounters an error.

| Syntax | Parameters | Comments |
|----------------------|---|--|
| oraInvokeSS() | 'Service Script Name' 'XPath' or null | Identifies a group element via XPath. If you specify the word null , then the document belonging to the parent node will be passed. If the parent node is not enough, then the entire document can always be passed using the following syntax: <pre>oraInvokeSS('service script', null, null, [\$SEQUENCEID])</pre> |

Example with the statement invoked within a JavaScript function:

```
function invokeSS {
    if (!oraInvokeSS('Fl-GetUsers', 'xmlGroup')) {
        oraShowErrorAlert();
        return;
    }
}
```

Example with the statement invoked within onClick.

```
<input type="button" class="oraButton" oraMdLabel="DISPLAY_LBL" onClick="oraInvokeSS('Fl-GetUserInfo');"/>
```

Refresh a Rendered Map or Portal Page

Refresh Map

This function is used to 'Refresh' only the map zone issuing the command.

Syntax

```
oraRefreshMap;
```

```
...
    <tr>
        <td/>
        <td><input type="button" onclick="oraRefreshMap();" value="Refresh"/>
    </td>
    </tr>
...
```

Refresh Page

This function is used to refresh all zones in the portal.

Syntax

```
oraRefreshPage;
```

```
...
    <tr>
        <td/>
        <td><input type="button" onclick="oraRefreshPage();" value="Refresh"/>
    </td>
    </tr>
```

...

Embed Framework Navigation

Navigate using Navigation Option

This function is used to navigate to another page using the information defined on a navigation option.

| Syntax | Parameters |
|------------------------------|---|
| <code>oraNavigate();</code> | 'Navigation Option code' 'Key XPath' |

Warning: This function is only intended for a UI map defined within a portal zone. It should not be used within a UI map launched by a BPA script.

The following example exhibits two possible uses of this function: as a URL and as a button. Note that the UI Map schema must contain a `fkRef` attribute. Refer to [FK Reference Formatting](#) for more information.

```
<schema>
  <userId fkRef="CI_USER"/>
</schema>
```

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>User Link: </td>
    <td><a href="" onclick="oraNavigate('userMaint','userId'); return false;">
      <span oraField="userId" oraType="fkRef:CI_USER"></span></a>
    </td>
  </tr>
  <tr>
    <td>User Button: </td>
    <td><input type="submit" onclick="oraNavigate('userMaint','userId') "
      value="Go to User"/></td>
  </tr>
</table>
</body>
<xml>
<root>
  <userId>SPLAXT</userId>
</root>
</xml>
</html>
```

HTML rendered.

| | |
|--------------|---|
| User Link: | Taranto, Armando |
| User Button: | <input type="button" value="Go to User"/> |

Launch BPA Script

Launch BPA Script

| Syntax | Parameters | Comments |
|-------------------------------|--------------------|----------|
| <code>oraRunScript();</code> | 'BPA script code'. | |

| Syntax | Parameters | Comments |
|--------|-----------------|--|
| | 'XPath Element' | One or more element values may be passed into the BPA where it may be referenced as temporary variables. |

Warning: This function is only applicable to UI maps displayed in portal zones. UI maps launched within a running BPA script cannot directly launch another BPA script from the UI map's HTML. Instead, return a value from the UI map and execute a Perform Script or Transfer Control step type.

Note: It is incumbent on the script author to pull information out of temporary storage in the initial steps of the script.

In the following example, a temporary variable named 'personId' is created with value '1234567890' and the BPA script named 'Edit Address' is launched.

```
<html>
<body>
<table>
  <tr>
    <td>
      <div oraField="address"></div>
      <span oraField="city"></span>
      <span></span>
      <span oraField="state"></span>
      <span oraField="zip"></span>
      <span oraField="country"></span>
      <a href="" onClick="oraRunScript('Edit Address','personId');">edit</a>
    </td>
  </tr>
</table>
</body>
<xml>
<root>
  <personId>1234567890</personId>
  <address>123 Main St</address>
  <city>Alameda</city>
  <state>CA</state>
  <zip>94770</zip>
</root>
</xml>
</html>
```

HTML rendered.

123 Main St
Alameda, CA 94770 [edit](#)

Launch BPA Script With Values

This function is used to launch a BPA, providing name/value pairs to push into temporary storage. Multiple values can be passed. The BPA script can then reference the temporary variables by name.

| Syntax | Parameters | Comments |
|---|----------------------------|--|
| oraRunScriptWithValues() BPA script code'. | 'XPath Element Name':value | One or more pairs of element names and values. |

Note: You would use this JavaScript function, instead of `oraRunScript`, if you need to push values to the BPA script that are not located in the UI Map's XML structure.

In the example below, a JavaScript function named `editUser()` is responsible for launching the BPA script named `UserEdit`. The temporary variable named `userId` will be created with value `'CMURRAY'`.

```
<html>
<head>
<script type="text/javascript">

function editUser() {
    var values = {'userId': 'CMURRAY'};
    oraRunScriptWithValues('UserEdit', values);
    return;
}

</script>
</head>
<body>
...
</body>
</html>
```

Exit UI Map with Bound Values

This function is used to exit a UI Map. When you quit the map you can specify a value to return to the script and, in addition, whether to return updated XML.

| Syntax | Parameters | Comments |
|-------------------------------|-------------------------------------|---|
| <code>oraSubmitMap();</code> | 'Return Value' Boolean value | Indicates if the updated XML should be returned. Default is true . |

In the following example, the Save button will return updated information, the Cancel button will not.

```
<html>
<body>
<table>
  <tr>
    <td/>
    <td style="padding-bottom:15px;">
      <a href="" onclick="oraShowErrorAlert(); return false;">
        <span oraErrorVar="ERRMSG-TEXT"></span></a>
      </td>
    </tr>
    <tr>
      <td >Address:</td>
      <td><input type="text" oraField="address"/></td>
    </tr>
    <tr>
      <td>City:</td>
      <td><input type="text" oraField="city"/></td>
    </tr>
    <tr>
      <td>State:</td>
      <td><input type="text" oraField="state"/></td>
    </tr>
    <tr>
      <td>Zip:</td>
      <td><input type="text" oraField="zip"/></td>
```

```

</tr>
<tr>
  <td/>
  <td style="padding-top:15px;">
    <input type="button" value="Save" onClick="oraSubmitMap('SAVE');"/>
    <input type="button" value="Cancel" onClick="oraSubmitMap('CANCEL',false);"/>
  </td>
</tr>
</table>
</body>
</xml>
<root>
  <address>123 Main St</address>
  <city>Alameda</city>
  <state>CA</state>
  <zip>94770</zip>
</root>
</xml>
</html>

```

Save and Cancel buttons rendered:

Include a Map Fragment

This function is used to embed a map fragment within another UI map. Note that it is possible to use the include node within a map or a map fragment.

| Syntax | Parameters | Comments |
|---|---|---|
| <pre><oraInclude map=' ' prefixPath=' '/></pre> | <pre>map='UI Map Code' prefixPath='Xpath'</pre> | <p>Optionally specify an xpath prefix to be appended onto every included oraField, oraLabel, oraList, oraSelect valuePath and descPath, oraDownloadData, and oraUploadData attribute value defined within the included UI map fragment's HTML.</p> <p> Note: This functionality only applies to XPath attribute values when those values do not appear beneath an oraList attribute. Any XPath value within a table containing an oraList attribute will not be affected by a prefixPath.</p> |

- An example of a map fragment with two buttons, named 'F1-SaveCancelButtons'.

```

<input onClick ="oraSubmitMap('SAVE');" oraMdLabel="SAVE_BTN_LBL" class="oraButton"
type="button"/>
<input onClick ="oraSubmitMap('CANCEL',false);" oraMdLabel="CANCEL_LBL" class="oraBut
type="button"/>

```

- An example of a map that includes the map fragment named 'F1-SaveCancelButtons'.

```

...
<tr>
  <td colspan="2" align="center">
<oraInclude map="F1-SaveCancelButtons"/>
  </td>
</tr>
...

```

Include a Web Component

A web component is a custom HTML element that produces a specific user interface feature. Each supported web component typically has one or more defined HTML attributes that affect how the web component functions and how it appears. The more complex web components may have a corresponding system configuration object that defines the behavior and information displayed by the resulting user interface element. For example the web component that produces a "tree" of information has a Tree configuration table, which defines the details about how to retrieve information for the tree and how to display each node.

Common Attributes

Some common attributes that may be used for each web component are:

- A reference to the specific instance of the configuration object that governs the details to produce.
- The ability to pass in context data as name and value pairs.
- A 'mode' that support showing a preview of the feature

Some attributes support a **single value** that is referenced. For these types of attributes, the value may be provided using one of the following references:

- Literal value. The value can be referenced directly. Example:

```
treeName="F1-Tree"
```

- XPath Reference. XPath references must use the explicit syntax **x[value]**. Example:

```
treeName="x[migrationTree]"
```

- Global or Portal context reference. These references must use the explicit syntax **c[value]**.

```
treeName="c[TREE_NAME]"
```

- Field label reference. These references must use the explicit syntax **md[value]**.

```
text=md[F1_ADD_LBL]"
```

- Field help text reference. These references must use the explicit syntax **mdh[value]**.

```
text=mdh[F1_OPERATIONS_LBL]"
```

For **complex attributes** that support one or more name / value pairs, the syntax for defining the names and values follows the same rules as above for literal values, XPath references and context. Colons (":") should be used to separate the name from the value and semi-colons (";") separate each pair.

```
context="FIELD_NAME1:x[value1];FIELD_NAME2:F1AB;x[fieldName3]:c[FIELD_NAME3];"
```

A given web component may have additional HTML attributes specific to its functionality.

Note: Any UI map that defines a web component must include the F1-OJETLIBSR map fragment within the "body" tag.

```
<body>
```

```
<oraInclude map="F1-OJETLIBSR"/>
..
</body>
```

Note: Standard HTML attributes may also be provided (e.g ID=".." and style=".."). These are defined as normal. It should be noted that the web components themselves may control some styling aspects directly and thus override any style settings provided on the HTML web component. For example, the Contextual Insights configuration provides settings for text color that would override any color defined in the HTML.

The following sections describe each supported web component.

Trees

Refer to [Trees](#) for more information about tree configuration.

| Syntax | Parameters | Comments |
|---|-------------------------------|--|
| <code><ou-tree...></ou-tree></code> | treename="singleValue" | You must supply a reference to the name of the tree object that defines the configuration of the tree to display. This attribute expects a single value that follows the syntax described in the single value section above. |
| | context="..." | Optionally pass in one or more name / value pairs. The syntax follows the example shown in the complex attributes information above. |

The following example uses an explicit reference to a tree and does not pass any context. The particular tree relies on global context, which the tree node algorithm has access to.

```
<ou-tree treename="C1-PremiseTree"></ou-tree>
```

Contextual Insight

Refer to [Contextual Insights](#) for information about the configuration related to defining contextual insights.

| Syntax | Parameters | Comments |
|--|-----------------------------------|---|
| <code><ou-insights ...></ou-insights></code> | insightType="singleValue" | Use this attribute to specify an insight type to display. Either this attribute or the insight class attribute must be supplied. This attribute expects a single value that follows the syntax described in the single value section above. |
| | insightClass="singleValue" | Use an insight class to display all the insight types for the insight group related to this class. This attribute expects a single value that follows the syntax described in the single value section above. |
| | context="..." | Optionally pass in one or more name / value pairs. The syntax follows the example shown in the complex attributes information above. |
| | mode="preview" | Optionally pass in a mode of preview to indicate to the underlying insight algorithm that prepares the data that the insight is being called in preview mode, with no context available. Ideally the algorithm returns sample information. |

| Syntax | Parameters | Comments |
|--------|------------------|--|
| | class=" " | <p>Optionally provide a CSS helper class to control aspects of the rendered insight. Supported values:</p> <p>class="card-full-width" - Applicable for card insights. Use this option class to ensure that the width for a card insight adjusts to the width of the zone that contains it. Card insights that don't set this parameter use a fixed width.</p> |

The following example is from the insight preview map where the insight type is the one in context. No context data is needed and the mode is 'preview'.

```
<ou-insights insightType="x[insightType]" mode="preview"></ou-insights>
```

The following example uses an insight class and passes in context values from XPath elements with explicitly defined context names.

