Groovy code can be incorporated in scripts using the step type **Groovy Members**. For each script with Groovy code, there will be a single Groovy class created by concatenating all **Groovy Members** steps.

For security, the product and third party Java classes available for scripting in Groovy are restricted. The allowable base classes may be viewed in the [Groovy Javadocs](#) viewer via the 'View Groovy Javadocs' link in the context sensitive Script Tips zone. The list of allowable third party classes can be viewed via the 'View third party Groovy allowlist' link in the Script Tips zone.

Note: This system supports the use of Groovy for back end processing purposes. It is not intended for user interfaces. Groovy is also not applicable to BPA scripts.

Groovy Script Engine

For scripts invoked from within Java and entirely written in Groovy should use a script engine version of **Groovy**. The system processes this type of script in a similar way to code written in Java. This avoids the need to convert the script to and from XML format and allows the use of code that acts directly on the system objects with consequent performance benefits.

The following script types support the Groovy engine version:

Plug In Scripts

Plug-in Scripts can be configured to use the Groovy engine if they contain only Groovy oriented step types. The system provides an automatically generated superclass that defines the plug-in spot API. Internally, the Groovy code must conform to the system conventions for Java based algorithm types, including the inclusion of an 'invoke' method that is the plug-in entry point, and the definition of 'soft' parameters using annotations.

Groovy Library Scripts

Groovy Library Scripts provide the ability to create groups of common routines written in Groovy that can be called from within other scripts. Scripts of this type must include a single step type of **Groovy Library Interface** in which the publicly available methods in the library are listed. The supporting code for those methods is defined in one or more **Groovy Members** step types within the library script. The methods defined in the library can accept arguments and return values of any type. Scripts of this type use the Groovy engine by default and cannot include scripting step types.

Scripts that need to invoke methods from a Groovy library can use the `createLibraryScript` method provided by the system to instantiate the library interface. Ensure that the class being instantiated includes the `.class` filename extension.

Invoking Groovy within the Scripting Engine

If a plug-in script or a service script is configured to use a scripting engine version, it can include a mixture of regular and **Groovy Members** step types. The script step types will define the process to be executed. The **Groovy Members** steps contain code that can be called from **Edit Data** step types within the script using the `invokeGroovy` command. Only Groovy methods that receive no arguments and return void are supported using this command. Refer to the section on [edit data](#) steps for more details.

For scripts using this option, the framework provides a superclass containing methods that support common scripting actions such as move commands, string evaluation, and methods to invoke business objects, business services and service scripts. Refer to the Groovy specific Javadocs for details of the supported methods.

Importing Groovy Classes

All the Groovy classes used by your script should be explicitly declared in a **Groovy Imports** step type. When saving a script, if the system finds classes referenced in the script that are not explicitly declared, the system issues a warning and automatically adds import statements for the classes. Script writers should review the imports to confirm that they are the correct classes (in case there is a class with the same name in two different packages).

Backward Compatibility

In previous releases, the system did not require explicit imports and had logic to automatically import all callable classes available to Groovy at run-time. For any existing script that does not explicitly declare its imports, the system continues to fall back on importing all callable classes at runtime. However, the recommendation is to identify and update any such script as this is not the recommended practice.

The system provides a batch program **F1-CAGVY** that reports all scripts that required the automatic import step to successfully compile. In addition, this batch program is useful when the version of Groovy is upgrade to proactively detect possible issues in compilation of existing scripts that may occur due to changes in Groovy. Implementations are encouraged to run this batch program in the short term to identify and fix any scripts missing explicit imports and also for any Groovy version upgrade to review any implementation owned scripts that may be reported.

Plug-In Scripts

Note: This section assumes you are familiar with the notion of plug-in spots (algorithm entities) and plug-ins. See [The Big Picture Of Algorithms](#) for more information.

As an alternative to writing a java program for a plug-in spot, the framework supports creating plug-ins using the defined script steps, Xpath commands, Groovy code or a combination of these three options.

The following topics describe basic concepts related to plug-in scripts.

A Plug-In Script's API

Like program-based plug-ins, plug-in scripts:

- Run on the application server.
- Have their API (input / output interface) defined by the plug-in spot (i.e., plug-in scripts do not get to declare their own API).
- Can only be invoked by the "plug-in spot driver".

For plug-ins configured to use a script engine version, the best way to understand the script's API is to use the **View Script Schema** hyperlink to view its parameters data area schema.

```

<schema>
  <parm type="group">
    <soft type="list">
      <value/>
    </soft>
    <hard type="group">
      <action use="input"/>
      <businessObject type="group" use="input">
        <id/>
      </businessObject>
    </hard>
  </parm>
</schema>

```

Notice the two groups: soft and hard. If you are familiar with plug-in spots, you'll recognize these as the classic soft and hard parameters:

- The **soft** parameters are the values of the parameters defined on the algorithm. Notice they are not named - if you want to reference them in your plug-in script, you must do it by position.

- The **hard** parameters are controlled by the plug-in spot (i.e., the algorithm entity). Notice that this plug-in spot has a single input parameter called "**businessObject/id**". Also notice the **use=** attribute - this shows that this parameter is input-only (i.e., you can't change it in the plug-in script).

Note: XPath. You can click on an element name to see the XPath used to reference the element in your script.

Plug-ins configured to use the **Groovy** engine version do not use an XML interface for the API and instead are processed in the same way as Java algorithms. The framework supplies a dynamically generated superclass that implements the plug-in spot for Groovy objects. Use the **View Script Superclass** hyperlink to view this superclass and the methods to set and get the hard parameters.

Note: For plug-in scripts using the **Groovy** engine version, soft parameters do not appear in the plug-in spot API as defined by the superclass. Plug-ins using only Groovy code define their soft parameters using annotations, in a similar way to Java algorithms, and fetch those values using methods defined in the algorithm code.

Setting Up Plug-In Scripts

The following points describe how to implement a plug-in script:

- Compose your plug-in [script](#), associating it with the appropriate algorithm entity (plug-in spot).
- Create a new algorithm type for the respective algorithm entity, referencing your plug-in script as the program to carry out the algorithm type's function. Only plug-in scripts associated with the algorithm entity may be referenced on the algorithm type.
- Set up an algorithm for the respective algorithm type and plug it in where applicable. Refer to [Setting Up Algorithm Types](#) for more information.

Service Scripts

BPA scripts run on the client's browser and guide the end-users through business processes. Service scripts run on the application server and perform server-based processing for [BPA scripts](#), [zones](#) and more. You may want to think of a service script as a common routine that is set up via scripting (rather than programming).

The following topics describe basic concepts related to service scripts.

A Service Script's API

As with any common routine, a service script must declare its input / output parameters (i.e., its API). A service script's API is defined on its [schema](#).

Note: Refer to [Schema Nodes and Attributes](#) for a complete list of the XML nodes and attributes available to you when you construct a schema.

Invoking Service Scripts

Any type of script configured to use a scripting engine version may [invoke a service script](#):

- A BPA script may invoke a service script to perform server-based processing.
- Plug-in scripts may invoke a service script (like a "common routine").
- A service script may call another service script (like a "common routine").

Map zones may be configured to invoke service scripts to obtain the data to be displayed. Refer to [Map Zones](#) for more information.

[Inbound web services](#) support interaction with service scripts allowing the outside world to interact directly with a service script.

You can also invoke a service script from a Java class.

Groovy Library Scripts

Just as service scripts can define common routines written in scripting language, Groovy library scripts are used to define groups of common components or methods written in Groovy. Groovy library code runs on the application server and performs server-based processing for scripts that utilize Groovy code.

The following topics describe basic concepts related to Groovy library scripts.

A Groovy Library Script's API

A Groovy library script's API is composed of one or more public methods whose code is defined in the script's steps. Those methods are defined in a step type of **Groovy Library Interface**. A Groovy library script must have one (and only one) step of this type.

Invoking Groovy Library Methods

Any type of script that supports the **Groovy Members** step type may invoke common methods defined in Groovy library scripts.

Code within a **Groovy Members** step must create an instance of the Groovy library interface definition to enable the interface methods to be invoked. Refer to the topic [Using Groovy Within Scripts](#) for more information.

Debugging Server-Based Scripts

The server can create log entries to help you debug your server scripts.

The logs contain a great deal of information including the contents of the referenced data area for **Move data**, **Invoke business object**, **Invoke business service** and **Invoke service script** steps.

Refer to the [Debug Mode](#) topic in the Configuration Tools chapter for details of how to execute the application in debug mode.

Maintaining Scripts

The script maintenance transaction is used to maintain your scripts. The topics in this section describe how to use this transaction.

Fastpath: Refer to [The Big Picture Of Scripts](#) for more information about scripts.

Script - Main

Use this page to define basic information about a script. Open this page using **Admin > System > Script**.

Use the **Script Query** portal to search for an existing script. Once a script is selected, you are brought to the maintenance portal to view and maintain the selected record.

Note: Script Tips. A context sensitive "Script Tips" zone is associated with this page. The zone provides links to [Edit Data Syntax](#) and [Advanced Schema Topics](#) so that users can quickly access those online help topics to aid in constructing scripts. In addition, the zone provides links to view the [Groovy Javadocs](#) viewer and the allowlist of third party Groovy classes so that users can verify the restricted list of classes available for Groovy coding in the script.

Description of Page

Enter a unique **Script** code and **Description** for the script. Use the **Detailed Description** to describe the purpose of this script in detail. **Owner** indicates if the script is owned by the base package or by your implementation (**Customer Modification**).

CAUTION: Important! If you introduce a new script, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Script Type indicates if this is a **BPA Script**, **Plug-In Script**, **Groovy Library Script** or **Service Script**. Refer to [The Big Picture Of BPA Scripts](#) and [The Big Picture Of Server Based Scripts](#) for more information.

Accessibility Option appears only for BPA scripts. Set this value to **Accessible from Script Menu** for any script that may be launched as a stand-alone script. Scripts with this configuration may be linked to a navigation option so that they may be invoked from a menu and may be configured by a user as a favorite script. Set this value to **Not Accessible from Script Menu** for any script that cannot be launched on its own. For example, any script that is invoked as a sub-script from another script should have this setting. In addition, any script that is designed to be launched from within a specific portal where certain data is provided to the script should include this setting.

Enter an **Application Service** if the execution of the script should be secured. The application service should include **Execute** as one of its access modes. Refer to [Securing Script Execution](#) for more information. This field does not appear if the script type is **Groovy Library Script**.

Algorithm Entity appears only for [plug-in scripts](#). Use this field to define the [algorithm entity](#) into which this script can be plugged in.

Business Object appears only for business object related plug-in scripts. Enter the [Business Object](#) whose elements are to be referenced by the plug-in script.

Script Engine Version defines key information affecting the context and execution of the script.

- Script engine version values of 1, 2 and 3 define the version of the XML Path Language (XPath) to be used for the script. Versions 2 and 3 use the XPath 2 engine supplied by the XQuery team. This is the same engine used inside the Oracle database. The current script engine version 3 is a modified version that offers performance improvements without impacting existing version 2 scripts.

The default script engine version is 3.0 for plug-in and service scripts. The default version for BPA scripts is 1.0 as higher level versions are not applicable.

There are some additional details to note about script engine version 1.0:

- The XPath library used is Jaxen
- For BPA scripts, it uses the browser's xpath and XML support except for Internet Explorer where the XsXML parser is used.
- XPath 1 (and even JavaScript) uses floating point arithmetic, which means that adding a collection of numbers with two decimal places might end up with a value of 10779.079999999998 instead of 10779.08
- A Script Engine Version value of **Groovy** is only applicable to plug-in scripts. It is used to indicate that only Groovy related step types are used in the script and signals to the system that there is no need to convert the data to and from an XML interface. This allows for greater efficiency in script execution.
- The value **Framework Version 2.1 Compatibility Mode** remains for upgrade purposes. This value should only be applicable to early versions of BPA scripts using syntax that is incompatible with XPath syntax.

Note: The **Script Engine Version** field does not appear for **Groovy Library** scripts. The script engine version for these scripts is set to **Groovy** by default and cannot be changed.

Click the **View Script Schema** to view the [script's data areas](#) on the [schema viewer](#) window. This link does not appear if the script engine version is **Groovy**.

Click the **View XSD** hyperlink to view a script's schema definition in XSD format. This link only appears if the script type is **BPA Script** or **Service Script**.

The **View Script Superclass** hyperlink appears only for plug-in scripts using an engine version of **Groovy**. Click this link to view the code of the runtime generated superclass for the related plug-in spot's implementation.

The **View Script As Text** hyperlink appears for server-based scripts only. Click this link to view the internal scripting commands in a separate window.

The [tree](#) summarizes the script's steps. You can use the hyperlink to transfer to the **Step** tab with the corresponding step displayed.

Script - Step

Use this page to add or update a script's steps. Open this page using **Admin > System > Script** and then navigate to the **Step** tab.

Note: Time saver. You can navigate to a step by clicking on the respective node in the tree on the Main tab.

Description of Page

The **Steps** accordion contains an entry for every step linked to the script. When a script is initially displayed, its steps are collapsed. To see a step's details, simply click on the step's summary bar. You can re-click the bar to collapse the step's details. Please see [accordions](#) for the details of other features you can use to save time.

Select the **Step Type** that corresponds with the step. Refer to [How To Set Up Each Step Type](#) for an overview of the step types.

CAUTION: The Step Type affects what you can enter on other parts of this page. The remainder of this section is devoted to those fields that can be entered regardless of Step Type. The subtopics that follow describe those fields whose entry is contingent on the Step Type.

Step Sequence defines the relative position of this step in respect of the other steps. The position is important because it defines the order in which the step is executed. You should only change a Step Sequence if you need to reposition this step. But take care; if you change the Step Sequence and the step is referenced on other steps, you'll have to change all of the referencing steps.

Note: Leave gaps in the sequence numbers. Make sure you leave space between sequence numbers so that you can add new steps between existing ones in the future. If you run out of space, you can use the **Renumber** button to renumber all of the steps. This will renumber the script's steps by 10 and change all related references accordingly.

Display Step is only enabled on BPA scripts for step types that typically don't cause information to be displayed in the [script area](#) (i.e., step types like **Conditional Branch**, **Go to a step**, **Height**, etc). If you turn on this switch, information about the step is displayed in the script area to help you debug the script.

CAUTION: Remember to turn this switch off when you're ready to let users use this script.

Note: If **Display Step** is turned on and the step has **Text**, this information will be displayed in the script area. If **Display Step** is turned on and the step does not have **Text**, a system-generated messages describing what the step does is displayed in the script area.

Display Icon controls the [icon](#) that prefixes the **Text** that's displayed in the script area. Using an icon on a step is optional. This field is only applicable to BPA scripts.

Text is the information that displays in the [script area](#) when the step executes. You need only define text for steps that cause something to display in the script area.

Fastpath: Refer to [How To Substitute Variables In Text](#) for a discussion about how to substitute variables in a text string.

Fastpath: Refer to [How To Use HTML Tags And Spans In Text](#) for a discussion about how to format (with colors and fonts) the text that appears in the script area.

The other fields on this page are dependent on the **Step Type**. The topics that follow briefly describe each step type's fields and provide additional information about steps.

Click on the **View Script Schema** hyperlink to view the script's data areas. Doing this opens the [schema viewer](#) window.

The **View Script As Text** hyperlink appears for server-based scripts only. Click this link to view the internal scripting commands in a separate window. The presented script syntax is valid within [edit data](#) steps.

How To Set Up Each Step Type

The contents of this section describe how to set up each type of step. Note that some step types are only applicable for BPA scripts and some step types are only supported for server based scripts. In addition, some BPA script steps are considered legacy functionality and therefore only supported on fixed pages and not portals. Each section indicates whether there are any script type limitations.

Conditional Branch Steps

Conditional branch steps allow you to conditionally jump to a different step based on logical criteria. For example, you could jump to a different step in a script if the customer is residential as opposed to commercial. In addition, several fields are required for **Conditional Branch** steps:

Compare Field Type and **Compare Field Name** define the first operand in the comparison. The **Field Type** defines where the field is located. The **Field Name** defines the name of the field. The following points describe each field type:

- **Current To Do Information.** Use this field type when the field being compared resides on the current To Do entry. Refer to [How To Use To Do Fields](#) for instructions on how to define the appropriate **Field Name**.
- **Data Area.** Use this field type when the field being compared is one that you put into one of the scripts data areas in an earlier step. **Field Name** must reference both a data area structure name as well as the field, for example "parm/charType". Refer to [How To Reference Fields In Data Areas](#) for instructions on how to construct the appropriate **Field Name**.
- **Page Data Model.** Use this field type when the field being compared resides on one of the tab pages in the [object display area](#). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**.
- **Predefined Value.** Use this field type when the field being compared is a [global variable](#).
- **Temporary Storage.** Use this field type when the field being compared is one that you put into temporary storage in an earlier step. The **Field Name** must be the same as defined in an earlier step.
- **User Interface Field.** Use this field type when the field being compared resides on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

Condition defines the comparison criteria:

- Use **>**, **<**, **=**, **>=**, **<=**, **<>** (not equal) to compare the field using standard logical operators. Enter the comparison value using the following fields.
- Use **In** to compare the first field to a list of values. Each value is separated by a comma. For example, if a field value must equal **1**, **3** or **9**, you would enter a comparison value of **1,3,9**.
- Use **Between** to compare the field to a range of values. For example, if a field value must be between **1** and **9**, you would enter a comparison value of **1,9**. Note, the comparison is inclusive of the low and high values.

Comparison Field Type, **Comparison Field Name** and **Comparison Value** define what you're comparing the first operand to. The following points describe each field type:

- **Current To Do Information.** Use this field type when the comparison value resides on the current To Do entry. Refer to [How To Use To Do Fields](#) for instructions on how to define the appropriate **Field Name**.
- **Data Area.** Use this field type when the comparison value resides in one of the scripts data areas. **Field Name** must reference both a data area structure name as well as the field, for example "parm/charType". Refer to [How To Reference Fields In Data Areas](#) for instructions on how to construct the appropriate **Field Name**.
- **Page Data Model.** Use this field type when the comparison value resides on one of the tab pages in the [object display area](#). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**.
- **Predefined Value.** Use this field type when the field being compared is a constant value defined in the script. When this field type is used, use **Comparison Value** to define the constant value. Refer to [How To Use Constants In Scripts](#) for instructions on how to use constants.
- **Temporary Storage.** Use this field type when the comparison value is a field that you put into temporary storage in an earlier step. The **Field Name** must be the same as defined in an earlier step.
- **User Interface Field.** Use this field type when the comparison value resides on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

Note: Conditional field types. The field types **Current To Do Information**, **Page Data Model** and **User Interface Field** are only applicable to BPA scripts. Only the field types **Temporary Storage** and **Predefined Value** are applicable when the Condition is **In** or **Between**.

The above fields allow you to perform a comparison that results in a value of **TRUE** or **FALSE**. The remaining fields control the step to which control is passed given the value:

- **If True, Go to** defines the step that is executed if the comparison results in a **TRUE** value.
- **If False, Go to** defines the step that is executed if the comparison results in a **FALSE** value.

Note: Numeric Comparison. Comparison of two values may be numeric or textual (left-to-right). Numeric comparison takes place only when values on both side of the comparison are recognized as numeric by the system. Otherwise, textual comparison is used. Fields for **Current To Do Information**, **Data Area**, **Page**

Data Model, and **User Interface Field** types are explicitly associated with a data type and therefore can be recognized as numeric or not. This is not the case for fields residing in **Temporary Storage** or those set as **Predefined Values**. A **Temporary Storage** field is considered numeric if it either holds a numeric value moved to it from an explicitly defined numeric value (see above) or it is a resultant field of mathematical operation. A **Predefined Value** field is considered numeric if the other field it is compared to is numeric. For example, if a numeric field is compared to a **Predefined Value** the latter is considered numeric as well resulting in numeric value comparison. However, if the two fields are defined as **Predefined Values** the system assumes their values are text strings and therefore applies textual comparison.

Display Text Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

CAUTION: Guiding scripts that interact with the user using the script area are limited to surf over fixed pages only and are considered legacy functionality. This technique is not supported on top of portal pages and is planned to be deprecated in a future release.

Display text steps cause a text string to be displayed in the script area. Steps of this type can be used to provide the user with guidance when manual actions are necessary. In addition, they can be used to provide confirmation of the completion of tasks.

The information you enter in the **Text** field is displayed in the [script area](#) when the step is executed.

The text string can contain [substitution variables](#) and [HTML formatting commands](#). Also note that for debugging purposes, you can display an entire data area (or a portion thereof) by entering `%+...+%` where `...` is the name of the node whose element(s) should be displayed.

Edit Data Steps

Edit data steps provide a free format region where you can specify commands to control your script processing.

Enter your scripting commands in the **Edit Data Text** field. Click the adjacent icon to open a window providing more space for defining the edit data step.

In general, the syntax available within edit data mimics the commands available within the explicit step types. However, there are a few commands that are available only within edit data. For example, the two structured commands: **For**, and **If**.

Note: Not all BPA step types are supported using the edit data syntax. Refer to the details below for more information on edit data commands and examples.

The topics in this section provide detail of the syntax supported in the edit data step type.

Comments

You can place comments into your script using the double slash notation `//` in the first two characters of the edit data step. Example:

```
//
// quit with error
//
if ("not(customer/securityEnabled)")
terminate with error (8000, 1001 %1="customer/id" %2='not allowed');
end-if;
```

Temporary Variables

Temporary variables can be declared within all types of scripts. They should be referenced by a leading single dollar sign ('\$'). However, temporary variables behave differently in the various script types:

- In BPA Scripts temporary variables remain persistent from one BPA script to another (refer to the [Perform Script and Transfer Control statements](#)), which means that you can use temporary variables to communicate between BPA scripts.
- Temporary variables cannot be passed from a BPA script to a service or plug-in script. Only data area elements can be passed between these types of scripts.
- Within service and plug-in scripts, temporary variables remain persistent only for the life of the particular script that declared the variable. This means that temporary variables cannot be passed between plug-in scripts and service scripts, only [global variables](#), [context variables](#) and data area elements can be passed between these types of scripts.

Declaring / Initializing / Defaulting Temporary Variables

When using a temporary variable, it should be declared or initialized with an appropriate value before using it. A typical method for declaring a variable is to simply move data to it in a move statement, for example.

```
move "0" to $index;
```

Fastpath: Refer to [Move to a Temporary Variable](#) for more information on implicit declaration of a temporary variable within a move statement.

For BPA scripts, as mentioned above, temporary variables may be passed from one BPA script to another. As such, it is common to reference a temporary variable in a BPA that should have been initialized by a previous BPA. However, if there is any reason that a temporary variable did not get initialized by a previous BPA, a reference to it will cause an error. It is good practice, therefore, to use the **default** statement that will initialize temporary variables that are not already created / initialized.

- The following statement will initialize the temporary variable \$InputAction – but only if the temporary variable has not yet been initialized:

```
default $InputAction;
```

- The following statement will set the value of the temporary variable \$InputAction to 'read' – but only if the variable has not yet been initialized:

```
default $InputAction as 'read';
```

Note: Scripts should take care not to define variables using a reserved keyword. The following table lists the reserved keywords.

| Keyword |
|-------------------|
| add |
| as |
| asError |
| bpa |
| branch |
| data |
| declareBO |
| declareBS |
| declareDA |
| declareMap |
| declareSS |
| default |

| Keyword |
|-----------------------------------|
| delete |
| edit |
| element |
| else |
| end-edit |
| end-for |
| end-if |
| error |
| escape |
| evaluate |
| fastAdd |
| fastUpdate |
| for |
| goto |
| if |
| in |
| invokeBO |
| invokeBS |
| invokeMap |
| invokeSS |
| label |
| map |
| move |
| navigate |
| navigateAndReloadDashboard |
| null |
| page |
| performScript |
| popup |
| read |
| readWithoutVersion |
| replace |
| suppress |
| target |
| terminate |
| to |

| Keyword |
|-----------------|
| transferControl |
| update |
| using |
| warn |
| with |

Context Variables

Context variables are only available within service scripts. The context variable will be available for the duration of the service script and all that it invokes. Therefore, you can use a context variable within a service script to communicate information to a lower level service script or schema. They should be referenced by leading double dollar signs ('\$\$').

Note: Because context variables are available for lower level scripts, they may sometimes be referred to as global variables or global context variables. But they should not be confused with [global variables](#).

Declaring / Initializing / Defaulting Context Variables

When using a context variable, it should be declared or initialized with an appropriate value before using it. A typical method for declaring a variable is to simply move data to it in a move statement, for example.

```
move 'context variable' to $$contextVariable;
```

Fastpath: Refer to [Move using a Context Variable](#) for more information.

Move Statement

The **move** statement copies a source value to a target. The following table highlights various options supported in the move statement.

| Statement | Example Description | Example Syntax |
|--|--|---|
| Move to Element move "xpath" to "xpath"; | Move statement with simple XPath reference. | <pre>move "acct/totalBalance" to "parm/formattedValue";</pre> |
|  Note: An XPath expression is surrounded by double quotes. | Move statement with XPath concatenate function. | <pre>move "concat(person/firstName, ', ', person/lastName)" to "parm/fullName";</pre> |
| | Move statement with XPath substring-before function. | <pre>move "substring-before(parm/fullName, ', ')" to "person/firstName";</pre> |
| | Move statement with XPath substring-after function. | <pre>move "substring-after(parm/fullName, ', ')" to "person/lastName";</pre> |
| | Move statement with XPath substring function. | <pre>move "substring(parm/date, 1, 4)" to "parm/year";</pre> |
| | Move statement using a literal string. | <pre>move 'okay for mailing' to "account/preferences[type="mail"]/text";</pre> |
| Move to Element move 'literal' to "xpath"; |  Note: A literal value is surrounded by single quotes. | |
| Move to Element move 'Boolean' to "xpath"; | Move statement with Boolean as literal string. | <pre>if ("account/balance > 0") move 'true' to "account/hasDebitBalance"; end-if;</pre> |
| | Moving an expression, which results in a Boolean. Note that the filter in the example below is located on a group node. | <pre><schema> <account> <hasDebitBalance type="boolean" /> > <balance/> </account> </schema></pre> |
| | | <pre>move "boolean(account[balance>0])" to "account/hasDebitBalance";</pre> |
| Move to Group move "xpath" to "xpath"; | Move a set of elements from one group with another. | <pre>move "account/custInfo" to "person";</pre> |
| | The system matches the initial level of element names and the group / list names from the source schema to the | This statement is equivalent to the following statement: |
| | | <pre>move "account/custInfo/*" to "person/*";</pre> |

| Statement | Example Description | Example Syntax |
|---|---|---|
| Move null move null to "xpath"; | You can remove information from the XML instance document through the special syntax of move 'null'. Note that you can specify either a node name in the XPath expression or a group name. If you specify a group then the group and all child elements will be eliminated from processing. | Remove a node and all of its child nodes: <pre>if ("boolean(customer/ securityEnabled) ") goto updateInfo; else move null to "customer"; end-if;</pre> Remove all child nodes of a group node with the suffix '/*': <pre>if ("boolean(customer/ securityEnabled) ") move null to "customer/*"; end-if;</pre> |

Go To Statement

The edit data step supports functionality analogous to the [Go To](#) step type. The syntax is **goto label**; where the label represents another location within the edit data text field (identified by this label) or represents another step in the script.

The following is an example of going to another location in the same step identified by the label **addSpouse**.

```
if ("string(parm/spouse/name) != $BLANK")
  goto addSpouse;
end-if;
addSpouse: invokeBO 'Person' using "parm/spouse" for add;
```

The following is an example of going to a different step within the same script. The step sequence is the reference used as the label.

```
if ("string(parm/spouse/name) != $BLANK")
  goto 110;
end-if;
.
.
.
110: invokeBO 'Person' using "parm/spouse" for add;
```

Conditional Branch Statement

The edit data step supports functionality analogous to the [Conditional Branch](#) step type. The syntax is **branch ("xpath") goto label else label**; where:

- The XPath condition in the **branch** statement must evaluate to a Boolean value of True or False.
- The targets for the **goto** and **else** statements are labels that represent another location within the edit data text field (identified by this label) or represent another step in the script.

The following example uses labels for **addSpouse** and **addAccount**

```
branch ("string(parm/spouse/name) !=
$BLANK") goto addSpouse else addAccount;
```

If Statement

The **if** statement is similar to the conditional branch statement. Either can be used to structure the logic of your script. This statement may optionally include an **else** statement but it should always end with an **end-if** statement.

Note: This is an example of a statement that is not represented as a separate step type. It is only available within the edit data text.

The syntax is **if (“xpath”) else end-if;**. The XPath condition must evaluate to a Boolean value of True or False. The following are some examples.

Example where the XPath contains a simple logical condition.

```
if ("string(parm/spouse/name) != $BLANK")
  //
  // Create spouse since spouse name present
  goto addSpouse;
else
  //
  // Create account without spouse
  goto addAccount;
end-if;
```

Example where the XPath contains a complex condition.

```
if ("string(parm/spouse/name) != $BLANK and string(parm/
hasSpouse) = true or boolean(parm/requireSpouse)")
  //
  // Create spouse since spouse name present
  goto addSpouse;
end-if;
```

Example of a stacked set of statements used to evaluate multiple possible values of a field.

```
if ("parm/rowCount = 0")
  //
  // no rows found
  goto quit;
end-if;
if ("parm/rowCount = 1")
  //
  // one row found
  goto process;
end-if;
if ("parm/rowCount > 1")
  //
  // more than one row found
  goto quit;
end-if;
quit: terminate;
```

The following XPath shows Boolean based on the existence of the node. In this example, if the node exists in the XML instance document being processed, the statement will evaluate to True. If no element is found, the statement evaluates to false.

Note: When treating XPath nodes as Boolean variables be aware that an empty node evaluates to True. Only a missing node return False.

```
if ("boolean(parm/spouse/name) ")
  goto addSpouse;
else
  //
  // Create account without spouse
```

```

goto addAccount;
end-if;

if ("not(parm/spouse/name) ")
//
// Create account without spouse
goto addAccount;
else
goto addSpouse;
end-if;

```

For Statement

The **for** statement creates a list of nodes or values depending on your XPath expression. If you specify a list node then every child node of the list, along with its contents, will be available within the loop. If you specify a child node directly, then a list of values only will be available within the loop.

Note: For more information on creating new entries in a list, please refer to the [creating a new list instance](#) example.

Note: This is an example of a statement that is not represented as a separate step type. It is only available within the edit data text.

The syntax is **for (\$variable in "xpathList") end-for;**. The XPath condition must evaluate to a Boolean value of True or False.

The following examples are based on this sample schema:

```

<schema>
  <SAList type="list">
    <id/>
    <balance/>
  </SAList>
  <SAContributor type="list">
    <id/>
  </SAContributor>
</schema>

```

Example that specifies the list node in the XPath expression where all child nodes are available for processing.

```

move "0" to $AccountBalance;
move "0" to $index;
for ($SAList in "SAList")
  move "$SAList/balance + $AccountBalance" to $AccountBalance;
  //
  // keep track of each SA contributing to the balance in the SA Contributor list
  move "1 + $index" to $index;
  move "$SAList/id" to "SAContributor[$index]/id";
end-for;

```

Example that specifies a child node within the list node in the XPath expression. Only values of that node are available for processing.

```

move "0" to $AccountBalance;
for ($SABalance in "SAList/balance")
  move "$SABalance + $AccountBalance" to $AccountBalance;
end-for;

```

Example that shows that a filter can be used to limit the rows selected by the **for** loop.

```

move "0" to $AccountDebitBalance;
for ($SAList in "SAList[Balance>0]")

```

```

    move "$SAList/balance + $AccountDebitBalance" to $AccountDebitBalance;
end-for;

```

Example that shows the use of a filter when specifying child nodes.

```

move "0" to $AccountCreditBalance;
for ($SABalance in "SAList[Balance<0]/balance")
    move "$SABalance + $AccountCreditBalance" to $AccountCreditBalance;
end-for;

```

List Processing

This section provides details about processing lists. The examples in this section reference the following schema:

```

<schema>
  <parm type="group">
    <name/>
  </parm>
  <Person type="group">
    <names type="list">
      <type/>
      <name/>
    </names>
  </Person>
</schema>

```

Referencing a List Element. You can move a value to a particular list instance by referencing an identifying node in the list within a filter. The syntax is **move "xpath" to "xpathList[filter]/element"**; Example:

```

move "parm/name" to "Person/names[type='main']/name";

```

Creating a New List Instance. A special notation can be used within a move target statement to indicate a new list instance should be created. The "+" indicates to the script processor that a new instance of a list should be initiated for the target element. The syntax is **move "xpath" to "+xpathList"**; Example:

```

move "parm/name" to "Person/+names/name";

```

Deleting a List Instance. An XML list entry can be deleted from the database by moving an action attribute of 'delete' to the element name. To cause a database delete of a list entry requires an attribute of action="delete" in the target node and a subsequent update BO interaction. The syntax is **move 'delete' to "xpathList[@action]"**; Example:

```

if ("parm/action = 'd'")
  move "0" to $index;
  for ($CCList in "CCList")
    move "1 + $index" to $index;
    if ("$CCList/id = parm/id")
      move 'delete' to "CCList[$index]@action";
      goto update;
    end-if;
  end-for;
end-if;

```

The following shows the resulting XML.

```

<root>
  <CCList>
    <id>9876538976</id>
    <balance>309.98</balance>
  </CCList>
  <CCList action="delete">

```

```
<id>4321125899</id>
<balance>87.45</balance>
</CCList>
</root>
```

Note: Deleting a list instance through use of the action attribute is risky if iterative BO interactions are required. The XML document that contains the list instance to be deleted will not be altered after a successful BO interaction, which means the document will still contain the list instance even though it no longer exists. To solve this problem, it is essential to re-read the BO after any BO update where the action attribute of 'delete' has been used.