```
<ou-
insights insightClass="ClCI" context="PER_ID:x[personId];ACCT_ID:x[accountId];PREM_ID:x
ou-insights>
```

Button

The button web component provides support for the standard set of button formats used within the system.

| Syntax | Parameters | Comments |
|---|---------------------------|---|
| <ou-button...></ou-button> | type="singleValue" | <p>You must define the type of button to display. This attribute expects a single value that follows the syntax described in the single value section above. The valid type values are:</p> <ul style="list-style-type: none"> • image - image only • text - text only • imageText - image followed by text • menu - text plus a dropdown caret to open the menu • imageMenu - image plus a dropdown caret to open the menu <p>If no type attribute is supplied, a 'broken button' image will be displayed.</p> |
| | img="singleValue" | <p>Define the path of the image to display. Either this attribute or the image reference attribute must be supplied for a button type that includes an image. This attribute expects a single value that follows the syntax described in the single value section above.</p> <p>Note that for SVG images, if the reference includes only the SVG file name with no path, the path is assumed to be the Framework SVG repository.</p> |

| Syntax | Parameters | Comments |
|--------|-------------------------------|--|
| | imgRef="singleValue" | Define the display icon reference of the image to be used. Either this attribute or the image attribute must be supplied for a button type that includes an image. This attribute expects a single value that follows the syntax described in the single value section above. |
| | text="..." | Define the various text elements needed by the button. The syntax follows the example shown in the complex attributes information above. The valid text element name values are: <ul style="list-style-type: none"> • label - the label text to be used for the button • tooltip - the hover text to be used for the button • aria-label - the ARIA label for the button |
| | menu="singleValue" | Define the menu to be used with the button. This attribute must be supplied for a button type that includes a menu control. This attribute expects a single value that follows the syntax described in the single value section above. |
| | disabled="singleValue" | This is a standard HTML attribute. A value of "true" or just the presence of the text "disabled" will result in an initially disabled button. |
| | security="..." | Optionally define the security settings for the button. The button will be hidden if the user does not have the appropriate security access. The syntax follows the example shown in the complex attributes information above. The valid security element name values are: <ul style="list-style-type: none"> • service - the application service whose security access governs access to the button • accessMode - the specific access mode for the service that determines a more granular level of access to the button |

| Syntax | Parameters | Comments |
|--------|--------------------------|---|
| | clickAction="..." | <p>Optionally define the action to be taken when the button is 'clicked'. The syntax follows the example shown in the complex attributes information above. There are specific 'name' values for the attribute as follows:</p> <ul style="list-style-type: none"> • action - the action to be taken. Valid values are 'BPA' and 'NAVIGATE' • script - the script to be performed when the action is 'BPA' • navopt - the navigation option to be used when the action is 'NAVIGATE' <p>The attribute may also include other name/value pairs that define information to be passed into the script or used as navigation context fields.</p> <p>In addition to the security attribute settings, the system will check that the user has access to the script or navigation path before performing the action.</p> <p>The standard HTML 'onClick' attribute may still be used. If the HTML includes an 'onClick' attribute as well as the 'clickAction', the 'onClick' attribute will take precedence</p> |

The following is an example of a simple button with text.

```
<ou-button type="text" text="label:md[F1_BOOKMARK_LBL];"></ou-button>
```

The following is an example of an icon button using a display icon reference.

```
<ou-button type="image" imgRef="F1CMNT"></ou-button>
```

The following is an example of an image menu button.

```
<ou-  
button type="imageMenu" imgRef="F1STTGS" menu="CI_CONTEXTSCRIPT" text="tooltip:md[F1INSTR]  
ou-button>
```

The following is an example of text button that navigates to another page.

```
<ou-  
button type="text" text="label:md[ALG_CD];tooltip:md[GOTO_ALG]" clickAction="action:NAVIGATE"  
ou-button>
```

Show Schema Default on Add

Default values within in the UI map's schema will be displayed on a UI map's input fields if an embedded <action> node has a value of 'ADD' or blank.

| Syntax |
|---|
| <action>ADD</action> |
| <action> </action> |

The schema default for the <description> element will be displayed:

```
<schema>
  <action/>
  <boGroup type="group">
    <key/>
    <description default="enter description here"/>
  </boGroup>
</schema>
```

```
<html>
<body>
<table summary="" border="1" cellpadding="1" cellspacing="1">
  <tr>
    <td>Description </td>
    <td><input oraField="boGroup/description"></td>
  </tr>
</table>
</body>
<xml>
<root>
  <action>ADD</action>
  <boGroup>
    <key/>
    <description/>
  </boGroup>
</root>
</xml>
</html>
```

HTML rendered.

| | |
|-------------|---|
| Description | <input type="text" value="enter description here"/> |
|-------------|---|

Configure a Chart

In addition to integrating charts with zones, the system supports using the same attributes within the UI Map HTML to configure a graphical representation of an XML list. The designer can control the type, size, position, and contents of the chart using these attributes. For details of the attributes and syntax, refer to [Data Explorer Graph Configuration](#).

Graph Examples

- Sample of a pie chart configuration:

```
<html>
<head>
<title>Pie Chart</title>
</head>
<body>

<div style="width:100%; height:290px;"
  oraChart="type:pie;"
  oraChartSeries1="list:set; labelPath:date; amount:amount; "
  oraChartBroadcast="BILL_ID:billId;">
</div>

</body>

<xml>
<root>
  <set>
```

```

<date>05-02-2003</date>
<amount>163.24</amount>
<billId>592211649441</billId>
  </set>
  <set>
<date>06-02-2003</date>
<amount>97.29</amount>
<billId>592211649442</billId>
  </set>
  <set>
<date>07-02-2003</date>
<amount>54.38</amount>
<billId>592211649443</billId>
  </set>
</root>
</xml>
</html>

```

- A pie chart rendered for a single series:

- Sample of a line, cluster, or stacked graph configuration - each with two series:

```

<html>
<head>
<title>Stacked Chart</title>
</head>
<body>

<div style="width:100%; height=300px;"
  oraChart="type:line;"
  oraChartSeries1="list:set; xaxis:date; label:Charge; amount:amount; "
  oraChartSeries2="list:set; xaxis:date; label:Balance; amount:balance; "
  oraChartBroadcast="BILL_ID:billId;">
</div>

<div style="width:100%; height=300px;"
  oraChart="type:cluster;"
  oraChartSeries1="list:set; xaxis:date; label:Charge; amount:amount; "
  oraChartSeries2="list:set; xaxis:date; label:Balance; amount:balance; "
  oraChartBroadcast="BILL_ID:billId;">
</div>

<div style="width:100%; height=300px;"
  oraChart="type:stacked;"
  oraChartSeries1="list:set; xaxis:date; label:Charge; amount:amount; "
  oraChartSeries2="list:set; xaxis:date; label:Balance; amount:balance; "
  oraChartBroadcast="BILL_ID:billId;">
</div>

```

```
</body>

<xml>
<root>
  <set>
<date>05-02-2003</date>
<amount>163.24</amount>
<balance>163.24</balance>
<billId>592211649441</billId>
  </set>
  <set>
<date>06-02-2003</date>
<amount>97.29</amount>
<balance>260.53</balance>
<billId>592211649442</billId>
  </set>
  <set>
<date>07-02-2003</date>
<amount>54.38</amount>
<balance>314.91</balance>
<billId>592211649443</billId>
  </set>
</root>
</xml>
</html>
```

- Three types of chart rendered for two series each: line, cluster, and stacked.

Upload and Download a CSV File

The following HTML attributes can be used to manage both an upload and a download between a list defined within the map's schema and a CSV (comma separated value) file. Note that this technique is only recommended for a small to medium volume of data, for example no more than several hundred rows. For higher volumes, it is recommended to use batch upload / download functionality instead.

The syntax is `oraUploadData="type:embed;path:list xpath;useLabels:true;showCount:true"`

Upload configuration requires you to name a CSV file to be uploaded, and an XML list as target. By convention, each CSV row will create a separate list instance. Each comma-separated field in the file will be uploaded as a separate element in the list. To embed an upload dialog within a map, the **oraUploadData** attribute must be associated with a container element such as a div, td, or span.

The optional **useLabels:true** value indicates that while parsing the upload CSV file, the headers are expected to be labels

Note: If you do not specify the **useLabels:true** value and the XML target element name is "camelCase" then the corresponding spreadsheet header should be title case with a space between words, e.g.;"Camel Case". Letters and special characters are not considered a different word, for example Address1 must be uploaded into the target XML element address1.

Specifying the optional **showCount:true** value will display the number of records uploaded.

CAUTION: If you are using a grid in conjunction with the **oraUploadData** function, then you must maintain the grid's list with a 'replace' business object action. Refer to [BO Replace Action](#) for more information.

Sample of **oraUploadData="embed"** within a div element.

```
<html>
<head>
  <title>File Upload</title>
</head>
<body>

  <div oraUploadData="type:embed;path:myList"> </div>

</body>

<xml>
<root>
  <myList>
<id>838383930</id>
  <name>Janice Smith</name>
  </myList>
  <myList>
<id>737773730</id>
  <name>Bill McCollum</name>
  </myList>
</root>
</xml>
</html>
```

This file upload dialog will be embedded into the body of the page where the oraUploadData is defined.

oraUploadData="type:popup;path:list xpath;useLabels:true;showOk:true;showCount:true"

Upload configuration requires you to name a CSV file to be uploaded, and an XML list as target. By convention, each CSV row will create a separate list instance. Each comma-separated field in the file will be uploaded as a separate

element in the list. To upload a CSV file using a pop-up dialog, the `oraUploadData` attribute must be associated with an input element such as a button, text link, or image.

The optional `useLabels:true` value is used to indicate that while parsing the upload CSV file, the headers are expected to be labels

Note: If you do not specify the `useLabels:true` value and the XML target element name is "camelCase" then the corresponding spreadsheet header should be title case with a space between words, e.g., "Camel Case". Letters and special characters are not considered a different word, for example `Address1` must be uploaded into the target XML element `address1`.

Specifying the optional `showOk:true` value will display an "Ok" button once the upload finishes. The popup will stay open until the button is pressed. Additionally, specifying the `showCount:true` value will display number of records uploaded.

CAUTION: If you are using a grid in conjunction with the `oraUploadData` function, then you must maintain the grid's list with a 'replace' business object action. Refer to [BO Replace Action](#) for more information.

Sample of `oraUploadData="popup"` associated with a button:

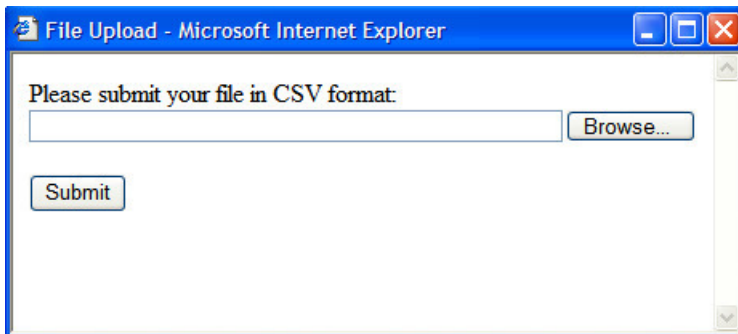

```
<html>
<head>
  <title>File Upload</title>
</head>
<body>
  <input type="button" name="submitButton" oraUploadData="type:popup;path:myList;" value="Get Data" />
  <table oraList="myList">
    <tr/>
    <tr>
      <td><span oraField="id"/></td>
      <td><span oraField="name"/></td>
    </tr>
  </table>
</body>
<xml>
<root>
  <myList>
    <id>838383930</id>
    <name>Janice Smith</name>
  </myList>
  <myList>
    <id>73773730</id>
    <name>Bill McCollum</name>
  </myList>
</root>
</xml>
</html>
```

HTML Rendered:

838383930 Janice Smith

73773730 Bill McCollum

Pressing the "Get Data" button will launch a standard file upload dialogue (provided by Framework) as shown below.

oraDownloadData="list xpath"

Download configuration requires you to name an XML list to be downloaded. By convention, each list instance will represent a separate row in the created file. By default every element of the list will be comma separated in the file.

Note: The number formatting is based on the user profile setting. For localities where the decimal symbol is a comma, an implementation may configure a property setting (`spl.csv.delimiter.useFromDisplayProfile=true`) to cause the system to use a semicolon as the delimiter that separates the elements rather than a comma.

Sample of oraDownloadData.