Note: An alternative to the delete attribute described here, is to use the BO action of [replace](#). Manipulating a list to use the replace action avoids the problem described above concerning stale information in request documents post BO update.

Functions for Processing a List

XPath provides several functions that are useful to process elements of a list including **count**, **sum** and **last**.

The following examples are based on this sample XML document:

```
<xml>
  <ft>
    <type>bill</type>
    <date>20100101</date>
    <amt>30.30</amt>
    <cat>tax</cat>
  </ft>
  <ft>
    <type>adj</type>
    <date>20100301</date>
    <amt>20.20</amt>
    <cat>int</cat>
  </ft>
  <ft>
    <type>bill</type>
    <date>20100201</date>
    <amt>10.10</amt>
    <cat>tax</cat>
  </ft>
</xml>
```

The following is an example of a sum. The syntax is **move "sum(xpathList/element)" to \$variable**; The example sums the total balance.

```
move "sum(ft/amt)" to $TotalBalance;
```

The following is an example of a sum using a filter to get a subtotal. The example sums the balance of the entries that have the 'tax' category.

```
move "sum(ft[cat='tax']/amt)" to $TaxBalance;
```

The following is an example of a count. The syntax is **move "count(xpathList)" to \$variable**; The example finds the count of the number of FT entries in the list.

```
move "count(ft)" to $TranCount;
```

The following is an example of 'last', which is used to locate the last entry. The syntax is **move "last(xpathList)" to \$variable**; The example finds the last amount in the FT list.

```
move "ft[last()]/amt" to $LastAmount;
```

Declare and Invoke Schema Based Objects

You can invoke a business object, business service or service script within the edit data step. To support the dynamic invoke, a dynamic data area name can be declared.

The schema being declared may be a business object (BO) schema, a business service (BS) schema, a service script (SS) schema, data area (DA) schema or a UI map schema. The declare statement will differ based on the type of schema, but the syntax is analogous.

- **declareBO** 'BO Name' | \$variable | "xpath" as 'DynamicDataArea';
- **declareBS** 'BS Name' | \$variable | "xpath" as 'DynamicDataArea';
- **declareSS** 'SS Name' | \$variable | "xpath" as 'DynamicDataArea';
- **declareDA** 'DA Name' | \$variable | "xpath" as 'DynamicDataArea';
- **declareMap** 'Map Name' | \$variable | "xpath" as 'DynamicDataArea';

When invoking a BO, BS or SS, the name of the object can be specified as a literal or it can be a value contained within an element or a variable. For every Invoke, you must supply an XPath reference to a group name.

When invoking a business object, an action must be supplied. The syntax is **invokeBO 'BO Name' | \$variable | "xpath" using "xpath" for action**; The valid actions are as follows:

- **read**. This action reads the current view of the BO data.
- **add**. This action will add the object and read and return the resulting view of the BO.
- **fastAdd**. This action will add the object but does not perform a subsequent 'read' to return the resulting view of the BO. This option is better than add for performance purposes if there is no reason to re-read the record.
- **update**. This action will update the object and read and return the resulting view of the BO. This action executes a 'merge' of the information specified in the invoke statement's request XML document with existing BO data. Using this action allows the script to only indicate the elements that are changing.
- **fastUpdate**. This action will update the object but does not perform a subsequent 'read' to return the resulting view of the BO. This option is better than update for performance purposes if there is no reason to re-read the record.
- **delete**. This action deletes the object.
- **replace**. This action is an alternate to the update action. The replace action completely replaces existing BO data with the information in the request document. Typically, the replace action is used when a BO contains a list because it is easier to simply replace all instances of a list rather than attempt a list merge, which requires special logic to [delete a list instance](#) explicitly.

Note: The replace action must be used when using the UI map functionality to [Upload a CSV File](#).

Note: The replace action is currently not supported for any maintenance object that is maintained in a 'fixed' page that uses a list metaphor to show all the records in the page at once. Currency is an example of this type of page.

Examples:

```
invokeBO 'BusinessObject' using "dataArea" for fastAdd;
invokeBO $variableBO using "dataArea" for fastUpdate;
invokeBO "daName/boElement" using "dataArea" for replace;
```

The syntax of the invoke statements for both a business service and service script are similar. The BS / SS is specified along with the XPath reference to the group name:

- **invokeBS** 'BS Name' | \$variable | "xpath" using "xpath";

- `invokeSS 'SS Name' | $variable | "xpath" using "xpath";`

The examples use the `invokeBS` statement but the statements are similar for the `invokeSS` statement.

```
invokeBS 'BusinessService' using "dataArea";
invokeBS $variableBS using "dataArea";
invokeBS "daName/bsElement" using "dataArea";
```

BO Warnings. Note that for BPA scripting, the `invoke` statements may also indicate how to handle warnings.

| Syntax | Description | Examples |
|-----------------------|---|--|
| with warn asError | Indicates that a warning should be treated as an error displayed in the UI map. The text asError is optional. | <code>invokeBO 'BusinessObject' using "dataArea" for</code> <code>invokeSS 'ServiceScript' using "dataArea" with</code> |
| with warn popup | Indicates that a warning should be presented in the standard framework popup. In this scenario, the user is presented with standard OK and Cancel buttons. If the user clicks OK, it means that the process should continue. If the user clicks Cancel, the processing should discontinue. This is the recommended setting. | <code>invokeBS "daName/ bsElement" using "dataArea" with warn popup;</code> |
| with warn suppress | Indicates that a warning should be suppressed. This is the default if no warning syntax is added to the invoke statement. | <code>invokeBS "daName/ bsElement" using "dataArea" with warn suppress</code> <code>invokeSS 'ServiceScript' using "dataArea";</code> |

Note: For service scripts, all objects invoked from the service script will inherit their warning level. Therefore, if the service script is invoked **with warn**, all nested `invoke` statements will also be invoked **with warn**.

For BPA scripts, there should also be logic following the invocation to handle errors and warnings (if **with warn as popup** is used). The system variable `$WARNING` is set to **true** if the user has clicked the Cancel button in the warning popup. If a map was shown, the logic should redisplay the map (where the warning message will be redisplayed.) This allows the user to potentially make changes and save again. If no map was shown prior to the warning, then the logic should terminate.

The system variable `$ERROR` indicates that an error was received. If a map was shown prior to the error, then the logic should redisplay the map where the error will be shown. If no map was shown, then the product provides a BPA Script **F1-HandleErr** that should be used to display the error. The following is an example of typical error handling logic.

```
invokeBO "F1-DetermineBo/output/  
bo" using "boSchema" for update with warn popup;  
if (" $WARNING")  
  if ("map_schema/action = 'DEL'")  
    terminate;  
  else  
    goto maintMap;  
  end-if;  
end-if;  
if (" $ERROR")
```

```

if ("map_schema/action != 'DEL'")
  goto maintMap;
else
  transferControl 'Fl-HandleErr';
end-if;
end-if;

```

System and Global Variables

The following tables highlight system and global variables available for script writing.

System Variables - All Script Types

The following system variables are available for all script types (service scripts, plug-in scripts, and BPA scripts).

| Variable | Description | Example |
|------------------------------|--|--|
| \$BLANK | Represents an empty node. | <pre> if ("string(parm/spouse/ name) != \$BLANK") goto addSpouse; end-if; </pre> |
| \$CURRENT-DATE | <p>Represents the current date.</p> <p>For BPA scripts, this is the browser date.</p> <p>For server scripts this is the server date (and is affected by the system date override logic).</p> | <pre> move "\$CURRENT- DATE" to \$tempDate; </pre> |
| \$CURRENT-STD-DTTM | Represents the current date-time expressed in standard time (meaning without any adjustments for summer time / daylight savings time). | <pre> move "\$CURRENT-STD- DTTM" to \$tempDateTime; </pre> |
| \$DEVICE-OS | Represents the user's device operating system. | <pre> move "\$DEVICE- OS" to \$tempDeviceOs; </pre> |
| \$DEVICE-BROWSER | Represents the user's device browser. | <pre> move "\$DEVICE- BROWSER" to \$tempDeviceBrowser; </pre> |
| \$DEVICE-DISPLAY-TYPE | Represents the user's device screen display type whether it is Desktop size or Medium or Small size. Returned values may be like oraDesktop, oraTablet and oraPhone. | <pre> move "\$DEVICE-DISPLAY- TYPE" to \$tempDeviceDisplayType; </pre> |
| \$DEVICE-INFO | Provides the combination of all three device properties (DEVICE-OS, DEVICE-BROWSER and DEVICE-DISPLAY-TYPE) and each property value is separated by semi-colon. | <pre> move "\$DEVICE- INFO" to \$tempDeviceInfo; </pre> |

System Variables - BPA Scripts Only

The following system variables are only available / applicable for BPA script types.

| Variable | Description | Example |
|-----------------------|--|--|
| \$DOUBLE_QUOTE | Represents a double quote. | <pre>move "\$DOUBLE_QUOTE" to \$tempField;</pre> |
| \$SINGLE_QUOTE | Represents an apostrophe. | <pre>move "\$SINGLE_QUOTE" to \$tempField;</pre> |
| \$SPACE | Contains a single space value. | <pre>move "\$SPACE" to \$tempField;</pre> |
| \$SYSTEM-DATE | Represents the server date. Note that this date is affected by the system date override logic) | <pre>move "\$SYSTEM-DATE" to \$tempDate;</pre> |

System Variables - Server Scripts Only

The following system variables are only available / applicable for service script and plug-in script types.

| Variable | Description | Example |
|-----------------------------------|--|--|
| \$ADDITIONAL-IP-INFO | An HTTP request includes an "additional IP address" header field. This may be populated by an implementation if there is some information available on the proxy server or load balancer, such as the originating IP address. | <pre>move "\$ADDITIONAL-IP-INFO" to "parm/request/headerIpAddress";</pre> |
| \$CURRENT-DTTM | Represents the current date-time. | <pre>move "\$CURRENT-DTTM" to \$tempDateTime;</pre> |
| \$F1-INSTALLATION-TIMEZONE | Represents the time zone code defined on the installation options . | <pre>move "\$F1-INSTALLATION-TIMEZONE" to \$timeZone;</pre> |
| \$LANGUAGE | Represents the language code the script is using. Typically this is the user's default language. | <pre>move "\$LANGUAGE" to \$tempLanguage;</pre> |
| \$PROCESS-DATE | Represents the process date. The process date differs from the current date because the process date will remain consistent throughout the duration of the process being executed. For example, if a service script stores several business objects – the process date is initialized at the start of the service script execution and each business object will have the same process date defaulted. The current date, especially the current date time, will reflect the actual time of processing. | <pre>move "\$PROCESS-DATE" to \$tempDate;</pre> |
| \$PROCESS-DTTM | Represents the process date-time. Note that the process date and time is initialized at the start of a particular process and will not reflect the exact date and time of an update. | <pre>move "\$PROCESS-DTTM" to \$tempDateTime;</pre> |
| \$REQUESTING-IP-ADDRESS | Represents the IP address from the HTTP request. Note that if the request is routed through a proxy server or load balancer, this IP address is be the IP address of the proxy or load balancer, not the IP address of the end user. Refer to the \$ADDITIONAL-IP-INFO variable for information. | <pre>move "\$REQUESTING-IP-ADDRESS" to "parm/request/systemIpAddress";</pre> |

Global Variables

BPA scripts and service scripts have access to the values defined in [Global Context](#).

When a BPA script is launched from the user interface, these variables will be automatically initialized. They may be referenced with a single dollar sign in front of the field name. For example if PER_ID is a supported global variable, then \$PER_ID can be referenced within the BPA script:

```
move "$PER_ID" to "schema/customerId";
```

For service scripts, global variables may only be referenced if the service script has been invoked directly from a BPA script or a zone on a portal. When a service script is invoked from a BPA script or portal zone, it will have access to the suite of global context variables populated in the UI session. For service scripting, the global fields must be prefixed by two dollar signs (instead of one like in BPA scripting). For example if PER_ID is a supported global context variable, then \$\$PER_ID can be referenced within the service script.

```
move $$PER_ID to "schema/customerId";
```

Note: As described in [Context Variables](#), a service script may declare context variables that use the same two dollar sign syntax.

Perform Script and Transfer Control Statements

The edit data step supports functionality analogous to the [Perform script](#) step type and the [Transfer Control](#) step type. These are both applicable only to BPA scripts.

| Syntax | Valid Values | Comments |
|-----------------|---|--|
| performScript | 'BPA Script Name' | Script to perform is explicitly provided. |
| | \$Variable | Script to perform is found in a variable. |
| | "XPath" | Script to perform is found in an element, referenced by its XPath. |
| transferControl | Analogous to the performScript statement | |

Note: When the script named in the **performScript** statement has finished, control will be returned to the calling BPA script. When the script named in the **transferControl** statement has finished, you will not be returned to the calling script, complete control will be granted to the transferred to script.

Navigate Statement

The edit data step supports functionality analogous to the [Navigate to a page](#) step type. This is applicable only to BPA scripts.

| Syntax | Valid Values | Comments |
|----------|-------------------|--|
| navigate | 'Navigation Code' | Navigation option is explicitly provided. |
| | \$Variable | Navigation option is found in a variable. |
| | "XPath" | Navigation option is found in an element, referenced by its XPath. |

In addition, the edit data step supports the ability to indicate that the sidebar should be refreshed when navigating. This is only applicable to BPA scripts.

| Syntax | Valid Values |
|----------------------------|--|
| navigateAndReloadDashboard | Analogous to the navigate statement |

Declare BO with BO Group

This statement is specific to BPA scripts that plan to use the base script Main BO Maintenance Processing (**F1–MainProc**) for its Generate Edit Map statements. This script expects that the data used to display in the map is within a **boGroup** tag.

| Syntax | Valid Values | Comments |
|----------------------|--------------|---|
| declareBOWithBOGroup | 'BO Name' | BO is explicitly provided. |
| | \$Variable | BO is found in a variable. |
| | "XPath" | BO is found in an element, referenced by its XPath. |

The following table highlights additional syntax for this statement.

| Syntax | Valid Values |
|--------|-----------------------|
| as | 'Dynamic Schema Name' |

Examples:

```
declareBOWithBOGroup 'BusinessObject' as 'newMapSchema';
declareBOWithBOGroup $variableBO as 'newMapSchema';
declareBOWithBOGroup "daName/boElement" as 'newMapSchema';
```

Invoke Map Statement

The edit data step supports functionality analogous to the [Invoke map](#) step type. This is applicable only to BPA scripts.

| Syntax | Valid Values | Comments |
|-----------|--------------|---|
| invokeMap | 'Map Name' | UI Map is explicitly provided. |
| | \$Variable | UI Map is found in a variable. |
| | "XPath" | UI Map is found in an element, referenced by its XPath. |

The following table highlights additional syntax for this statement.

| Syntax | Valid Values | Comments |
|--------|------------------------|---|
| using | "Data Area group name" | Indicates the data area to be passed to and from the server when rendering the HTML form associated with the map. |
| target | bpa | |
| | page | |

| Syntax | Valid Values | Comments |
|--------|--------------|----------|
| | popup | |

Refer to the [Invoke map](#) step type for more information about the **target** values.

If the UI map is configured to return a value, then it can be evaluated using the **\$MAP-VALUE** variable.

```

invokeMap 'UI Map' using "dataArea";

invokeMap $variableMap using "dataArea";

invokeMap "daName/mapElement" using "dataArea" target bpa;

// $MAP-VALUE is a variable returned by the invoked map.
if ("$MAP-VALUE='continue' ")
    goto 300;
else
    terminate;
end if;

```

Generate Edit Map Statements

The 'generate edit map' statements are used to dynamically generate and launch a UI edit map based on a schema definition. The schema used may be a BO schema, a BS schema, an SS schema or a DA schema. This is applicable only to BPA scripts. The generate statement will differ based on the type of schema, but the syntax is analogous.

| Syntax |
|-------------------|
| generateBOEditMap |
| generateBSEditMap |
| generateSSEditMap |
| generateDAEditMap |

The BO code / BS code / SS code / DA code may be specified using a literal (surrounded by single quotes), as a temporary variable or by referencing an XPath schema location (surrounded by double quotes).

The following table highlights additional syntax for this statement.

| Syntax | Valid Values | Comments |
|--------|------------------------|---|
| using | "Data Area group name" | Indicates the data area to be passed to and from the server when rendering the HTML form associated with the map. |
| target | bpa page popup | |

The target values indicate where the generated map should be displayed as described in the [Invoke map](#) step type. If the UI map is configured to return a value, then it can be evaluated using the **\$MAP-VALUE** variable.

The examples use the **generateBOEditMap** but the statements are similar for the other schema types.

```
generateBOEditMap 'BO Name' using "dataArea";
generateBOEditMap $variableMap using "dataArea";
generateBOEditMap "daName/mapElement" using "dataArea" target bpa;

// $MAP-VALUE is a variable returned by the invoked map.
if ("$MAP-VALUE='continue' ")
    goto 300;
else
    terminate;
end if;
```

Terminate Statement

The edit data step supports functionality analogous to the [Terminate](#) step type.

The following is an example of a simple **terminate** step that will stop the script.

```
if ("not (parm/spouse/name) ")
    terminate;
else
    goto addSpouse;
end-if;
```

The **terminate with error** statement is only available in a service script.

Note: For issuing an error from a BPA script refer to [Useful Tips and Tricks](#).

| Syntax | Attributes | Comments |
|--|--|--|
| terminate with error (x, y %n= element=) | 'x' represents the message category 'y' represents the message number %n="Element XPath" or %n='literal' element='Element XPath' or element=\$variable | Required. Required. Specify the substitution parameters supported by the message using either literal values or XPath references. When the value to substitute is an element within a list, use the XPath of the element within the list qualified by the list occurrence. Optionally specify an element name within a UI map to highlight as part of the error. When the element in error is within a list, use the XPath of the element within the list qualified by the list occurrence. |

Example of a simple field:

```
if ("string(customer/lastName) = $BLANK")
    terminate with error (8000, 1001 %1="customer/  
lastName" %2='Last name required' element='customer/lastName');
end-if;
```

Example of terminate where the element to mark is in a list:

```
for ($list in "parm/hard/newBusinessObject/listName")
    if /** check some condition for elementName
```

```

        terminate with error (11000, 11000 %1="$list/
elementName" element='$list/elementName');
    end-if;
end-for;

```

Fastpath: For more information on presenting errors in a UI map, please refer to [Display Errors](#).

Invoking Groovy Code

If you have a plug-in script or a service script that mixes XPath scripting and Groovy scripting, the edit data step supports the ability to invoke Groovy code using the syntax **invokeGroovy 'method'**; where 'method' is the name of a method defined in a **Groovy Members** step within the script. Only methods that do not receive arguments and return void can be invoked in this way. However, the method invoked from the edit data step can be supported by additional Groovy code in other **Groovy Members** step types.

Example Edit Data step:

```
invokeGroovy 'invoke';
```

Example Groovy Members step:

```

void invoke() {
    initParms()
    readBO()
    initConfig()
    retrieve()
    updateBO()
}

```

Note: As mentioned in [Using Groovy Within Scripts](#), if this is a plug-in script and the code is only Groovy, you should use the **Groovy** script engine version rather than the above technique. This is considered more efficient as it avoids the conversion of the data to and from the XML interface.

Debugging a BPA Script

If a BPA script has height greater than zero, then selected nodes of the script's data area can be displayed at runtime. The XML data is displayed during script execution within the BPA script's display area. Specify the XPath of an XML node from any of the BPA script's data areas, between the paired characters: '%+' and '+%'.

For example, the entire contents of the schema group node named 'input', and the specific contents of the schema element named 'output/status' will be displayed in the BPA script's display area. The debug text must be entered into the BPA script's text area and not within the script's edit data field. Debug text can be declared for any explicit step of the script.

```
display input: %+input+% , and output status: %+output/status+%
```

Useful Tips and Tricks

This section provides some suggestions about how to implement some common logic.

Finding the Logged In User in a BPA

For server based scripts, the **\$USER** variable is populated with the current logged in user. This variable is not available for BPA scripts. The BPA can call the service script **F1-GetUser** if this information is needed.

Issuing an Error from a BPA script

For server based scripts, you use the **terminate with error** statement to return an error message to display to the user. The BPA can display that error by transferring control to **F1-HandleErr** as described in the [Declare and Invoke Schema Based Objects](#). This is not supported in a BPA script. A technique that is available to a BPA for issuing an

error is to call the business service **F1-RethrowError** passing the error details. This business service populates the appropriate system error fields needed to issue the error. Then transfer control to **F1-HandleErr**.

```
if ("string($assignedToUser) != string(F1-GetUser/user) ")
  declareBS 'F1-RethrowError' as 'errorMsg';
  move '11010' to "errorMsg/messageCategory";
  move '11511' to "errorMsg/messageNumber";
  move "$toDoEntryId" to "errorMsg/messageParameters/+parameters/
parameterValue";
  invokeBS 'F1-RethrowError' using "errorMsg";
  transferControl 'F1-HandleErr';
end-if;
```

Go To Steps

Go to steps allow you to jump to a step other than the next step. Additional fields required for **Go To** steps:

Next Step defines the step to which the script should jump.

Height Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

CAUTION: Guiding scripts that interact with the user using the script area are limited to surf over fixed pages only and are considered legacy functionality. This technique is not supported on top of portal pages and is planned to be deprecated in a future release.

Height steps are used to change the height of the [script area](#) to be larger or smaller than the standard size.

The following additional fields are required for **Height** steps:

Script Window Height defines the number of **Pixels** or the **Percentage** (according to the **Height Unit**) that the script window height should be adjusted. The percentage indicates the percentage of the visible screen area that the script area uses. For example, a percentage value of **100** means that the script area will use the entire area.

Note: Standard Number of Pixels. The default number of pixels used by the script area is **75**.

Note: Adjust script height in the first step. If you want to adjust the height of the script area, it is recommendation to define the **height** step type as your first step. Otherwise, the script area will open using the standard height and then readjust, causing the screen to redisplay.

Note: Hide script area. You could use this type of step to set the height to **0** to hide the script area altogether. This is useful if the script does not require any prompting to the user. For example, perhaps you define a script to take a user to a page and with certain data pre-populated and that is all.

Note: Automatically close script area. If you want the script area to close when a script is completed, you could define the final step type with a height of 0.

Input Data Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

CAUTION: Guiding scripts that interact with the user using the script area are limited to surf over fixed pages only and are considered legacy functionality. This technique is not supported on top of portal pages and is planned to be deprecated in a future release.

Input data steps cause the user to be prompted to populate an input field in the script area. The input value can be saved in a field on a page or in temporary storage. A **Continue** button always appears adjacent to the input field. You may configure steps of this type to display one or more buttons in addition to the **Continue** button. For example, you may want to provide the ability for the user to return to a previous step to fix incorrect information. The user may click on any of these buttons when ready for the script to continue.

The following additional fields are required for **Input Data** steps:

Destination Field Type and **Destination Field Name** define where the input field will be saved. The **Field Type** defines where the field is located. The **Field Name** defines the name of the field. The following points describe each field type:

- **Page Data Model.** Use this field type to put the input field into a field that resides on any of the tab pages in the [object display area](#) (i.e., the field populated doesn't have to reside on the currently displayed tab page, it just has to be part of the object that's currently displayed). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**.
- **Temporary Storage.** Use this field type to put the input field into temporary storage. Use **Field Name** to name the field in temporary storage. Refer to [How To Name Temporary Storage Fields](#) for more information.
- **User Interface Field.** Use this field type to put the input field into a field that resides on the currently displayed tab page. Note, if you want to execute underlying default logic, you must populate a **User Interface Field**. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

The **Prompt Values** grid may be used to define additional buttons. A separate button is displayed in the script area for each entry in this grid.

- **Prompt Text** is the verbiage to appear on the button. Refer to [How To Substitute Variables In Text](#) for a description of how you can substitute field values into the prompts.
- **Sequence** controls the order of the buttons.
- **Next Script Step** defines the step to execute if the user clicks the button.

Invoke Business Object Steps

Invoke business object steps allow you to interact with a [business object](#) in order to obtain or maintain its information.

The following additional fields are required for **Invoke business object** steps:

Use **Warning Level** to indicate whether warnings should be suppressed and if not, how they should be presented to the user. By default, warnings are suppressed. If **Warn As Popup** is used, the warning is displayed using the standard popup dialog. If **Warn As Error** is used processing is directed to the **If Error, Go To** step. This field is only applicable to BPA scripts. Refer to [BO warnings](#) for more information about handling warnings when invoking a BO.

Group Name references the [data area](#) to be passed to and from the server when communicating with the **Business Object**. Indicate the **Action** to be performed on the object when invoked. Valid values are **Add, Delete, Fast Add (No Read), Fast Update (No Read), Read, Replace, Update**.

Fastpath: Refer to [BO Actions](#) for more information about the various actions.

The business object call will either be successful or return an error. The next two fields only appear when the call is issued from a BPA script, to determine the step to which control is passed given the outcome of the call.

If Success, Go To defines the step that is executed if the call is successful. This field is only applicable to BPA scripts.

If Error, Go To defines the step that is executed if the call returns on error. Please note that the error information is held in [global variables](#). This field is only applicable to BPA scripts.

Note: Error technique. Let's assume a scenario where a business object is invoked from a BPA script and the call returned an error. If the BPA script is configured to communicate with the user using a UI map, you may find it useful to invoke the map again to present the error to the user. Alternatively, you may invoke a step that transfers control to a script that displays the error message information and stops.

Invoke Business Service Steps

Invoke business service steps allow you to interact with a [business service](#).

The following additional fields are required for **Invoke business service** steps:

Use **Warning Level** to indicate whether warnings should be suppressed and if not, how they should be presented to the user. By default, warnings are suppressed. If **Warn As Popup** is used, the warning is displayed using the

standard popup dialog. If **Warn As Error** is used processing is directed to the **If Error, Go To** step. This field is only applicable to BPA scripts.

Group Name references the [data area](#) to be passed to and from the server when the **Business Service** is invoked.

The business service call will either be successful or return an error. The next two fields only appear when the call is issued from a BPA script, to determine the step to which control is passed given the outcome of the call.

If Success, Go To defines the step that is executed if the call is successful. This field is only applicable to BPA scripts.

If Error, Go To defines the step that is executed if the call returns on error. Please note that the error information is held in [global variables](#). This field is only applicable to BPA scripts.

Note: Error technique. Let's assume a scenario where a business service is invoked from a BPA script and the call returned an error. If the BPA script is configured to communicate with the user using a UI map, you may find it useful to invoke the map again to present the error to the user. Alternatively, you may invoke a step that transfers control to a script that displays the error message information and stops.

Invoke Function Steps

Note: Functions were implemented prior to the introduction of business services (BS), service scripts (SS) and business objects (BO). The functionality is still supported, but the recommendation for implementations going forward is to use a step that invokes one of the above configuration tool objects in a script rather than defining a function.

Note: BPA scripts only. This step type is only applicable to BPA scripts.

Invoke function steps may be used to retrieve or update data independent of the page currently being displayed. For example, if you design a script that takes different paths based on the customer's customer class, you could invoke a function to retrieve the customer's customer class.

Fastpath: You must set up a function before it can be referenced in a script. Refer to [Maintaining Functions](#) for the details.

The following additional fields are required for **Invoke Function** steps:

Function defines the name of the function. The function's **Long Description** is displayed below.

When a function is invoked, it will either be successful or return an error. The next two fields control the step to which control is passed given the outcome of the function call:

- **If Success, Go to** defines the step that is executed if the function is successful.
- **If Error, Go to** defines the step that is executed if the function returns on error. Refer to [How To Use Constants In Scripts](#) for a list of the global variables that are populated when a function returns an error.

Note: Error technique. If a function returns an error, we recommend that you invoke a step that transfers control to a script that displays the error message information and stops (note, the error information is held in [global variables](#)). You would invoke this script via a **Transfer Control**.

The **Send Fields** grid defines the fields whose values are sent to the function and whose field value source is not **Defined On The Function**. For example, if the function receives an account ID, you must define the name of the field in the script that holds the account ID.

- **Field** contains a brief description of the field sent to the function.
- **Source Field Type** and **Mapped Field / Value** define the field sent to the function. Refer to the description of Source Field under [How To Set Up Move Data Steps](#) for a description of each field type.
- **Comments** contain information about the field (this is defined on the function).

The **Receive Fields** grid defines the fields that hold the values returned from the function. For example, if the function returns an account's customer class and credit rating, you must set up two fields in this grid.

- **Field** contains a brief description of the field returned from the function.

- **Destination Field Type** and **Mapped Field** define the field returned from the function. Refer to the description of Destination Field under [How To Set Up Move Data Steps](#) for a description of each field type.
- **Comments** contain information about how the field (this is defined on the function).

Invoke Map Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

Invoke map steps are used to invoke a [UI Map](#) to display, capture and update data using an HTML form. You may configure steps of this type to display one or more buttons in addition to the **Continue** button. For example, you may want to provide the ability for the user to return to a previous step to fix incorrect information. The user may click on any of these buttons when ready for the script to continue.

The following additional fields are required for **Invoke map** steps:

Group Name references the [data area](#) to be passed to and from the server when rendering the HTML form associated with the **Map**.

Use **Target Area** to designate where the map will be presented.

- Select **BPA Zone** if the map should be presented within the [script area](#).
 -  **CAUTION:** Guiding scripts that interact with the user using the script area are limited to surf over fixed pages only and are considered legacy functionality. This technique is not supported on top of portal pages and is planned to be deprecated in a future release.
- Select **Page Area** if the map should be presented in the [object display area](#), i.e. the frame typically used to house a maintenance page.
- Select **Pop-up Window** if the map should be launched in a separate window.

The **Returned Values** grid contains a row for every button defined on the map.

- **Returned Value** is the value returned when the user clicks the button.
- **Use as Default** can only be turned on for one entry in the grid. If this is turned on, this value's Next Script Step will be executed if the returned value does not match any other entry in the grid. For example, if the user closes a pop-up (rather than clicking a button), the default value will be used.
- **Next Script Step** defines the step to execute if the user clicks the button.

Invoke Service Script Steps

Invoke service script steps allow you to execute a [service script](#).

The following additional fields are required for **Invoke service script** steps:

Use **Warning Level** to indicate whether warnings should be suppressed and if not, how they should be presented to the user. By default, warnings are suppressed. If **Warn As Popup** is used, the warning is displayed using the standard popup dialog. If **Warn As Error** is used processing is directed to the **If Error, Go To** step. This field is only applicable to BPA scripts.

Group Name references the [data area](#) to be passed to and from the server when the **Service Script** is invoked.

The service script call will either be successful or return an error. The next two fields only appear when the call is issued from a BPA script to determine the step to which control is passed given the outcome of the call.

If Success, Go To defines the step that is executed if the call is successful. This field is only applicable to BPA scripts.

If Error, Go To defines the step that is executed if the call returns on error. Please note that the error information is held in [global variables](#). This field is only applicable to BPA scripts.

Note: Error technique. Let's assume a scenario where a service script is invoked from a BPA script and the call returned an error. If the BPA script is configured to communicate with the user using a UI map, you may find it useful to invoke the map again to present the error to the user. Alternatively, you may invoke a step that transfers control to a script that displays the error message information and stops.

Groovy Imports Steps

Note: Server based scripts only. This step type is not applicable to BPA scripts.

Groovy Imports step types provide a free format text area where you list the Groovy classes to be imported for use by the code in **Groovy Member** steps within the script.

Enter a description of the imports step in the **Text** field. Click the adjacent icon to open a window providing more space for entering text.

Enter the list of classes to import in the **Edit Data Text** field using the syntax **import 'class'**; where 'class' is the fully qualified package name of the Groovy class. Click the adjacent icon to open a window providing more space for editing the text.

When saving a script, if the system has been configured accordingly, when the system detects references to a Groovy class that is not explicitly listed in this step, the system warns the user and adds an explicit import for that class. (If no Groovy Import step type exists for the script, one will be added.) Users should review the imported class to ensure it is the expected class, in the case of multiple classes with a similar name.

Note: For security, the classes that may be imported are restricted to those allowed by the Framework. The warning and automatic update to the script is controlled by a property setting. Refer to the topic [Using Groovy Within Scripts](#) for more information.

Groovy Library Interface Steps

Note: Server based scripts only. This step type is not applicable to BPA scripts.

Groovy Library Interface steps are only applicable to **Groovy Library Scripts**. They provide a free format text area where you can list the Groovy methods defined within the script that are available for use by other scripts.

Enter a description of the interface step in the **Text** field. Click the adjacent icon to open a window providing more space for entering text.

Enter the list of interface methods in the **Edit Data Text** field. Click the adjacent icon to open a window providing more space for editing the list.

Note: Every **Groovy Library Script** must have one and only one step of type **Groovy Library Interface**. The supporting code for the available methods is defined using one or more **Groovy Member** steps in the same script. Refer to the topic [Using Groovy Within Scripts](#) for more information.

Groovy Member Steps

Note: Server based scripts only. This step type is not applicable to BPA scripts.

Groovy Member steps provide a free format text area where you can enter Groovy code.

Enter a description of the code block in the **Text** field. Click the adjacent icon to open a window providing more space for entering text.

Enter your code in the **Edit Data Text** field. Click the adjacent icon to open a window providing more space for editing the code.

Note: While it is possible to set up multiple steps of type **Groovy Member** the system treats these steps as a single class for compilation and execution purposes. Refer to the topic [Using Groovy Within Scripts](#) for more information.

Label Steps

Label steps allow you to describe what the next step(s) are doing. Steps of this type are helpful to the script administrators when reviewing or modifying the steps in a script, especially when a script has many steps. When designing a script, the label steps enable you to provide a heading for common steps that belong together. The script tree displays steps of this type in a different color (green) so that they stand out from other steps.

There are no additional fields for **Label** steps.

Mathematical Operation Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

Mathematical operation steps allow you to perform arithmetic on fields. You can also use this type of step to add and subtract days from dates. For example, you could calculate a date 7 days in the future and then use this value as the customer's next credit review date. The following additional fields are required for **Mathematical Operation** steps:

Base Field Type and **Base Field Name** define the field on which the mathematical operation will be performed. The **Field Type** defines where the field is located. The **Field Name** defines the name of the field. The following points describe each field type:

- **Page Data Model.** Use this field type when the field resides on any of the tab pages in the [object display area](#). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**.
- **Temporary Storage.** Use this field type when the field resides in temporary storage. You must initialize the temporary storage field with a Move Data step before performing mathematical operations on the field. Refer to [How To Set Up Move Data Steps](#) for more information.
- **User Interface Field.** Use this field type when the field resides on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

Math Operation controls the math function to be applied to the **Base Field**. You can specify +, -, /, and *. Note, if the base field is a date, you can only use + or -.

Math Field Type, **Math Field Name** and **Math Field Value** define the field that contains the value to be added, subtracted, divided, or multiplied. The following points describe each field type:

- **Current To Do Information.** Use this field type when the value resides on the current To Do entry. Refer to [How To Use To Do Fields](#) for instructions on how to define the appropriate **Field Name**.
- **Page Data Model.** Use this field type when the value resides on any of the tab pages in the [object display area](#). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**.
- **Predefined Value.** Use this field type when the value is a constant. When this field type is used, use **Source Field Value** to define the constant value. Refer to [How To Use Constants In Scripts](#) for more information. Note, if you are performing arithmetic on a date, the field value must contain the number and type of **days/ months/ years**. For example, if you want to add 2 years to a date, the source field value would be **2 years**.
- **Temporary Storage.** Use this field type when the value is a field that you put into temporary storage in an earlier step. The **Field Name** must be the same as defined in an earlier step.
- **User Interface Field.** Use this field type when the value resides in a field on the current tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

Move Data Steps

Move data steps allow you to move data (from a source to a destination). The following additional fields are required for **Move data** steps:

Source Field Type, **Source Field Name** and **Source Field Value** define what you're moving. The following points describe each field type:

- **Context Variable.** Use this field type in a plug-in or service script if the source value is a variable initiated in a higher level script. This is only applicable to Service Scripts and Plug-in Scripts.
- **Current To Do Information.** Use this field type when the source value resides on the current To Do entry. Refer to [How To Use To Do Fields](#) for instructions on how to define the appropriate **Field Name**. This is only applicable to BPA Scripts.
- **Data Area.** Use this field type when the field being compared is one that you put into one of the script's data areas in an earlier step. **Field Name** must reference both a data area structure name as well as the field, for example "parm/charType". Refer to [How To Reference Fields In Data Areas](#) for instructions on how to construct the appropriate **Field Name**.
- **Global Context.** Use this field type when the source value is a [global context variable](#). This is only applicable to BPA Scripts.

- **Page Data Model.** Use this field type when the source value resides on any of the tab pages in the [object display area](#) (i.e., the source field doesn't have to reside on the currently displayed tab page, it just has to be part of the object that's currently displayed). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**. This is only applicable to BPA Scripts.
- **Portal Context.** Use this field type when the source value is a variable in the portal context. This is only applicable to BPA Scripts.
- **Predefined Value.** Use this field type when the source value is a constant value defined in the script. When this field type is used, use **Source Field Value** to define the constant value. Refer to [How To Use Constants In Scripts](#) for instructions on how to use constants.

Note: Concatenating fields together. You can also use **Predefined Value** if you want to concatenate two fields together. For example, let's say you have a script that merges two persons into a single person. You might want this script to change the name of the person being merged out of existence to include the ID of the person remaining. In this example, you could enter a **Source Field Value** of **%ONAME merged into person %PERID** (where **ONAME** is a field in temporary storage that contains the name of the person being merged out of existence and **PERID** contains the ID of the person being kept). Refer to [How To Substitute Variables In Text](#) for a description of how you can substitute field values to compose the field value.

- **Temporary Storage.** Use this field type when the source value is a field that you put into temporary storage in an earlier step. The **Field Name** must be the same as defined in an earlier step.
- **User Interface Field.** Use this field type when the source value resides on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**. This is only applicable to BPA Scripts.

Destination Field Type and **Destination Field Name** define where the source field will be moved. The **Field Type** defines where the field is located. The **Field Name** defines the name of the field. The following points describe each field type:

- **Context Variable.** Use this field type in your plug-in or service script if you use a variable to communicate information to a lower level service script or schema. This is not applicable to BPA Scripts.
- **Data Area.** Use this field type when the destination field resides on one of the scripts data areas. **Field Name** must reference both a data area structure name as well as the field, for example "parm/charType". Refer to [How To Reference Fields In Data Areas](#) for instructions on how to construct the appropriate **Field Name**.
- **Page Data Model.** Use this field type when the destination field resides on any of the tab pages in the [object display area](#) (i.e., the field populated doesn't have to reside on the currently displayed tab page, it just has to be part of the object that's currently displayed). Refer to [How To Find The Name Of Page Data Model Fields](#) for instructions on how to find the appropriate **Field Name**. This is only applicable to BPA Scripts.
- **Portal Context.** Use this field type when the destination to be updated is in the current portal context. This is only applicable to BPA Scripts.
- **Temporary Storage.** Use this field type when the destination field resides in temporary storage. Use **Field Name** to name the field in temporary storage. Refer to [How To Name Temporary Storage Fields](#) for more information.
- **User Interface Field.** Use this field type when the destination field resides on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**. This is only applicable to BPA Scripts.

Note: Conditional field types. The field types **Current To Do Information**, **Page Data Model** and **User Interface Field** are only applicable to BPA scripts.

Navigate To A Page Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

Navigate to a page steps cause a new page (or tab within the existing page) to be displayed in the object display area. Steps of this type are a precursor to doing anything on the page. The following additional field is required for **Navigate to a page** steps:

Navigation Option defines the transaction, tab, access mode (add or change) and any context fields that are passed to the transaction in change mode. For example, if you want a script to navigate to Person - Characteristics for the

current person being displayed in the sidebar, you must set up an appropriate navigation option. Refer to [Defining Navigation Options](#) for more information.

Note: Navigating to a page in update mode. Before you can navigate to a page in change mode, the page data model must contain the values to use for the navigation option's context fields. If necessary, you can move values into the page data model using a [Move Data step](#) first. For example, before you can navigate to a page in change mode with an account ID in context, you may need to move the desired account ID into the ACCT_ID field in the page data model. The actual field name(s) to use are listed as context fields on the [navigation option](#).

Perform Script Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

Perform script steps cause another BPA script to be performed. After the performed script completes, control is returned to the next step in the original script. You might want to think of the scripts referred to on steps of this type as "subroutines". This functionality allows you to encapsulate common logic in reusable BPA scripts that can be called from other BPA scripts. This simplifies maintenance over the long term.

The following additional field is required for **Perform script** steps:

Subscript is the name of the script that is performed.

Press A Button Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

CAUTION: Guiding scripts that interact with the user using the script area are limited to surf over fixed pages only and are considered legacy functionality. This technique is not supported on top of portal pages and is planned to be deprecated in a future release.

Press a button steps cause a button or link text to be 'pressed' in the [object display area](#), the [application toolbar](#) or the [page title area](#). For example, you could use this type of step to add a new row to a person's characteristic (and then you could use a **Move Data** step to populate the newly added row with a given char type and value). The following additional fields are required for **Press a button** steps:

Button Name is the name of the button to be pressed. This button must reside on the currently displayed tab page (or in the application toolbar or page actions toolbar). Refer to [How To Find The Name Of A Button](#) for more information.

Prompt User Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

CAUTION: Guiding scripts that interact with the user using the script area are limited to surf over fixed pages only and are considered legacy functionality. This technique is not supported on top of portal pages and is planned to be deprecated in a future release.

Prompt user steps cause the user to be presented with a menu of options. The options can be presented using either buttons or in the contents of a drop down. You can also use steps of this type to pause a script while the user checks something out (and when the user is ready to continue with the script, they are instructed to click a prompt button). The following additional fields are required for **Prompt User** steps:

Prompt Type controls if the prompt shown in the script area is in the form of **Button(s)** or a **Dropdown**. Note, if you use a **Dropdown**, a Continue button appears adjacent to the dropdown in the script area when the step executes. The user clicks the Continue button when they are ready for the script to continue.

The **Prompt Values** grid contains a row for every value that can be selected by a user. Note, if you use a **Prompt Type** of **Button(s)**, a separate button is displayed in the script area for each entry in this grid.

- **Prompt Text** is the verbiage to appear on the button or in the dropdown entry. Refer to [How To Substitute Variables In Text](#) for a description of how you can substitute field values into the prompts.

- **Sequence** controls the order of the buttons or dropdown entries.
- **Use As Default** can only be turned on for one entry in the grid. If this is turned on for a dropdown entry, this value is defaulted in the grid. If this is turned on for a button, this button becomes the default (and the user should just have to press `Enter` (or `space`) rather than click on it).
- **Next Script Step** defines the step to execute if the user clicks the button or selects the dropdown value.

Set Focus To A Field Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

CAUTION: Guiding scripts that interact with the underlying page's fields and buttons are limited to surf over fixed pages only and are considered legacy functionality. This technique is not supported on top of portal pages and is planned to be deprecated in a future release.

Set focus to a field steps cause the cursor to be placed in a specific field on a page. A **Continue** button always appears in the script area when this type of step executes. The user may click the **Continue** button when they are ready for the script to continue. You may configure steps of this type to display one or more buttons in addition to the **Continue** button. For example, you may want to provide the ability for the user to return to a previous step to fix incorrect information. The user may click on any of these buttons when ready for the script to continue.

The following additional fields are required for **Set focus to a field** steps:

Destination Field Name defines the field on which focus should be placed. This field must reside on the currently displayed tab page. Refer to [How To Find The Name Of User Interface Fields](#) for instructions on how to find the appropriate **Field Name**.

The **Prompt Values** grid may be used to define additional buttons. A separate button is displayed in the script area for each entry in this grid.

- **Prompt Text** is the verbiage to appear on the button. Refer to [How To Substitute Variables In Text](#) for a description of how you can substitute field values into the prompts.
- **Sequence** controls the order of the buttons.
- **Next Script Step** defines the step to execute if the user clicks the button.

Terminate Steps

Terminate steps cause a server-based script to end processing successfully or issue an error.

The following additional fields are required for **Terminate** steps:

Error indicates whether an error should be thrown or not. If error, **Error Data Text** must be specified, indicating the error message and any message substitution parameters. Refer to [Edit Data Syntax](#) the actual syntax of initiating an error message.

Note: The ability to terminate a step in error is only supported for server-based scripts.

Transfer Control Steps

Note: BPA scripts only. This step type is only applicable to BPA scripts.

Transfer control steps cause the current BPA script to terminate and the control to pass to another BPA script. You might want to construct a BPA script with steps of this type when the script has several potential logic paths and you want to segregate each logic path into a separate BPA script (for ease of maintenance).

The following additional fields are required for **Transfer control** steps:

Subscript is the name of the script to which control is transferred.

Additional Topics

The contents of this section provide additional information about steps.

How To Find The Name Of User Interface Fields

This section is only relevant if you are using the legacy capability of BPA scripts to bring a user to a base [fixed page](#) and populate information into fields on that page.

CAUTION: Guiding scripts that interact with and surf over fixed pages are considered legacy functionality. This technique is not supported on top of [portal pages](#) and is planned to be deprecated in a future release.

Follow these steps to find the name of a field that resides on a fixed page:

- Navigate to the page in question.
- Right click in the body of the page.
- Select **Inspect** from the pop-up menu to display the HTML.
- In the search look for the text "Widget Info". Note that if there are multiple sections on the page, you will find multiple "Widget Info" results. Based on the details shown, you are able to confirm which section you are looking for. For example, the following is an example from the Algorithm - Main page:

```
* Widget Info:
*   Widget_ID , Element Type - label info - label
*   ALG_CD, IT - CI_ALG$ALG_CD - Algorithm Code
*   IM_ALG_CD, IM - $SEARCH_FOR_ALG_LBL - Search for Algorithm
*   OWNER_FLG, IS - $OWNER_FLG - Owner
*   DESCR50, IT - $DESCR50 - Description
*   IM_Main_algtypCont, IM - $F1_SHOW_ALG_CTX - Show Algorithm Context Menu
*   ALG_TYPE_CD, IT - $ALG_TYPE_CD - Algorithm Type
*   IM_ALG_TYPE_CD, IM - $SEARCH_ALGTYPE_LBL - Search for Algorithm Type
*   ALG_TYPE_DESCR50, PL - $DESCR50 - Description
*   ALG_TYPE_LONG_DESC, IA - $DESCRLONG - Detailed Description
*   IM_VerScroll_lftArrow, IM - $PREVIOUS_ALG_LBL - Previous Version
*   ALG_VER$recordCount, SN - $OF_LBL - Of
*   IM_VerScroll_rtArrow, IM - $NEXT_ALG_LBL - Next Version
*   IM_ADD, IM - $ADD_ALG_LBL - Add Version
*   IM_DEL, IM - $DELETE_ALG_LBL - Delete Version
*   ALG_VER$EFFDT, IT - $EFFDT - Effective Date
*   L_OWNER_LBL, LP - $OWNER_FLG - Owner
*   ALG_VER$OWNER_FLG, IS - $OWNER_FLG - Owner
*   resultGrid, GD
```

The field names that you'll reference in your scripts are defined on the left side of the HTML (e.g., ALG_CD, DESCR50, ALG_TYPE_CD, etc.).

The names of fields that reside in scrolls are in a slightly different format. The following is an example of the HTML for the version scroll that appears on Algorithm - Main. Notice that the fields in the scroll are prefixed with the name of the scroll plus a \$ sign. For example, the effective date is called **ALG_VER\$EFFDT**.

```
*   IM_VerScroll_lftArrow, IM - $PREVIOUS_ALG_LBL - Previous Version
*   ALG_VER$recordCount, SN - $OF_LBL - Of
*   IM_VerScroll_rtArrow, IM - $NEXT_ALG_LBL - Next Version
*   IM_ADD, IM - $ADD_ALG_LBL - Add Version
*   IM_DEL, IM - $DELETE_ALG_LBL - Delete Version
*   ALG_VER$EFFDT, IT - $EFFDT - Effective Date
*   L_OWNER_LBL, LP - $OWNER_FLG - Owner
*   ALG_VER$OWNER_FLG, IS - $OWNER_FLG - Owner
```

The names of fields that reside in grids are in a slightly different format. The following is an example of the HTML for the algorithm parameters grid that appears on Algorithm - Main. Notice that the fields in the grid are prefixed with the name of the grid plus a :x\$. For example, the algorithm parameter label is called **ALG_PARM:x\$ALG_PARM_LBL**. When you reference such a field in your script, you have the following choices:

- Substitute **x** with the row in the grid (and keep in mind, the first row in a grid is row **0** (zero); this means the second row is row **1**).
- If you want to reference the "current row" (that is, the row in which the cursor will be placed), you can keep the **x** notation (**x** means the "current row").

```
* Widget Info:
*   Widget_ID , Element Type - label info - label
*   ALG_PARM:x$ALG_PARM_LBL, IL - CI_ALG_TYPE_PRM_L$ALG_PARM_LBL - Parameter
*   ALG_PARM:x$SEQNO, IL - $SEQNO - Sequence
*   ALG_PARM:x$ALG_PARM_VAL, IA - $ALG_PARM_VAL - Value
*
```

How To Find The Name Of Page Data Model Fields

You find the name of a **Page Data Model** field in the same way described under [How To Find The Name Of User Interface Fields](#). The only restriction is that you cannot refer to hidden / derived fields. However, you can refer to any of the object's fields regardless of the tab page on which they appear. For example, if you position the object display area to the Main tab of the Account transaction, you can reference fields that reside on all of the tab pages.

CAUTION: If you populate a **Page Data Model** field, none of the underlying default logic takes place. For example, if you populate a customer contact's contact type, none of the characteristics associated with the customer contact type are defaulted onto the customer contact. If you want the underlying defaulting to take place, you must populate a **User Interface Field**.

How To Find The Name Of A Button

This section is only relevant if you are using the legacy capability of BPA scripts to bring a user to a base fixed page and perform functionality by executing existing buttons on that page.

CAUTION: Guiding scripts that interact with and surf over fixed pages are considered legacy functionality. This technique is not supported on top of [portal pages](#) and is planned to be deprecated in a future release.

If you want a **Press a button** step to press a button or click a link in the application toolbar, use one of the following names:

| |
|----------------------|
| Button Name |
| IM_GOBACK |
| IM_HISTORY |
| IM_GOFORWARD |
| IM_menuButton |
| IM_USER_HOME |
| IM_MY_PREF |
| IM_helpButton |

If you want a **Press a button** step to press a button in the page actions toolbar, use one of the following names:

| |
|--------------------|
| Button Name |
| IM_SAVE |

| |
|-------------------------|
| Button Name |
| IM_REFRESH |
| IM_CLEAR |
| IM_COPY |
| IM_DELETE |
| IM_ScrollBack |
| IM_ScrollForward |

The following buttons are also supported:

| Button Name | Comments |
|------------------------------|--|
| IM_TO_DO | |
| IM_CurrentTo Do | This navigates to the To Do Entry page for the user's current To Do. Refer to Working On A To Do for more information. |
| IM_MINIMIZE_DASHBOARD | Pressing this will collapse the sidebar. Note that when a script is finished, it will return the sidebar to the state it was when the script was launched. |
| IM_MAXIMIZE_DASHBOARD | Pressing this will expand the sidebar. Note that when a script is finished, it will return the sidebar to the state it was when the script was launched. |

Follow these steps to find the name of other buttons that reside in the object display area of a fixed page:

- Navigate to the page in question.
- Right click in the body of the page
- Select **Inspect** from the pop-up menu.
- In the search look for the text "Widget Info". Note that if there are multiple sections on the page, you will find multiple "Widget Info" results. Based on the details shown, you are able to confirm which section you are looking for.
- Iconized buttons (e.g., search buttons) are represented as HTML images and their field names are prefixed with **IM**. The following is an example of the HTML on the Algorithm - Main page (notice the **IM** fields for the iconized buttons).

```
* Widget Info:
*   Widget_ID , Element Type - label info - label
*   ALG_CD, IT - CI_ALG$ALG_CD - Algorithm Code
*   IM_ALG_CD, IM - $SEARCH_FOR_ALG_LBL - Search for Algorithm
*   OWNER_FLG, IS - $OWNER_FLG - Owner
*   DESCR50, IT - $DESCR50 - Description
*   IM_Main_algtypCont, IM - $F1_SHOW_ALG_CTX - Show Algorithm Context Menu
*   ALG_TYPE_CD, IT - $ALG_TYPE_CD - Algorithm Type
*   IM_ALG_TYPE_CD, IM - $SEARCH_ALGTYPE_LBL - Search for Algorithm Type
```

- Transaction-specific actions buttons are represented as switches. The following is an example of the HTML on the Batch Job Submission - Main page (notice the **SW** fields for the buttons). Note, if you want to **Set focus** to such a field, you would move a **Predefined Value** of **TRUE** to the switch.

```
*   ACTION_Q_SW, BU - $ACTION_Q_SW - Duplicate & Queue
*   ACTION_CANCEL_SW, BU - $CANCEL_SW - Cancel
```

How To Substitute Variables In Text

You can substitute field values into a step's text string. You do this by prefixing the field name whose value should be substituted in the string with a `%`. For example, the message, "On `%COMPLETION_DTTM` this bill was completed, it's ending balance was `%ENDING_BALANCE`" contains two substitution variables (the bill's completion date / time and the bill's ending balance).

To substitute the value of an element from a data area you need to reference its XPath location as follows: `%=XPath=%`. If you want to substitute the whole XML node, not just the value, you need to reference it as follows `+%XPath+%`.

Only fields linked to the [current To Do](#) and fields that reside in [temporary storage](#) and [global variables](#) can be substituted into a text string.

Note: You can substitute fields that reside in the User Interface or Page Data Model by first moving them into temporary storage (using a **Move data** step).

You can also substitute field values into the verbiage displayed in [prompts](#) using the same technique.

How To Use HTML Tags And Spans In Text Strings and Prompts

You can use HTML tags in a step's text string. For example, the word "Continue" will be italicized in the following text string "Press<i>Continue</i> after you've selected the customer" (the `<i>` and `</i>` are the HTML tags used to indicate that the surrounded text should be italicized).

The following are other useful HTML tags:

- `
` causes a line break in a text string. If you use `

` a blank line will appear.
- ` text ` causes the surrounded text to be colored as specified (in this case, red). You can also use hex codes rather than the color name.

Please refer to an HTML reference manual or website for more examples.

Note: Refer to [Color Contrast](#) for information about the use of the HTML color 'red' and its impact on accessibility.

How To Use Constants In Scripts

Some steps can reference fields called **Predefined Values**. For example, if you want to compare an input value to the letter "Y", the letter **Y** would be defined as a Predefined Value's field value.

Special constants are used for fields defined as switches. When you move **TRUE** to a switch, it turns it on. When you move **FALSE** to a switch, it turns it off.

You can use a [global variable](#) as a Predefined Value. For example, if you wanted to move the current date to a field, you'd indicate you wanted to move a Predefined Value named `%CURRENT_DATE`.

How To Use Global Variables

Some explicit steps can reference fields called **Predefined Values**. In addition to referencing an ad hoc constant value (e.g., the letter **Y**), you can also reference a global variable in such a field value. A global variable is used when you want to reference system data.

Note that when using the Edit Data step type, the variable available are slightly different. Refer to [Edit Data Syntax](#) for details.

The following global variables exist for BPA scripts:

| Variable Name | Comments |
|---------------------------------|--|
| <code>%PARM-<name></code> | This is the value of a parameter of that name passed in to the application when launched via the standard system URL. Refer to Launching A Script When Starting the System for more information on these parameters. |

| Variable Name | Comments |
|-----------------------|---|
| %PARM-NOT-SET | This is to be used to compare against %PARM-< > parameters to check if the parameter has been set or not when the application was launched. A parameter that has not been set would be considered equal to this global variable. It is recommended to compare parameters against this global variable before using them for the first time. |
| %BLANK | A constant that contains a blank value (no value). |
| %SPACE | A constant that contains a single space value. |
| %CURRENT-DATE | The current date as known by the browser, not the server. |
| %SYSTEM-DATE | The server date. Note that this date is affected by the system date override logic) |
| %SAVE-REQUIRED | A flag that contains an indication of whether the data on a page has been changed (and thus requires saving). You may want to interrogate this flag to force a user to save their work before executing subsequent steps. This flag will have a value of TRUE or FALSE . |
| %NEWLINE | A constant that contains a new line character (carriage return). Upon substitution, a line break is inserted in the resultant text.  Note: This constant does not have the desired effect when the resultant text is HTML. For example, a step's text and prompt strings. This is because HTML ignores special characters such as new lines. Refer to How To Use HTML Tags And Spans In Text to learn how to cause a line break in an HTML text. |

To refer to a [global context](#) variable, use %FIELD_NAME. For example, if the field SP_ID is in the global context, you may reference %SP_ID to reference the ID of the service point currently in context. In addition, the following special values are supported:

| Variable Name | Comments |
|---------------------------|---|
| %CONTEXT-PERSONID | A constant that contains the ID of the current person. |
| %CONTEXT-ACCOUNTID | A constant that contains the ID of the current account. |
| %CONTEXT-PREMISEID | A constant that contains the ID of the current premise. |

In addition, if the script is invoking something else via one of the various “Invoke” step types and an error is returned, the following global variables contain information about the error:

| Variable Name | Comments |
|--|--|
| %ERRMSG-CATEGORY %ERRMSG-NUMBER | The unique identifier of the error message number. |
| %ERRMSG-TEXT | The brief description of the error. |
| %ERRMSG-LONG | The complete description of the error. |

How To Name Temporary Storage Fields

Input Data and **Move Data** steps can create fields in temporary storage. You specify the name of the temporary storage field in the step's **Field Name**. The name of the field must not begin with % and must not be named the same as the [global variables](#). Besides this restriction, you can use any **Field Name** that's acceptable to JavaScript (i.e., you can name a field in temporary storage almost anything). Keep in mind that field names are case-sensitive.

How To Work With Dates

Before we discuss how to work with dates in your scripts, we need to point out that there are two types of date fields: date-only and date-time. Date-only fields only contain a date. Date-time fields contain both a date and a time. The following topics describe how to work with dates on the various step types.

Note: If you're working with a field that resides on the database (as opposed to a temporary storage field), the database field name will tell you what type of date it is: date-only fields are suffixed with **DT**, and date-time fields are suffixed with **DTTM**.

Move Data

If you intend to use a **Move data** step to populate a *date-time* field, please be aware of the following:

- If the destination field resides in the *page data model*, the source field value must be in the format YYYY-MM-DD-HH.MM.SS or YYYY-MM-DD. If the field is in the format YYYY-MM-DD, the time of 12:00 am will be defaulted.
- If the destination field resides in the *user interface*, you must use two steps if you want to populate both date and time. To explain this, we'll assume the field you want to populate is called EXPIRE_DTTM:
 - First, you populate the date portion of the field. To do this, you'd move a date (this value can be in any valid date format that a user is allowed to enter) to a field called EXPIRE_DTTM_FWDDTM_P1. In other words, you suffix **_FWDDTM_P1** to the field name.
 - If you want to populate the time, you'd move the time (again, the field value can be in any format that a user could use to enter a time) to a field called EXPIRE_DTTM_FWDTTM_P2. In other words, you suffix **_FWDDTM_P2** to the field name.

If you intend to use a **Move data** step to populate a *date-only* field, please be aware of the following:

- If the destination field resides in the *page data model*, the source field value must be in the format YYYY-MM-DD.
- If the destination field resides in the *user interface*, the source field can be in any valid date format that a user is allowed to enter.

Note: **%CURRENT-DATE**. Keep in mind that the [global variable](#) **%CURRENT-DATE** contains the current date and you can move this to either a page data model, user interface, or temporary storage field. If you move **%CURRENT-DATE** to a temporary storage fields, it is held in the format YYYY-MM-DD.

Mathematical Operation

If you intend to use a **Mathematical operation** step to calculate a date, you can reference both date-only and date-time fields. This is because mathematical operations are only performed against the date portion of date-time fields.

Mathematical operations are limited to adding or subtracting days, months and years to / from a date.

Note: A useful technique to perform date arithmetic using the current date is to move the [global variable](#) **%CURRENT-DATE** to a temporary storage field and then perform the math on this field.

Input Data

If you intend to use an **Input data** step on a *date-time* field, please be aware of the following:

- If the field resides in the *page data model*, the user must enter a value in the format YYYY-MM-DD-HH.MM.SS (and therefore we do not recommend doing this).
- If the field resides in the *user interface*, you must use two steps if you want to populate both date and time. To explain this, we'll assume the field you want to populate is called EXPIRE_DTTM:
 - First, you populate the date portion of the field. To do this, you'd input the date (this value can be in any valid date format that a user is allowed to enter) in a field called EXPIRE_DTTM_FWDDTM_P1. In other words, you suffix **_FWDDTM_P1** to the field name.
 - If you want to populate the time, you'd input the time (again, the field value can be in any format that a user could use to enter a time) in a field called EXPIRE_DTTM_FWDTTM_P2. In other words, you suffix **_FWDDTM_P2** to the field name.

If you intend to use an **Input data** step to populate a *date-only* field, please be aware of the following:

- If the field resides in the *page data model*, the user must enter a value in the format YYYY-MM-DD (and therefore we do not recommend doing this).
- If the field resides in the *user interface*, the user can enter any valid date format.

How To Use To Do Fields

As described under [Executing A Script When A To Do Entry Is Selected](#), you can set up the system to automatically launch a script when a user selects a To Do entry. These types of scripts invariably need to access data that resides on the selected To Do entry. The following points describe the type of information that resides on To Do entries:

- **Sort keys.** These values define the various ways a To Do list's entries may be sorted. For example, when you look at the bill segment error To Do List, you have the option of sorting the entries in error number order, account name order, or in customer class order. There is a sort key value for each of these options.
- **Message parameters.** These values are used when the system finds *%n* notation within the message text. The *%n* notation causes field values to be substituted into a message before it's displayed. For example, the message text **The %1 non-cash deposit for %2 expires on %3** will have the values of three fields merged into it before it is displayed to the user (%1 is the type of non-cash deposit, %2 is the name of the customer, and %3 is the expiration date of the non-cash deposit). Each of these three values is stored as a separate message parameter on the To Do entry.
- **Drill keys.** These values are the keys passed to the page if a user drilled down on the entry (and the system wasn't set up to launch a script). For example, a To Do entry that has been set up to display an account on the account maintenance page has a drill key of the respective account ID.
- **To Do ID.** Every To Do entry has a unique identifier referred to as its To Do ID.