```
<html>
<head>
<title>File Download</title></head>
<body>
<input type="button" name="downloadButton" oraDownloadData="myList" value="Download"/
>
</body>
<xml>
<root>
  <myList>
    <id>881-990987</id>
    <name>John Mayweather</name>
  </myList>
  <myList>
    <id>229-765467</id>
    <name>Anna Mayweather</name>
  </myList>
  <myList>
    <id>943-890432</id>
    <name>Andrew Brewster</name>
  </myList>
</root>
</xml>
</html>
```

HTML Rendered:

Download

Pressing the "Download" button will launch a standard file download dialogue (provided by Framework) as shown below.

A successful download will result in a CSV file:

| | A | B | C |
|---|-----------|-----------------|---|
| 1 | | | |
| 2 | Id | Name | |
| 3 | 881-99098 | John Mayweather | |
| 4 | 229-76546 | Anna Mayweather | |
| 5 | 943-89043 | Andrew Brewster | |
| 6 | | | |

To download data from a sub list use the attribute `oraDownloadDataInList` instead of `oraDownloadData`. The attribute `oraDownloadDataInList` will have the sub list name. The XPath of the sub list is used to pick data of the specific row from the parent list. Thus only the specific sub list is downloaded.

`oraDownloadDataUseLabels="true"`

The `oraDownloadDataUseLabels` attribute can be used in conjunction with the `oraDownloadData` attribute described above. Specify `oraDownloadDataUseLabels` if you want the generated CSV file to use the element labels for columns headers rather than element names.

Construct Portal Zone Map Fragments

Portal zones can reference a UI map for the zone header and filter area. This UI map is not a complete HTML document, but is instead configured as a UI Map fragment. When constructing a zone map fragment you can reference the following substitution variables. Note that these variables will be dynamically populated at run time with information particular to the map's zone within the portal:

| Variable | Replacement Logic |
|-------------------|---|
| [ZONEDescription] | Zone's description text. |
| [SEQUENCEID] | Zone's sequence ID. |
| [ZONENAME] | Zone's name. |
| [SHELPTXT] | Zone's help text. |
| [ZONEPARAMNAME] | Zone parameter's value (or blank if it has not been specified). |

Warning:

- Refer to one of the following maps as examples: F1-UIMapHeader and F1-ExplorerHeader.
- These maps make use of the `oraInclude` tag to incorporate HTML fragments for the header menu and framework actions. Refer to the zone type parameters for the UI Map fragments you should include in your HTML.

- If you wish to have the "help text" icon appear next to your zone description, you should have `id="title_[$SEQUENCEID]"` on the `<td>` that contains your description.
- If it is necessary to encapsulate JavaScript within a UI Map fragment, it will be necessary to bound the JavaScript within a `![CDATA[]]` tag to ensure a valid XML document. Note that the tags themselves may need to be commented out to promote compatibility with older browsers. For example:

```
<script type="text/javascript">
  /*![CDATA[ */
  //
  //javascript
  //
  /*]]> */
</script>
```

Note: If you wish to preserve the values of a filter input field, within a filter map fragment, for the framework 'Go Back' and 'Go Forward' functionality, you must associate the input field (text box, select, etc.) with a unique HTML id. Input field values associated with a unique id will be captured in the framework's 'memento'. The 'memento' is used to rebuild the input map when the portal zone is navigated to using the 'Go Back' or 'Go Forward' functionality.

Note: Many specialized functions exist to manipulate zone behavior, for example:

- **oraGetZoneSequence(zoneName)**. Uses the zone's code to retrieve its sequence number.
- **oralsZoneCollapsed(sequenceId)**. Uses the zone's sequence to determine if collapsed.
- **oraHandleCollapse(seq)**. Collapse a zone.
- **oraHandleExpand(seq,refresh)**. Expand and/or refresh a zone.

All of these, and many more functions, are located within the JavaScript library [userMapSupport.js](#) described below.

Note: When executing `oraLoad` within a fragment UI map, and you need to execute a JavaScript function during page load (where the function invokes a business object, business service, or service script) you can use the special syntax `"oraLoad[$SEQUENCEID]"`. Refer to the [Load Page Event](#) section for more information.

Example of `oraLoad[$SEQUENCEID]` used within a function:

```
<script type="text/javascript">
function oraLoad[$SEQUENCEID]() {
  checkRebateClaimStatus();
}

function checkRebateClaimStatus() {
  var work = id('analyticsFilterText[$SEQUENCEID]',
document).cells[0].innerText.split(' ');
  var rebateClaimId = work[work.length - 3];
  id('rebateClaimId', document).value = rebateClaimId;
  oraInvokeSS('C1-CheckRCSt','checkRebateClaimStatus', false);
  var statusIndicator = id('statusInd', document).value;
  if (statusIndicator == 'C1PE' || statusIndicator == 'C1ID') {
    id('addRebateClaimLine', document).style.display = '';
  } else {
    id('addRebateClaimLine', document).style.display = 'none';
  }
}
</script>
```

F1-ExplorerHeader rendered:

 [\$ZONEDESCRIPTION]

Invoking a Business Object

The oraInvokeBO function may be used within a portal zone header or zone filter map. It is similar to the command described in [Invoke BO Function](#) which allows for a business object to be invoked within the UI map's HTML. Refer to that section for a description of the first three parameters.

| Syntax | Parameters | Comments |
|----------------------|--|--|
| oraInvokeBO() | 'BO Name' 'XPath' or null 'action' null [\$SEQUENCEID] true false | This must be specified as the fourth argument. This must be specified as the fifth argument. Specify true if the fragment is used within a portal zone header. Specify false if the fragment is used with a zone filter map. |

Example in a portal zone header:

```
oraInvokeBO('CM-User','xmlGroup','read', null, [$SEQUENCEID], true)
```

Invoking a Business Service

The oraInvokeBS function may be used within a portal zone header or zone filter map. It is similar to the command described in [Invoke BS Function](#) which allows for a business service to be invoked within the UI map's HTML. Refer to that section for a description of the first two parameters.

| Syntax | Parameters | Comments |
|----------------------|--|--|
| oraInvokeBS() | 'BO Name' 'XPath' or null null [\$SEQUENCEID] true false | This must be specified as the fourth argument. This must be specified as the fifth argument. Specify true if the fragment is used within a portal zone header. Specify false if the fragment is used with a zone filter map. |

Example in a portal zone header:

```
oraInvokeBS('CM-UserSearch','xmlGroup', null, [$SEQUENCEID], true)
```

Invoking a Service Script

The oraInvokeSS function may be used within a portal zone header or zone filter map. It is similar to the command described in [Invoke SS Function](#) which allows for a service script to be invoked within the UI map's HTML. Refer to that section for a description of the first two parameters.

| Syntax | Parameters | Comments |
|----------------------|---|----------|
| oraInvokeSS() | 'Service Script Name' 'XPath' or null | |

| Syntax | Parameters | Comments |
|--------|---------------------|--|
| | null | This must be specified as the fourth argument. |
| | [SEQUENCEID] | This must be specified as the fifth argument. |
| | true false | Specify true if the fragment is used within a portal zone header. Specify false if the fragment is used with a zone filter map. |

Example in a portal zone header:

```
oraInvokeSS('UserSearch','xmlGroup', null, [SEQUENCEID], true)
```

Detecting Unsaved Changes

Use this function to return a Boolean set to true if there are unsaved changes. The system will interrogate the function when the user attempts to navigate and issue a warning accordingly. This function is only needed if a UI map is using custom javascript to manage elements such that the system is not able to detect whether changes have been made. Also note that it's the responsibility of the UI map javascript to manage the values in the Boolean used for this function.

```
function hasUnsavedChanges() {
    return isDirtyFlag;
}
```

Hiding Portal Tabs

The product provides the ability to use JavaScript to hide a tab on the current portal based on some condition using the oraAuthorizeTab JavaScript API. This API accepts a function as a parameter and turns off the tab index indicated.

For example, the UI Map may have a function to turn off one or more tab indexes.:

```
function overrideTabIndex(index) {
    if (index == 2) return false;
    if (index == 3) return false;
}
```

The JavaScript is referenced “on load”:

```
<body class="oraZoneMap"
onLoad="oraAuthorizeTabs(overrideTabIndex);">
```

Required JavaScript Libraries

All of the functionality described in this document depends on a pair of JavaScript libraries. If you are writing and executing your maps entirely within the UI map rendering framework - you do not need to manually insert the following libraries - the framework will insert them for you when the UI Map is rendered.

Warning: When executing HTML outside of the framework you must include the following references explicitly within your HTML. In addition, the tool you use to render the HTML must have access to a physical copy of privateUserMapSupport.js for bind support.

```
src="privateUserMapSupport.js"
```

Your HTML document must reference this library to execute binding in a stand-alone environment.

Warning: Referencing functions within this JavaScript library is dangerous - because these functions are owned by framework and they may be changed during version upgrade or via the normal patch process.

```
<script type="text/javascript" src="privateUserMapSupport.js"></script>
```

```
src="userMapSupport.js"
```

To take advantage of optional toolset features, you must reference this library.

Note: You can reference the functions within this JavaScript library to write custom functions within the UI map..

```
<script type="text/javascript" src="userMapSupport.js"></script>
```

```
onload="oraInitializeUserMap();"
```

To execute binding in a stand-alone environment, you must embed the following onload function into the <body> node.

```
<body onload="oraInitializeUserMap();" >
```

UI Map Standards

Basic UI Map Templates

All UI Maps share the same basic structure regardless of placement (page area, zone, pop-up) or usage (display only, input).

Sample XML

All information in this document is based upon the following XML structure.

```
<xml>
  <root>
    <address>123 Main St</address>
    <city>Alameda</city>
    <state>CA</state>
    <zip>94770</zip>
    <contactInformation>
      <type>Home Phone</type>
      <number>510-555-2287</number>
    </contactInformation>
    <contactInformation>
      <type>Cell Phone</type>
      <number>510-555-4285</number>
    </contactInformation>
  </root>
</xml>
```

Display Only UI Map

```
<html>
<head>
  <title oraMdLabel="ADDRESS_LBL"></title>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body class="oraZoneMap">
<table cellpadding="4" width="100%">
  <colgroup>
    <col class="oraLabel oraTableLabel" />
    <col class="oraNormal oraTableData" />
  </colgroup>
  <tr>
    <td oraLabel="address"></td>
    <td oraField="address"></td>
  </tr>
</table>
```

```

        <td oraLabel="city"></td>
        <td oraField="city"></td>
    </tr>
    <tr>
        <td oraLabel="state"></td>
        <td oraField="state"></td>
    </tr>
    <tr>
        <td class="oraSectionEnd" oraLabel="zip"></td>
        <td class="oraSectionEnd" oraField="zip"></td>
    </tr>
    <tr>
        <td colspan="2" class="oraSectionHeader" oraMdLabel="CONTACT_LBL"></
td>
    </tr>
    <tr>
        <td colspan="2" class="oraSectionStart oraEmbeddedTable">
            <table oraList="contactInformation" cellspacing="2">
                <thead >
                    <tr>
                        <th class="oraGridColumnHeader" nowrap="nowrap">
                            <span oraLabel="contactInformation/type"></span>
                        </th>
                        <th class="oraGridColumnHeader" nowrap="nowrap">
                            <span oraLabel="contactInformation/number"></
span>
                        </th>
                    </tr>
                </thead >
                <tbody>
                    <tr>
                        <td class="oraNormalAlt oraDisplayCell">
                            <span oraField="type"></span>
                        </td>
                        <td class="oraNormal oraDisplayCell">
                            <span oraField="number"></span>
                        </td>
                    </tr>
                </tbody>
            </table>
        </td>
    </tr>
</table>
</body>
<xml>
    <root>
        <address>123 Main St</address>
        <city>Alameda</city>
        <state>CA</state>
        <zip>94770</zip>
        <contactInformation>
            <type>Home Phone</type>
            <number>510-555-2287</number>
        </contactInformation>
        <contactInformation>
            <type>Cell Phone</type>
            <number>510-555-4285</number>
        </contactInformation>
    </root>
</xml>
</html>

```

Input UI Map