You can access this information in the following types of steps:

- **Move Data** steps can move any of the above to any data area. For example, you might want to move a To Do entry's drill key to the page data model so it can be used to navigate to a specific page.
- **Conditional Branch** steps can perform conditional logic based on any of the above. For example, you can perform conditional logic based on a To Do entry's message number (note, message numbers are frequently held in sort keys).
- **Mathematical Operation** steps can use the above in mathematical operations.

A To Do entry's sort key values are accessed by using a **Field Type** of **Current To Do Information** and a **Field Name** of **SORTKEY[index]**. Note, you can find an entry's potential sort keys by displaying the entry's To Do type and navigating to the [Sort Keys](#) tab. If you want to reference the first sort key, use an index value of **1**. If you want to use the second sort key, use an index value of **2** (and so on).

A To Do entry's drill key values are accessed by using a **Field Type** of **Current To Do Information** and a **Field Name** of **DRILLKEY[index]**. Note, you can find an entry's potential drill keys by displaying the entry's To Do type and navigating to the [Drill Keys](#) tab. If you want to use the first drill key, use an index value of **1**. If you want to use the second drill key, use an index value of **2** (and so on).

A To Do entry's message parameters are accessed by using a **Field Type** of **Current To Do Information** and a **Field Value** of **MSGPARAM[index]**. Note, because a To Do type can have an unlimited number of messages and each message can have different parameters, finding an entry's message parameters requires some digging. The easiest way to determine these values is to display the To Do entry on [To Do maintenance](#). On this page, you will find the entry's message category/number adjacent to the description. Once you know these values, display the message category/number on [Message Maintenance](#). You'll find the message typically contains one or more *%n* notations (one for each message parameter). For example, the message text **The %1 non-cash deposit for %2 expires on %3** has three message parameters. You then need to deduce what each of the message parameters are. You do this by comparing the message on the To Do entry with the base message (it should be fairly intuitive as to what each message parameter is). If we continue using our example, %1 is the non-cash deposit type, %2 is the account name, and %3 is the expiration date. You can access these in your scripts by using appropriate index value in **MSGPARAM[index]**.

A To Do entry's unique ID is accessed by using a **Field Type** of **Current To Do Information** and a **Field Value** of **TD_ENTRY_ID**.

In addition, any of the above fields can be [substituted into a text string or prompt](#). Simply prefix the To Do field name with a % as you would fields in temporary storage. For example, assume you want your script to display the following

text in the script area: "ABC Supply does not have a bill cycle" (where ABC Supply is the account's name). If the first sort key linked to the To Do entry contains the account's name, you'd enter a text string of **%SORTKEY[1] does not have a bill cycle**.

How To Reference Fields In Data Areas

Various step types involve referencing field elements residing in the [script's data areas](#). To reference an element in a data area you need to provide its absolute XPath notation starting from the data area name. For example, use "F1-BatchControl/batchControl" to reference a top-level "batchControl" element in a script data area called "F1-BatchControl".

You don't have to type in long XPath notations. Use the **View Script Schema** hyperlink provided on the [Script - Step](#) tab page to launch the script's data areas schema.

Figure 4: Schema Viewer

Doing this opens the [schema viewer](#) window where you can:

- Click on the field element you want to reference in your script step. The system automatically populates the text box on the top with the element's absolute XPath notation.
- Copy the element's XPath notation from the text box to your script.

You can also use the **View Data Area**, **View Service Script Data Area**, or **View Plug-In Script Data Area** links on [Script - Data Area](#) to the same effect. These open up the schema viewer for a specific data area respectively.

Script Engine Version 2 and Above Notes

Scripting using the engine version 2 or above requires some extra syntax to take advantage of XPath 2 functionality. In general, any variable declared will be assumed to be a string. This means, that if you intend to construct a mathematical statement then it is necessary to explicitly declare the data type of variables as integers, numbers, or dates.

Note: Unless otherwise noted, all XPath examples in this topic are for the Version 1 engine – which means XPath 1. Statements that function using XPath 1 will not necessarily work for XPath 2. This is especially true when executing math, see below for examples.

Date and Time Arithmetic

XPath date/time and interval data types support arithmetic operations ('+', '-', '*' etc.) and functions, which can be used for time calculations in the same way as '1 + xs:integer(value)' is used for numeric calculations.

Compare time duration:

```
if (xs:dateTime(fn:current-dateTime()) - xs:dateTime($updateDateTimeX)
ge xs:dayTimeDuration(concat('PT', BO/
hoursBetweenStatisticsUpdate, 'H')))
  goto 60;
end-if;
```

Compare one date to another:

```
if (xs:date(parm/endDate) < xs:date(parm/startDate))
  terminate with error (11108, 11507 element='endDate');
end-if;
```

Compare a date against today's date:

```
if ("xs:date(parm/startDate) <= xs:date($CURRENT-DATE)")
    terminate with error (11108, 11507 element='endDate');
end-if;
```

Calculate the end of month:

```
// covert to ISO
move "concat($year, '-', $mon2, '-01T00:00:00')" to $monthStart;

// calculate
move "xs:dateTime($monthStart) + xs:yearMonthDuration('P1M') - xs:dayTimeDuration('P0DT1M')
    to $monthEnd;

// convert from ISO to OUAF
move "concat($year, '-',
$mon2, '-', substring(string($monthEnd), 9, 2), '-23.59.59')" to $endDateTime;
```

Note: XPath date/time/interval formats use the ISO standard, which needs to be converted to/from formats supported in the framework.

Comparing Date/Times in String Format

Any ISO-like string format for date/time preserves the YYYY MM DD HH MM SS sequence, which is zero-padded. Regardless of separators, this format will remain appropriate for comparison operations. In particular, date/time values in the framework format “YYYY-MM-DD.HH.MM.SS” can be used with “=”, “!=”, as well as “>”, “>=”, “<”, “<=” operators.

```
// retrieve framework date/time value
invokeBS 'CM-MAXMSRMT' using "CM-MAXMSRMT";
move "string(cm-MAXMSRMT/results[1]/measurementDateTime)" to $lastMsmtDT;

// construct another date/time
move "concat($year, '-01-01-00.00.00')" to $startDateTime;

// compare using string operators
if ("{$lastMsmtDT} >= {$startDateTime}")
    move "substring($lastMsmtDT, 1, 4)" to $latestMsmtYear;
```

Converting Date/Times Between Framework and ISO

Conversion of date/time from framework format to ISO is only necessary for date/time arithmetic. Comparisons can be done with the framework format directly. The only difference between the framework format and ISO date/time formats is in the separators:

Framework: “YYYY-MM-DD.HH.MM.SS”

ISO: “YYYY-MM-DDTHH:MM:SS”

Example of converting from the framework format to ISO:

```
move "concat(substring($ouafDT, 1, 10), 'T', translate(substring($ouafDT, 12), '.', ':'))" to $isoDT;
```

Example of converting from ISO to the framework format:

```
move "concat(substring($isoDT, 1, 10), '.', translate(substring($isoDT, 12), ':', '.'))" to $ouafDT;
```

Round Money With a Dynamic Currency Scale

Because different currencies support a different number of decimals, the framework provides an API for rounding a monetary amount based on a given currency.

```
move "parm/amount" to $qty;
move "currency/decimals" to $decimals;
move "fn:round(xs:decimal($qty) * math:exp10(xs:double($decimals)))
  div math:exp10(xs:double($decimals))" to "parm/roundedAmount";
```

Looping through Sequences

In XPath 2 it is possible to organize a for-loop over a sequence of integers, not only a node list.

This example shows a loop over a range of months. This is a sequence-forming construct in XPath. The XPath node list, which we are familiar with, is just another type of sequence.

```
for ($month in "1 to 12")
```

This example shows a loop over a give range of years in descending order:

```
for ($year in "fn:reverse(parm/startYear to parm/endYear)")
  move "concat($year, '-01-01-00.00.00')" to $startDateTime;
  move "concat($year, '-12-31-23.59.59')" to $endDateTime;
  ...
```

This example shows a loop through a node list using 'index', so that other node lists can be accessed:

```
for ($idx in "1 to count(parm/touData/touList)")
  move "parm/touData/
  touList[$idx]" to $tou; // access any list with this index
```

The above syntax can be used as an elegant alternative to maintaining indices separately, for example instead of the following:

```
move "0" to $idx;
for ($item in "parm/touData/touList")
  move "1 + xs:integer($idx)" to $idx;
```

String Padding and Decimal Formatting

This is used with specific input formats or output formatting. It is applicable to zero, space and other types of padding.

This example shows prefixing for date/time components, for example producing "2010-01-02" instead of "2010-1-2".

```
move "substring(concat('0',string($month)), string-
length(string($month)), 2)" to $mon2;
```

This example shows suffixing for adding decimal zero-padded alignment, for example producing "12.30" and "4.00" instead of "12.3" and "4". The example performs 3 tasks: rounding to 2 decimals, inserting a period if necessary, and zero padding.

```
// round and zero-pad to 2 decimals
move "$item/amount" to $qty;
move "fn:round(xs:double($qty) * 100) div 100" to $qty;
move "string($qty)" to $qty;
```

```
move "concat(substring-
before(concat($qty, '.'), '.'), '.', substring(concat(substring-
after($qty, '.'), '00'), 1, 2))" to $qty;
```

Ternary Operation

This makes a choice between values based on a condition, so that it could be used in a single expression instead of an if/else block. It is known in C/C++ as 'cond ? value1 : value2' or in BASIC as 'IFF(cond, value1, value2)'. In XPath the syntax is: "if (cond) then value1 else value2". Note this is not the top-level scripting if-statement block.

In XPath this is an expression, which can be combined with other expressions. In scripting it can be used as:

```
move "if (string(D1-UnitOfMeasure/
measuresPeakQuantity) = 'D1MP') then 'D1MX' else 'D1SM' " to $func;
```

Pipeline Processing

In scripting, it is not easy to create a simple reusable piece of code as there are no local functions, and a separate script call is a coding overhead and requires packing/unpacking parameters. To avoid copying and pasting the same code block between similar script stages, consider 'pipelining', which is breaking the overall process into separate top-level steps, some of which could be shared between alternating paths. This is common for parameter preparation and output formatting. An intermediate result between stages can be stored in a "parm" substructure.

Instead of this code:

```
if ("type = A")
  prepare params ...
  call services for A ...
  format output ...
end-if;
if ("type = B")
  prepare params ...
  call services for B ...
  format output ...
end-if;
```

Consider this alternative:

```
prepare params ...

if ("type = A")
  call services for A ...
end-if;
if ("type = B")
  call services for B ...
end-if;

format output ...
```

XPath 2 Functions

Script engine versions 2 and above support XQuery 1.0 Functions and Operators, and the XQuery 1.0 standard itself with some minor limitations. Below are the URLs to both specifications. The first link has the functions/operators available to use from XQuery.

- <http://www.w3.org/TR/xpath-functions/>
- <http://www.w3.org/TR/xquery/>

The following can only access local file systems. (For other protocols like http they will return an empty sequence):

- fn:doc
- fn:collection

Script - Data Area

Use this page to define the data areas used to pass information to and from the server or any other data area describing your temporary storage. Open this page using **Admin > System > Script** and then navigate to the **Data Area** tab.

Note: Conditional tab page. This tab page does not appear for [Groovy Library scripts](#) or [plug-in scripts](#) using the **Groovy** engine version.

Description of Page

The grid contains the script's data areas declaration. For steps that invoke an object that is associated with a schema, you must declare the associated schema as a data area for your script. In addition, if you have defined one or more data areas to describe the script's temporary storage, you need to declare them too. The following bullets provide a brief description of each field on a script data area:

- **Schema Type** defines the type of schema describing the data area's element structure.
- The data area's schema is the one associated with the referenced **Object**. Only objects of the specified Schema Type may be selected.
- **Data Area Name** uniquely identifies the data area for referencing purposes. By default, the system assigns a data area with the associated object name.
- Click on the **View Data Area** link to view the data area's schema in the [schema viewer](#) window.

The **View Service Script Data Area** link appears for service scripts only. Use this link to view the script's parameters data area schema in the [schema viewer](#) window.

The **View Plug-In Script Data Area** link appears only for plug-in scripts using a script engine version. Use this link to view the script's parameters data area schema in the [schema viewer](#) window.

Fastpath: Refer to [A Script May Declare Data Areas](#) for more information on data areas.

Script - Schema

Use this page to define the data elements passed to and from a service script. Open this page using **Admin > System > Script** and then navigate to the **Schema** tab.

Note: Conditional tab page. This tab page only appears for [service scripts](#).

Description of Page

The contents of this section describe the zones that are available on this portal.

The **General Information** zone displays the script name and description.

The [Schema Designer](#) zone allows you to edit the service script's parameters schema. The purpose of the schema is to describe the input and output parameters used when invoking the script.

Note: Refer to [Schema Nodes and Attributes](#) for a complete list of the XML nodes and attributes available to you when you construct a schema.

The **Schema Usage Tree** zone summarizes all cross-references to this schema. For each type of referencing entity, the [tree](#) displays a summary node showing a total count of referencing items. The summary node appears if at least one referencing item exists. Expand the node to list the referencing items and use their description to navigate to their corresponding pages.

Script - Eligibility

Use this page to define a script's eligibility rules. Open this page using **Admin > System > Script** and then navigate to the **Eligibility** tab.

Note: Conditional tab page. This tab page only appears for [BPA scripts](#).

Description of Page

Use the **Eligibility Option** to indicate whether the script is **Always Eligible**, **Never Eligible** or to **Apply Eligibility Criteria**. The remaining fields on the page are only visible if the option is **Apply Eligibility Criteria**.

CAUTION: The following information is not intuitive; we strongly recommend that you follow the guidelines under [The Big Picture Of Script Eligibility](#) before attempting to define this information.

The **Eligibility Criteria Group** scroll contains one entry for each group of eligibility criteria. The following fields may be defined for each group:

- Use **Sort Sequence** to control the relative order in which the group is executed when the system determines if the script should appear in the [script search](#).
- Use **Description** and **Long Description** to describe the criteria group.
- Use **If Group is True** to define what should happen if the eligibility criteria (defined in the following grid) return a value of **True**.
 - Choose **Eligible** if this script should appear.
 - Choose **Ineligible** if this script should not appear.
 - Choose **Check Next Group** if the next criteria group should be checked.
- Use **If Group is False** to define what should happen if the eligibility criteria (defined in the following grid) return a value of **False**.
 - Choose **Eligible** if this script should appear.
 - Choose **Ineligible** if this script should not appear.
 - Choose **Check Next Group** if the next criteria group should be checked.

The grid that follows contains the script's eligibility criteria. Think of each row as an "if statement" that can result in the related eligibility group being true or false. For example, you might have a row that indicates the script is eligible if the current account in context belongs to the residential customer class. The following bullets provide a brief description of each field on an eligibility criterion. Please refer to [Defining Logical Criteria](#) for several examples of how this information can be used.

- Use **Sort Sequence** to control the order in which the criteria are checked.
- Use **Criteria Field** to define the field to compare:
 - Choose **Algorithm** if you want to compare anything other than a characteristic. Push the adjacent search button to select the algorithm that is responsible for retrieving the comparison value.
 - Some products may also include an option to choose **Characteristic**. Choosing this option displays adjacent fields to define the object on which the characteristic resides and the characteristic type. The objects whose characteristic values may be available to choose from depend on your product.
- Use **Criteria Comparison** to define the method of comparison:
 - Choose **Algorithm** if you want an algorithm to perform the comparison and return a value of True, False or Insufficient Data. Push the adjacent search button to select the algorithm that is responsible for performing the comparison.
 - Choose any other option if you want to compare the **Criteria Field** using a logical operator. The following options are available:
 - Use **>**, **<**, **=**, **>=**, **<=**, **<>** (not equal) to compare the **Criteria Field** using standard logical operators. Enter the comparison value in the adjacent field.
 - Use **IN** to compare the **Criteria Field** to a list of values. Each value is separated by a comma. For example, if a field value must equal **1, 3 or 9**, you would enter a comparison value of **1,3,9**.
 - Use **BETWEEN** to compare the **Criteria Field** to a range of values. For example, if a field value must be between **1** and **9**, you would enter a comparison value of **1,9**. Note, the comparison is inclusive of the low and high values.
- The next three fields control whether the related logical criteria cause the eligibility group to be considered true or false:
 - Use **If True** to control what happens if the related logical criterion returns a value of True. You have the options of **Group is true**, **Group is false**, or **Check next condition**. If you indicate **Group is true** or **Group is false**, the script is judged **Ineligible** or **Eligible** based on the values defined above in **If Group is False** and **If Group is True**.
 - Use **If False** to control what happens if the related logical criterion returns a value of False. You have the options of **Group is true**, **Group is false**, or **Check next condition**. If you indicate **Group is true** or **Group is false**, the script is judged **Ineligible** or **Eligible** based on the values defined above in **If Group is False** and **If Group is True**.
 - Use **If Insufficient Data** to control what happens if the related logical criterion returns a value of "Insufficient Data". You have the options of **Group is true**, **Group is false**, or **Check next condition**. If you indicate

Group is true or **Group is false**, the script is judged **Ineligible** or **Eligible** based on the values defined above in **If Group is False** and **If Group is True**.

Merging Scripts

Use the Script Merge page to modify an existing script by copying steps from other scripts. The following points summarize the many diverse functions available on the Script Merge transaction:

- You can use this transaction to renumber steps (assign them new sequence numbers).
- You can use this transaction to move a step to a different position within a script. When a step is moved, all references to the step are changed to reflect the new sequence number.
- You can use this transaction to delete a step.
- You can use this transaction to copy steps from other scripts. For example:
 - You may want to create a script that is similar to an existing script. Rather than copying all the information from the existing script and then removing the inapplicable steps, this page may be used to selectively copy steps from the existing script to the new script.
 - You may have scripts that are very similar, but still unique. You can use this transaction to build large scripts from smaller scripts. In this scenario, you may choose to create special 'mini' scripts, one for each of the various options that may make a script unique. Then, you could use the script merge page to select and merge the mini scripts that are applicable for a main script.

Note: The target script must exist prior to using this page. If you are creating a new script, you must first create the [Script](#) and then navigate to the merge page to copy step information.

Note: Duplicate versus Merge. The [Script](#) page itself has [duplication](#) capability. You would duplicate a script if you want to a) create a new script and b) populate it with *all* the steps from an existing script.

Script Merge

Open **Admin > System > Script Merge** to open this page.

Description of Page

For **Original Script**, select the target script for merging steps.

For **Merge From Script**, select the template script from which to copy the steps.

Note: You may only copy steps from one Merge From script at a time. If you want to copy steps from more than one script, select the first Merge From script, copy the desired steps, save the original script, and then select the next Merge From script.

The left portion of the page displays any existing steps for the **Original Script**. The right portion of the page displays the existing steps for the **Merge From Script**.

You can use the **Copy All** button to copy all the steps from the **Merge From** script to the **Original** script. If you use **Copy All**, the steps are added to the end of the original script.

Each time you save the changes, the system rennumbers the steps in the original script using the **Start From Sequence Number** and **Increment By**.

Merge Type indicates **Original** for steps that have already been saved in the original script or **Merge** for steps that have been merged, but not yet saved. The **Sequence**, **Step Type** and **Description** for each step are displayed.

The topics that follow describe how to perform common maintenance tasks:

Resequencing Steps

If you need to resequence the steps:

- Use the up and down arrows in the Original Script grid to reorder the steps.
- Make any desired changes to the **Start From Sequence Number** or **Increment By**.
- Click Save.

The steps are given new sequence numbers according to their order in the grid.

Removing a Step from Script

If you want to remove a record linked to the Original script, click the delete button to the left of the record.

For example, to remove the **Reset existing bundle XML** step, click the  icon.

| | | Merge Type | Sequence | Step Type | Description |
|---|---|------------|----------|-----------|---|
|  |   | Original | 10 | Edit data | Edit data - Check that the BO is an Export Bundle |
|  |   | Original | 20 | Edit data | Edit data - Read the Bundle |
|  |   | Original | 30 | Edit data | Edit data - Reset existing bundle XML |
|  |   | Original | 40 | Edit data | Edit data - Create new bundle XML |

After removal, the grid displays:

| | | Merge Type | Sequence | Step Type | Description |
|---|---|------------|----------|-----------|---|
|  |   | Original | 10 | Edit data | Edit data - Check that the BO is an Export Bundle |
|  |   | Original | 20 | Edit data | Edit data - Read the Bundle |
|  |   | Original | 40 | Edit data | Edit data - Create new bundle XML |

Note: You cannot delete a step that is referenced by other steps unless you also delete the referencing steps, such as **Go to step** or **Prompt** type steps. The system informs you of any missing referenced steps when you attempt to save the original script.

Adding a Step to a Script

You can move any of the steps from the Merge From script to the Original Script by clicking the left arrow adjacent to the desired step. Once a record is moved it disappears from the Merge From information and appears in the Original information with the word **Merge** in the Merge Type column.

For example, to copy the **Navigate to a page** step, click the left arrow.

| | Merge Type | Sequence | Step Type | Description |
|--|------------|----------|-----------|-------------|
| | | | | |

| | Sequence | Step Type | Description |
|---|----------|--------------------|--|
| ↔ | 10 | Height | Height - 0% |
| ↔ | 20 | Move data | Move data - Copy 'APP_SVC_ID' to 'APP_SVC_ID' |
| ↔ | 30 | Move data | Move data - Copy 'USR_GRP_ID' to 'USR_GRP_ID' |
| ↔ | 40 | Navigate to a page | Navigate to a page - userGroupAppService |
| ↔ | 50 | Conditional branch | Conditional branch - Compare ACTION with UPDATE |
| ↔ | 60 | Press a button | Press a button - IM_scrollSec_add |
| ↔ | 70 | Move data | Move data - Copy 'APP_SVC_ID' to 'UGP\$APP_SVC_ID' |
| ↔ | 80 | Label | Label - End of Script |

The step is moved to the left portion of the page.

| | Merge Type | Sequence | Step Type | Description |
|---|------------|----------|-----------|--|
| ↔ | ↔ | Merge | 40 | Navigate to a page - userGroupAppService |

| | Sequence | Step Type | Description |
|---|----------|--------------------|--|
| ↔ | 10 | Height | Height - 0% |
| ↔ | 20 | Move data | Move data - Copy 'APP_SVC_ID' to 'APP_SVC_ID' |
| ↔ | 30 | Move data | Move data - Copy 'USR_GRP_ID' to 'USR_GRP_ID' |
| ↔ | 50 | Conditional branch | Conditional branch - Compare ACTION with UPDATE |
| ↔ | 60 | Press a button | Press a button - IM_scrollSec_add |
| ↔ | 70 | Move data | Move data - Copy 'APP_SVC_ID' to 'UGP\$APP_SVC_ID' |
| ↔ | 80 | Label | Label - End of Script |

Note: If you add a step, such as **Go to step** or **Prompt** type steps, that references other steps, you must also add the referenced steps. The step references are updated to use the new sequence numbers when you save the original script. The system informs you of any referenced steps that haven't been added when you attempt to save the original script.

Removing an Uncommitted Step from a Script

| | Merge Type | Sequence | Step Type | Description |
|---|------------|----------|-----------|--|
| ↔ | ↔ | Merge | 40 | Navigate to a page - userGroupAppService |

Remove Merged Step - Script Merge - row 1

| | Sequence | Step Type | Description |
|---|----------|--------------------|--|
| ↔ | 10 | Height | Height - 0% |
| ↔ | 20 | Move data | Move data - Copy 'APP_SVC_ID' to 'APP_SVC_ID' |
| ↔ | 30 | Move data | Move data - Copy 'USR_GRP_ID' to 'USR_GRP_ID' |
| ↔ | 50 | Conditional branch | Conditional branch - Compare ACTION with UPDATE |
| ↔ | 60 | Press a button | Press a button - IM_scrollSec_add |
| ↔ | 70 | Move data | Move data - Copy 'APP_SVC_ID' to 'UGP\$APP_SVC_ID' |
| ↔ | 80 | Label | Label - End of Script |

Maintaining Functions

Note: Functions were implemented prior to the introduction of business services (BS), service scripts (SS) and business objects (BO). The functionality is still supported, but the recommendation for implementations going forward is to use one of the above configuration tool objects in a script rather than defining a function. The documentation has not been updated throughout this section to highlight where BS, SS or BO could be used to perform the equivalent logic.

Invoke function steps may be used to retrieve or update data independent of the page currently being displayed. For example, if you design a script that takes different paths based on the customer's customer class, you could

invoke a function to retrieve the customer's customer class. Doing this is much more efficient than the alternative of transferring to the account page and retrieving the customer class from the Main page.

An **Invoke function** step retrieves or updates the relevant data by executing a service (on the server). These types of steps do not refer to the service directly. Rather, they reference a "function" and the function, in turn, references the service.

Note: Functions are abstractions of services. A function is nothing more than meta-data defining the name of a service and how to send data to it and retrieve data from it. Functions allow you to define a scriptwriter's interface to services. They also allow you to simplify a scriptwriter's set up burden as functions can handle the movement of data into and out of the service's XML document.

The topics in this section describe how to set up a function.

Note: You can retrieve data from all base-package objects. If you know the name of the base-package "page" service used to inquire upon an object, you can retrieve the value of any of its fields for use in your scripts. To do this, set up a function that sends the unique identifier of the object to the service and retrieves the desired fields from it.

Function - Main

Use this page to define basic information about a function. Open this page using **Admin > System > Function**.

Description of Page

Enter a unique **Function** code and **Description** for the function.

Use the **Long Description** to describe, in detail, what the function does.

Define the **Internal Service** that the function invokes.

Note: Only page services can be invoked.

The tree summarizes the following:

- The fields sent to the service. You can use the hyperlink to transfer to the **Send Fields** tab with the corresponding field displayed.
- The fields received from the service. You can use the hyperlink to transfer to the **Receive Fields** tab with the corresponding field displayed.
- Scripts that reference the function. You can use the hyperlink to transfer to the script page.

Function - Send Fields

Use this page to add or update the fields sent to the service. Open this page using **Admin > System > Function** and then navigate to the **Send Fields** tab.

Note: Displaying a specific field. Rather than scrolling through each field, you can navigate to a field by clicking on the respective node in the tree on the Main tab. Also note, you can use the Alt+right arrow and Alt+left arrow accelerator keys to quickly display the next and previous entry in the scroll.

Note: You're defining the service's input fields. On this tab, you define which fields are populated in the XML document that is sent to the service. Essentially, these are the service's input fields.

Description of Page

Use **Sequence** to define the order of the **Send Fields**.

Enter a unique **Function Field Name** and **Description** for each field sent to the application service. Feel free to enter **Comments** to describe how the field is used by the service.

Use **Field Value Source** to define the source of the field value in the XML document sent to the service:

- If the field's value is the same every time the function is invoked, select **Defined On The Function**. Fields of this type typically are used to support "hard-coded" input values (so that the scriptwriter doesn't have to populate the field every time they invoke the function). Enter the "hard-coded" **Field Value** in the adjacent field.

- If the field's value is supplied by the script, select **Supplied By The Invoker**. For example, if the function retrieves an account's customer class, the script would need to supply the value of the account ID (because a different account ID is passed each time the function is invoked). Turn on **Required** if the invoker must supply the field's value (it's possible to have optional input fields).

Regardless of the Field Value Source, use **XML Population Logic** to define the XPath expression used to populate the field's value in the XML document sent to the service.

Function - Receive Fields

Use this page to add or update the fields received from the service. Open this page using **Admin > System > Function** and then navigate to the **Receive Fields** tab.

Note: Displaying a specific field. Rather than scrolling through each field, you can navigate to a field by clicking on the respective node in the tree on the Main tab. Also note, you can use the Alt+right arrow and Alt+left arrow accelerator keys to quickly display the next and previous entry in the scroll.

Note: You're defining the application service's output fields. On this tab, you define which fields are populated in the XML document that is received from the service. Essentially, these are the service's output fields.

Description of Page

Use **Sequence** to define the order of the **Receive Fields**.

Enter a unique **Function Field Name** and **Description** for each field received from the service. Feel free to enter **Comments** to describe the potential values returned from the service.

Turn on **Required** if the invoker must use the field.

Regardless of the Field Value Source, use **XML Population Logic** to define the XPath expression used to retrieve the field's value from the XML document received from the service.

Note: Fields in multiple lists. If a field within the list is unique across the service, the generic list reference is sufficient for the XML population logic. However, if the field you are trying to reference is in multiple lists, the XPath must include the list name. For example, instead of `/pageBody/list/listBody/field[@name='FIELD_NAME']`, the XPath Population Logic must read `/pageBody/list[@name='LIST_NAME']/listBody/field[@name='FIELD_NAME']`.

Maintaining Managed Content

The Managed Content object is used to store various types of text content. Some content is used internally such as Allowlists. Other content may be used by implementations such as XSL files used for communicating messages with an external system, JavaScript include files, and CSS files. These files may then be maintained in the same manner as the HTML in UI Maps.

Open this page using **Admin > System > Managed Content**.

Use the **Managed Content Query** portal to search for an existing managed content entry. Once the managed content is selected, you are brought to the maintenance page to view and maintain the selected record.

Most fields on the page are self explanatory.

Use **Managed Content Type** to indicate the type of content.

- **Allowlist**

is used to capture a list of supported values for given functionality. For example, the product provides allowlists for SQL functions and valid HTML tags.

- **XSLTC** is used to reference XSL files. These may be used internally for user interface referencing. Additionally, the XSLs may be referenced for sending messages to external system using [outbound message](#) and for receiving messages in SOAP as [inbound messages](#).

Note: The value FIX (XSLT) is no longer supported and will be deprecated in a future release. Other managed content values are not currently supported by any current framework functionality and are reserved for future use.

Use the **Schema** tab to view and maintain the contents of the managed context text.

Defining Entity Tags

This portal is used to maintain an entity tag along with the list of entities associated with it. Entity tagging supports grouping of configuration, demo and test related entities so they can better describe a logical function. Each group is represented by a unique tag name and entities may be associated with multiple tags.

An entity tag may explicitly restrict the type of entities it can be associated with by referencing a specific maintenance object as part of the entity tag record.

You can access the portal from the **Admin Menu > Implementation Tools > Entity Tag**. You are brought to a query portal with options for searching for a specific tag name. Once an entity tag has been selected you are brought to the maintenance portal to view and maintain the selected record.

A [Tags](#) sidebar zone allows you to review, add and remove tags for the current entity you review. For configuration type of entities, you may use this portal to tag multiple entities at once.

The following zones may appear as part of the portal's **Main** tab page

- **Entity Tag.** This zone provides information about the selected entity tag.
- **Tagged Entities.** This zone lists entities associated with the selected entity tag. You may also use the zone to remove entities from the list.
- **Tag Entities.** Use this zone to add configuration entities to the selected tag.

Advanced Schema Topics

The topics in this section describe some advanced information related to schemas used for business objects, business services, service scripts and UI maps.

Schema Nodes and Attributes

For business object definition, the purpose of the schema is to create a link between the schema and a maintenance object. For business service definition you are specifying the link between the schema and a service (either a general service, search service, or a maintenance object service). For service script definition, you are defining the API for passing information to and from the script. The following documentation is a complete list of the XML nodes and attributes available to you when you construct a schema.

Note: The definition of a schema may include user interface related attributes that represent a separate aspect of the schema for presentation purposes. These attributes belong to a separate name space known as UI Hints and as such are not part of the schema's data structure. Refer to [Understanding UI Hints](#) on page 176 for more information.

The Four Element Types

A schema element can be one of four different structure types. Note that there are two classes of element types: the structural nodes group and list, and the data containing nodes of field and raw.

| Mnemonic | Valid Values | Description | Examples |
|----------|--------------|---|----------|
| type= | "field" | The field type is the default type for any element not explicitly labeled as something other than a field. Therefore, you virtually never have to explicitly label an element as a field. Note that a field element, unlike group or list, will contain information in its nodes - rather than other nodes. | |

| MnemonicValid Values | Description | Examples |
|---|--|--|
| <p data-bbox="342 212 440 239">"group"</p> | <p data-bbox="695 218 1040 342">The group element is typically a structural element of the schema only, in which case it has no mapping.</p> <p data-bbox="695 363 1068 548">Note that when grouping several elements that are all used to map an XML structure of a CLOB / XML field of a business object driven record, the mapping may be at the group level.</p> | <p data-bbox="1089 218 1450 275">Example where a group is used to create a structure</p> <pre data-bbox="1089 296 1471 579" style="background-color: #f0f0f0;"> <schema> <input type="group" <userId/> </input> <output type="group"> <firstName/> <lastName/> </output> </schema> </pre> <p data-bbox="1089 600 1458 657">Example where the group includes the mapping:</p> <pre data-bbox="1089 678 1585 982" style="background-color: #f0f0f0;"> <parameters type="group" mapXML="BO_DATA_AREA" mdField= "F1_TODOSUMEMAIL_PARM_LBL"/ > <numberOfDays mdField="F1_NBR_DAYS" required="true"/> <frequency mdField="F1_FREQUENCY"/ > </pre> |

| MnemonicValid Values | Description | Examples |
|----------------------|---|--|
| "list" | The list node is structural node like the group node. The only difference is that the list structure has the ability to repeat multiple times in an XML document. | <p>Example of a schema with a list:</p> <pre data-bbox="1092 268 1464 485"><schema> <statesList type="list"> <state isPrimeKey="true"/> > <description/> </statesList> </schema></pre> <p>Example of a schema with a list:</p> <pre data-bbox="1092 556 1464 947"><xml> <statesList> <state>AK</state> <description>Alaska</description> </statesList> <statesList> <state>AL</state> <description>Alabama</description> </statesList> ... </xml></pre> |
| "raw" | The raw data type is used to capture a chunk of raw text that doesn't have any inherent structure associated with it. | <pre data-bbox="1092 999 1464 1052"><sendDetail type="raw" /></pre> <p>Example of an XML instance for the above schema:</p> <pre data-bbox="1092 1167 1464 1409"><sendDetail> <messageInfo> <senderAddress>123 W. Main St</senderAddress> <corpZone>3A</corpZone> </messageInfo> </sendDetail></pre> |

The Data Type of a Field Element

Of the four different element types, only a field can have a data type.

| MnemonicValid Values | Description | Examples |
|----------------------|--|---|
| dataType="string" | By default, a field element is a string. Therefore, there is no requirement to specify the string data type. | <pre data-bbox="995 1656 1464 1776"><schema> <custName dataType="string" /> </schema></pre> |

| MnemonicValid Values | Description | Examples |
|--|--|--|
| <p>"number"</p> | <p>Defines an element that is a number.</p> <p> Note: UI hints include a setting to Suppress Automatic Number Formatting.</p> <p> Note: Use currencyRef attribute for auto-display of currency symbol that is associated with the referenced currency code. The currency decimal positions are ignored by this formatting allowing you to display a currency symbol for a unit rate with many decimals.</p> | <p>Examples</p> <pre data-bbox="998 273 1461 409"><schema> <count dataType="number"/> </schema></pre> <pre data-bbox="998 430 1461 567"><schema> <taxRate dataType="number" currencyRef="currency"/> </schema></pre> |
| <p>"money"</p> <p>Optional additional attributes</p> <p>currencyRef="element name"</p> | <p>Defines an element that represents a monetary amount.</p> <p>The currency reference is optional and if left blank the installation currency will be used. Automatic formatting and validation to be applied based on the currency. For example, the currency symbol will be shown when auto-rendering. In addition, the number of decimal places must not exceed the valid number defined for the currency.</p> <p> Note: Refer to Referencing Other Elements for supported syntax for referring to other elements.</p> | <pre data-bbox="998 840 1461 1018"><schema> <currency default="USD" suppress="true"/> <balance dataType="money" currencyRef="currency"/> </schema></pre> |
| <p>"lookup"</p> <p>Required additional attribute</p> <p>lookup="field name"</p> | <p>Defines an element that has valid values defined using a lookup. The lookup field is required.</p> | <pre data-bbox="998 1438 1461 1564"><schema> <status dataType="lookup" lookup="STATUS_FLG"/> </schema></pre> |
| <p>"lookupBO"</p> <p>Required additional attribute</p> <p>lookupBO="bo name"</p> | <p>Defines an element that has valid values defined using an extendable lookup. The extendable lookup's business object is required.</p> | <pre data-bbox="998 1617 1461 1764"><schema> <category dataType="lookupBO" lookupBO="CM-BusinessCategory"/> </schema></pre> |
| <p>"boolean"</p> | <p>Defines an element that has values of "Y" and "N".</p> | <pre data-bbox="998 1816 1461 1942"><schema> <allowsEdit dataType="boolean"/> </schema></pre> |
| <p>"date"</p> | <p>Defines an element that represents a date.</p> | <pre data-bbox="998 1995 1461 2100"><schema> <startDate dataType="date"/> </schema></pre> |

Referencing Other Elements

There are several attributes that allow for a reference to another element in the same schema. The supported syntax of the XPath reference is the same in every case. This section provides examples using the default reference attribute (**defaultRef**).

Reference a sibling element:

```
<schema>
  <id mapField="ACCT_ID" required="true"/>
  <altId defaultRef="id" required="true"/>
</schema>
```

Reference an element in a higher group:

```
<schema>
  <id mapField="ACCT_ID" required="true"/>
  <msgInfo type="group" mapXML="XML_FIELD">
    <altId defaultRef="../id" required="true"/>
  </msgInfo>
</schema>
```

Reference an element in a lower group:

```
<schema>
  <id mapField="ACCT_ID" defaultRef="msgInfo/altId" required="true"/>
  <msgInfo type="group" mapXML="XML_FIELD">
    <altId required="true"/>
  </msgInfo>
</schema>
```

Reference an element in another group:

```
<schema>
  <acctInfo type="group">
    <id mapField="ACCT_ID" required="true"/>
  </acctInfo>
  <msgInfo type="group" mapXML="XML_FIELD">
    <altId defaultRef="../acctInfo/altId" required="true"/>
  </msgInfo>
</schema>
```

Standard Time Considerations

Most date / time fields represent "legal" time such that if a time zone changes their clocks for winter and summer time, the date / time field captures the current observed time. However, some date / time fields should always be captured in standard time to avoid confusion / ambiguity. A good example is a date and time related to detailed interval data. Refer to [Designing Time Zones](#) for more information.

When defining an element with **dataType="dateTime"**, you may optionally configure **stdTime="true"** indicating that data captured in the element always represents standard time in the 'base' time zone. The 'base' time zone is specified on the [Installation options](#).

Note: If an element is mapped to a table / field with a Standard Time Type of **Physical**, then **stdTime="true"** is implied. Refer to [Fields](#) for more information.

Example:

```
<schema>
  <startTime dataType="Time" stdTime="true"/>
</schema>
```

If the time zone that represents the date / time field is not the installation time zone, use the optional setting **stdTimeRef**="XPath to time zone element" on a date / time element to indicate that the element represents standard time and indicates the time zone to use. Refer to [Referencing Other Elements](#) for supported syntax for referring to other elements. .

Example:

```
<schema>
  <alternateTimeZone fkRef="F1-TZONE" suppress="true"/>
  <startDateTime dataType="dateTime" stdTimeRef="alternateTimeZone"/>
</schema>
```

Note: If an element is mapped to a table / field with a Standard Time Type of **Referenced**, then **stdTime**="XPath" is implied. Refer to [Fields](#) for more information.

Note: When schema elements are captured in standard time the UI map supports HTML notation to automatically display the data applying a daylight savings time / summer time correction. Refer to the HTML attribute **oraType**="dateTime; stdTime:true" for more information.

There may be cases where the date / time is captured as standard time in one time zone, but should be displayed using a different time zone. In this case, the attribute **displayRef**="XPath" may be used in addition to the appropriate attribute that identifies the time zone that the data is capture in. Refer to [Referencing Other Elements](#) for supported syntax.

```
<schema>
  <displayTimeZone fkRef="F1-TZONE" suppress="true"/>
  <startDateTime dataType="dateTime" stdTime="true" displayRef="displayTimeZone"/>
</schema>
```

The Mapping Attributes

When constructing your schema, you can choose from one of the following mapping attributes.

| Mnemonic | Valid Values | Description | Examples |
|-----------------|--------------|--|---|
| mapField | "field name" | In the case of a business object, the mapField attribute is used to identify the database column the element is related to. For business service schemas, the mapField attribute is used to link a schema element with a service element. | <pre><schema> <factId mapField="FACT_ID"/ > </schema></pre> |
| mapChild | "table name" | The mapChild attribute is used only for business object mapping. It is used in two ways: <ul style="list-style-type: none"> First, to create a list in the business object that corresponds to a child table of an MO. Second, you can use mapChild to identify the child table a flattened field lives in. For more information on flattening, refer to flattening section below. | <p>Example of a list within a child table in a BO:</p> <pre><persons type="list" mapChild="CI_ACCT_PER" > <personId mapField="PER_ID"/ > </persons></pre> |

| Mnemonic/Valid Values | Description | Examples |
|---|---|--|
| mapList = "list name" | <p>The mapList attribute is used only for business service mapping. It is used in two ways:</p> <ul style="list-style-type: none"> • First, to create a list in the business service that corresponds to a list in the service. • Second, you can use mapList to identify the list that a flattened field lives in. For more information on flattening, refer to flattening section below. | <p>Example of a list within a business service:</p> <pre data-bbox="1101 302 1581 554"><selectList type="list" mapList="DE" <value mapField="COL_VALUE"> <row mapList="DE_VAL"> <SEQNO is="2"/> > </row> </value> </selectList></pre> |
| mapXML =field name" | <p>The mapXML attribute is typically used to map XML structures into a large character/XML field of the service. Note that when you use mapXML to map either a list or group structure (type="list" or type="group") you don't have to map all the child elements within the structure. It is also possible to map list elements to a large character field associated with the list child.</p> | <pre data-bbox="1101 699 1598 1226"><enrollmentRequest type="group" mapXML="CASE_CLOB"> <messageID/> <sender/> </enrollmentRequest> <enrollmentKey mapXML="CASE_CLOB"/> <enrollmentInfo type="list" mapChild="CI_CASE_CHILD"> <sequence mapField="CHILD_SEQ"/> > <name mapXML="CASE_CHILD_CLOB"/> > <value mapXML="CASE_CHILD_CLOB"/> > </enrollmentInfo></pre> |
| isPrimeKey =true" | <p>You must specify a primary key for a list defined within a mapped XML element (type="list" mapXML="CLOB"). The primary key is used by the framework to determine whether a list element add, update or delete is required during a business object update.</p> <p> Note: You do not need to specify the prime key for a business object list mapped to maintenance object list. When a physical list is mapped, the prime key is derived from existing physical meta-data.</p> | <pre data-bbox="1101 1287 1598 1457"><questionnaire type="list" mapXML="CASE_CLOB"> <question isPrimeKey="true"/> <answer/> </questionnaire></pre> |
| orderBy = "XPath asc desc, XPath asc desc" | <p>By default, a list defined within a mapped XML element (type="list" mapXML="CLOB") is sorted by the first element of the list. A different sort order may be</p> | <pre data-bbox="1101 1917 1549 2087"><questionnaire type="list" orderBy="page/ section, page/sequence" mapXML="CASE_CLOB"> <question isPrimeKey="true"/> ></pre> |

Descriptive Attributes

The following attributes can be used to describe a schema element and provide additional configuration related to the element. Typically, these attributes are useful for field elements only.

| Mnemonic | Valid Values | Description | Examples |
|---|---------------------------|---|--|
| <code><!--</code> comment <code>--></code> | | Use this to add a comment to a schema by using special open and close characters: <code><!--</code> and <code>--></code> . | <pre><schema> <!-- This schema is used to capture business information only, please refer to the 'HUMAN' BO for person information --> </schema></pre> |
| description | <code>text</code> | The description of an element may be used to provide an internal description of the element to help a reader of the schema to understand the business reason for the element. | <pre><schema> <active type="boolean" description="active account" label="Active"/> </schema></pre> |
| label | <code>"text"</code> | The label of an element is meant to be a short bit of verbiage that would typically precede the element in a user interface. | <pre><schema> <active type="boolean" description="active account" label="Active"/> </schema></pre> |
| required | <code>"true"</code> | Used to require the existence of an element during object interaction.  Note: For included schemas, the <code>required="true"</code> attribute is not processed on business object and business service schemas when they are included within a service script schema. This is to support the ability of the service script to populate required elements before an embedded business object or business service is invoked from the service script. | <pre><schema> <logDate mapField="LOG_DT" default="%CurrentDate" required="true" private="true" </schema></pre> |
| mdField | <code>"field code"</code> | The meta-data field attribute is used to associate an element with a field's metadata. The field defines data type, as well as its label and help text. If you link an element with a meta-data field, you don't need to specify any of these attributes.  Note: For a business object schema, the <code>mapField</code> attribute is used to derive the data type and label. An <code>mdField</code> attribute may | <pre><schema> <active mdField="CM_ACTIVE_SW"/ > </schema></pre> |

Schema Constants

There are some product owned schemas where the design warrants a value to be defaulted in the schema, but where the value is implementation specific and therefore cannot be defined by the product. For these situations, the product may use a technique called a schema constant. The design of the schema will include a declared constant. At implementation time, a configuration task will include defining the appropriate value for the constant.

For example, imagine the product delivers an algorithm that will create an outbound message when a certain condition occurs. The outbound message type to use must be configured by the implementation. To use a schema constant to define the outbound message type, the base product will configure the following:

- An option type lookup value for the lookup **F1CN_OPT_TYP_FLG** is defined. For example, **M202** - Activity Completion Outbound Message Type with a Java Value Name of **outmsgCompletion**
- The base schema that is used to create the "complete activity" outbound message references the schema constant using the Java Value Name of the option type's lookup value

```
...
<outboundMessageType mapField="OUTMSG_TYPE_CD" default="%Constant(outmsgCompletion)"/>
>
...
```

At implementation time, the administrative users must configure the appropriate outbound message type for "activity completion". Then, navigate to [Feature Configuration](#), choose the **Schema Constants** feature type, choose the option type **Activity Completion Outbound Message Type** and enter the newly created outbound message type in the option value.

Schema constants may also be used in the flattening syntax to define [the row elements required for flattening](#).

Defaulting and System Variables

The default attribute can be used to default values into field elements as well as [the row elements required for flattening](#). You can default a field to a constant or to one of several system variables.

When an element is required, the default value is applied at the server level when adding or changing the record where no value is provided for this element.

When an element is optional, a default value may be configured to provide a suggested value to the user when populating the record on the user interface in Add mode. Users should be able to remove the default value for this type of element and the system will not attempt to populate it at save time.

Note:

The standard for our 'list' maintenance is to show an empty row for a new list that a user may or may not choose to populate. As such, UI default values are not shown for list elements.

It is not recommended to configure a default attribute for an optional element that is not editable or visible on the user interface in Add mode (for example an element with **suppress="true"** or **suppress="input"** or a list element whose default value is not shown per the previous point). The default for this type of element is still

applied but the user doesn't have the ability to reset the value. This may result in inconsistencies as defaulting does not occur for optional fields added by a use case other than the UI interaction.

| MnemonicValid Values | Description | Examples |
|----------------------------|--|--|
| default= "value" | Use this attribute to default an element to a specified value. The values that are valid depend on the dataType setting. | <pre><schema> <perType mapField="PER_OR_BUS_E default="P" required="true"/ > </schema></pre> <pre><schema> <frequency dataType="number" default="1" required="true"/ > </schema></pre> |
| "%CurrentDate" | Used to default the element to the current date. This is only applicable to date elements. | <pre><schema> <logDate mapField="LOG_DT" default="%CurrentDate" required=" > </schema></pre> |
| "%CurrentDateTime" | Used to default the element to the current date / time. This is only applicable to date / time elements. | <pre><schema> <logDateTime mapField="LOG_DTTM default="%CurrentDateTime" required="true"/> </schema></pre> |
| "%StandardDateTime" | Used to default the standard date and time. The standard date and time is identical to the current date and time, unless daylight savings time / summer time is in effect for the base time zone. This may be used with the stdTime attribute. | <pre><schema> <startDateTime mapField="START_ default="%StandardDateTime" required="true"/> </schema></pre> |
| |  Note: Refer to Standard Time Considerations for more information. | |
| "%ProcessDate" | You can default the process date. The process date differs from the current date because the process date will remain constant throughout the duration of the process being executed. The current date will reflect the actual date of processing. This is similar to the batch business date that is a standard batch parameter . | <pre><schema> <billDate mapField="BILL_DT" default="%ProcessDate" required="true"/> </schema></pre> |
| "%ProcessDateTime" | This is similar to "%ProcessDate" but for date / time fields. | <pre><schema> <calcDateTime mapField="CALC_DT default="%ProcessDateTime" required="true"/> </schema></pre> |
| "%CurrentUser" | Used to default the element to the current user. | <pre><schema> <logUser mapField="LOG_USER" default="%CurrentUser" required="true"/> </schema></pre> |

| MnemonicValid Values | Description | Examples |
|----------------------|---|--|
| "%Constant()" | You can default an element value using a schema constant . | The following is an example of a schema constant used as a default value, where the Java Value Name of the Lookup Value is 'customerLanguage'. <pre><language mapField="CUSTOMER_LANGUAGE" default="%Constant(customerLanguage)" required="true"/></pre> |
| "%Context()" | You can default a value contained in a context variable.  Warning: Context variables must be initialized within a server script before the schema context default can be applied. Refer to Context Variables for more information. | An example of a context variable used as a default value: <pre><source mapField="PER_ID" default="%Context(source)" required="true"/></pre>  Note: When defining a context variable in scripting, it should be prefixed with \$\$\$. When referring to the variable in the %Context() syntax, the prefix is not included. |
| defaultRef="XPath" | Use this attribute to default the value of one element to the value of another one. | Refer to Referencing Other Elements for supported syntax for referring to other elements. |

The Flattening Nodes and Attributes

The term "flattening" is used to describe the act of defining one or more single elements for a schema that are actually part of a list within the maintenance object. Flattening is possible if there are other attributes of the list that can be defined to uniquely describe the element or elements. A common use case for flattening is a characteristic. Rather than defining the characteristics of an object using a collection where the user must choose the characteristic type and then define the value, the characteristics are defined as actual elements with the appropriate label already displayed. This technique enables the designer of the schema and the user interface to display each separate characteristic in the logical place in the user interface rather than all lumped together.

Note: A flattened element represents a unique row in the database. This row is inserted when the flattened values are created. The row is updated when any of the flattened values are changed. The row is deleted when all the flattened values are removed. The behavior of effective dated elements is slightly different - please see [Flattening an Effective Dated List](#).

Note: The flattening feature can also be used to define a list, see [Flattened List](#).

Identifying the List or Child Table

When flattening a child table, the row node is required to identify the list / child table that the element comes from. Within the row node, at least one element must be defined with an **is=** definition that ensures that the element is a unique row in the database. It may also define elements or fields in the row that are suppressed and are populated using default value configuration.

- For a business object, the row node defines the child table the flattened field belongs to.

The syntax is `<row mapChild="table name">`. This example is for the list of persons for an account in the customer care and billing product. One person may be marked as the "main" person. This illustrates how to define an explicit element for the main person ID to simplify references to that field. It is part of the CI_ACCT_PER child table. What makes it unique is that the MAIN_CUST_SW is **true** (and only one row may have that value)

```
<custId mapField="PER_ID" mdField="CM-MainCust">
  <row mapChild="CI_ACCT_PER">
    <MAIN_CUST_SW is="true" />
    <ACCT_REL_TYPE_CD default="MAIN" />
  </row>
</custId>
```

Note: The above example illustrates that the row node may also define elements within the list that are suppressed and assigned a default value. This syntax is never used to identify a particular row. Note that a default value can either be a literal string, or a [system variable](#).

- For a business service, the row node identifies the list name the flattened field belongs to.

The syntax is `<row mapList="list name">`. This example shows two entries from a list being flattened to a field value and description.

```
<selectList type="list" mapList="DE">
  <value mapField="COL_VALUE">
    <row mapList="DE_VAL">
      <SEQNO is="2"/>
    </row>
  </value>
  <description mapField="COL_VALUE">
    <row mapList="DE_VAL">
      <SEQNO is="3"/>
    </row>
  </description>
</selectList>
```

Uniquely Identifying the Flattened Field or List

The **is=** syntax within a row or rowFilter element is used to uniquely identify the row.

| Mnemonic | Valid Values | Description | Examples |
|------------|--------------|---|--|
| is= | "value" | Use this attribute to reference a value directly. | <pre><tdTypeCd mapField="CHAR_VAL_FK1"> <row mapChild="F1_EXT_LOOKUP_VAL_CHAR"> <CHAR_TYPE_CD is="CM-TD-TYPE"/> </row> </tdTypeCd></pre> |

| MnemonicValid Values | Description | Examples |
|----------------------|---|--|
| "%Constant()" | You can configure a flattened element using a schema constant . During a service interaction the value of the schema constant will be used to identify the flattened element in its child row. | An example of a schema constant used in flattening syntax where the Java Value Name of the Lookup field value is 'cmRate'. <pre><unitRate mapField="CHAR_VAL" dataType="number"> <row mapChild= "F1_EXT_LOOKUP_VAL_CHAR"> <CHAR_TYPE is ="%Constant(cmRate)"/> </row> </unitRate></pre> |
| "%n" | The %n substitution value is used to reference a relative list instance. A relative list instance is typically used to configure a flattened element for a child table keyed by sequence number. The value of <i>n</i> should be a positive integer value. During a business object read interaction the relative list instance (position) specified by the integer will be returned. | An example with a relative list instance - where the first instance of the row is returned. <pre><schema> <mainPhone mapField="PHONE"> <row mapChild="CI_PER_PHONE"> <PHONE_TYPE_CD is="%Constant(mainPhoneType)"/> > <SEQ_NUM is="%1"/> </row> </mainPhone> </schema></pre> |

Fastpath: Additional values for **is=** are used when [Flattening an Effective Dated List](#). Refer to that section for more information.

Flattening a Pre-defined Characteristic Type

If the flattened field is in a characteristic collection and the characteristic type is a predefined characteristic, automatic UI rendering will generate a dropdown for the list of valid values. For example, the schema below will generate a dropdown for the Usage element showing the valid values of the Status Reason Usage (**F1-SRUSG**) characteristic type.

```
<usage mdField="STATUS_RSN_USAGE" mapField="CHAR_VAL">
  <row mapChild="F1_BUS_OBJ_STATUS_RSN_CHAR">
    <CHAR_TYPE_CD is="F1-SRUSG"/>
    <SEQ_NUM is="1"/>
  </row>
</usage>
```

Defining Multiple Elements from the List

When attempting to include multiple columns from the same list, the system provide shorthand notation for copying the flattening rules defined on another element so that the flattening rules do not need to be repeated. To do this, the row node includes the **rowRef** attribute and it indicates the other element name that defines the mapping information. The following example illustrates flattening the fields Customer ID and Receives Copy of Bill from the same list of Persons for an Account (where the **MAIN_CUST_SW** is **true**).

```
<custId mapField="PER_ID">
  <row mapChild="CI_ACCT_PER">
    <MAIN_CUST_SW is="true" />
    <ACCT_REL_TYPE_CD default="MAIN" />
  </row>
</custId>
```

```
<copyBill mapField="RECEIVE_COPY_SW" rowRef="custId"/>
```

Note that the above notation also illustrates that the **rowRef** may be defined directly in the element's attribute definition.

Note: Refer to [Referencing Other Elements](#) for supported syntax for referring to other elements.

Flattening Two Layers Deep

If your maintenance object or service has nested lists two layers deep, the system supports flattening an element within a flattened element. This technique also uses the **rowRef** attribute. The flattening of the second level refers to the flattened element of the first level. The following example illustrates flattening a characteristic into an element called `legalContact` for the "main" customer. Notice that the `legalContact` element has two row nodes: one to refer to the flattening information for its parent record and one to define its child table

```
<custId mapField="PER_ID">
  <row mapChild="CI_ACCT_PER">
    <MAIN_CUST_SW is="true" />
    <ACCT_REL_TYPE_CD default="MAIN" />
  </row>
</custId>
<legalContact mapField="CHAR_VAL_FK1">
  <row rowRef="custId">
    <row mapChild="CI_ACCT_PER_CHAR" >
      <CHAR_TYPE_CD is="LEGAL" />
    </row>
  </row>
</legalContact>
```

Note that the above notation also illustrates that the **rowRef** may be defined as an attribute of a row node rather than directly in the element's attribute definition.

Defining a Flattened List

There are times that a list or child table supports multiple values of the same "type" and these should be presented as a list. To continue with the example above, the list of persons for an account may identify one person as the "main" person. This person has been flattened to a single element (with the account relationship type defaulted and suppressed). To maintain the other persons related to an account, you can define a list where each row captures the Person Id and the Account Relationship Type.

Rather than a row node, the flattened list is configured with a **rowFilter** element. The following schema illustrates the described example. The list node defines the child table. The **rowFilter** includes the criteria that identify the rows within the table to include. The elements of the list are defined within the list node outside the **rowFilter** element.

```
<custId mapField="PER_ID">
  <row mapChild="CI_ACCT_PER">
    <MAIN_CUST_SW is="true" />
    <ACCT_REL_TYPE_CD default="MAIN" />
  </row>
</custId>
<miscPersons type="list" mapChild="CI_ACCT_PER">
  <rowFilter>
    <MAIN_CUST_SW is="false" />
  </rowFilter>
  <relType mapField="ACCT_REL_TYPE_CD"/>
  <personId mapField="PER_ID"/>
</custId>
```

Note that the system will validate that if a schema contains flattened single elements and flattened lists from the same child table, the criteria that defines what makes them unique must be analogous.

Flattening an Effective Dated List

There are some lists in the application that are effective dated (and still others that have effective date and time). For example, there are some effective dated characteristic collections. In these collections, the design is to capture a single value for a characteristic type that may change over time. It is not meant to support multiple characteristic values in effect at the same time.

There are some maintenance objects that have effective dated characteristics and no sequence based characteristics. For those entities, implementations may want to use the characteristic to define an additional field that doesn't require effective dates.

When considering designing an element for your schema that represents a value in an effective dated collection, consider if the value is one that is used in processes, like calculating a bill, such that it is important to capture changes to the value over time.

- If it is not important to track the changes to the value, the recommendation is to set the effective date to a fixed value in the schema. (Examples below).
- If it is important to track the changes to the value, then you need to consider how you want to design the schema.
 - One option is to define a flattened list as described above. Both the value and the effective date are elements in this list. In this use case, you manage the list just like any list. You can add or remove values.
 - Another option is to define a flattened single value in the schema. With this option, when retrieving the record, the latest effective value is returned. In this design, the important question is how is the reference date defined.

Note: Refer to [Referencing Other Elements](#) for supported syntax for referring to other elements.

Flattened Elements Where Changes Are Not Tracked

The following is an example of flattening an element in an effective dated collection where the value does not need to be effective dated. The recommendation in this case is to simply hard-code the date in the `is=` attribute.

```
<schema>
  <externalReference mapField="ADHOC_CHAR_VAL" mdField="CM_EXT_REF" dataType="string">
    <row mapChild="CI_SA_CHAR">
      <CHAR_TYPE is="CM_EXT_REF"/>
      <EFFDT is="2000-01-01"/>
    </row>
  </externalReference>
</schema>
```

Flattened Elements Where Changes Are Effective Dated

If you want the BO schema to flatten an effective dated value that should keep track of changes over time, the flattened value will represent the latest effective entry. In this case, the recommendation is to explicitly define the date

or date/time field as an element. Then there is syntax for the **is=** attribute to indicate that the explicit date field is the date to use for the value.

| Mnemonic | Valid Values | Description | Examples |
|------------|-----------------------------|---|--|
| is= | "%effectiveDate" | Use this configuration to indicate that the date to use is the value of another element.  Note: Refer to Referencing Other Elements for supported syntax for referring to other elements. | <pre><schema> <price mapField="CHAR_VAL" dataType="number" required="true"> <row mapChild="CI_SA_CHAR"> <CHAR_TYPE is="PRICE"/> <EFFDT is="%effectiveDate(priceEdate)" / > </row> </price> <priceEdate mapField="EFFDT" rowRef="price"/> </schema></pre> |
| | "%effectiveDateTime" | Use this configuration to indicate that the date / time to use is the value of another element.  Note: Refer to Referencing Other Elements for supported syntax for referring to other elements. | <pre><schema> <price mapField="CHAR_VAL" dataType="number"> <row mapChild="RATE_CHAR"> <CHAR_TYPE is="PRICE"/> <EFFDTTM is="%effectiveDateTime(priceEdatetime)" / > </row> </price> <priceEdatetime mapField="EFFDTTM" rowRef="price"/> </schema></pre> |

You should consider if the explicit date or date/time element should be displayed on the user interface when the flattened field is shown or if that should be suppressed. Designers should also consider the user dialogue for updating the value. It may be more intuitive for the flattened field to be display only and to have a separate dialogue for updating the effective dated value.

For this option, the suggestion is that the maintenance page for the object includes a separate zone that shows the history of the effective dated values over time. The latest value may be included in that zone as well.

Note that for backward compatibility, the system also supports the following options. However, they are not recommended. They implicitly defined the reference date as the current date at all times. The options supported adding new effective dated rows when the value changed. But the technique also caused new effective dated rows to appear when other elements of the same schema were updated. The new rows would have the current date or date/time with the same row value because the reference date or date/time is the current date, which is a change. The

product does not recommend managing an effective dated characteristic without defining the date or date/time as an explicit element.

| Mnemonic | Valid Values | Description | Examples |
|----------|----------------------|---------------------------------------|--|
| is= | "%effectiveDate" | This configuration is not recommended | <pre><schema> <price mapField="CHAR_VAL" dataType="number"> <row mapChild="CI_SA_CHAR"> <CHAR_TYPE is="PRICE"/> <EFFDT is="%effectiveDate"/> </row> </price> </schema></pre> |
| | "%effectiveDateTime" | This configuration is not recommended | <pre><schema> <price mapField="CHAR_VAL" dataType="number"> <row mapChild="RATE_CHAR"> <CHAR_TYPE is="PRICE"/> <EFFDT is="%effectiveDateTime" /> </row> </price> </schema></pre> |

Search Zone

A UI Map schema element can be configured to enable an automatic search dialog when the schema is included within a maintenance UI map.

Note: Please note that an fkRef can be configured with a search zone. If a schema element has an fkRef but no explicit search attributes (as described here) then the fkRef search information will be used in the UI map. In other words, if the schema element already has an fkRef, then these explicit search attributes in the schema are only used to override the fkRef search information.

Note: Refer to the [UI Map Attributes and Functions](#) for more information on search zone configuration.

```
search="search zone"
```

The search attribute can be used within a UI map schema and is used to automatically generate the oraSearch UI map attribute. The search zone is an explorer zone configured as a search.

```
<person fkRef="PER" search="C1_PSRCH"/>
```

```
searchField="search field:element|'literal';"
```

The searchField attribute can only be used in conjunction with the search attribute. The searchField attribute is used to build the oraSearchField UI map attribute. The searchField value is used to populate a search zone filter with an initial value when the search zone is launched. The initial value can be a literal also. The searchField value is used to match to the filter mnemonic also named searchField.

Search field: element|'literal'. The search field represents the search zone filter to populate on launch. The element is the map's schema element used to populate the filter. The element is optional, if left blank, it will default to the element that this attribute is specified on. The searchField also takes 'literal' as input value

Note: Multiple filters can be populated within the search zone at launch, but multiple search field pairs must be constructed within the attribute value. The value specified here will be used to directly build the HTML attribute `oraSearchField` within the UI map where this schema is specified.

Note: Note that the element reference is *relative*. Refer to [Referencing Other Elements](#) for supported syntax for referring to other elements.

```
<person fkRef="PER" search="C1_PSRCH" searchField="PERSON; PER_TYPE:personType; "/>
```

```
searchOut="search field:element;"
```

The `searchOut` attribute can only be used in conjunction with the `search` attribute. The `searchOut` attribute is used to build the `oraSearchOut` UI map attribute. The `searchOut` value is used to capture a selected value from the search zone and move it to a UI map element. The `searchOut` value specified should match the `ELEMENT_NAME` mnemonic within the search result zone parameter.

Search field: element. The search field represents the search zone result brought back to the UI map. The element is the map's schema element to be populated. The element is optional, if left blank, it will default to the element that this attribute is specified on.