```

<html>
<head>
  <title oraMdLabel="ADDRESS_LBL"></title>
  <link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
  <link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
</head>
<body>
<table width="100%" cellpadding="12">
  <tr class="oraErrorText">
    <td><a href="" onclick="oraShowErrorAlert(); return false;">
      <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span></a>
    </td>
  </tr>
</table>
<table cellspacing="4" width="100%">
  <colgroup>
    <col class="oraLabel oraTableLabel" />
    <col class="oraNormal oraTableData" />
  </colgroup>
  <tr>
    <td oraLabel="address"></td>
    <td><input type="text" oraField="address"/></td>
  </tr>
  <tr>
    <td oraLabel="city"></td>
    <td><input type="text" oraField="city"/></td>
  </tr>
  <tr>
    <td oraLabel="state"></td>
    <td><input type="text" oraField="state"/></td>
  </tr>
  <tr>
    <td oraLabel="zip"></td>
    <td><input type="text" oraField="zip"/></td>

<tr>
    <td colspan="2" class="oraSectionStart oraEmbeddedTable">
        <table cellspacing="2">
            <tr>
                <td>
                    <input class="oraButton" oraMdLabel="C1_SAVE_LBL" type="button"
                        onClick="oraSubmitMap('OK');"/>
                </td>
                <td>
                    <input class="oraButton" oraMdLabel="CANCEL_LBL" type="button"
                        onClick="oraSubmitMap('CANCEL', false);"/>
                </td>
            </tr>
        </table>
    </td>
</tr>
</table>
</body>
</xml>
<root>
    <address>123 Main St</address>
    <city>Alameda</city>
    <state>CA</state>
    <zip>94770</zip>
    <contactInformation>
        <type>Home Phone</type>
        <number>510-555-2287</number>
    </contactInformation>
    <contactInformation>
        <type>Cell Phone</type>
        <number>510-555-4285</number>
    </contactInformation>
</root>
</xml>
</html>

```

Basic HTML and Styles

The basic templates introduced the standard HTML and styles used for UI Maps. These standards are described individually in the following sections.

Stylesheets

The styles to apply the standard look to the maps are all contained in stylesheets. These stylesheets should be included in all UI Maps.

```

...
<link rel="stylesheet" type="text/css" href="cisDisabled.css"/>
<link rel="stylesheet" type="text/css" href="cisEnabled.css"/>
...

```

Title

Each UI Map should have a <title> tag.

```
...
  <title oraMdLabel="ADDRESS_LBL"></title>
...
```

This will give the UI Map a descriptive title.

- If the UI Map is presented in a "pop-up", the title will be in the window title bar.
- If the UI Map is presented in the page area, the title will be added as a tag to the UI Map and will appear at the top of the UI Map.
- If the UI Map is presented as a zone map, it will be ignored. The <title> tag should still be included in the HTML as standard.

Zone Maps

When the map is presented in a zone as part of a portal, the UI Map should have a border so that the information is "contained" within the zone.

```
...
  <body class="oraZoneMap">
...
```

Page Area Maps vs Pop-Up Maps

The presentation of the UI Maps can vary from design to design. The following standards have been applied to decide when to use a Page Area UI Map and when to use a Pop-Up Map:

- If there are multiple UI Maps in the sequence, always use the Page Area.
- If the UI Map has many input fields, always use a Page Area.
- If the UI Map is a "confirmation" type dialog or only has one or two input fields, use a Pop-Up.

Note: The difference between "just a few input fields" and "many input fields" can be discretionary. The final decision should rest with the dialog designer.

Error Messages

Input maps have a ability to present error messages to the User.

```
...
<table width="100%" cellpadding="12">
  <tr class="oraErrorText">
    <td><a href="" onclick="oraShowErrorAlert(); return false;">
      <span class="oraErrorText" oraErrorVar="ERRMSG-TEXT"></span></a></td>
  </tr>
</table>
...
```

This HTML structure provides the provides the necessary elements and functions to display errors to the User. It should be directly after the <body> tag. When there is no error, nothing will be visible on the UI Map. It will be made visible if an error occurs and the UI Map is re-presented to the User. Clicking on the link (when visible) will result in a pop-up alert appearing with the long error message text.

Standard Layout and Styles

The information is presented on the UI Map by using a <table> to organize the information in rows and columns.

```
...
<table cellpadding="4" width="100%">
  <colgroup>
  <col class="oraLabel oraTableLabel" />
  <col class="oraNormal oraTableData" />
...
```

```

    </colgroup>
    ...

```

The `<colgroup>` and `<col>` tags allow for the application of classes to the columns (the label is in the first column and the data is in the second column.). Using these tags mean that the class attribute (to apply styles) does not need to be defined on every `<td>`.

Grids (Tables of Data)

A UI Map could contain information that is best presented as a grid. These are referred to as "Embedded Tables". The embedded table can be used to display information or input information.

Example Embedded Table HTML

The embedded table will be included within a row (`<tr>`) of the basic layout:

```

...
<tr>
  <td colspan="2" class="oraEmbeddedTable">
    <table oraList="contactInformation" cellspacing="2">
      <thead >
        <tr>
          <th class="oraGridColumnHeader" nowrap="nowrap">
            <span oraLabel="contactInformation/type"></span>
          </th>
          <th class="oraGridColumnHeader" nowrap="nowrap">
            <span oraLabel="contactInformation/number"></span>
          </th>
        </tr>
      </thead >
      <tbody>
        <tr>
          <td class="oraNormalAlt oraDisplayCell">
            <span oraField="type"></span>
          </td>
          <td class="oraNormal oraDisplayCell">
            <span oraField="number"></span>
          </td>
        </tr>
      </tbody>
    </table>
  </td>
</tr>
...
<xml>
  <root>
    <address> 123 Main St</address>
    <city>Alameda</city>
    <state>CA</state>
    <zip>94770</zip>
    <contactInformation>
      <type>Home Phone</type>
      <number>510-555-2287</number>
    </contactInformation>
    <contactInformation>
      <type>Cell Phone</type>
      <number>510-555-4285</number>
    </contactInformation>
  </root>
</xml>

```

Embedding the Table

The embedded table is included within the overall table structure. The `colspan` attribute ensures that the embedded table can span the standard two columns of the overall layout table.

```

...
<tr>
  <td colspan="2" class="oraEmbeddedTable">
    ...
    ...
    ...
  </td>
</tr>
...

```

Embedded Table Structure

The embedded table is very similar to the basic layout table.

```

...
<table oraList="contactInformation" cellspacing="2">
<thead>
  ...
  ...
</thead>
<tbody>
  ...
  ...
</tbody>
</table>
...

```

- The `<table>` tag has a slightly smaller cellspacing and it defines the "list" element contained in the XML that will be used to provide the data.
- The `<thead>` element is used to give the embedded table headings for the columns.
- The `<tbody>` element is the element that will be repeated for each referenced "list" element in the XML. In the previous example, there are two "contactInformation" list elements, so the displayed embedded table will have two rows.

Column Headings

Embedded tables should have headings for the displayed columns. The `<thead>` tag defines these.

```

...
<thead>
  <tr>
    <th class="oraGridColumnHeader" nowrap="nowrap">
      <span oraLabel="contactInformation/type"></span>
    </th>
    <th class="oraGridColumnHeader" nowrap="nowrap">
      <span oraLabel="contactInformation/number"></span>
    </th>
  </tr>
</thead>
...

```

The "nowrap" attribute prevent the column heading from taking multiples lines. If multiples lines are required, the "nowrap" may be removed.

Input Fields

Embedded tables may be used for input as well as display only. The framework provides a convenient control to assist in the creation of editable embedded tables.

```

...
<tr>
  <td colspan="2" class="oraEmbeddedTable">
    <table oraList="contactInformation" cellspacing="2">
      <thead >
        <tr>
          <th class="oraGridColumnHeaderButton"></th>
          <th class="oraGridColumnHeaderButton"></th>
          <th class="oraGridColumnHeader" nowrap="nowrap">
            <span oraLabel="contactInformation/type"></span>
          </th>
          <th class="oraGridColumnHeader" nowrap="nowrap">
            <span oraLabel="contactInformation/number"></span>
          </th>
        </tr>
      </thead >
      <tbody>
        <tr>
          <td oraType="addGridRow"></td>
          <td oraType="deleteGridRow"></td>
          <td>
            <input type="text" oraField="type"/>
          </td>
          <td>
            <input type="text" oraField="number"/>
          </td>
        </tr>
      </tbody>
    </table>
  </td>
</tr>
...

```

There are two new columns added to the input embedded table.

- `oraType="addGridRow"` will add a "+" button to the row. This will allow the User to add an additional row to the existing grid.
- `oraType="deleteGridRow"` will add a "-" button to the row. This will allow the User to delete an existing row from the grid.

Note: The `<thead>` tag also requires these two new columns to be added.

These controls are, as standard, placed at the beginning of the row in the order shown. Either of the controls may be omitted if required (if, for example, Users are not permitted to delete information).

The presence of either of these controls will activate the "empty list" process. This means that if the XML has no data for the "list" specified, the input grid will display with an empty row ready for the input of new information.

Action Buttons

Example Action Button HTML

Action buttons are used to perform some specified function from the UI Map. The actions are as varied as the information being displayed/updated. Below are two common examples:

- Save. Normally used on an Input UI Map to allow a User to save any changes they have made.
- Cancel. Normally used on an Input UI Map to allow a User to cancel changes in progress.

...

```

<tr>
  <td colspan="2" class=" oraEmbeddedTable">
    <table cellpadding="2">
      <tr>
        <td>
          <input class="oraButton" oraMdLabel="C1_SAVE_LBL" type="button"
            onClick="oraSubmitMap('OK');"/>
        </td>
        <td>
          <input class="oraButton" oraMdLabel="CANCEL_LBL" type="button"
            onClick="oraSubmitMap('CANCEL', false);"/>
        </td>
      </tr>
    </table>
  </td>
</tr>
...

```

Button Standards

The following points highlight some standards related to buttons.

- Buttons are included as an embedded table.
- Buttons should be grouped together. They should not be placed in different areas of the UI Map.
- The location of the buttons depends mainly on the type of UI Map.
 - Display Only UI Maps should have a Record Actions section in the upper right section of the UI map.
 - Input UI Maps should have the buttons at the foot of the UI Map (after all input fields).

Available Styles

Styles are all contained in the referenced CSS stylesheets. They are applied by the HTML "class" attribute. The actual style settings used are not documented here as they may be adjusted. This section only specifies when a particular style should be used.

Note: The "class" attribute may reference more than one style (class="oraLabel oraSectionEnd")

| Style | Comments | Example |
|-------------------------|---|---|
| oraButton | Applied to <input> elements where the type is button. | <pre> ... <input class="oraButton" oraMdLabel="CANCEL_LBL" type="button" onClick="oraSubmitMap('CANCEL', fa ... </pre> |
| oraDisplayCell | Applied to the <td> tag of an embedded table. It defines how the table cell looks (not the data contained inside the cell). | <pre> ... <td class="oraDisplayCell"> </td> ... </pre> |
| oraEmbeddedTable | Applied to the <td> tag that will contain the embedded table. | <pre> ... <tr> <td colspan="2" class=" oraEmbedd <table cellpadding="2"> </table> </td> </tr> ... </pre> |

| Style | Comments | Example |
|----------------------------------|--|--|
| oraError | <p>This style is applied to elements that are identified as "error elements". Refer to Display Errors for more information.</p> <p> Note: This style is not normally applied directly in the UI Map HTML</p> | |
| oraErrorText | <p>This style is applied to the elements concerned with error messages.</p> | <pre>... <table width="100%" cellpadding="12" <tr class="oraErrorText"> <td> </td> </tr> </table> ...</pre> |
| oraGridColumnHeader | <p>This style is applied to the <td> tags that define column headers within embedded table.</p> | <pre>... <thead > <tr> <th class="oraGridColumnHeader" <th class="oraGridColumnHeader" <th class="oraGridColumnHeader" nowrap="nowrap"> <span oraLabel="contactInform </th> <th class="oraGridColumnHeader" nowrap="nowrap"> <span oraLabel="contactInform </th> </tr> </thead > ...</pre> |
| oraGridColumnHeaderButton | <p>This style is applied to the <td> tags that define the column headers for the "+" and "-" buttons used on editable embedded tables.</p> | <pre>... <thead > <tr> <th class="oraGridColumnHeader" </th> <th class="oraGridColumnHeader" </th> <th class="oraGridColumnHeader" <span oraLabel="contactInform </th> <th class="oraGridColumnHeader" nowrap="nowrap"> <span oraLabel="contactInform </th> </tr> </thead > ...</pre> |
| oraInput | <p>This style is applied to input fields:</p> <ul style="list-style-type: none"> • <input type="text"> • <input type="checkbox"> • <select> | <pre>... <input type="text" class="oraInput" oraField="address"/> ...</pre> |

Using OJET

There are some UI maps delivered by the product that use UI widgets provided by Oracle JavaScript Extension Toolkit (OJET). Releases for OJET do not always align with releases of the framework. In addition, there are times when OJET adjusts APIs that the product uses. The framework will attempt to ensure that each release of the product has the latest and greatest version of the OJET libraries. Implementations are discouraged from attempting to use features in OJET that are not used by the product because the product is not necessarily testing those features and is not ensuring that upgrades to the APIs for those features are backward compatible.

Note that the product isolates the references to OJET into a UI map fragment that is included in the maps that use OJET widgets. This is so that changes to future versions of OJET are minimized to a single place. The map is called F1-OJETLIBS. If your implementation wants to use OJET, the recommendation is to use this UI map fragment.

Process Flows

This section describes concepts and provides guidelines related to the configuration of various type of process flows.

Understanding Process Flows

A process flow is a user interface guiding a user through a series of actions in order to accomplish a specific task. The task can be as simple as the collection of information in order to update business data or involve more complex logic such as submitting and tracking batch processes, exchanging messages with an external system, etc.

This section describes topics related to designing and working with process flows.

A Process Flow Is Made Of Panels

Each process flow consist of a number of sequential "steps" needed to accomplish a certain task. Each step is represented by a stop on a progress bar and an associated panel.

Progress is linear in that each step may only lead to a single next step. A process flow always starts at a single initial step but allows for one or more final steps at which the user may choose to complete the process.

At any step the user may take the following actions:

- Enter data or take action as prompted by the step's panel.
- Continue to a next step, if any.
- Navigate back to any step they have previously visited.
- Finish the process flow if the current step is a final step.
- Save off their work on the process flow and either continue their work or navigate away. At a later time the user may resume their work on the process flow from where they have left off.
- Cancel the process flow.

A process flow type defines the entire metadata needed to control the behavior of process flows of a given type. This includes the sequence of steps, the panel and rules associated with each step and more.

Panel Presentation

The panel presented on each step of the process flow is rendered based on the panel type selected on the step configuration.

For a **Data Area** type of panel, the panel is rendered using UI Hints built into the schema of a specified data area.

For a **UI Map** type of panel, the panel is rendered using a specified UI map fragment.

For a **Panel Set** type of panel, the panel is rendered as a set of tabs, one for each panel that references the current panel as its parent panel. Clicking on each tab renders the UI based on the selected panel's type. The behavior of a panel set is analogous to or can be thought of as a nested process flow within a single panel. A panel set may not include another panel set.

A Single UI Map

While the user enters data one panel at a time, data is collected and captured at the entire process flow level. All the elements edited and displayed on the various panels of the process flow must be included in the overall process schema and referenced by their appropriate XPath location in that schema. Each type of process flow defines its unique schema on a designated UI map.

The UI map's HTML should simply include the **Process Flow Controller (F1-ProcessController)** UI map fragment and nothing else. The latter is designed to render the user interface for a process flow based on the metadata defined on its process flow type.

Panel Scripts

A single **Pre-Processing** service script may be associated with a panel for the purpose of preparing the data before the panel is presented to the user. The system calls the script each time the user navigates to this panel on a non-finalized process flow.

A single **Post-Processing** service script may be associated with a panel for the purpose of validating the data entered by the user on that panel. The system calls the script each time the user exits the panel on a non-finalized process flow.

Process Flow Scripts

A single **Process Start** service script may be associated with a process flow for the purpose of preparing the data before a newly initiated process flow is presented to the user.

A single **Process End** service script is executed when the user clicks on the **Finish** or **Cancel Process** buttons to complete the process flow. The entire set of data collected by the process flow UI map schema is provided to this service script for final processing.

Note: The schema of these scripts should be the same as the **Process Flow UI map** schema. This would ensure that business rules have access to the entire data captured by the user.

Summary Panel

By default, when a user finishes a process flow, as well as when they view an already closed process, the process flow portal displays the last panel the user was working on. For more complex process flows, you may provide a panel that summarizes information from the entire process. When specified on the process flow type, the system displays that summary panel instead of the default view of a closed process. The user may toggle between the summary view and the detailed view at any time.

The summary panel may be implemented as a UI map fragment or a data area like other panels but may not be associated with any panel script.

Launching A New Process Flow

Each process flow must be initiated and executed by a designated BPA script that has the following simple steps:

- Set BPA area height to zero.
- Populate the temporary variable **\$processCode** with the code of the specific process flow type.
- Transfer control to the **Process Flow Navigation (F1-PROCEXEC)** common BPA script.

Launching a process flow of a specific type is assumed to be made from a designated menu option or within a specific context applicable to that type of work. As such, this item needs to be configured specifically for each type of process flow. The navigation option associated with that launching option should reference the BPA script associated with the corresponding type of process flow.

Saving Off Work

The user may save off their work on a process flow at any time. If enabled on the process flow type, the system would also automatically save the data when the user navigates to another panel or away from the process flow portal.

On either manual or automatic save operations, the **Process Manager** script defined on the process flow type is called to save off the entire process flow data on a designated record in the database.

The base product provides a generic **Process Flow** maintenance object that is designed to support the storage of any type of process flow as well as a corresponding process manager script. Should process flows of a specific type be stored elsewhere, then a dedicated process manager script should be implemented and used instead.

Review Process Flow Records

A process flow record is created when a user saved off their work or the process flow type enables automatic saving. When the user finishes a process flow, depending on the process flow type configuration the record may be deleted or retained for audit purposes.

Reviewing process flow records of a specific type is assumed to be made from a designated menu option or within a specific context applicable to that type of work. As such this item needs to be configured specifically for each type of process flow. The navigation option associated with that item should reference a query portal designed to query and manage the specific type of process flow records.

In addition to standard query features, the query portal should allow the user to resume their work on a non-finalized process flow as well as review the data captured on a completed record. When implementing such a query portal, refer to the sample **Process Flow Query (F1PRSTRQ)** portal for key features. Your specific product may already include such query portals for process flow types it supports. Refer to your specific product documentation for additional information.

Designing Process Flows

A wide range of process flows may be designed to implement online tasks business users may need to perform. Refer to [Understanding Process Flows](#) for more information.

Below is a high-level summary of the steps required to design and configure various types of process flows.

Analyze The Task

The following provides a the high-level guidance in analyzing the necessary data and rules needed to support an implementation of a new type of process flow:

- Identify the data and business rules that are needed to complete the entire task.
 - When possible, organize data into logical groups of details defined as data areas.
 - Design logic for the final processing script that accepts the entire data entered along with the user's action to either complete or cancel the task.
 - If data needs to be initially prepared for a newly initiated process flow, design logic for a corresponding initial processing script.
 - Determine whether a summary panel may be useful for the user to review the outcome of a completed process.
- Design the sequence of panels the user should follow to complete the task. Identify the initial and final panels.
- Review each panel and determine the following:
 - Is it a single panel or a nested process flow (i.e. a panel set)?
 - What is the title of the panel and its label on the progress bar?
 - How should the layout be rendered? Use a data area that leverages UI Hints to describe the panel layout when possible. For more complex HTML requirements you may use a UI map fragment.
 - Should details on this panel be defaulted with some initial values when the user enters this panel? If so, design logic for a corresponding pre-processing script.
 - If data entered on this panel should be validated before the user exits the panel, design logic for a corresponding post-processing script.
- Design the summary panel if needed.
- Determine whether this type of process flow should be automatically saved by the system or solely rely on the user to control when data is saved.
- Determine whether a record of a completed process flow should be retained for audit purposes or deleted upon completion.

- Determine whether a user may delete in progress records of such process flow.
- Determine whether process flows of this type are saved and stored in a dedicated table in the database or are saved in the generic table provided by the base product. The assumption is that introducing new designated storage maintenance objects is not common. Refer to your edge product documentation for additional maintenance objects that may have been provided to support specific types of process flows shipped with the product.
- Determine the context in which a user can initiate, resume work on, and review process flows of that type.
 - The process flow may be launched from a menu or a favorite script etc.
 - Design the query portal a user would use to find and resume a saved off process flow of this type as well as review completed process flow records. Depending on the context of this task, the query may be associated with the same menu line that initiates the process flow.

Using UI Map Panels

Typically a map fragment is rendered as part of a complete UI map but when used as a process flow panel the system renders the panel assuming the fragment contains a complete map.

Therefore, such fragment should includes the following items:

- The standard error message section used for reporting errors.
- This line `<xml style="display:none"></xml>` at the end of the HTML content for proper binding of data to their HTML elements.

A UI map based panel allows for more control over some of the buttons available to the user. For example, the panel may prevent the user from proceeding to the next panel unless required information is entered. Refer to the explicit APIs listed in the process controller UI Map (F1-ProcessController) for more information.

Configure The Process Flow Type

The following describes the high-level steps needed to configure a new type of process flow:

- Create the UI map for the process flow. Its schema should contain all the details needed to complete the task. Its HTML should only include the process controller UI map fragment.
- Create a start processing service script if needed.
- Create a final processing service script such that it applies all the rules needed to complete or cancel the task.
- For each panel perform the following:
 - Create a UI map fragment for it unless it corresponds to a data area already included in the process flow schema. Make sure the XPath of each element references in the data area or UI map is the same XPath of that element in the process flow's UI map schema.
 - Create a pre-processing service script if needed. Not applicable to the summary panel.
 - Create a post-processing service script if needed. Not applicable to the summary panel.
 - Set up a label and title MD fields if existing ones cannot be used.
- Create a BPA script for the process flow.
- Configure the [process flow type](#) record.
- Set up a navigation option and reference the BPA script on it. Associate the navigation option with a menu or provide other means for the user to initiate the process flow.
- Create a query portal for the specific type of process flow records. Add the new query portal to a menu or provide other means for the user to resume work on a process flow they have saved off or review completed records.