Note: Multiple elements can be populated as a result of search zone selection, but multiple search field pairs must be constructed within the attribute value. The value specified here will be used to directly build the HTML attribute `oraSearchOut` within the UI map where this schema is specified.

Note: Note that the element reference is *relative*. Refer to [Referencing Other Elements](#) for supported syntax for referring to other elements.

```
<person fkRef="PER" search="C1_PSRCH" searchField="PER_ID"
searchOut="PER_ID;PRIMARY_PHONE:personPhone;"/>
```

Extend Security for Service Script

Application service security will be enforced when either a business object or a service script is invoked from a BPA script or a UI map, but not from a service script. If you want security to be enforced when the business object or a service script is invoked from a service script, you must add the following attribute to the service script's schema.

```
appSecurity="true"
```

The `appSecurity` attribute is only available for service script schemas. If specified, any business object or service script directly invoked by the service script will have their application service evaluated for access.

```
<schema appSecurity="true">
  . . .
</schema>
```

Overriding Action for a Business Service

If you want to invoke a business service with an action other than 'read', you need to specify the action attribute on the primary node business service schema.

```
pageAction="add, change, delete"
```

The action attribute is used to override the default action of read on a business service schema. Valid values are:

- add
- update (only allowed for maintenance object service)
- change (not allowed for maintenance object service)
- delete
- read (this is the default action if no `pageAction` specified)

Example:

```
<schema pageAction="change">
  <parm type="group">
    <ele1/>
    <ele2/>
  </parm>
</schema>
```

Specifying searchBy for a Search Service

If you want to invoke a search service then you must explicitly specify the searchBy attribute appropriate for the elements mapped in the schema.

```
searchBy="MAIN"
```

The value values of the searchBy attribute can be found by viewing the XML schema linked to the business service, use the View XML URL. Typical values are:

- MAIN
- ALT
- ALT2
- ALT3
- etc.

```
<schema searchBy="MAIN">
  <AccountID mapField="ACCT_ID"/>
  <Results type="list">
    <AccountID mapField="ACCT_ID"/>
  </Results>
</schema>
```

Including Other Schemas

There are no limitations on your ability to include a schema into another schema - all types can be included in all other types. Nested includes are also allowed - and at present there is no limitation on the depth of the nesting.

Including a schema requires two parts:

1. The include node
2. The name attribute

The following table highlights the supported include statements.

| Mnemonic | Description | Examples |
|--|--|---|
| <code><includeBO name=" "/></code> | <p>Including a business object schema into another schema is allowed.</p> <p>Note that the mapping rules of a business object or business service schema may or may not make sense in the context of the parent schema. Include other schemas at your own risk. However, a very useful aspect of XML processing is that the framework ignores non-pertinent attributes. In other words, it will not hurt to have mapping attributes included into a script schema.</p> | <pre><schema> <cust type="group"> <includeBO name="C1-Person"/> </cust> <spouse type="group"> <includeBO name="C1-Person"/> </spouse> </schema></pre> |
| <code><includeBS name=" "/></code> | Used to include a business service schema. | <pre><schema> <includeBS name="F1-ReadMOLog"/> </schema></pre> |
| <code><includeDA name=" "/></code> | Used to include a data area schema. | <pre><schema> <includeDA name="F1CommonSchemaFieldData"/ > </schema></pre> |
| <code><includeMP name=" "/></code> | Used to include a UI map schema. | <pre><schema> <includeMP name="F1-DisplayRecordActions"/ > </schema></pre> |
| <code><includeSS name=" "/></code> | Used to include a service script schema. | <pre><schema> <includeSS name="F1-ActShowZn"/> </schema></pre> |

Compatibility Attributes

These attributes were added as part of upgrades from previous versions of the Framework.

`fwRel="2"`

This attribute has been added to schemas created in Framework 2 as part of a Framework 4 upgrade. New schemas will not need this attribute. It is not advisable to modify this attribute without understanding the following behavior differences as improper changes could result in errors:

Note: Schemas created in Framework 2 with the `fwRel="2"` attribute will store any XML mapped fields under groups as top-level XML elements in the `mapXML` field. This means that if two or more fields, in different group structures, were to have the same field name, their storage would conflict with one another resulting in errors. The new behavior, without the `fwRel="2"` attribute, will preserve the group structure and avoid the conflicts.

```
<schema fwRel="2"
...

```

```
</schema>
```

Schema Designer

The Schema Designer is a user-friendly interface for performing the following common schema editing tasks:

- Displaying existing schemas.
- Creating schema elements.
- Moving elements within a schema.
- Adding attribute values.

The designer provides two view modes:

- **Text** mode shows the schema elements and their attributes written in the proper syntax and allows for direct text entry.
- **Tree** mode is a view showing the elements in a tree format with many of the key attributes of each element in tabular form. While in this mode, the **Node Display** controls allow the user to choose between displaying the elements by their internal identifiers or their associated screen labels while viewing or editing the schema.

Note: Schemas that are not owned by the current installation owner are protected in both view modes.

The following sections provide more information about functionality available in the Tree mode.

- If the schema definition refers to another schema using an 'include' statement, a triangle is visible to the left of the tree area. One can expand that schema by clicking the triangle.
- Detailed information about an element's definition can be displayed and if applicable, updated from the **Tree** view by clicking the edit icon for that element, which appears on the right.  Note that the element attributes are only editable if the element is defined in this schema. When viewing the attributes of an element that is part of an 'include' of another schema, the attributes are display only.
- Context-sensitive embedded help is provided for fields and controls in the edit pane by clicking the Help icon .
- There is a menu dropdown icon visible to the left of the tree for any element that is defined in the current schema being viewed. It is not visible for elements included from another schema. New elements may be added in the

Tree mode. Clicking that dropdown displays options to Add, Delete or Move an element.   Note that not all options are visible, based on what is allowed for the element adjacent to the menu. For example, on the main "schema" node, only the Add option is visible as deleting or moving the "schema" node is not applicable.

When adding a new element, you are prompted first for the element position, which is either a sibling node to the current element or a child node of that element. For either option, the new element is added below the one adjacent to where the menu is clicked. You are then prompted for the element type.

The following lists the possible element types. Most are self explanatory and represent standard schema options.

- **Characteristic List.** This is a special type of Flattened List element that is used to map list elements that include a sequence and a characteristic value for a given characteristic type. This element is only applicable for maintenance objects that have one or more characteristic child tables where the primary key is the maintenance object's key, characteristic type and sequence. Effective dated characteristic collections are not supported. The user defines the list name, the characteristic value element name and the characteristic type. The system will configure the remaining flattening information accordingly.
- **Characteristic.** This is a special type of Flattened Field element that is used to map a single element to the characteristic for a given characteristic type. This element is only applicable for maintenance objects that have one or more characteristic child tables where the primary key is the maintenance object's key, characteristic type and

sequence. Effective dated characteristic collections are not supported. The user defines the element name and the characteristic type. The system will configure the remaining flattening information accordingly.

- Comment. This adds a comment to the schema.
- Embedded HTML. This is specific to a schema enabled for UI Hints. It is used to include a UI map fragment.
- Field
- Flattened Field
- Flattened List
- Group
- Include BO Schema
- Include BS Schema
- Include DA Schema
- Include Map Schema
- Include SS Schema
- Input Map Title. This is specific to a schema enabled for UI Hints. It is used to define a title element for the map.
- List
- Nested Flattened Field. This is a flattened field from a child table.
- Raw Element. This element is used to capture text as is. It is typically used to capture an XML structure without any details of the definition of the individual nodes.
- Section. This is specific to a schema enabled for UI Hints. It is used to define a section within the map.
- Simple Field. This is a special type of Field element that is used to define an element that is mapped to a column that supports data defined in an XML structure. (This is either a column with the character large object data type (CLOB) or the XML data type).

The **Schema Designer** is available by choosing the **Schema** tab on the [Business Object](#), [Data Area](#), [UI Map](#), [Business Service](#), and [Script](#) pages.

Schema Viewer

The schema viewer shows a tree-view presentation of a schema in its expanded form.

Note: If the schema includes presentation instructions and attributes they are not included in this view. Refer to [Understanding UI Hints](#) on page 176 for more information.

The schema illustrates the structure to be used when communicating with the schema's associated object. The following takes place when a schema is expanded:

- If the schema definition includes references to other schemas, these references are replaced with the corresponding schema definitions.
- Also, if the schema definition contains **private** elements, they are omitted from this view.

Clicking on any node on the tree populates the text box on the top with the node's absolute XPath expression. You will find this feature very useful when writing scripts interacting with schema-based objects. [Scripting](#) often involves referencing elements in a schema-based XML document using their absolute XPath expression. You can use this feature on the schema viewer to obtain the XPath expression for an element and copy it over to your script.

Business Event Log

Business Event Log may be viewed as a tool designed to capture any type of business event worth noting. You configure business objects to represent the various types of events your application calls for. The following type of details may be captured for each event:

- The business object representing the type of event.
- The date and time the event took place and who initiated it.
- The business entity for which this event is logged.
- Standard application message to describe the event.
- Additional context information that is available at the time of the event and varies for each type of event. The Business Event Log maintenance object supports a standard characteristics collection as well as an XML storage

(CLOB) field. The event's business object determines where each piece of information resides. Refer to [Business Objects](#) for more information.

One common type of event may be the audit of changes made to sensitive data, for example, tracking an address change. Whenever an entity associated with a business object is added, changed, or deleted the system summarizes the list of changes that took place in that transaction and hands them over to **Audit** business object algorithms to process. You may design such an algorithm to audit the changes as business event logs. Refer to [a business object may define business rules](#) for more information.

You can also allow users to initiate business event logs to capture important notes about a business entity by exposing a [BPA Script](#) to invoke the event's corresponding business object.

Bottom line is that any process can create a business event log by invoking the business object representing the appropriate type of event.

Miscellaneous Topics

The following sections describe miscellaneous system wide topics.

Javadocs Viewer

The system provides a Javadocs viewer and a Groovy Javadocs viewer, which are interactive tools that allows you to browse Java documentation files (Javadocs) for Java classes that execute on the application server. For information about how to use Javadocs and navigate within the viewer, refer to Javadocs help.

Javadocs

To launch the Javadocs viewer, open **Admin > Implementation Tools > Javadocs**.

Note: Proprietary Java Classes. A small number of Java classes have been suppressed due to their proprietary nature.

Additionally, when viewing a record that references a Java program in the [algorithm type](#) page, the [batch control](#) page or the [FK reference](#) page, an icon adjacent to Java program allows you to view the Javadocs for that program.

Groovy Javadocs

The Groovy Javadocs viewer includes the Java classes that are accessible to Groovy code within scripts. Launch this viewer using the 'View Groovy Javadocs' link in the Script Tips zone on the [script](#) page.

Module Configuration

The system provides the ability to simplify the user interface based on functionality areas practiced by your organization.

Menu items and other user interface elements are associated with function modules. By default, all function modules are accessible. If a function module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information on how to turn off a module.

If a function module is made non-accessible, i.e. turned off, its related elements are suppressed from the user interface. In addition the system may validate that related functionality is not accessed. This also means that turning off the wrong module may cause any of the following to occur:

- Menu items may not appear. Refer to [Menu Item Suppression](#) to better understand how menu item suppression works.
- Entire menus may not appear. Refer to [Menu Suppression](#) to better understand how menu suppression works.
- Tabs on pages may not appear.
- Fields may not appear.
- The system may return an error message when you attempt to use a function (indicating the function is turned off).

To correct the above situation, simply remove the module from the turned off list thus making it accessible again.

Your module configuration setup is displayed on the [installations](#) record.

Menu Item Suppression

The following points describe how your module configuration can suppress [menu items](#).

- Menu items that are owned by the base product (as opposed to those your implementation adds) are associated with one or more function modules. If your module configuration has turned off all of the menu item's modules, the menu item is suppressed. If at least one of the modules is accessible, i.e. turned on, the menu item is not suppressed.
- If a menu line doesn't contain any accessible items, the menu line is suppressed.
- If all lines on the [Admin menu](#) are suppressed, the menu itself is suppressed in the application toolbar. This is not expected to ever occur for the Main menu as the user preferences is on that menu and the expectation is that all users have access to their preferences.
- Menu items that are suppressed are not visible in the [Menu Item Search](#) results.

Menu Suppression

In addition to the above Menu Item Suppression logic, the following points describe how your module configuration can suppress an entire menu.

- Menus that are owned by the base product (as opposed to those your implementation adds) are associated with one or more function modules.
- If your module configuration has turned off all of the menu's modules, the entire menu is suppressed. If at least one of the modules is accessible, i.e. turned on, the menu is not suppressed.

Turn Off A Function Module

The base package is provided with a **Module Configuration** [Feature Configuration](#) that allows your organization to turn off base package function modules.

To turn off any of the base package function modules add a **Turned Off** option to this feature configuration referencing that module. Refer to the **MODULE_FLG** lookup field for the complete list of the application's function modules.

Any module not referenced on this feature configuration is considered turned on, i.e. accessible. To turn on a module, simply remove its corresponding **Turned Off** option from this feature configuration.

You may view your module configuration setup on the [installation options](#) page.

Note: Only one. The system expects only one **Module Configuration** feature configuration to be defined.

Global Context Overview

The framework web application provides each product the ability to nominate certain fields to act as a "global context" within the web application. For example, in Oracle Utilities Customer Care and Billing, the global context fields include Account ID, Person ID and Premise ID. The values of these fields may be populated as a result of searching or displaying objects that use these fields in their keys. If you navigate to the Bill page and display a bill, the global context is refreshed with the Account ID associated with that bill. The global context for Person ID and Premise ID are refreshed with data associated with that account.

The fields designated as global context for the product are defined using the lookup **F1_UI_CTXT_FLDS_FLG**.

Changing the values of the global context typically cause data displayed in zones on the sidebar to be refreshed to show information relevant to the current values of these global context fields.

When the value of one of the global context fields changes, an algorithm plugged into the [installation record](#) is responsible for populating the remaining global context values accordingly. Refer to your specific product for more information about the base algorithm that is provided for that product.

System Data Naming Convention

There are several maintenance objects in the system that include owner flag in one or more of its tables. We refer to the data in these tables as "system data". Some examples of system data tables include Algorithm Type, Batch Control, Business Object and Script. Implementations may introduce records to the same tables. The owner flag for records created by an implementation is set to **CM** (for customer modification), however the owner flag is not part of

the primary key for any of the system data tables. As a result, the base product provides the following guidelines for defining the primary key in system data tables to avoid any naming conflict.

Base Product System Data

For any table that includes the owner flag, the base product will follow a naming convention for any new data that is owned by the base product. The primary key for records introduced by the product is prefixed with **xn-** where **xn** is the value of the owner flag. For example, if a new background process is introduced to the framework product, the batch code name is prefixed with **F1-**.

Note: There are some cases where the hyphen is not included. For example, portal codes omit the hyphen.

For most system data, the remainder of the primary key is all in capital case. An exception is schema oriented records. For business objects, business services, scripts, data areas and UI maps, the product follows the general rule of using CapitalCase after the product owner prefix. For example, **F1-AddToDoEntry** is the name of a base product business service.

Note: Data Explorer Business Services. For business services used to invoke a data explorer zone, it is recommended to name the Business Service the same name as the related zone rather than defining a different CapitalCase name for the business service.

Please note that this standard is followed for all new records introduced by the base product. However, there are base product entries in many of these system data tables that were introduced before the naming convention was adopted. That data does not follow the naming convention described above.

Note: Schema naming conventions. A context sensitive "Schema Tips" zone is associated with any page where a schema may be defined. The zone provides recommended naming conventions for elements within a schema along with a complete list of the XML nodes and attributes available to you when you construct a schema.

Implementation System Data

When new system data is introduced for your implementation you must consider the naming convention for the primary key. The product recommends prefixing records with **CM**, which is the value of the owner flag in your environment. This is consistent with the base product naming convention. This convention allows your implementation to use the CM packaging tool in the Software Development Kit as delivered. The extract file provided with the tool selects system data records with an owner flag of **CM** and with a **CM** prefix.

Note: If you choose not to follow the CM naming convention for your records and you want to use the CM packaging tool, your implementation must customize the extract file to define the appropriate selection criteria for the records to be included in the package. Refer to the Software Development Kit documentation for more information.

Also note that owner flag may be introduced to an existing table in a new release. When this happens, the CM packaging tool is also updated to include these new system data tables. Your implementation will have existing records in those tables that probably do not follow any naming convention. After an upgrade to such a release, if you want to include this data in the CM packaging tool, you must customize the extract file for the tables in question.

Accessibility Considerations

This section provides information about topics related to accessibility that should be considered when extending the system via configuration tools.

Color Contrast

The HTML color **red** (RGB code #FF0000) when used for text on a white background does not comply with the accessibility color contrast guidelines. When it is desired to use red for text for emphasis in a zone, map or in a text string, the product recommends the shade of red with the RGB code #E0292F.

Note that in addition, the product provides a special CSS class **textColorRedOnWhite** which may be used when HTML references are used for applying the red color. For example, UI map, zone help text and scripting.

Referencing URIs

There are some configuration objects that require a reference to a URI, including file path URIs. The following sections highlight some functionality supported by the product with respect to defining / accessing URIs.

Note: In order for the functionality described below to occur, specific APIs must be used by the underlying code related to the fields that capture or process the file path or URL information. If you find that there is a URI-related field that does not provide the functionality described here, please contact customer support.

Note: For schema elements in a business object that reference a [Field](#) with the **URI** data type or define the element with the **URI** data type configured in the [schema](#) will automatically use the appropriate API that validates the value that may reference a substitution variable or must be checked against the allowlist if applicable.

Validation Against an Allowlist

Based on a property setting, your implementation may be configured to define a allowlist of URIs. If this setting is enabled, the system will issue an error if the URI is not defined in the allowlist. Consult your system administrator to verify if this setting is enabled or not for your implementation.

Fastpath: Refer to [URI Substitution](#) for information about how defining substitution tokens for URIs using the properties file technique automatically adds the defined URI to the allowlist.

URI Substitution

The system supports the ability to define substitution variables (sometimes referred to as tokens) for both URL values and file path values that reference native file storage locations. For URLs, the system supports defining variables in a Substitution Variable properties file. For native file storage paths, there are two options: the Substitution Variable properties file or via a File Storage configuration extendable lookup. More details on both these options are found below.

- Substitution variables properties file. A substitution variable for all or part of the URI definition may be configured in a properties file. This allows the system administrators to define the proper URI locations in a properties file whereas the configuration users only need to know the variable name. For example, when defining a location for an extract file in an extract batch job, instead of typing a file path of `h:\oracle\serverName\1.0.0.0\batch\extract\`, the batch user can enter `@FILE_EXTRACT@`, assuming there is an entry in the substitution variables file with a name of `FILE_EXTRACT`, and a value of `h:\oracle\serverName\1.0.0.0\batch\extract\`. Another example is that the batch user could enter `@BATCH_FILES@\extract\`, assuming that the URI variable for `BATCH_FILES` is defined as `h:\oracle\serverName\1.0.0.0\batch\`.
 -  **Note:** The product automatically populates the value of `SPLOUTPUT` in the properties file so that this may be used in URI configuration. In addition, the product may supply some pre-defined variable names for other common references. As part of this, the 'advanced' menu in the system installation steps may prompt for installers to define the values of these pre-defined variables, if desired. Installations may opt to define additional substitution variables for various URI references. Refer to the *System Administration Guide* for more information.
- File Storage extendable lookup. Specifically for file paths that reference the native file system, the system also supports the ability to define a path using the **File Storage Configuration** extendable lookup. The following points highlight the steps to take for this option.
 - Navigate to [Extendable Lookup](#) and search for the **File Storage Configuration** lookup.
 - Click **Add** to create a new entry. Define a lookup value name. This will be used when configuring a file path that uses this value. Choose the File Adapter value of **Native File Storage**. Enter the desired file path value. The values defined here may in turn refer to values defined in the Substitution Variables properties file. For example, the file path can reference `@SPLOUTPUT@`.
 - To reference this value in system configuration, use the syntax `file-storage://XXXX`, where `XXXX` is the extendable lookup value. Using the same example from above, if you define an extendable lookup value of `CM-FileExtract` with a file path of `h:\oracle\serverName\1.0.0.0\batch\extract\`, then when configuring the extract file path for an extract batch job, enter `file-storage://CM-FileExtract`. Another example is that if the extendable lookup value's file path is configured as `h:\oracle\serverName\1.0.0.0\batch\`, then the user configuring the file path on the batch extract can enter `file-storage://CM-FileExtract/extract`

When should you define substitution variables in the properties file and when you define them in the extendable lookup? The following points highlight differences between the options that may help this decision.

- Substitution variables for URLs are only supported via the properties file.
- The properties file can typically only be modified by a system administrator. If there are values that are set at installation time and don't change, then defining the values in the properties file may be beneficial.
- When defining additional environments, such as test environments or production, the values in the extendable lookup may be copied using CMA. Ideally the values are defined such that they are the same between various regions.

External File Storage

The system supports using Oracle Cloud Object Storage for managing files in cloud implementations and can be configured to read files from or write files to this external location. Refer to Oracle Cloud Object Storage documentation for more information about obtaining an account and defining appropriate file locations or "buckets".

Once your cloud storage information is defined, the following points highlight the configuration steps required in the application.

- Define a [signature key ring](#). When the system tries to communicate with cloud object storage, it must provide a signature key so that cloud storage can confirm that the request is from a trusted source.
 - Navigate to [Key Ring](#) in add mode and select the **RSA Signature Key Pair** business object.
 - Define a key ring code, which will be used in the File Storage configuration (below) along with a description.
 - Once the key ring is added, click **Generate Key** to generate a private / public key pair.
 - Click View Public Key to launch a pop-up that displays the public key, allowing the user to copy the key.
- At this point, the user should navigate to cloud object storage and register the public key. Refer to Cloud Services Administration Guide for more information on this step. Once this is done, the key ring is now ready to be configured in file storage configuration.
- Next, confirm that the region where your object storage is defined is configured in the system and if not, define the value.
 - Navigate to [Extendable Lookup](#) and search for the **OCI Region** lookup. Review the list of regions already provided.
 - If your region is not listed, click the Add button. Be sure that the Region Key and the Region Identifier match the values defined in the OCI region documentation. The region key is a three digit identifier. For example, the one for Sydney region in Australia is SYD. The region identifier follows a pattern of a two digit realm id followed by the city name, followed by a single digit, all separated by hyphens. For example, the one for the Sydney region is "ap-sydney-1".
- Use a File Storage extendable lookup to define the location and connection information so that you may reference this location in system configuration. The following points highlight the steps to take for this option.
 - Navigate to [Extendable Lookup](#) and search for the **File Storage Configuration** lookup.
 - Click **Add** to create a new entry. Define a lookup value name. Note that the lookup value should not have a slash or backslash in its name. This will be used when configuring a file path that uses this value. Choose the File Adapter value of **Oracle Cloud Object Storage**. Provide the following information that identifies the cloud storage options: User, Tenancy, Compartment, Namespace and Region. For the Key Ring, choose the value defined above.
- To reference this value in system configuration, use the syntax **file-storage://XXXX/...**, where XXXX is the extendable lookup value and any additional path information that is appropriate. For example, if you define an extendable lookup value of **CM-CloudStorage** and you have a bucket defined in Cloud Storage for processUpload, when configuring the file path for the upload batch job, enter **file-storage://CM-CloudStorage/processUpload**.
- The product supports referencing virtual folders for a bucket. Simply add the virtual folder name(s) after the bucket name. For example, if there is a bucket called 'financials' and a virtual folder for 'paymentUpload', the file path may have this value: **file-storage://CM-CloudStorage/financials/paymentUpload**. For extract processes, if the file path references a virtual folder that does not exist for the referenced bucket, the virtual folder is created as part of the extract process.

- You may optionally use a Bucket Name Prefix on the file storage configuration to support defining different Bucket Names for different environments. For example, imagine you want to have a separate "processUpload" bucket for a development region, a test region and a production region. In the Cloud Storage configuration you can define separate buckets for "DEV_processUpload", "TEST_processUpload" and "PROD_processUpload". If you needed to define the full bucket on each file path reference on various batch jobs, migrating the batch job configuration from one environment to another would require a manual step to change all the bucket references. Instead, the system supports defining a Bucket Name Prefix, which if populated will be prepended to bucket reference before connecting to Cloud Storage. This means that the prefix is defined once and all the references throughout the system can keep the common part of the Bucket name (such as "processUpload"). Then only the File Storage configuration needs to differ between the different regions.
- If your implementation integrates with an external reporting tool that can write the report output to specific delivery channels (buckets) check the Reporting Configuration switch. Define one or more Bucket Names for the buckets that the reporting tool may use for delivery channel options.

Note: Refer to the [Key Ring](#) documentation for information about practicing key rotation.

Caching Overview

A great deal of information in the system changes infrequently. In order to avoid accessing the database every time this type of information is required by an end-user or a batch process, the system maintains a cache of static information on the web server and in the batch thread pool worker. These are referred to as the "application caches". Some examples of application caches include

- System messages
- Field label and other field information
- Security Information

The framework product provides many specific caches for commonly used (and infrequently changed) data. In addition, specific edge applications may introduce additional caches as appropriate.

Information may also be cached on each user's browser.

The following topics highlight information about refreshing the various caches.

Server Cache

The server cache refers to data that is cached on the web server. An important use of this cache is for users' online access to the application. The caches aid in better performance while navigating throughout the system, allowing for data to be accessed from the cache rather than by always accessing the database. Besides user access to the web server cache, other functionality deployed to the web server uses caches in a similar way. For example, web services are deployed to the web server and access their own version of the cache.

The contents of the cache are cleared whenever the web server is restarted. This means that fresh values are retrieved from the database once users and web services start using the application again.

The product also supplies a flush command that one can issue in the browser's URL to immediately clear the contents of the cache. The command **flushAll.jsp** flushes every cache.

For example, assume the following:

- the web server and port on which you work is called **OU-Production:7500**
- you add a new record to a control table and you want it to be available on the appropriate transactions immediately

You would issue the following command in your browser's address bar: **http://OU-Production:7500/flushAll.jsp**. Notice that the command replaces the typical `cis.jsp` that appears after the port number.

If your system has been configured correctly, the **flushAll** command will submit a request to do a "global" flush of caches (including the web services cache and the thread pool worker cache). This functionality uses a JMS Topic to publish the flush request. Refer to the *Server Administration Guide* for details on how to configure the JMS topic.

Also note that the system provides a business service **F1-FlushAllService**, which is equivalent to the `flushAll` command (except that it does not restart your browser session). This may be useful for any processes that are built

to orchestrate updates to configuration data where you want to ensure that the cache is immediately flushed. This business service is also exposed as a REST web service.

Batch Cache

When submitting a batch job, the batch component uses a Hibernate data cache to cache administrative data that doesn't change very often. The tables whose records are included in this cache are configured using the Caching Regime value of **Cached for Batch**. This is often referred to as the "L2 cache". Refer to [Tables](#) for more information. When starting a thread pool worker, data in tables marked as cached is loaded and cached for as long as that thread pool is running.

In addition batch jobs may also access application caches when applicable. When starting a thread pool worker, application data that is cached is loaded and cached for as long as that thread pool is running.

If there are any batch jobs that update any tables that are marked as **Cached for Batch**, you must run that batch job using a special thread pool that is configured with the caching disabled. Contact your system administrator to confirm the thread pool that is configured this way.

If there is a change in cached data that should be available for the next batch job, the following points highlight how the cache can be refreshed:

- By default the system is configured to automatically refresh the Hibernate cache every 60 seconds. However, an implementation may override the configuration to either change the number of seconds between intervals or to disable the automatic caching altogether. Application caches used by the batch jobs are not impacted by this refresh.
- Restart the thread pool workers.
- Run the **F1-FLUSH** (Flush all Caches) background process. This background process will flush the application data cached for all thread pool workers for all thread pools.
- If your the region has configured the thread pool workers to "listen" to requests for global flush as described in the [Server Cache](#) section, the thread pool worker caches are also refreshed when a **flushAll** command is issued.

Client Cache

In addition to the web server's cache, information is also cached on each user's browser. After clearing the cache that's maintained on the web server, you must also clear the cache that's maintained on your client's browser. To do this, follow the following steps (note that depending on the browser you use, the steps may vary slightly):

- Select **Tools** on your browser's menu bar
- Select **Internet Options...** on the menu that appears.
- Click the **Delete Files** button on the pop-up that appears.
- Turn on **Delete all offline content** on the subsequent pop-up that appears and then click **OK**.
- And then enter the standard URL to re-invoke the system.

Note: Automatic refresh of the browser's cache. Each user's cache is automatically refreshed based on the **maxAge** parameter defined in the web.xml document on your web server. We recommend that you set this parameter to **1** second on development / test environments and **28800** seconds (8 hours) on production environments. Please speak to system support if you need to change this value.

Expression Parser

The product provides support for defining expressions that may be of a mathematical or logical/boolean nature. The expression may include variables and functions.

The data explorer [column parameter](#) is an example of where this may be used. That parameter supports the definition of a formula. Edge applications may include support for a formula or expression using this parser as well. For example, several application include a type of 'rule' object (calculation rule, form rule or usage rule) that is used for validation or calculation that may support applying a formula.

The following tables highlight what is supported in the expressions that use this parser.

| Category | Supported in Expression | Description |
|--------------------|---|---|
| Data types | Number String Boolean List | |
| Literals | Numbers Strings surrounded with either single quote or double quote.  Note: 'Escaping' special characters is not currently supported. Boolean values: true and false . | |
| Operations | + — / * ^ or ** % | Plus Minus Division Multiplication Power Modulus |
| Logical operations | = > >= < <= != or <> | Equal Greater than Greater than or equal to Less than Less than or equal to Not equal to |

This table identifies the functions that are supported. Note that several of the functions are applicable to a list of values. Note that although the functions are listed in lower case, the column parameter syntax in data explorer indicates referencing the functions as all capital letters. The system converts the data explorer column formula to lowercase before being evaluated.

| Function | Parameter | Results | Comments |
|------------------|---|--|----------|
| size() | List element | Number of elements in the list. | |
| isEmpty() | List element | Returns true if the list is empty. | |
| sum() | List element of type 'number' | Returns the sum of the numbers in the list. | |
| avg() | List element of type 'number' | Returns the average of the numbers in the list. | |
| | One or more numbers separated by commas | Returns the average of the number arguments. | |
| max() | List element | Returns the largest value in the list. | |
| | One or more comparable elements. | Returns the largest value of the number arguments. | |
| min() | List element | Returns the smallest value in the list. | |

| Function | Parameter | Results | Comments |
|------------------|----------------------------------|--|---|
| | One or more comparable elements. | Returns the smallest value of the number arguments. | |
| abs() | Number | Returns the absolute value. | |
| ceiling() | Number | Rounds the number to the ceiling. | |
| exp10() | Number | Raises 10 to the number power. | |
| acos() | Number | Returns the arc cosine of the number in radians. | The result will lose precision in the system's double float b |
| asin() | Number | Returns the arc sine of the number radians. | The result will lose precision in the system's double float b |
| atan() | Number | Returns the arc tangent of the number radians. | The result will lose precision in the system's double float b |
| cos() | Radian | Returns the cosine of the radian angle input. | The result will lose precision in the system's double float b |
| exp() | Number | Raises e to the number power. | The result will lose precision in the system's double float b |
| log10() | Number | Takes the log, base 10, of the number. | The result will lose precision in the system's double float b |
| log() | Number | Takes the natural log (base e) of the number. | The result will lose precision in the system's double float b |
| sin() | Radian | Returns the sine of the radian angle input. | The result will lose precision in the system's double float b |
| sqrt() | Number | Returns the square root of the number. | The result will lose precision in the system's double float b |
| tan() | Radian | Returns the tangent of the radian angle input. | The result will lose precision in the system's double float b |
| floor() | Number | Rounds the number to the floor. | |
| round() | Number | Assumes a scale of 0. The default rounding mode of "round half up" is applied. | |
| | Number, Scale | The default rounding mode of "round half up" is applied. | |
| | Number, Scale, Mode | The mode must be set to one of the following: <ul style="list-style-type: none"> • "ROUND_CEILING" • "ROUND_DOWN" • "ROUND_FLOOR" • "ROUND_HALF_DOWN" • "ROUND_HALF_UP" • "ROUND_HALF_EVEN" • "ROUND_UP" • "ROUND_UNNECESSARY" | |
| negate() | Number | Returns the negative value of the number. | Only available in data c |

The following are special functions supported in the application for a list of values. In each case, the syntax is *function [indexVariable in listName | expression using indexVariable]*, where the *indexVariable* is chosen by the formula writer to represent each entry in the list and the expression used to evaluate each entry must reference that variable.