Control Visibility of Standard Buttons

You may leverage the following JavaScript functions to control the visibility of standard process flow buttons:

- Next: **enableNext(), disableNext(), hideNext() , showNext()**
- Finish: **enableFinish(), disableFinish(), hideFinish() , showFinish()**

- Save: **enableSave()**, **disableSave()**, **hideSave()** , **showSave()**.

Defining Process Flow Types

This portal is used to maintain process flow types.

Refer to [Understanding Process Flows](#) for more information.

You can access the portal from the **Admin Menu > System > Process Flow Type**.

The following zones may appear as part of the portal's **Main** tab page

- **Process Flow Type List.** This zone lists all process flow types. Broadcast a record to display the details of the selected process flow type.
- **Process Flow Type.** This zone provides information about the selected process flow type.

Action Method

Action method is an object that may be used to define configuration based on some criteria. For example, when initiating a Start Service scenario, the service request type may differ based on the CIS division and the customer class. When a user initiates a Start Service process, the system can prompt the user for information about the customer that can determine the CIS division and the customer class. The system can then call an algorithm passing this information to retrieve the appropriate service request type to use as defined in the action method. Throughout this section, the term 'criteria' is used to identify the information used to determine the desired configuration and the term 'details' or 'results' is used to identify the configuration information being determined.

If you were to design a use case to use this functionality consider the following:

- What information needs to be identified (the 'details/' 'results')? The example above uses a configuration object as its example (service request type). However, the information you are determining could be anything that can differ by some combination of attributes. You could use this to determine which collection algorithm to execute based on criteria. Or the number of days to wait to continue with some process for some use case.
- When and where do I need to determine this information and what do I do with it once I receive it?
 - Is this needed as part of a user interaction?
 - Or is this needed for internal processing?
- What is the criteria needed to determine the desired information? Do I have this information at the time that I need it? Or do I need to prompt a user for the information?

The framework product supplies the generic objects needed to support this type of functionality. The individual edge products or implementations can build their use cases with the tools provided. The topics in this section further describes the provided features.

Action Method Role

The action method functionality is driven by the Action Method Role, which represents a given use case. Some examples of action method roles that may be relevant in an enterprise product are 'Start Service', 'Stop Service' and 'Transfer Service'. The valid action method roles are defined using an extendable lookup and referenced on the Action Method. One and only one action method may be defined for one action method role.

The action method role record may reference an action method role BPA script, if the use case for this Action Method Role involves user interaction. The responsibility of this script, if needed is to take the action method role value, determine the action method that references the role and identify the more specific Action Processing BPA script (defined on the business object) and transferring control to that script. This reference may be used for audit or information purposes, depending on how you have implemented the user experience. The action method role BPA is ideally configured on an appropriate menu entry or an action button on a specific user interface related to this use case.

If your business use case does not require user interaction, then an action method role BPA script is not necessary.

Action Method Business Object

The action method's business object is used to define the information that needs to be configured for both the criteria and the results. Continuing to use the above example, the business object for a Start Service use case defines a list that captures the CIS division and customer class along with the service request type to use. The information is configured in the XML data area for the action method and the schema design is dictated by the business requirements. For example, it may be that your use case dictates a default value for the results (in our case, the service request type) plus override values based on a division and customer class combination.

Get Action Method Details Plug-in

Besides defining the schema information for capturing the criteria and results, the business object defines the algorithm that should be invoked to retrieve the results based on the criteria.

The plug-in spot is **Get Action Method Details**. Its API is flexible in the information it receives and returns so that each action method use case can design the algorithm based on its business requirements.

The algorithm receives a list of 'Criteria Data' using a 'name' and up to 5 values (to handle multi-part primary keys). Typically only 'value 1' is needed for each entry. The algorithm type designed for a given action method business object can determine what information it receives. It could be that it expects the criteria elements defined on the action method. In our example, the algorithm type could expect to receive the CIS division and customer class. Alternatively, the algorithm type could be designed to receive a value that can be used to determine the criteria needed. For example, it could receive the account ID and use that information to determine the CIS division and customer class.

The algorithm returns one or more results as 'Details'. The information returned is based on the use case. In our example, the service request type is returned. Your business requirements may use the action method role to return multiple results, for example a service request type and a process flow type to invoke to capture all the information needed to start service.

The product provides a business service **F1-RetrieveActionMethodDetails** to call the algorithms for a given action method value.

Action Processing BPA

If your business requirement requires user interaction either to determine the criteria to pass to the Get Action Method Details algorithm or to use the resulting information to continue with an online action, an Action Processing BPA is needed. This BPA should be designed and linked to your action method business object as an option using the **Action Processing BPA Script** option type.

The design of this BPA depends on your business requirements. But at a high level, it may need to prompt the user for information needed to determine the criteria associated with the action method details, then call the **F1-RetrieveActionMethodDetails** business service to execute the algorithms for your action method. Once the results are returned, the script would proceed with the next step in the business use case.

Note: If any additional information needs to be gathered by the server before or after the call to the business service that executes the algorithms, then the recommendation is that the BPA should call a service script that does all the server level logic at one time.

Action Method Role vs. Action Method Business Object

The action method role defines the use case. The business object is used to design the schema for the criteria and the results and identifies the action processing BPA and the Get Action Method Details plug-in. It may warrant a unique business object for each action method role. However, there may be cases where more than one action method role and its action method can reuse the same business object. For example, imagine there are different service request types for Start Service, Stop Service and Transfer Service, however in all cases the valid value is driven by the CIS division and customer class. These three separate action method roles and action methods can reuse a common business object defining the criteria of CIS division and customer class determining the appropriate service request type.

Defining Action Methods

Refer to [Action Method](#) on page 260 for an overview of action method functionality.

To maintain the action methods applicable to your implementation, open **Admin > System > Action Method**.

This is a standard [All-in-One portal](#) and includes the standard List and display zones for an action method.

The information captured on the action method depends on the business objects supported by your product or implementation. Refer to the embedded help text for more information.

Algorithms

In this section, we describe how to set up the user-defined algorithms that perform many important functions including:

- Validating the format of a phone number entered by a user.
- Validating the format of a latitude/longitude geographic code entered by a user.
- In products that support payment and billing:
 - Calculating late payment charges.
 - Calculating the recommended deposit amount.
 - Constructing your GL account during the interface of financial transactions to your GL
- And many other functions...

The Big Picture Of Algorithms

Many functions in the system are performed using an algorithm. Algorithms are called at strategic points (often referred to as a "plug-in spot") within system processing to perform specific code. The plug-in spots are preconfigured with the product and vary from object to object. Algorithms are used by the base product to provide out of the box functionality. The algorithm framework provides a means for implementations to insert their own custom code, which can be instead of the base delivered code or in addition to it.

Note: Algorithm = Plug-in. We use the terms plug-in and algorithm interchangeably throughout this documentation.

Algorithm Type Versus Algorithm

Often the documentation will just use the term 'algorithm', but in actuality there are two important objects that provide this plug-in functionality.

- An **Algorithm Type** defines program to execute and identifies the plug-in spot. The program may be defined using Java or using a [plug-in script](#). The algorithm type may also define parameters that must be supplied to algorithms of this type.
- An **Algorithm** is an instance of an **Algorithm Type**. If the algorithm type does not define any parameters, then there will be only one algorithm for the algorithm type. If the algorithm defines parameters, then there could be several algorithms for a given algorithm type, one for each unique set of parameter values for a given use case. The algorithm is the object that gets referenced on a given control table when configuring your system.

Algorithm Plug-in Spot

The plug-in spot, also called Algorithm Entity and System Event, defines several aspects of the functionality for algorithms that are executed.

- When in system processing are algorithms of this plug-in spot executed? For example, algorithms for the Installation Option - To Do Pre-creation are called when a To Do is getting added, before any insert to the database is performed.
- The API for the plug-in spot. This is often referred to as the "hard parameters" for the plug-in spot. What information is every algorithm program provided when called? Additionally, if the algorithm is expected to return information to the caller, this is also part of the hard parameters. For example, the Installation Option - To Do Pre-creation plug-in spot receives all the information about the To Do that is about to be added. It may add or update values. It may also return an indication to not create the To Do, if desired.

Note: The hard parameters are different from the parameters defined on the algorithm type. Those are referred to as the "soft parameters". Those parameters are used to configure settings that the algorithm type code uses per its specific functionality.

- What is the responsibility of algorithms for the plug-in spot? When defining a plug-in spot, the product defines the responsibility of the code for the algorithm types created for that spot. For example, is the algorithm determining information and returning it? Or is it supposed to perform an update? Algorithms for the Installation Option - To Do Pre-creation plug-in spot should not do any updates. Rather they should adjust the To Do information (if desired) in the hard parameters and return them. The calling logic will use that adjusted information when inserting the To Do record.
- Where do you configure the algorithm? We have been using the Installation Option - To Do Pre-creation plug-in spot as an example. As the description suggests, these algorithms are configured on the Installation Option - Algorithm collection. Each plug-in spot defines where (on which control table) the algorithms are plugged in. The system standard for the description of the Algorithm Entity flag value that defines the available plug-in spots is "Control Table Name - Event". For example the To Do Type - Calculate Priority algorithm plug-in spot means that algorithms are configured on the To Do Type. This information also indicates the granularity of the algorithm. Installation Option algorithms are system wide. But an algorithm plugged in on To Do Type, for example, indicates that only To Do Entries for that To Do Type will have that algorithm executed.
- Are multiple algorithms allowed? There are some plug-in spots where it doesn't make sense to support multiple algorithms. An example of this is the Batch Control - Select Records plug-in. This plug-in is used by the plug-in driven batch process and is responsible for selecting the records to process. Only one algorithm of this type is allowed on a given Batch Control. An example of a plug-in spot that would support multiple algorithms is a validation plug-in spot. Note that when a plug-in spot supports multiple algorithms, there can be yet additional aspects of the plug-in spot design.
 - In some cases, this type of plug-in spot simply executes each algorithm. A validation plug-in spot is an example of this.
 - In some cases, the algorithm could return an indication to the plug-in spot 'driver' to not execute any subsequent algorithms. Business Object Status - Enter is an example of a plug-in spot that supports this capability.
 - In some cases, the plug-in spot may support sharing information from one algorithm to the next. Migration Plan - Pre-Compare is an example of a plug-in spot that supports this capability.

Refer to [Algorithm Entity](#) on page 264 for information about a portal provided to display information about a plug-in spot.

Base Product Algorithms

The base product provides many, many algorithm types and algorithms out of the box. Sometimes algorithms are delivered to provide support for common use cases that we know our clients will need. Many algorithms, however, are provided because we are implementing system functionality using the same infrastructure and capabilities that our implementation use for their own custom code.

When an algorithm type is delivered, the decision as to whether an algorithm is also provided depends on some factors related to whether soft parameters are defined for the algorithm type.

- If no parameters are defined for the algorithm type, a corresponding algorithm is typically also provided.
- If parameters are defined and the values are on configuration data that is normally owned by the implementation, a base algorithm will probably not be defined.
- If parameters are defined and the values are not dependent on configuration data, it's possible that one or more algorithms are provided.

To review the algorithm types that are delivered with the product, go to the Algorithm Type query. The query provides several search options, including searching by the algorithm entity lookup value.

How To Add A New Algorithm

Before you can add a new algorithm, you must determine if you can use one of the [algorithm types](#) supplied with the system by using the algorithm type query.

If you can use one of the algorithm types, simply add the algorithm and then reference it on the respective control table. Refer to [Defining Algorithms](#) for how to do this.

If you have to add a new algorithm type, you may have to involve a programmer. Let's use an example to help clarify what you can do versus what a programmer must do. Assume that you require an additional geographic type validation algorithm. To create your own algorithm type you must:

- Write a new program to validate geographic type in the appropriate manner. Alternatively, you may configure a plug-in script to implement the validation rules. The advantage of the latter is that it does not require programming. Refer to [plug-in script](#) for more information.
- Create an Algorithm Type called **Our Geographic Format** (or something appropriate). On this algorithm type, you'd define the name of the program (or the plug-in script) that performs the function. You'd also define the various parameters required by this type of algorithm.
- After creating the new Algorithm Type, you can reference it on an Algorithm.
- And finally, you'd reference the new Algorithm on the Geographic Type that requires this validation.

Minimizing The Impact Of Future Upgrades

The system has been designed to use algorithms so an implementation can introduce their own logic in a way that's 100% upgradeable (without the need to retrofit logic). The following points describe strong recommendations about how to construct new algorithm type programs so that you won't have to make program changes during future upgrades:

- Do not alter an algorithm type's hard parameters. For example, you might be tempted to redefine or initialize parameters defined in an algorithm type's linkage section. Do not do this.
- Follow the naming conventions for the new algorithm type code and your source code, i.e., both the source code and the algorithm type should be prefixed with "CM". The reason for this naming convention is to make it impossible for a new, base-package algorithm type from overwriting your source code or algorithm type meta-data (we will never develop a program or introduce meta-data beginning with CM).
- Avoid using embedded SQL to perform insert/update/delete. Rather, invoke the base-package's object routines or common routines.
- Avoid using base messages (outside of common messages, i.e., those with a message number < 1000) as we may deprecate or change these messages in future releases. The most common problem is caused when an implementation clones a base package algorithm type program because they need to change a few lines of logic. Technically, to be 100% upgradeable, you should add new messages in the "90000" or greater category (i.e., the category reserved for implementation-specific messages) for every message in your new program even though these messages may be duplicates of those in the base package.

Algorithm Entity

This portal is used to view information about a plug-in spot (algorithm entity). Refer to [Algorithm Plug-in Spot](#) on page 262 for more information.

Navigate using **Admin > System > Algorithm Entity**.

Use the **Algorithm Entity Query** portal to search for an existing plug-in spot. Each plug-in spot is defined in the Algorithm Entity lookup (**ALG_ENTITY_FLG**). Once an algorithm entity is selected, you are brought to the viewing portal to view details about the algorithm entity.

The following zones appear on the Main page.

- **Algorithm Entity**. This zone provides information about the plug-in spot, including a link to view the Plug-in Spot API, also called the hard parameters for the plug-in spot. In addition it displays the detailed description, which should provide information about the algorithm's responsibility and when it is called.

Note: This information is also available via a help icon on the algorithm type page and when defining a plug-in script, once you select the algorithm entity value.

- **Algorithm Types**. All existing algorithm types for the plug-in spot are listed. If there are algorithms, the count of algorithms are displayed. Clicking the count opens another zone.
- **Algorithms**. If you clicked the algorithm count for an algorithm type, another zone appears with information about the algorithms for that type.

Refer to the embedded help in the portal for more information about each zone.

Defining Algorithm Types

The system provides many algorithm types to support base product functionality. If you need to introduce a new type of algorithm, open **Admin > System > Algorithm Type**.

Use the **Algorithm Type Query** portal to search for an existing algorithm type. Once an algorithm type is selected, you are brought to the maintenance portal to view and maintain the selected record.

Fastpath: Refer to [The Big Picture Of Algorithms](#) for more information.

CAUTION: Important! If you introduce a new algorithm type, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Description of Page

Enter an easily recognizable **Algorithm Type** and **Description**.

Owner indicates if this algorithm type is owned by the base package or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add an algorithm type. This information is display-only.

Enter a **Detailed Description** that describes, in detail, what algorithms of this type do.

Use **Algorithm Entity** to define where algorithms of this type can be "plugged in". If a detailed description about an algorithm entity is available, a small help icon is visible adjacent to the dropdown. Click the icon to view the information.

Note: The values for this field are customizable using the [lookup](#) table. This field name is **ALG_ENTITY_FLG**.

Use **Program Type** to define if the algorithm's program is written using **Java**, a **Plug-In Script**, or **Java (Converted)**, meaning the program has been converted to Java.

Note: **Java (Converted)** program types are not applicable to all products.

Use **Program Name** to define the program to be invoked when algorithms of this type are executed:

- If the Program Type is **Java (Converted)**, enter the name of the converted program.
- If the Program Type is **Java**, enter the Java class name.
- If the Program Type is **Plug-In Script**, enter the plug-in [script](#) name. Only plug-in scripts defined for the algorithm entity may be used.

Note: **View the source.** If the program is shipped with the base package, you can use the adjacent button to display the source code of this program in the [Javadoc](#) viewer. For plug-in scripts, drill into the plug-in script to view the details.

Use the **Parameter Types** grid to define the types of parameters that algorithms of this type use. The following fields should be defined for each parameter:

- Use **Sequence** to define the relative position of the **Parameter**.
- Use **Parameter** to describe the verbiage that appears adjacent to the parameter on the Algorithm page.
- Indicate whether the parameter is **Required**. This indicator is used when parameters are defined on algorithms that reference this algorithm type.
- **Owner** indicates if the parameter for this algorithm type is owned by the base package or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add an algorithm type with parameters. This information is display-only.

Note: When adding a new algorithm type that is for a Java program, the parameters are automatically generated based on the Java code. Once an algorithm type exists, any additional parameters defined in the Java code should be manually added to the algorithm type. For other program types, algorithm type parameters must be manually defined.

Note: When a new algorithm type parameter is added for any program type, existing algorithms for the algorithm type do not automatically get updated with the new parameter. The algorithms must be manually updated.

Defining Algorithms

This portal is used to view and maintain information about an algorithm.

You can access the portal from the **Admin Menu > System > Algorithm**. You are brought to a query portal with options for searching for a specific algorithm. Once an algorithm has been selected you are brought to the maintenance portal to view and maintain the selected record.

Refer to [The Big Picture Of Algorithms](#) for more information.

CAUTION: Important! If you introduce a new algorithm, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Algorithm.** This zone provides information about the selected algorithm.
- **Other Algorithms.** This zone lists other algorithms of the same algorithm type. The zone is only visible when such algorithms exist.

The following zones may appear as part of the portal's **References** tab page

- **Algorithm References.** This zone list various configuration entities referencing the current algorithm.

Note: If the product delivers an algorithm with parameter values defined, an implementation may override the base provided parameter values by adding an additional effective dated collection of parameters.

Note: If an algorithm is defined and subsequently a new parameter is added to the algorithm type, existing algorithms for the algorithm type should be updated to add a new effective dated entry to the parameter collection. At this point the latest list of parameters for the algorithm type are visible. Configure the parameters accordingly.

Advanced Algorithm Tips

Initiating Actions that Cannot be Rolled Back

If you have an algorithm that creates a sync request or performs some other logic that could cause a message to be sent and cannot be rolled back, you should be sure to cater for warnings in the design.

- The algorithm should be performed after all validations that could accumulate warnings.
- The algorithm should include a step to call the Business Service **F1-CheckWarning** and see if any warnings have been accumulated. If so, don't perform the action. It means that the user will get a warning and if they click "OK", all the processing will happen again, but this time without accumulating any warnings. Refer to the plug-in script **F1-GnChgDCap** for an example.

Script Options

We use the term "script" to define processing rules that your implementation sets up to control both front-end and back-end processing:

- Rules that control front-end processing are called [Business Process Assistant](#) (BPA) scripts. For example, your implementation could set up a BPA script to assist a user through your organization's payment cancellation process.
- Rules that control back-end processing are called [Server-based](#) scripts. For example, your implementation could set up a server-based script to control the processing that executes whenever a given type of adjustment is canceled.

The topics in this section describe how to configure your scripts.

The Big Picture Of Scripts

This section describes features and functions that are shared by both BPA scripts and server-based scripts.

Scripts Are Business Process-Oriented

To create a script, you must analyze the steps used to implement a given business process. For example, you could create a "stop auto pay" BPA script that:

- Asks the user to search and select the customer / taxpayer
- Asks the user to define the date on which the person would like to stop making automatic payments
- Invokes a server-based script that populates the end-date on the account's latest automatic payment instructions.

After you understand the business process, you can set up a script to mimic these steps. If the business process is straightforward (e.g., users always perform the same steps), the script configuration will be straightforward. If the business process has several logic branches, the composition of the script may be more challenging.

A Script Is Composed Of Steps

A script contains one or more steps. For example, a "stop auto pay" BPA script might have three steps:

- Ask the user to search and select the customer / taxpayer
- Ask the customer the date on which they'd like to stop making automatic payments (and default the current date)
- Invoke a server-based script that, in turn, updates the account's auto pay options.

Each step references a step type. The step type controls what happens when a step executes. It might be helpful to think of a script as a macro and each step as a "line of code" in the macro. Each step's step type controls the function that is executed when the step is performed.

Fastpath: Refer to [How To Set Up Each Step Type](#) for a detailed description of all available step types and how to set them up.

A Script May Declare Data Areas

Both BPA and server-based scripts may have one or more [data areas](#):

- If the script contains steps that exchange XML documents, you must declare a data area for each type of XML document. For example, if a BPA script has a step that invokes a service script, the BPA script must declare a data area that holds the XML document that is used to pass information to and from the service script.
- You can use a data area as a more definitive way to declare your temporary storage. For example, you can describe your script's temporary storage variables using a [stand-alone data area](#) schema and associate it with your script.

Various step types involve referencing the script's data areas as well as support the ability to compare and move data to and from field elements residing in the data areas.

An Edit Data step supports the syntax to dynamically declare data areas as part of the step itself. This technique eliminates the need to statically declare a data area. Refer to [Edit Data Syntax](#) for more information on edit data commands and examples of the use of dynamic data areas.

Note: Some server based scripts may not use data areas as means of defining or exchanging data, depending on script type and the chosen scripting technique. Refer to [The Big Picture Of Server Based Scripts](#) for an overview of server scripts and their applicable scripting options.

Securing Script Execution

The system supports the ability to secure the execution of scripts by associating the script with an Application Service. Refer to [The Big Picture of Application Security](#) for more information. Application security is optional for user-invocable BPA scripts. If a script is not associated with an application service, all users may execute the script. Otherwise, only users that have **Execute** access to the application service may execute the script. For service scripts, the application service is required.

The Big Picture Of BPA Scripts

Fastpath: Refer to [The Big Picture Of Scripts](#) to better understand the basic concept of scripts.

Users may require instructions in order to perform certain tasks. You may set up scripts that step a user through your business processes. For example, you might want to create scripts to help users do the following:

- Add a new person to an existing account

- Set up a customer to pay automatically
- Modify a customer who no longer wants to receive marketing information
- Modify a customer's web password
- Record a trouble order
- Merge two accounts into one account
- Fix a bill with an invalid rate

Users execute these business processes by [initiating BPA scripts](#) (BPA). Users can also define their favorite BPA scripts in their [user preferences](#).

BPA scripts may be designed by either of the following approaches:

- **Self-contained** and standalone flows. With this approach, the script is executed as an independent flow that cannot interact with the current application pages. Every step in these flows is contained within the script itself, including prompting for additional information from the user and performing server functions etc.
- **Guiding** flows that surf on top of one or more application pages and interact with these pages in parallel to script execution.

CAUTION: This approach is considered legacy functionality and as such limited to fixed pages. It does not work with portal pages. With portals being the product's modern user interface technology, the overall support for this type of BPA scripts is planned to be deprecated in a future release.

CAUTION: Future upgrade issues. There may be times when fixed pages are changed or converted to portals to leverage modern user experience capabilities. Such changes made by the base-package will necessitate a redesign of these guided flows. Please refer to the release notes for such changes.

The topics in this section describe background topics relevant to BPA scripts.

How To Invoke Scripts

Refer to [Initiating Scripts](#) for a description of how end-users initiate scripts.

Developing and Debugging Your BPA Scripts

We recommend considering the approaches outlined below when you construct scripts.

While designing your scripts, determine the most maintainable way to set them up. Rather than creating complex, monolithic scripts, we recommend dividing scripts into smaller sections. For example

- Determine if several scripts have similar steps. If so, set up a script that contains these common steps and invoke it from the main scripts using a **Perform script** step.
- Determine if a large script can be divided into logical sections. If so, set up a small script for each section and create a "master script" to invoke each sub script via a **Transfer control** step.

For debugging purposes, you may find it helpful to categorize the step types into two groups: those that involve some type of activity in the [script area](#), and those that don't. The following step types cause activity in the script area: **Height, Display text, Prompt user, Input data, Input Map, Set focus to a field.**

CAUTION: Guiding scripts that interact with the user using the script area are limited to surf over fixed pages only and are considered legacy functionality. This technique is not supported on top of portal pages and is planned to be deprecated in a future release.

The rest of the step types are procedural and involve no user interaction. There are two techniques you can use to assist in debugging these step types.

- You can instruct the system to display text in the script area.
- You can display an entire data area (or a portion thereof) in the script area by entering `%+...+%` where ... is the name of the node whose element(s) should be displayed.

Note: Time saver. When you develop a new BPA script, change your [user preferences](#) to include the script as your first "favorite". This way, you can press `Ctrl+Shift+1` to invoke the script (eliminating the need to select it from the [script menu](#)).

Launching A Script From A Menu

You can create menu items that launch BPA scripts rather than open a page. To do this, create a [navigation option](#) that references your script and then add a menu item that references the navigation option.