Note: The syntax supported for a given use of the formula in a functional area is driven by that particular functional area. For example, in Oracle Public Sector Revenue Management, a formula is supported in the “conditional element validation” form rule. In that form rule all variables including lists are declared in the form rule using letters and the formulas in turn use these letters. In that scenario, the functions below would reference the declared variable letter as the “listName”. Other specific functional area that use this expression parser may support different syntax for referencing elements or lists.

| Function | Description | Examples |
|--------------------|---|--|
| any [] | This function returns the value true if any of the entries in list satisfies the expression. | The following returns true if any entry in the Balance list is greater than 0. <pre>any [i in list/Balance i > 0]</pre> |
| all [] | This function returns the value true if all of the entries in the list satisfy the expression. | The following returns true if all phone numbers are populated. <pre>all [i in list/phoneNumber i != '']</pre> |
| collect [] | This function returns a new list of elements from the referenced list where the value of each entry of the new list is the result of the expression applied to each original value. | The following returns a new list with the tax rate applied to each amount. <pre>collect [i in list/amount i * taxRate]</pre> |
| select [] | This function returns a list of all the values of the original list that satisfy the Boolean expression. | The following returns a new list with only the amounts that are negative numbers. <pre>select [i in list/amount i < 0]</pre> |
| reject [] | This function returns a list of all the values of the original list that do not satisfy the Boolean expression. | The following returns a new list with only the amounts that are not negative numbers. <pre>reject [i in list/amount i < 0]</pre> |

Debug Mode

Your implementation team can execute the system using a special mode when they are configuring the application. To enable this mode, enter **?debug=true** at the end of the URL that you use to access the application. For example, if the standard URL was **http://CD-Production:7500/cis.jsp**, you'd enter **http://CD-Production:7500/cis.jsp?debug=true** to enable configuration mode.

In addition, if you have security access to the application service **F1OUDBUG**, you can enable this mode without changing the URL via the [Help Menu](#) - Enable Debug option. If debug mode is enabled, the help menu entry shows a Disable Debug option, allowing you to turn it off without changing the URL.

When in this mode certain debugging oriented tools become available via an icon visible.  Clicking the icon displays a slide-out panel with options defined below.

The following are related to the advanced debugger:

- **Start Debug** starts a logging session. During this session the processing of various configuration tools objects are logged. For example, the log will show the data areas that are passed in at each step and the data areas returned after the step is processed.

- **Stop Debug** stops the logging session.
- **Show Trace** opens a window that contains the logging session. All of the steps are initially collapsed.
- **Clear Trace** clears your log file.

Note: The buttons are secured. An application service **FICONFIGLOG** has been provided for this functionality to allow implementations to restrict user access to these buttons. An additional application service **FIDEBUG** is checked when the environment is not a 'development' environment and is only applicable on premises. This allows implementations to provide an additional layer of security for their production users. (For cloud customers, the advanced debugger is only available in a development environment).

The following are available to view log entries captured while using the system.

- **Show User Log** allows you to view your own log entries. The number of "tail" entries to view may be specified in the adjacent **Log Entries** field before clicking the button. Limiting the number of entries to view allows the user to quickly and easily see only the latest log entries without having to manually scroll to the end of the log.
- **Show Log** allows for advanced settings. It provides for a date / time range to allow a user to target the output for a specific period. In addition, administrative users may request to view logs of other users. The following are examples of when this capability is needed:
 - Batch and integration logs are captured by special user codes created for this type of processing. These users typically do not represent a human and therefore wouldn't access logs using "show user log". Instead someone else would be accessing these logs.
 - Customer admins would like to retrieve logs for an end user possibly for support reasons. An end user might not have technical skills to gather or assess the logs nor would they be given the privilege to access the logs for security reasons
- Checking the **Global Debug** indication starts various tracing options that are added to the user log.

Note: Show User Log button is secured. An application service **FUSERLOG** has been provided for this functionality to allow implementations to restrict user access to this button. Only users with access to the **Administrative** access mode of the application service are allowed to view logs of other users. Such restrictions may be called for in production environments.

For Cloud implementations only, the following buttons are available in this mode:

- **Restart TPWs** - This button forces batch containers to terminate, interrupting all running batches. New containers will spin up and the interrupted batches resume. Refer to the Batch Best Practices technical reference paper for more information about this button and when to use it.
- **Restart CM Jar Servers** - This button is provided to aid with support in the cloud for custom Java code in certain use cases. Refer to the Cloud Services Implementation Guide for more information.

Other parts of the system may show additional configuration oriented icons when in this mode. For example, explorer zones may provide additional tools to assist in debugging zone configuration. These icons are described in the context of where they appear.

Also, in debug mode drop down lists in data explorer and UI map zones will contain the code for each item in addition to the item's display string.

Prepare Issue Details

When a user encounters an error with the product and submits a service request, information about the environment, the release and the configuration of the user is often very helpful in understanding the cause of the problem. The system provides a script to capture the environment details and issue description for reporting purposes.

To access the script use **Menu > Tools > Prepare Issue Details**. The option is also available in the help menu in the toolbar.

A pop-up window is provided to display the details that are being captured, including a generated Issue ID to uniquely identify the report. The pop-up allows the user to add additional information describing the specific issue. When the user presses Save, the details are added to the system log with the issue ID, which can be searched when investigating the problem. A message will be displayed to either confirm the details were successfully logged or indicate that an error occurred.

Note: The script and menu item are secured. An application service **F1-PREISSUEDTLS** has been provided to allow implementations to restrict user access to this functionality.

System Override Date

The system provides a way to override the system date used for online operations. This feature is available if the server administrator has enabled it in the environment properties. For instructions on configuring environment properties see the *Server Administration Guide*. The system date override feature is not recommended for production environments.

Under the **General System Configuration** [Feature Configuration](#), the **System Override Date Option Type** holds the date the application will use as the global system date instead of retrieving the same from the database. This feature can be especially useful in running tests that require the system date to be progressed over a period of time.

The system override date feature is also available at the user level. This is useful when a user wants override the system date to run tests without affecting the system date for other users in the environment. In order to override the system date for the user, open the [User — Characteristics](#) page, add the **System Override Date** characteristic type with a characteristic value set to the desired date in the YYYY-MM-DD format.

If system override dates are defined at both the feature configuration level and the user level, the date set at the user level will take precedence.

Additional Search Options

The product supports fuzzy searching in explorer zone types using the Oracle Text CONTAINS operator.

Refer to the DBA guide for details on setting up the database to support fuzzy searching. Note that there are some implementations where fuzzy searching will not be possible. For example, it's only available for implementations using the Oracle database. Additionally, not all languages are supported. Refer to the Oracle Database documentation for more information about fuzzy searching.

For information about the particular syntax to use in the explorer zones, refer to [SQL Statement](#) in the zone parameter details section.

Extensions Dashboard

This portal provides a high level summary of configuration entities that have been customized and extended to meet your business requirements. Included are customer owned entities and extended product owned entities. The portal is intended to be used by your implementation team to get an appreciation of areas that have been customized and may need to be reviewed or retested for various reasons.

Use **Admin > Implementation Tools > Extensions Dashboard** to navigate to the portal.

The following zones may appear as part of the portal's **Main** tab page

- **Extensions Summary.** This zone provides a summary of customized entities by maintenance object. You may select a specific maintenance objects to review entities of this type.
- **Extension Entities.** This zone lists customized entities of the selected maintenance object. It is only visible when a maintenance object is selected on the Extensions Summary zone.
- **Extension Details.** This zone provides additional information as to which specific tables contain the custom owned content for the selected entity. It is only visible when a specific customized entity is selected.
- **Revision Control.** This zone lists revisions made to the selected entity. It is only visible when revision information exists for the selected entity.
- **Configuration Migration.** This zone lists CMA migration objects that applied changes to the selected entity. It is only visible when import information exists for the selected entity.

The following zone may appear as part of the portal's **Review** tab page

- **Duplicate Configurations.** This zone highlights duplicate configuration issues that may rarely arise after an upgrade. Customers should use this information to adjust thir configuration accordingly.

To Do Lists

Certain events that occur within the system will trigger messages describing work that requires attention. For example, if a bill segment has an error, the system generates a To Do message to alert the person responsible for correcting such errors.

Each type of message represents a To Do list. For example, there are To Do lists for bill segment errors, payment errors, customer contact reminder, etc.

We refer to each message as a **To Do Entry**. Each To Do entry is assigned a specific **To Do Role**. The role defines the users who may work on the entry. A To Do entry has a **To Do log** that maintains record of the progress on the To Do entry. For example, the To Do log indicates when the To Do entry was created, when it was assigned to a user and to whom it was assigned, and when and by whom it was completed.

Fastpath: Refer to [To Do Processing](#) for a description of end-user queries and tools assisting in reviewing, assigning and processing To Do entries.

The Big Picture of To Do Lists

The topics below provide more information about To Do configuration.

To Do Entries Reference A To Do Type

Every [To Do entry](#) references a To Do type. The To Do type controls the following functions:

- The page into which a user is taken when they drill down to the related object on an entry.
- The message associated with the To Do that appears on various pages. Note this message can be overridden for specific To Do messages by specifying a different message number in the process that creates the specific To Do entry. For example, the process that creates To Do entries associated with bill segments that are in error displays the error message rather than a generic "bill segment is in error" message.
- The To Do entry [sort keys](#). Note that the processes that create To Do entries are responsible for populating the sort key values.
- Whether (and how) the To Do entry is downloaded to an external system (e.g., an email system).
- The roles to which an entry may be reassigned.
- The default priority of the To Do entry. Note that this value may be overridden by a **Calculate Priority** algorithm.
- An indication of whether a To Do of that type may be created manually by a user.
- The algorithms used to perform specific business rules for To Do entries of this type.
- The characteristics applicable to the To Do.

To Do Entries Reference A Role

Every [To Do entry](#) references a role. The role defines the users who may be assigned to **Open** entries.

The permissible roles that may be assigned to a To Do entry are defined on the entry's To Do type. After an entry is created, its role may be changed to any role defined as valid for the entry's To Do type.

The base package determines the initial To Do Role as follows:

- The system checks if an entry's message category / number is rerouted to a specific role. If so, it defaults this role. Refer to [Adjusting the To Do Role](#) for more information.
- There may be some other condition related to the object linked to your To Do entry that warrants an override role. A [To Do pre-creation plug-in](#) would be used to check the conditional logic and override the role, if applicable.
- If a Role wasn't determined in one of the previous steps and a Role is provided by the initiating process (algorithm or background process), the entry is created with that Role.
- If the entry does not have a role after the above takes place, the entry's To Do type's default role is assigned to the entry.

Note:

At installation time, the system provides a default role assigned to the system To Do types when first installed called **F1_DFLT**. This is done to allow testing of the system prior to implementing of appropriate

To Do roles for your organization. The recommendation is to configure all the To Do Types with appropriate business oriented To Do roles once they are defined.

Supervisors for a Role

Most organizations have the notion of a supervisor who is responsible for all entries assigned to a given role. A user that is considered a supervisor should be a valid user in a role. In addition, application security is used to provide supervisors access to additional capabilities, namely the ability to review To Do entries assigned to other users and the ability to assign To Do entries to other users.

The pages listed in [To Do Supervisor Functions](#) are meant for supervisors only. So security for these pages should be restricted to those users that are considered supervisors. The [To Do Management](#) portal and the [To Do Search](#) page are available to all users. There is a special access mode for Supervisors to allow those users the ability to assign To Do entries to other users.

The Lifecycle Of A To Do Entry

The following state transition diagram will be useful in understanding the lifecycle of a To Do entry.

A To Do entry is typically created in the **Open** state. Entries of this type can be viewed by all users belonging to the entry's role. Refer to [How Are To Do Entries Created?](#) for information about how entries are created.

An **Open** entry becomes **Assigned** when it is assigned to a specific user or when a user proactively assumes responsibility for the entry. While an entry is **Assigned**, it is visible on the To Do Summary page only by the user who is assigned to it.

Note: To Do entries may be created in the Assigned state. Some To Do background processes may create To Do entries in the **Assigned** state. When a user adds a To Do entry online and assigns the To Do to a user (as opposed to a role), the To Do entry is also created in the **Assigned** state.

An **Assigned** entry may be forwarded to a different user or role. If the entry is forwarded to a role, it becomes **Open** again. This may also be referred to as "reopening" or "unassigning" a To Do entry.

While a To Do Entry is in the **Assigned** state, if your implementation has configured it, you may further indicate the substatus of **In Progress** or **On Hold**.

- When you are ready to start work on an entry you can put it in the **In Progress** state. Refer to [Working On A To Do](#) for more information on how to do this.
- If you are not able to complete the To Do entry, you can put it **On Hold**, or stop working on it to put it back to the **Assigned** state (basically resetting the substatus). In either case, the To Do entry is still assigned to you.
- You may only have one To Do entry in the **In Progress** state. If you already have an entry in this state and you perform any action that puts a new To Do entry in **In Progress**, the other To Do entry will automatically be put into the **On Hold** state.

Important: To configure the system to allow users to use the substatus capability, you simply need to give users security for the Start Progress and Hold Progress and Stop Work access modes on the To Do Entry application service (**CILQTDEP**). The recommendation is that an implementation either grants all To Do users access to these access modes or grants no users access to these access modes.

Note: The substatus values are captured in a separate field (**TD_SUB_STATUS_FLG**). They are only populated if the main status field (**ENTRY_STATUS_FLG**) is in the Assigned status (**W**). But most pages in the system treat these substatus values as another status value. You typically won't see both values Assigned and In Progress or Assigned and On Hold. You'll just see In Progress and On Hold.

When an entry becomes **Complete**, it is no longer visible in various To Do queries (but it remains on the database for audit purposes). There are two ways an entry can become **Complete**:

- A user can manually indicate it is **Complete** (there are several ways to do this).
- For To Do entries that are logically associated with the state of some object, the system automatically marks the entry **Complete** when the object is no longer in the respective state. For example, an entry that's created when an account doesn't have a bill cycle is completed when the account has a bill cycle.

Important: The automatic completion of To Do entries occurs when the background process responsible for creating entries of a given type is executed. Therefore, if you only run these processes once per day, these entries remain **Assigned** even if the object is no longer in the respective state.

- The To Do monitor process may be used to evaluate whether or not the To Do entry can be closed automatically. Refer to [Monitoring a To Do Entry](#) for more information.

How Are To Do Entries Created?

A To Do Entry may be created in the following ways:

- A [background process](#) can create To Do Entries.
- An [algorithm](#) can create entries of a given type. Because the use of algorithms is entirely dependent on how you configure the control tables, the number of types of such entries is indeterminate.
- A user can create entries of To Do types that have a **Manual** usage. Refer to [To Do Entries Created Manually](#) for information about setting up manual To Do types.

For any base product process that includes logic to create a To Do entry, the system supplies a sample To Do type that may be used. Although the To Do types provided by the product are system data, the following information related to each To Do type may be customized for an implementation and is not overwritten during an upgrade:

- The creation process. If the To Do is created by a background process where the background process is referenced on a To Do type. Refer to [To Do Entries Created By Background Processes](#) for more information.
- The routing process. Refer to [To Do Entries May Be Routed Out of the System](#) for more information.
- The priority. Refer to [To Do Type - Main](#) for more information.
- The [roles](#) that may be associated with the To Do type. Refer to [To Do Entries Reference a Role](#) for more information.
- The [message override](#) information. Refer to [Suppress the Creation of the To Do Entry, Adjusting the To Do Role and What Happens When You Work A To Do Entry](#) on page 370 for more information.

Suppress the Creation of the To Do Entry

The system provides the ability to indicate that a To Do Entry should not be created based on conditions. When the system detects that no To Do should be created, there is no error. The system simply returns to the caller with an indication that no To Do was created. This functionality only applies to automatic To Do Entries created by an algorithm or background process. It does not apply to manually created To Do Entries.

Suppress Based on To Do's Message

There are some types of To Do Entries that are generated with a message that is specific to a condition that was found for a record. For example, business errors found when trying to update a record through a system process will generate a To Do entry using the error message as the To Do Entry's message. There may be some use cases where the error reported is not something that a user needs to address and it may be beneficial to your organization to suppress

the To Do Entry. Note that this is only appropriate if the message generated is for informational or warning purposes and doesn't require action or if you know that the error will be resolved by a subsequent step.

The configuration to suppress a To Do entry based on its message is on the [To Do type's message overrides](#) page.

Note: Message Category / Message Number. Every error in the system has a unique message category / number combination. Refer to [The Big Picture of System Messages](#) for more information about message categories and numbers.

We do not supply documentation of every possible message that can be handled by a given To Do type. The best way to build each To Do type's reroute list is during the pre-production period when testing the system. During this period, compile a list of the messages that warrant special behavior described here.

Note that if the To Do type is configured to reference a specific message category / number, it means all To Do entries have the same message. If your organization does not want To Do entries created for this To Do type, then rather than using this suppression technique, you should identify the background process or algorithm that generates the To Do entries of this type and change the configuration there such that it does not try to create the To Do in the first place.

Suppress Based on a Condition

There may be use cases where a To Do entry should be suppressed based on some conditional logic. For example, consider the billing process in Oracle Utilities Customer Care and Billing. There is typically a bill cycle schedule that allows for attempting to bill all the accounts for the bill cycle over a multi-day window. There are some errors that occur on day 1 of the window that may be resolved by day 2 or 3. An implementation may choose to suppress To Do entries for this condition if this is day 1 or day 2 of the bill cycle. If the error still occurs on day 3, then the To Do entry should be generated. This type of condition needs to be determined using an algorithm. The To Do pre-creation plug-ins support returning an indication to suppress the To Do entry. Refer to [To Do Pre-creation Plug-ins](#) for more information.

To Do Entries Created By Background Processes

There are different types of To Do entries created by background processes:

- To Do entries created by dedicated To Do background processes
- To Do entries created for object-specific errors detected in certain background processes
- To Do entries created based on a specific condition

Dedicated To Do Background Processes

There are To Do entries that are created by system background processes whose main purpose is to create To Do entries based on a given condition. For these background processes, the To Do Type indicates the creation background process.

Note that the [Plug-in Driven batch program](#) cannot be used for this purpose. This program assumes that any To Do Type that references it as a creation process is using the link for the [Object-Specific Error Condition](#) use case. If you want to use the plug-in driven batch process to create To Do entries based on a given condition, then you need to follow the pattern described in [To Dos Created by Background Processes for Specific Conditions](#).

Note: If you don't schedule the background process, the entries will not be created! The To Do entries of this type will only be created if you have scheduled the associated background process. Therefore, if you want the system to produce a given entry, schedule the background process.

To Dos Created for Object-Specific Error Conditions

A system background process may create a To Do entry when an error is detected during object-specific processing. This is applicable for processes that do not have built in error handling, for example where there is an explicit "error" state or where the record has an explicit "exception" record.

For these background processes, the To Do Type must reference the creation background process.

To have the system create To Do entries for some or all of the errors generated by one of these processes, you must do the following:

- If you want the system to generate To Do entries for errors detected by one of the background processes below, go to the appropriate To Do type and populate the creation background process.
- If you want the system to generate To Do entries for some errors for the process, but not for all errors, populate the creation background process and then proceed to the [message overrides](#) tab to [suppress](#) certain messages. Do this by indicating the message category and message number you want to suppress. Any error that is suppressed is written to the [batch run](#) .

The functionality will only create a new To Do entry if there is not already an existing (non-complete) To Do for the same To Do type, drill key and message category / message number. It will also check for an existing To Do for a successfully processed record and complete that To Do.

If you do not populate the creation background process, the errors are written to the [batch run](#) .

Note: Errors received while creating a To Do entry. If the background process cannot successfully create a To Do entry to report an object-specific error, the error is written to the batch run tree along with the error encountered while attempting to create the To Do entry.

Note: System errors are not included. To Do entries are not created for a system error, for example an error related to validation of input parameter. These errors are written to the [batch run](#) . Refer to [Processing Errors](#) for more information.

To Dos Created by Background Processes for Specific Conditions

There are some system background processes that create a To Do entry when the process detects a specific condition that a user should investigate. For each background process, the To Do type is an input parameter to the process. The system provides To Do types for each base package background process that may create a To Do entry.

Note: No Creation Process. These To Do types do not need (and should not have) a **Creation Process** specified.

To Do Entries Created By Algorithms

There are To Do entries that are created by algorithm types supplied with the base package. The system supplies a To Do Type for each of these To Do entries that you may use.

If you want to take advantage of these types of entries for system algorithm types, you must do the following:

- Create an [algorithm](#):
 - This algorithm must reference the appropriate Algorithm Type.
 - These algorithms have a parameter of the To Do Type to be created. You should specify the To Do Type indicated in the table.
- Plug the algorithm into the respective control table.

To Do Entries Created Manually

You must set up manual To Do entry types if you want your users to be able to create To Do entries online. Users may create a manual To Do entry as a reminder to themselves to complete a task. Online To Do entries may also be used like electronic help tickets in the system. For example, if a user is having a problem starting service, the user can create a To Do that describes the problem. The To Do can be assigned to a help resolution group that could either resolve the problem or send the To Do back to the initiating user with information describing how to resolve the problem.

If you want to take advantage of manual To Do entries, create a To Do type and specify the following information.

On the Main tab:

- Set the **To Do Type Usage** flag to **Manual**.
- Set the **Navigation Option** to **ToDoEntryMaint** (To Do entry maintenance).
- Set the **Message Category** and **Message Number** to the message you want to be used for To Do entries of this type. The system will populate the message parameter with the Subject. To show only the subject in the To Do's message, use a message with "%1" as its text.

On the Roles tab:

- Specify the [To Do roles](#) that may be assigned to To Do entries of this type.
- Indicate the To Do role that should be defaulted when you create To Do entries of this type.

On the Sort Keys tab:

When a user adds a manual To Do entry, the system creates an entry with three sort key values. (Sort keys may be used on the To Do list page to sort the entries in a different order.) The To Do type should be set up to reference the sort keys as follows:

| Sequence | Description |
|----------|----------------------|
| 1 | Created by user ID |
| 2 | Created by user name |
| 3 | Subject |

We recommend that the keys have an **Ascending** sort order and that the Subject is made the default sort key.

Note: It is possible to define additional sort keys and use a To Do Post Processing algorithm to populate the values. In this case, the base sort keys defined above should still be defined.

On the Drill Keys tab:

When a user adds a manual To Do entry, it is created with a drill key value equal to the To Do entry's ID. When the user clicks the Go To button next to the message in the To Do list, the system uses the drill down application service (defined on the main tab) and the drill key to display the associated To Do entry.

The To Do type must be set up with a drill key that reference the To Do entry table and the To Do entry ID:

| Sequence | Table | Field |
|----------|-------------|-------------|
| 1 | CI_TD_ENTRY | TD_ENTRY_ID |

Refining a To Do Entry's Details at Creation Time

When a To Do Entry is created, the key information provided to the system are the To Do Type and the drill key, which is the identifier of the object related to the To Do entry. With this information, system logic along with algorithms called at creation time can add details to the To Do entry or update important attributes so that the To Do can be worked on by the right team in the right priority.

The topics in this section will highlight the features provided to further refine a To Do Entry at creation time.

Linking Additional Information to a To Do Entry

Additional information may be linked to a To Do entry using characteristics. This may include master data so that the To Do entry is associated with one or more specific main objects in the system. It may also include other information that is helpful to any user that may be working on the To Do entry.

For **manual** To Do entries, the valid characteristic types that may be linked to the To Do entry must be defined on the [To Do Type](#) for that To Do entry. When create a manual To Do entry, the user populates the related characteristics as part of creating the To Do.

For **automatic** To Do entries, the program that generates the To Do may link related data to the To Do using characteristics.

In addition, the system [To Do Pre-creation plug-ins](#) can be used to link additional characteristics. These algorithms would use the drill key, which is the related object for the To Do entry. Based on the drill key, it can look up other information and create appropriate characteristics. Your specific product may be providing one or more algorithms to determine key master data records associated with the related object. For example, Oracle Utilities Customer Care and Billing provides an algorithm that attempts to link a related person, account, premise, service agreement and service point for that drill key. Other edge applications provide a similar algorithm for their relevant entities.

Any information that your user may need to have to help work a To Do entry should be linked to the To Do via a characteristic. For example, if the Rate Class of an account is important or the amount of the previous bill will help determine the priority of the To Do entry, this information may need to be linked as a characteristic.

Note: With the volume of To Do entries in the system, it is recommended to carefully consider what information you are linking to the To Do as a characteristic. Users can drill down on details when investigating a To Do entry. Only very important and critical information that would help users in reviewing To Do entries in the [To Do Management](#) portal and make decisions about prioritization and assignments should be linked as characteristics.

Note, before you can set up these algorithms, you must define the characteristic types that you'll use to hold each of these entities. Also note that it is not necessary to define these characteristics as valid characteristic types on the To Do type.

If your To Do entries reference characteristics that are related to your global context data, you may want to configure an alert algorithm to display an alert if a related entry is **Open** or **Assigned**. Refer to [Installation Options](#) for more information.

Note: Count of related To Do entries. There are some user interfaces that display a count of related To Do entries. This logic looks at foreign key characteristics linked to the To Do entry where the underlying object is a master or transaction object. It counts the distinct list of other non-closed To Do entries that reference the same characteristic(s).

Adjusting the To Do Role

When creating a To Do entry, for a To Do type, there may be attributes of the To Do entry that require that a special set of users work on it. This is sometimes referred to as 'rerouting the To Do entry' to a different role. This section highlights ways to override the role based on conditions specific to a To Do entry.

The information in this section only applies to automatic To Do Entries created by an algorithm or background process. It does not apply to manually created To Do Entries.

Refer to [To Do Entries Reference A Role](#) for the hierarchy used to determine the role .

Reroute Based on To Do's Message

As described in [Suppress the Creation of the To Do Entry](#), To Do entries created for a given To Do type may have different messages based on the specific condition for a record. You may decide that based on the message, the To Do should be routed to a specific Role that is more knowledgeable about a specific error condition. The same [message override](#) configuration that may be used for suppression of a To Do entry, may alternatively be used to assign a specific Role. For example, if certain bill segment errors are always resolved by the rate specialist team, you can indicate the role for that team on the To Do type, message override.

Reroute Based on a Condition

The [To Do Pre-creation plug-ins](#) may be used to assign a specific role based on some condition related to the To Do entry's specific data.

The product provides configuration on [access group](#) to define To Do assignment overrides. The override list defines a To Do type and To Do role. This is useful if your product associates access groups with specific master data for row level security purposes and you would also like to direct To Do entries related to this data to a specific role.

Oracle Utilities Customer Care and Billing also defines similar To Do assignment override configuration on CIS division and Account Management Group.

A pre-creation algorithm is responsible for checking if data linked to the To Do entry is related to a configuration object that supports an assignment override and then looks for an override for the To Do type. You can decide if this algorithm should be plugged in at the To Do Type level or the Installation level. The decision is based on how many To Do types you define overrides for. If it's a small number, then it makes more sense to plug the algorithm in for each To Do type that you define an override for. This ensure that the configuration is only checked for To Do entries that will have an override. However, if the number of To Do types that are eligible for overrides is larger or if the list changing or growing often, it may be better to plug the algorithm in at the Installation level to ensure that every To Do is checked for a possible override.

Note: Note that your product may already provide a base delivered pre-creation algorithm that is checking for this override. If so, that can be used by your implementation. If not, your implementation can provide an appropriate algorithm.

To Do Pre-creation Plug-ins

The system provides two To Do Pre-creation plug-in spots that allow for functionality to add or update information on the To Do Entry that is about to be created. The two plug-in spots are [To Do type](#) and [installation options](#). In general, the installation option To Do pre-creation algorithms would be used for logic that applies to many To Do types and the To Do type pre-creation algorithms would be used for logic that is specific to that To Do type.

If at least one To Do pre-creation algorithm is plugged in on the To Do type, only those algorithms are executed when creating the To Do entry and the installation option algorithms are ignored. The system provides a base delivered To Do type pre-creation algorithm that executes the Installation option To Do pre-creation algorithms. This allows you to control whether the installation algorithms should also be executed for a To Do type that has specific algorithms and if so, when.

The following points highlight functionality supported by both To Do pre-creation plug-in spots.

- Indicate that the To Do entry should be suppressed (not created). The expectation is that this type of algorithm is configured on the To Do type rather than at the installation options level, as this allows for more granular conditions to be checked for a given To Do entry. Refer to [Suppress the Creation of the To Do Entry](#) for more information.
- Linking context specific data to the To Do entry using characteristics. Refer to [Linking Related Information to a To Do Entry](#) for more information.
- Overriding the Role of a To Do entry based on specific configuration related to the To Do's characteristic data. Refer to [Adjusting the To Do Role](#) for more information.

Assigning a Priority

As described in [The Priority of a To Do Entry](#), a To Do type may reference a Calculate Priority algorithm. If so, this algorithm is called as part of the steps to create a To Do entry. The algorithm may use the drill key or any of the related information linked to the To Do as described above to determine priority information.

The Priority Of A To Do Entry

Some To Do entries may be more urgent to resolve than others. A To Do entry is associated with a priority level representing its relative processing order compared to other entries.

Priority level is assigned as follows:

- If one or more **Calculate Priority** plug-ins are defined on the To Do entry's type, the system calls them to determine the entry's priority. They are called initially when a To Do entry is created and each time it gets updated. You may want to use this method if an entry's priority is based on context or time-based factors. For example, when priority takes into consideration account specific attributes. The system also provides a batch process (**F1-TDCLP**) that calls the calculate priority algorithms "at will" for non-closed To Do entries. This is useful when the priority should be reassessed periodically based on factors external to the To Do entry's information. Refer to [To Do Type](#) for more information on priority calculation algorithms. When the priority is determined by one of the algorithms, a log entry is created indicating that the priority was calculated.
- If a priority value has not been determined by a plug-in, the system defaults a To Do entry's initial priority to the value specified on its type.

A user may manually override a To Do entry's priority at any time. When a user overrides the priority, a log entry is created indicating that the priority was overridden. Notice that once a To Do entry's priority is overridden, **Calculate Priority** plug-ins are no longer called so as to not override the value explicitly set by the user.

Note: The system does not use priority values to control order of assignment nor processing of To Do entries. Priority is available to assist your organization with supporting a business practice that ensures higher priority issues are worked on first.

What Happens When You Work A To Do Entry

Many user interface tools allow the user to indicate that they will start working on a To Do entry. Refer to [Working On A To Do](#) for more details. When a user works on an entry, the user is transferred to the maintenance page associated with the entry (the To Do entry's drill key). The page to which the user is taken is configured on the To Do type.

It is also possible to configure the To Do type to launch a script when a user works on a To Do entry rather than taking the user to a specific page. The script can check conditions related to the To Do entry to determine a more appropriate page or could be configured to walk the user through the steps required to resolve the To Do entry.

A script is linked to a To Do type based on its message number using the [To Do type's message overrides](#). Refer to [Executing A Script When A To Do Is Selected](#) for more information.

In certain pages, taking an action to work on a To Do entry automatically assigns the To Do entry to the user. For users in implementations that also take advantage of the assignment substatus values, the To Do entry is also updated to the **In Progress** substatus. Refer to [The Lifecycle Of A To Do Entry](#) on page 363 for information about configuring the system to use the substatus values.

Monitoring A To Do Entry

A To Do type may reference a To Do monitor [algorithm](#). The algorithms are executed by the To Do monitor background process (F1-TDMON). The process executes the monitor algorithms for any non-complete To Do entry whose To Do type references at least one monitor algorithm.