If the navigation option is referenced on a [context menu](#) and the navigation option has a "context field", a temporary storage variable will be created and populated with the unique identifier of the object in context. For example, if you add a "script" navigation option to the bill context menu and this navigation option has a context field of BILL_ID, the system will create a temporary storage variable called BILL_ID and populate it with the respective bill id when the menu item is selected.

Launching A Script When Starting The System

You can set the system to launch a script upon startup. This may be used for integrations from an external system or for use cases within the application where a link has been configured to launch the application in a new browser tab, allowing the original page to remain open. Refer to [Creating Application Links in External Applications](#) for details of what is supported.

Executing A Script When A To Do Entry Is Selected

The system creates [To Do entries](#) to highlight tasks that require attention (e.g., records in error). Users can complete many of these tasks without assistance. However, you can set up the system to automatically launch a script when a user selects a To Do entry. For example, consider a To Do entry that highlights a bill that's in error due to an invalid mailing address. You can set up the system to execute a script when this To Do entry is selected by a user. This script might prompt the user to first correct the customer's default mailing address and then re-complete the bill.

The following points provide background information to help you understand how to implement this functionality:

- Every To Do entry references a [To Do type](#) and a [message category and number](#). The To Do type defines the category of the task (e.g., bill errors). The message number defines the specific issue (e.g., a valid address can't be found.). Refer to [The Big Picture of System Messages](#) for more information about message categories and numbers.
- When a user drills down on a To Do entry, either a script launches OR the user is transferred to the transaction associated with the entry's To Do type. You control what happens by configuring the To Do type accordingly:
 - If you want to launch a script when a user drills down on an entry, you link the script to the [To Do type and message number](#). Keep in mind that you can define a different script for every message (and some To Do types have many different messages).
 - If the system doesn't find a script for an entry's To Do type and message number, it transfers the user to the To Do type's default transaction.

Note: How do you find the message numbers? We do not supply documentation of every To Do type's message numbers (this list would be impossible to maintain and therefore untrustworthy). The best way to determine which message numbers warrant a script is during pre-production when you're testing the system. During this period, To Do entries will be generated. For those entries that warrant a script, simply display the entry on [To Do maintenance](#). On this page, you will find the entry's message number adjacent to the description.

- These types of scripts invariably need to access data that resides on the selected To Do entry. Refer to [How To Use To Do Fields](#) for the details.

The Big Picture Of Script Eligibility Rules

You can configure [eligibility criteria](#) on the scripts to limit the scripts that a user sees in the [script search](#). For example, you could indicate a script should only appear on the script menu if the user belongs to the level 1 customer service representative group. You may also indicate that a script should only appear if the data a user is viewing has certain criteria. For example, if you are using Oracle Utilities Customer Care and Billing, you can indicate that a script should only appear if the current account's customer class is residential. By doing this, you avoid presenting the user with scripts that aren't applicable to the current data in context or the user's role.

The topics in this section describe eligibility rules.

Script Eligibility Rules Are Not Strictly Enforced

The [script search](#) gives a user a choice of seeing all scripts or only scripts that are eligible (given the current data in context and their user profile). This means that it's possible for a script that isn't eligible for the given context data / user to be executed via this search. In other words, the system does not strictly enforce a script's eligibility rules.

It might be more helpful to think of eligibility rules as "highlight conditions". These "highlight conditions" simply control whether the script appears in the [script search](#) when a user indicates they only want to see eligible scripts.

You Can Mark A Script As Always Eligible

If you don't want to configure eligibility rules, you don't have to. Simply indicate that the script is always eligible.

You Can Mark A Script As Never Eligible

If you have scripts that you do not want a user to select from the script menu, indicate that it is never eligible. An example of a script that you wouldn't want a user to select from the menu is one that is [launched when a To Do entry is selected](#). These types of scripts most likely rely on data linked to the selected To Do entry. As a result, a user should only launch scripts of this type from the To Do entry and not from the script menu.

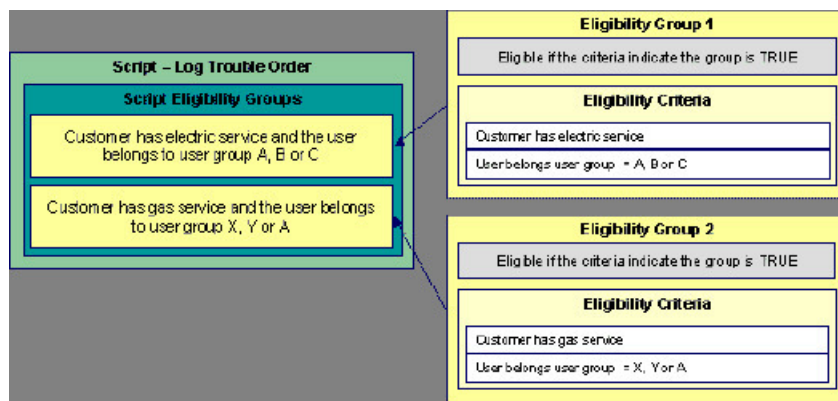

Criteria Groups versus Eligibility Criteria

Before we provide concrete examples of eligibility criteria, we need to explain two concepts: Criteria Groups and Eligibility Criteria. A script's criteria groups control whether a user is eligible to choose a script. At a high level, it works like this:

- A criteria group has one or more eligibility criteria. A group's criteria control whether the group is considered true or false.
- When you create a group, you define what should happen if the group is true or false. You have the following choices:
 - The user is eligible to choose the script.
 - The user is not eligible to choose the script.
 - The next group should be checked.

We will use the following example from Oracle Utilities Customer Care and Billing to help illustrate these points. Assume a script is only eligible if:

- The customer has electric service and the user belongs to user group A, B or C.
- OR, the customer has gas service and the user belongs to user group X, Y or A.

This script requires two eligibility groups because it has two distinct conditions:

- IF (Customer has electric service AND (User belongs to user group A, B or C))
- IF (Customer has gas service AND (User belongs to user group X, Y or A))

If either condition is true, the script is eligible.

You would need to set the following criteria groups in order to support this requirement:

| Group No. | Group Description | If Group is True | If Group is False |
|-----------|-------------------|------------------|-------------------|
|-----------|-------------------|------------------|-------------------|

| | | | |
|---|--|-----------------|-------------------------|
| 1 | Customer has electric service and the user belongs to user group A, B or C | Eligible | Check next group |
| 2 | Customer has gas service and the user belongs to user group X, Y or A | Eligible | Ineligible |

The following criteria are required for each of the above groups:

| Group 1: Customer has electric service and the user belongs to user group A, B or C | | | | |
|--|--------------------------------------|---------------------------------|----------------------------------|-----------------------|
| Seq | Logical Criteria | If Eligibility Criteria is True | If Eligibility Criteria is False | If Insufficient Data |
| 10 | Customer has electric service | Check next condition | Group is false | Group is false |
| 20 | User belongs to user group A, B or C | Group is true | Group is false | Group is false |

| Group 2: Customer has gas service and the user belongs to user group X, Y or A | | | | |
|---|--------------------------------------|---------------------------------|----------------------------------|-----------------------|
| Seq | Logical Criteria | If Eligibility Criteria is True | If Eligibility Criteria is False | If Insufficient Data |
| 10 | Customer has gas service | Check next condition | Group is false | Group is false |
| 20 | User belongs to user group X, Y or A | Group is true | Group is false | Group is false |

The next section describes how you might configure the specific logical criteria in each of the groups.

Defining Logical Criteria

When you set up an eligibility criterion, you must define two things:

- The field to be compared
- The comparison method

You have the following choices in respect of identifying the *field to be compared* :

- You can execute an algorithm to retrieve a field value from somewhere else in the system.
- Some products may support choosing a characteristic linked to an appropriate object in the system (such as an account or person).

You have the following choices in respect of identifying the *comparison method*:

- You can choose an operator (e.g., >, <, =, BETWEEN, IN, etc.) and a comparison value.
- You can execute an algorithm that performs the comparison (and returns True, False or Insufficient Data). This is also a very powerful feature, but it's not terribly intuitive. We'll present a few examples later in this section to illustrate the power of this approach.

The [Examples Of Script Eligibility Rules](#) provide examples to help you understand this design.

Examples Of Script Eligibility Rules

The topics in this section provide examples about how to set up script eligibility rules.

A Script With A Time Span Comparison

A script that is only eligible for senior citizens has the following eligibility rules:

- Customer class = Residential
- Birth date equates to that of a senior citizen

These rules require only one eligibility group on the script. It would look as follows:

| Group No. | Group Description | If Group is True | If Group is False |
|-----------|--------------------------------|------------------|-------------------|
| 1 | Residential and Senior Citizen | Eligible | Ineligible |

The following criteria will be required for this group:

| Group 1: Residential, Calif, Senior | | | | | |
|--|--|------------------------------|---------------------------------|-----------------------|-----------------------|
| Seq | Field to Compare | Comparison Method | If True | If False | If Insufficient Data |
| 10 | Algorithm: retrieve account's customer class | = R | Check next condition | Group is false | Group is false |
| 30 | Person characteristic: Date of Birth | Algorithm: True if senior | Group is true | Group is false | Group is false |

The first criterion is easy; it calls an algorithm that retrieves a field on the current account. This value, in turn, is compared to a given value. If the comparison results in a True value, the next condition is checked. If the comparison doesn't result in a True value, the **Group is false** (and, the group indicates that if the group is false, the script isn't eligible).

The last criterion contains a time span comparison. Time span comparisons are used to compare a date to something. In our example, we have to determine the age of the customer based on their birth date. If the resultant age is > 65, they are considered a senior citizen. To pull this off, you can take advantage of a comparison algorithm supplied with the base script as described below.

- Field to Compare. The person characteristic in which the customer's birth date is held is selected.
- Comparison Method. We chose a comparison algorithm that returns a value of **True** if the related field value (the customer's date of birth) is greater than 65 years (refer to **SECC-TIMESPN** for an example of this type of algorithm). Note that this time span algorithm can be used to compare days, weeks and months as well.

You'll notice that if a value of **True** is returned by the **True if senior** algorithm, the group is true (and we've set up the group to indicate a true group means the script is eligible).

A Script With Service Type Comparison

Imagine a script that is only eligible if the current customer has gas service and the user belongs to user groups A, B or C. This script would need the following eligibility rules:

- Customer has gas service
- User belongs to user group A, B, or C

These rules require only one eligibility group on the script. It would look as follows:

| Group No. | Group Description | If Group is True | If Group is False |
|-----------|--|------------------|-------------------|
| 1 | Has gas service and user is part of user group A, B or C | Eligible | Ineligible |

The following criteria are required for this group:

| Group 1: Has gas service and user is part of user group A, B, or C |
|---|
|---|

| Seq | Field to Compare | Comparison Method | If True | If False | If Insufficient Data |
|-----|--|-------------------|-----------------------------|-----------------------|-----------------------|
| 10 | Algorithm: check if customer has gas service | = True | Check next condition | Group is false | Group is false |
| 20 | Algorithm: check if user belongs to user group A, B or C | = True | Group is true | Group is false | Group is false |

Both criteria are similar - they call an algorithm that performs a logical comparison. These algorithms are a bit counter intuitive (but understanding them provides you with another way to implement complex eligibility criteria):

The first criterion works as follows:

- **Field to Compare.** We chose a "field to compare" algorithm that checks if the current account has service agreements that belong to a given set of service types. It returns a value of **True** if the customer has an active service agreement that matches one of the service types in the algorithm. In our example, the "check if customer has gas service" algorithm returns a value of **True** if the customer has at least one active service agreement whose SA type references the gas service type. The "check if customer has electric service" algorithm is almost identical, only the service type differs.
- **Comparison Method.** We simply compare the value returned by the algorithm to True and indicate the appropriate response.

The second criterion works similarly:

- **Field to Compare.** We chose a "field to compare" algorithm that checks if the user belongs to any user group in a set of user groups. It returns a value of **True** if the user belongs to at least one user group defined in parameters of the algorithm. Refer to algorithm type **SECF-USRNGRP** for an example of this type of logic.
- **Comparison Method.** We simply compare the value returned by the algorithm to True and indicate the appropriate response.

Note: Bottom line. The "field to compare" algorithm isn't actually returning a specific field's value. Rather, it's returning a value of **True** or **False**. This value is in turn, compared by the "comparison method" and the group is set to true, false or check next accordingly.

The Big Picture Of Server-Based Scripts

Fastpath: Refer to [The Big Picture Of Scripts](#) to better understand the basic concept of scripts.

Server-based scripts allow an implementation to configure backend business processes. The system supports three types of server-based scripts, **Plug-In** scripts, **Service** scripts and **Groovy Library** scripts.

- **Plug-in** scripts allow an implementation to develop routines that are executed from the system's various plug-in spots. For example, an implementation could configure a plug-in script that is executed every time an adjustment of a given type is frozen.
- **Service** scripts allow an implementation to develop common routines that are invoked from both front-end and back-end services. For example, an implementation could create a service script that terminates an account's automatic payment preferences. This service script could be invoked from a BPA script initiated by an end-user when a customer asks to stop paying automatically, and it could also be executed from a plug-in script if a customer fails to pay their debt on time. Service scripts are typically written using xpath scripting.
- **Groovy Library** scripts allow an implementation to develop groups of common routines written in the Groovy language which may be invoked from **Groovy Member** step types.

The topics in this section describe background topics relevant to server-based scripts.

Additional Coding Options For Server Scripts

Server based scripts often perform complex functions best supported by coding in languages with more comprehensive command sets than the base script steps. The system supports two common third-party languages for this purpose.

XML Path Language (XPath) is a language for querying and evaluating elements or nodes in an XML document. XPath commands and expressions can be used directly within [edit data](#) step types. The script engine version is used to define the applicable XPath version.

Groovy is an object-oriented, dynamic language for the Java platform. The framework supports the use of Groovy within server-based scripts to provide restricted and controlled access to Java-like code, particularly for cloud based implementations. The following topic provides more information on how to incorporate Groovy code into scripts.

Using Groovy Within Scripts