Monitor algorithms may be useful if there are business requirements where a To Do could be automatically completed based on criteria that the algorithm can review. For example, an algorithm may be used to detect if the situation that caused the To Do Entry to be generated has been remedied in the meantime, allowing for the To Do Entry to be completed.

To Do Entries Have Logs

Each [To Do entry](#) has a To Do log that maintains a record of the To Do's progress in the system. For example, the To Do log indicates when the To Do entry was created, when it was assigned to a user and to whom it was assigned, and when and by whom it was completed. Users can view the log to see who assigned them a particular To Do and whether any work has already been done on the To Do.

A log entry is created for all actions that can be taken on a To Do entry. Log entries are created for the following events:

- A To Do entry is created (either by the system or by a user)
- A To Do entry is completed (either by the system or by a user)
- A user takes an open To Do entry
- A supervisor assigns a To Do entry
- The To Do entry's status is updated and the event is not already covered by another log entry type
- A user forwards an entry to another user or role
- A user sends back a To Do to the user who forwarded it
- A user manually adds a log entry to record details about the To Do's progress
- A user manually overrides the To Do entry's priority
- The To Do entry's priority was updated as a result of a calculate priority algorithm.

Fastpath: For information about the contents of log entries for each of the events, refer to [Log Entry Events](#).

Implementing Additional To Do Entry Business Rules

If your business practice calls for additional validation rules or processing steps to take place after a To Do Entry is created or updated, you may want to take advantage of the **To Do Post Processing** plug-ins defined on [To Do type](#).

For example, you may want to validate that To Do entries are only assigned to users with the proper skill levels needed to resolve them. Refer to **F1-VAL-SKILL** for a sample algorithm handling such validation.

To Do Entries May Be Routed Out Of The System

A To Do type can be configured so that its entries are interfaced to another system.

For example, a given To Do type can be configured to create an Email message whenever a new To Do entry is created. The following points describe how to do this:

- Define the name of the background process responsible for interfacing the new To Do entries to another system on the respective To Do type. The base package contains a batch process called **F1-TDEER** that can be used for most situations. This batch process invokes the **External Routing algorithms** defined on each entry's To Do type.
- Plug in an appropriate **External Routing** algorithm on the respective To Do type. The logic in this type of algorithm performs the interface efforts for a specific To Do entry. For example, if an Email message should be created for a To Do entry, the logic in the algorithm would compose and send the Email message(s) for a specific To Do entry.

To Do Information May Be Formatted By An Algorithm

A **To Do Information** algorithm may be plugged in on the [installation record](#) to format the standard To Do information that appears throughout the system. This algorithm may be further overridden by a corresponding plug-in on the [To Do Type](#).

Periodically Purging To Do Entries

The To Do Entry is configured for [Information Lifecycle Management](#) on page 139. This is the recommended tool for managing older records.

A purging batch process is also supplied **F1-TDPG**. However, it has some limitations that should be considered. The purging process does not perform any referential integrity. As such, if you are proactively purging records that are not very old, they could be referenced by other objects that are still active.

The process purges **Completed** To Do entries. This background process offers you the following choices:

- You can purge all To Do entries older than a given number of days.
- You can purge To Do entries for a specific list of To Do types that are older than a given number of days.
- You can purge all To Do entries except for a specific list of To Do types that are older than a given number of days.

Note: Different retention periods for different types of To Do entries. Keep in mind that the purge program allows you to retain different types of entries for different periods of time.

Setting Up To Do Options

The topics in this section describe how to set up To Do management options.

Installation Options

There are a number of installation options that may be configured to govern various aspects of To Do processing.

- A **To Do Information** algorithm may be plugged in on the Installation record. Refer to [To Do Entries My be Formatted By An Algorithm](#) for more information.
- A **To Do Pre-creation** algorithm may be plugged in on the Installation record to set additional information for a To Do entry before it is created. Refer to [To Do Pre-creation Plug-ins](#) for more information.
- A **Next To Do Assignment** algorithm must be plugged into the Installation record if your organization opts to use the next assignment feature supported by the [Current To Do Zone](#). The algorithm is responsible for determining the next To Do entry the user should work on. Make sure you provide users with security access rights to the zone's next assignment action. Refer to the [Work Distribution](#) zone for more information.
- If your To Do entries reference characteristics related to your global context data and your product supports sidebar alerts generated by algorithms, you may want configure an algorithm to display an alert if an entry is **Open** or **Assigned** for the data currently in context. Refer to your product's documentation to determine if these types of alerts are supported.

Messages

You need only set up new messages if you use algorithms to create To Do entries or prefer different messages than those associated with the base package's To Do types.

Feature Configuration

The base package is provided with a generic **Activity Queue Management** [Feature Configuration](#) type. You may want to set up a feature configuration of this type to define any To Do management related options supporting business rules specific to your organization.

For example, the base package provides the following plug-ins to demonstrate a business practice where To Do entries are only assigned to users with the proper skill levels to work on them.

- The base **To Do Post Processing** To Do Type algorithm **F1-VAL-SKILL** validates that a user has the necessary skill levels required to work on a given To Do entry.
- The base **Next To Do Assignment** installation options algorithm **F1-NEXT-TDSK** has the ability to assign To Do entries to users that have the proper skills to work on them. This plug-in is applicable if your organization practices [work distribution](#) "on demand."

You must set up such an **Activity Queue Management** feature configuration if you want to use any of the above base package plug-ins.

The following points describe the various **Option Types** provided with the base package:

- **Skill.** This option provides a reference to a skill category. For example, if you were using characteristics to represent skill categories then you should reference each characteristic type using this option.
- **Override Skill.** This option provides an override skill information reference for a specific message. For example, if you were using a To Do Type characteristic to specify an override skill category and level for a specific message category / number then you would reference this characteristic type using this option.

Note: Skill Setup. Refer to the description of the above base package algorithms for further details on how to setup skill level information.

Note: More Options. Your implementation may define additional options types. You do this by add new lookup values to the lookup field **F1QM_OPT_TYP_FLG**.

Note: Only one. The system expects only one **Activity Queue Management** feature configuration to be defined.

Defining To Do Roles

This section describes the control table used to maintain To Do roles.

To Do Role - Main

The **Main** page is used to define basic information about a To Do role.

To maintain this information, select **Admin > General > To Do Role**.

Description of Page

Enter a unique **To Do Role** and **Description** for the To Do role.

The grid contains the ID of each **User** that may view and work on entries assigned to this role. The First Name and Last Name associated with the user is displayed adjacent.

Note: System Default Role. The system supplies a default role **F1_DFLT** linked to each system To Do type. This is done so that To Do functionality may be tested prior to the creation of appropriate business oriented To Do roles.

In addition, various "type" objects or algorithms may reference a To Do role to use when creating a To Do for a given business scenario. This is dependent on your specific product.

To Do Role - To Do Types

The **To Do Types** page defines the To Do types that may be viewed and worked on by users belonging to a given To Do role.

To maintain this information, select **Admin > General > To Do Role** and navigate to the **To Do Types** page.

Description of Page

Enter the ID of each **To Do Type** whose entries may be viewed and worked on by the role.

Use As Default is a display-only field that indicates if the role is assigned to newly created entries of this type. You may define the default role for a given To Do type on the To Do Type maintenance page.

 **CAUTION:** If you remove a To Do type where this role is the default, you must define a new role as the default for the To Do type. You do this on the To Do Type maintenance page.

Defining To Do Types

This section describes the control table used to maintain To Do types.

To Do Type - Main

The **Main** page is used to define basic information about a To Do type.

Fastpath: Refer to [The Big Picture Of To Do Lists](#) for more information about To Do types and To Do lists in general.

To maintain this information, select **Admin > General > To Do Type**.

 **CAUTION:** Important! If you introduce a To Do type, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Description of Page

Enter a unique **To Do Type** and **Description** for the To Do type.

Owner indicates if this entry is owned by the base package or by your implementation (**Customer Modification**).

Use the **Detailed Description** to provide further details related to the To Do Type.

Enter the default **Priority** of To Do entries of this type in respect of other To Do types. Refer to [The Priority Of A To Do Entry](#) for more information.

For **To Do Type Usage**, select **Automatic** if To Dos of this type are created by the system (i.e., a background process or algorithm). Select **Manual** if a user can create a To Do of this type online.

Define the **Navigation Option** for the page into which the user is transferred when drilling down on a To Do entry of this type.

Use **Creation Process** to define the background process, if any, that is used to manage (i.e., create and perhaps complete) entries of this type. A **Creation Process** need only be specified for those To Do types whose entries are created by a background process. Refer to [To Do Entries Created By Background Processes](#) for more information.

Use **Routing Process** to define the background process that is used to download entries of a given type to an external system, if any. A **Routing Process** need only be specified for those To Do types whose entries are routed to an external system (e.g., an Email system or an auto-dialer). Refer to [To Do Entries May Be Routed Out Of The System](#) for more information.

Use **Message Category** and **Message Number** to define the message associated with this To Do type's entries. Note: this message will only be used if the process that creates the To Do entry does not supply a specific message number. For example, the process that creates To Do entries that highlight bill segments that are in error would not use this message; rather, the entries are marked with the message associated with the bill segment's error.

Use the characteristics collection to define a **Characteristic Type** and **Characteristic Value** common to all To Do entries of this type. You may enter more than one characteristic row for the same characteristic type, each associated with a unique **Sequence** number. If not specified, the system defaults it to the next sequence number for the characteristic type.

To Do Type - Roles

The **Roles** page defines the roles who may view and work on entries of a given To Do type.

To maintain this information, select **Admin > To Do Type > Search** and navigate to the **Roles** page.

Description of Page

Enter each **To Do Role** that may view and work on entries of a given type. Turn on **Use as Default** if the role should be assigned to newly created entries of this type. Only one role may be defined as the default per To Do type.

Fastpath: Refer to [To Do Entries Reference A Role](#) for more information about roles and To Do entries.

To Do Type - Sort Keys

The **Sort Keys** page defines attributes that may be used to sort To Do entries.

The To Do Information zone on the To Do Management portal provides the ability to search for To Do entries using sort keys and includes up to five sort key values as columns in the results, which may be used for sorting as required.

The To Do list page includes an **Extra Information** option to allow To Do entries to be sorted by a selected sort key. Note the default sort key for this type of sorting is also defined on To Do type.

Note that this information is captured as a string and is meant for sorting purposes. The system does not capture data type information to be able to format the information for display. For example, dates are not going to display as per the user's display profile configuration.

To maintain this information, select **Admin > To Do Type > Search** and navigate to the **Sort Keys** page.

CAUTION: Do not change this information unless you are positive that the process / algorithm that creates entries of a given type stores this information on the entries.

Description of Page

The following fields display for each sort key.

Sequence is the unique ID of the sort key.

Description is the description of the sort key that appears on various pages.

Use as Default indicates the default sort key that is initially used when a user opens the To Do List page. Only one sort key may be defined as the default per To Do type.

Sort Order indicates whether the To Do entries should be sorted in **Ascending** or **Descending** order when this sort key is used on the To Do List page.

Owner indicates if this entry is owned by the base package or by your implementation (**Customer Modification**).

To Do Type - Drill Keys

The **Drill Keys** page defines the keys passed to the application service (defined on the Main page) when you drill down on an entry of a given type.

To maintain this information, select **Admin > To Do Type > Search** and navigate to the **Drill Keys** page.

CAUTION: Do not change this information unless you are positive that the process / algorithm that creates entries of a given type stores this information on the entries.

Description of Page

Navigation Option shows the page into which the user is transferred when drilling down on a To Do entry of this type.

The following fields display for each drill key.

Sequence is the unique ID of the drill key.

Table and **Field** are passed to the application service when you drill down on an entry of a given type.

Owner indicates if this entry is owned by the base package or by your implementation (**Customer Modification**).

To Do Type - Message Overrides

The **Message Overrides** page is used if you want To Do entries that reference a given message category / number to be routed to a specific To Do role or suppressed altogether or if you want to associate a script to a given message category / number.

Fastpath: Refer to [To Do Entries Reference A Role](#) and [Suppress the Creation of the To Do Entry and Adjusting the To Do Role](#) for more information.

To maintain this information, select **Admin > To Do Type > Search** and navigate to the **Message Overrides** page.

Description of Page

The following fields display for each override.

Message Category and **Number** allow the message to be overridden.

Exclude To Do Entry indicates if a To Do entry of this type that references the adjacent **Message Category** and **Number** should not be created.

Override Role indicates the to do role to which a To Do entry of this type that references the adjacent **Message Category** and **Number** should be addressed. This field is protected if **Exclude To Do Entry** is on.

Script indicates the script that should execute when a user drills down on a To Do entry of this type that references the adjacent **Message Category** and **Number**. This field is protected if **Exclude To Do Entry** is on. Refer to [What Happens When You Work A To Do Entry](#) on page 370 for more information.

To Do Type - To Do Characteristics

The **To Do Characteristics** page defines characteristics that can be defined for To Do entries of this type. The characteristic types for characteristics that are linked to the To Do entry as a result of a pre-creation algorithm do not need to be defined here.

To maintain this information, select **Admin > General > To Do Type > Search** and navigate to the **To Do Characteristics** page.

Turn on the **Required** switch if the **Characteristic Type** must be defined on To Do entries of this type.

Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on. Use **Sequence** to control the order in which characteristics are defaulted.

To Do Type - Algorithms

The **To Do Algorithms** page defines the algorithms that should be executed for a given To Do type.

To maintain this information, select **Admin > To Do Type > Search** and navigate to the **Algorithms** page.

Description of Page

The grid contains **Algorithms** that control important To Do functions. If you haven't already done so, you must [set up the appropriate algorithms](#) in your system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|---------------------------|---------------------|--|
| Calculate Priority | Optional | <p>Algorithms of this type may be used to calculate a To Do entry's priority. Refer to The Priority of a To Do Entry for more information on when this plug-in is called.</p> <p>Note that it is not the responsibility of the algorithms to actually update the To Do entry with the calculated priority value but rather only return the calculated value. The system carries out the update as necessary.</p> <p>If more than one algorithm is plugged-in the system calls them one by one until the first to return a calculated priority.</p> |
| External Routing | Optional | <p>Algorithms of this type may be used to route a To Do entry to an external system.</p> <p>The base package F1-TDEER background process invokes the algorithms for every To Do entry that its type references the process as the Routing Process and that the entry was not already routed. The background process marks an entry as routed by updating it with the batch control's current run number.</p> <p>If more than one algorithm is plugged-in the batch process calls them one by one until the first to indicate the To Do entry was routed.</p> |
| To Do Information | Optional | <p>We use the term "To Do information" to describe the basic information that appears throughout the system to describe a To Do entry. The data that appears in "To Do information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the "To Do information" algorithm on installation options or the system default "To Do information" if no such algorithm is defined on installation options.</p> |

| System Event | Optional / Required | Description |
|------------------------------|---------------------|--|
| To Do Monitor | Optional | Algorithms of this type are executed by the To Do Monitor background process and may be used to periodically review a To Do entry and perform actions, if needed. Refer to Monitoring a To Do Entry for more information. |
| To Do Post-Processing | Optional | Algorithms of this type may be used to validate and/or further process a To Do entry that has been added or updated. |
| To Do Pre-Creation | Optional | Algorithms of this type are called when a To Do entry is being added. Refer to Refining a To Do Entry's Details at Creation Time for more information. To Do Type pre-creation algorithms override the Installation level pre-creation algorithms. |

Implementing The To Do Entries

To enable the To Do entries visible in the To Do Type page, you must configure the system as follows:

- Define the To Do roles associated with each To Do type and link the appropriate users to them. Once you have defined the roles appropriate for your organization's To Do types, remove the reference to this system default role **F1_DFLT**. Refer to [To Do Entries Reference A Role](#) for more information.
- For any To Do Type that is provided for a specific background process, the To Do simply needs to reference the appropriate Creation Background Process. When the background process is scheduled, To Dos are created based on the logic of the related background process. This applies to [To Dos Created for Object-Specific Error Conditions](#) and [Dedicated To Do Background Processes](#).
- For any To Do Type that is provided for creation by an algorithm or other process, there may be configuration required to populate that To Do type as an algorithm parameter or as an attribute on a control table.

Note: Refer to the description of the To Do type for more information.

Background Processes

This chapter covers various topics related to background processes. Besides providing an overview of background process functionality, the various tools available within the application to define, submit and monitor background processes are covered.

Note: Your specific source application may have additional background process topics. Please refer to the documentation section that applies to your source application for more information.

Understanding Background Processes

This section describes various topics related to the background processes that perform many important functions throughout your product such as:

- Processing To Do Entries
- Monitor processes that select records in a given state to progress them to their next state in their lifecycle
- Processes that purge data
- Processes that extract data

- And many more...

Background Processing Overview

While the system relies on a scheduler to secure and execute its background processes, there are additional issues that you should be familiar with:

- Batch control records are used for the following purposes:
 - Define the code that executes the logic associated with the background process.
 - For processes that extract information, the batch control record defines the next batch number to be assigned to new records that are eligible for extraction. For example, the batch control record associated with the process that routes To Do entries to an external system defines the next batch number to be assigned to new To Do entries that are configured with this batch control. When this To Do external routing process next runs, it selects all To Do entries marked with the current batch number (and increments the next batch number).
 - The batch control record for each background process organizes audit information about the historical execution of the background process. The system uses this information to control the restart of failed processes. You can use this information to view error messages associated with failed runs.
 - Many processes have been designed to run in parallel in order to speed execution. For example, the process that applies updates for a migration data set import for CMA can be executed so that multiple "threads" are processing a different subset of records (and multiple threads can execute at the same time). Batch control records associated with this type of process organize audit information about each thread in every execution. The system uses this information to control the restart of failed threads. Refer to [Parallel Background Processes](#) for more information.
 - Some processes define extra parameters. These parameters are defined with the batch control. Default values may also be captured for each parameter. They will be used when the [background process is submitted on-line](#).

The following diagram illustrates the relationships that exist for batch control records.

Results of each batch run can be viewed using the [Batch Run](#) portal.

Refer to [Batch Scheduler Integration](#) for information about the integration with the Oracle Scheduler.

Parallel Background Processes

Many processes have been designed to run in parallel in order to speed execution. This is referred to as running the process with multiple "threads".

The system provides two strategies for distributing the data to the multiple threads.

- **Thread Level SQL Select.** This strategy is sometimes referred to as the “thread iterator” strategy. In this strategy, the batch job uses the primary key to figure out how to evenly distribute key ranges to each thread. Each thread is then responsible for selecting the records. In this strategy, the threads should also re-select the data periodically to release the cursor, which aids in performance. Note that this strategy is preferred but may only be used under the following conditions:

- The data from only one maintenance object is being processed.
- The primary key for the maintenance object is a single, numeric system generated key.

Note: Parameters may be used to override the low and high id. Refer to [Parameters Supplied to Background Processes](#) for more information.

- **Job Level SQL Select.** This strategy is sometimes referred to as the “standard commit” strategy. In this strategy, the keys for the records to be processed by the batch job are all selected first and stored in a temporary table. The batch job then supplies each thread with a range of keys that it should process. This strategy is used if multiple maintenance objects are being processed by the batch job; if the primary key of the maintenance object has multiple parts or if the primary key is non-numeric.

The multi-threading logic relies on the fact that primary keys for master and transaction data are typically system generated random keys. In addition, if the data is partitioned, it is expected to be partitioned based on the primary key.

Note: The detailed description in the metadata for each batch control provided with the system should indicate if it may be run in parallel. Note that the strategy used is not typically indicated in the detailed description.

Note: Overriding the thread ranges. Your implementation has the ability to override the thread ranges if certain data in your system takes longer to process. For example, imagine you have a single account in Oracle Utilities Customer Care and Billing that has thousands of service agreements (maybe the account for a large corporation or a major city). You may want to set up the thread ranges to put this large account into its own thread and distribute the other accounts to the other threads. To do this, you should create the appropriate batch thread records ahead of time in a status of **Thread Ready (50)** with the key ranges pre-populated. Note that the base product does not provide the ability to add batch thread records online. If you are interested in more information about this technique, contact Customer Support.

Optimal Thread Count

Running a background process in multiple threads is almost always faster than running it in a single thread. The trick is determining the number of threads that is optimal for each process.

Note: A good rule of thumb is to have one thread for every 100 MHz of application server CPU available. For example if you have four 450 MHz processors available on your application server, you can start with 18 threads to begin your testing: $(450 * 4) / 100 = 18$.

This is a rule of thumb because each process is different and is dependent on the data in your database. Also, your hardware configuration (i.e., number of processors, speed of your disk drives, speed of the network between the database server and the application server) has an impact on the optimal number of threads. Please follow these guidelines to determine the optimal number of threads for each background process:

- Execute the background process using the number of threads dictated by the rule of thumb (described above). During this execution, monitor the utilization percentage of your application server, database server and network traffic.
- If you find that your database server has hit 100% utilization, but your application server hasn't one of the following is probably occurring:
 - There may be a problematic SQL statement executing during the process. You must capture a database trace to identify the problem SQL.
 - It is also possible that your commit frequency may be too large. Commit frequency is a parameter supplied to every background process. If it is too large, the database's hold queues can start swapping. Refer to [Parameters Supplied to Background Processes](#) for more information about this parameter.
- It is normal if you find that your application server has hit 100% utilization but your database server has not. This is normal because, in general, all processes are CPU bound and not IO bound. At this point, you should decrease

the number of threads until just under 100% of the application server utilization is achieved. And this will be the optimal number of threads required for this background process.

- If you find that your application server has not hit 100% utilization, you should increase the number of threads until you achieve just under 100% utilization on the application server. And remember, the application server should achieve 100% utilization before the database server reaches 100% utilization. If this proves not to be true, something is probably wrong with an SQL statement and you must capture an SQL trace to determine the culprit.

Another way to achieve similar results is to start out with a small number of threads and increase the number of threads until you have maximized throughput. The definition of "throughput" may differ for each process but can be generalized as a simple count of the records processed in the batch run time. For example, in the Billing background process in Oracle Utilities Customer Care and Billing, throughput is the number of bills processed per minute. If you opt to use this method, we recommend you graph a curve of throughput vs. number of threads. The graph should display a curve that is steep at first but then flattens as more threads are added. Eventually adding more threads will cause the throughput to decline. Through this type of analysis you can determine the optimum number of threads to execute for any given process.

Parameters Supplied To Background Processes

This section describes the various types of parameters that are supplied to background processes.

General Parameters

The following information is passed to every background process.

- **Batch code.** Batch code is the unique identifier of the background process.
- **Batch thread number.** Thread number is only used for background processes that can be run in multiple parallel threads. It contains the relative thread number of the process. For example, if the billing process has been set up to run in 20 parallel threads, each of the 20 instances receives its relative thread number (1 through 20). Refer to [Optimal Thread Count for Parallel Background Processes](#) for more information.
- **Batch thread count.** Thread count is only used for background processes that can be run in multiple parallel threads. It contains the total number of parallel threads that have been scheduled. For example, if the billing process has been set up to run in 20 parallel threads, each of the 20 instances receives a thread count of 20. Refer to [Optimal Thread Count for Parallel Background Processes](#) for more information.
- **Batch rerun number.** Rerun number is only used for background processes that download information that belongs to given run number. It should only be supplied if you need to download an historical run (rather than the latest run).
- **Batch business date.** Business date is only used for background processes that use the current date in their processing. For example, a billing process may use the business date to determine which bill cycles should be downloaded. If this parameter is left blank, the system date is used. If supplied, this date must be in the format YYYY-MM-DD. Note: this parameter is only used during QA to test how processes behave over time.

Note: There may be a slight lag in submission time for batch jobs submitted online. If the desired execution date/time is close to midnight, it is possible that your batch job will run on the day after you submit it. If you have left the business date blank in this case, keep in mind that your business date would be set to the day after you submit the job.

- **Override maximum records between commits.** This parameter is optional and overrides each background process's Standard Commit. You would reduce this value, for example, if you were submitting a job during the day and you wanted more frequent commits to release held resources. You might want to increase this value when a background process is executed at night (or weekends) and you have a lot of memory on your servers.
- **Override maximum minutes between cursor re-initiation.** This parameter is optional and overrides each background process's Standard Cursor Re-Initiation Minutes. You would reduce these values, for example, if you were submitting a job during the day and you wanted more frequent commits to release held resources (or more frequent cursor initiations). You might want to increase these values when a background process is executed at night (or weekends) and you have a lot of memory on your servers.
- **User ID.** Please be aware of the following in respect of user ID:
 - Both the user submitting the job and the user ID recorded on the batch submission should have access to the application service for the batch control that secures execution.

- Any batch process that stamps a user ID on a record it creates or updates uses this user ID in applicable processing.
- This user ID's [display profile](#) controls how dates and currency values are formatted in messages.
- When submitting a batch job online, the batch user, language and email address are defaulted to the details of the user submitting the job. Only users that are granted the User Override access mode on the Batch Job Submission application service can override the batch user ID.
- If the submission user has user override privileges, they have the ability to retain the original batch user details when duplicating or rerunning a batch job from online submission. If the 'Run as original user' box is checked, the batch user, language and email address from the original batch run will be copied to the new batch job. If not, the user details are defaulted from the submission user.
- **Password.** Password is not currently used.
- **Language Code.** Language code is used to access language-specific control table values. For example, error messages are presented in this language code.
- **Trace Program Start, Trace Program Exit, Trace SQL and Trace Output.** These switches are only used during QA and benchmarking. If trace program start is checked, a message is displayed whenever a program is started. If trace program exit is checked, a message is displayed whenever a program is exited. If trace SQL is checked, a message is displayed whenever an SQL statement is executed. If trace output is checked, special messages formatted by the background process are written.

Note: The information displayed when the trace output switch is turned on depends on each background process. It is possible that a background process displays no special information for this switch.

Common Additional Parameters

Each batch control supports the definition of additional parameters. There are some additional parameters that are common to all batch processes or common to a specific type of batch process. The batch control should be delivered with the appropriate additional parameters. However, when new additional parameters are introduced, existing batch controls may not be updated with the new additional parameter.

The following table highlights the common parameters that may be linked to a batch control. Note that for batch parameters, although there is a sequence number that controls the displayed order of the parameter, the batch process does not use the sequence to identify a particular parameter but rather uses the parameter name. In some cases multiple parameter names are supported (a 'camel case' version and an 'all caps' version).

| Parameter Name | Description | Additional Comments |
|-------------------------------|--|--|
| MAX-ERRORS / maxErrors | Each of the batch processes has, as part of its run parameters, a preset constant that determines how many errors that batch process may encounter before it is required to abort the run. A user can override that constant using this parameter. | The input value must be an integer that is greater than or equal to zero. The maximum valid value for this parameter is 999,999,999,999,999. |
| DIST-THD-POOL | Each batch process executes in a thread pool. This parameter is only necessary if the batch process should execute in a different thread pool than the default thread pool. | The default thread pool name is DEFAULT . |

| Parameter Name | Description | Additional Comments |
|---|---|---|
| emailMode | When the batch job is submitted with an associated email address, the default logic is to send an email when the job completes regardless of success or failure. Use this parameter to limit the email based on the status of the job when it ends. | Valid Values <ul style="list-style-type: none"> • ERROR — send an email only when the job ends in Error status. • SUCCESS — send an email only when the job ends in successfully. • ALL — always send an email only when the job ends. (This is the default.) |
| The following parameters are only applicable to jobs that use the Thread Level SQL Select method of distributing work to threads as described in Parallel Background Processes . | | |
| overrideLowIdValue | Specifies a new low id to use in calculating the range for a thread. The framework by default assumes that the Id is between 0's (e.g. 000000000) and 9's (e.g. 999999999), but this parameter will override the low value. | The parameter value can be an actual number or it can be set to auto . If auto is configured, it is set to the lowest current value on the database table associated with the background process. |
| overrideHighIdValue | Specifies a new high id to use in calculating the range for a thread. The framework by default assumes that the Id is between 0's (e.g. 000000000) and 9's (e.g. 999999999), but this parameter will override the high value. | The parameter value can be an actual number or it can be set to auto . If auto is configured, it is set to the highest current value on the database table associated with the background process. |
| idRangeOverrideClass | Use this parameter to specify a custom class to do thread range calculation. During batch execution, this override class is instantiated and the setter methods called to initialize the Ids as required. The low and high getter methods are called to retrieve the high and low ids to be used for the run. | The class name specified must implement interface <code>com.splwg.base.api.batch.BatchIdRangeOverride</code> . |
| The following parameters are only applicable to jobs that perform a single commit, for example for extract batch jobs. | | |
| numRecordsToFlush | This parameter defines how frequently to flush the Hibernate cache to prevent high heap consumption and Out Of Memory Errors. | |

Specific Batch Parameters

Some background processes define additional parameters that are specific to their functionality. When a process receives additional parameters, they are defined and documented in the batch control entry in the application.

When submitting a batch job online, any default parameter values configured on the batch control record will be defaulted and may be overridden. Note that if the parameter value is configured to be Encrypted on the batch control configuration, the value will be shown encrypted.

Indicating a File Path or File Name

Some of the system background processes use extra parameters to indicate a File Path and/or File Name for an input file or an output file. For example, most extract processes use File Path and File Name parameter to indicate where to place the output file.

For the file path parameter, refer to [Referencing URIs](#) for several points related to populating the file path and the supported syntax.

For the file name parameter, there are extract processes that support defining a file name that ends in ".zip" or ".gz", which will automatically result in writing the file with zip or gzip compression (based on the suffix). Similarly, there are upload processes that support decompression of files using the appropriate method based on the file name ending in ".zip" or ".gz". If the extract or upload process supports compression / decompression, it should be indicated accordingly in the description of the File Name parameter. If a batch control doesn't explicitly indicate that it supports compression or decompression in its description, the assumption should be that it is not supported.

In addition, there are extract and import processes that support automatic signing, encryption and decryption of the file content using PGP standards. File names ending in .pgp will be parsed to determine whether encryption, signing, compression or a combination of the three applies. If the file has a .pgp extension and requires decryption or signature verification, a runtime error will be issued if no encryption or signing key ring parameters are supplied.

Encrypting and Signing Files

Some files created by data export related batch processes, may need to be encrypted and/or digitally signed for security purposes. Similarly, batch upload processes may need to verify the signature and/or decrypt the content of the file being imported.

New batch parameters control whether encryption or digital signing applies to files extracted or uploaded by the process. Both encryption and signing use Pretty Good Privacy (PGP) standards.

Processes that include a file name parameter, such as those using the plug-in driven extract template, support a file name extension of '.pgp'. Files ending with this extension are encrypted and/or signed using the encryption key parameters described in the next section.

Processes that have an internally constructed format for the file name, such as those using the generalized initial export template, perform encryption and/or signing according to whether the encryption parameters are supplied. An extension of '.pgp' is added to the constructed file name.

Extract Process Encryption Parameters

| Parameter Name | Description | Additional Comments |
|----------------------------|--|--|
| encryptExternalKey | Use this key ring parameter to configure the external key provided by the recipient of the file. | If populated, the batch output file will be encrypted using a runtime generated key. The generated key will be encrypted using the active public key stored on the key ring. The recipient will use their private key to decrypt the generated key so the file may be decrypted. Only external public key rings may be used. |
| encryptSignatureKey | Use this key ring parameter to configure the internal key used to sign the file. | If populated, the batch output file will be signed using the active private key stored on the key ring. The assumption is that the corresponding public key has been shared with the recipient. Only internal file encrypting / signing key rings may be used. |

Upload Process Encryption Parameters

| Parameter Name | Description | Additional Comments |
|----------------------------|--|--|
| decryptInternalKey | Use this key ring parameter to configure the internal key to be used to decrypt the file to be uploaded. | If populated, the generated key received with the input file will be decrypted using the active private key stored on the key ring. The data is then decrypted using the generated key. Only internal file encrypting / signing key rings may be used. |
| decryptSignatureKey | Use this key ring parameter to configure the public signature key provided by the sender of the file. | If populated, the input file signature will be verified using the active public key stored on the key ring. Only external key rings may be used. |

You may use the Batch Control Query portal to find all batch controls supporting these options.

Refer to [File Encryption and Signing Keys](#) for more information on maintaining internal and external encryption keys.

Manifest File

Batch processes that create files, for example data export related batch processes, may create one or more files in each processing thread. External applications that consume these files need to process them only when the entire batch process is successfully completed. To automate the consumption of such files, the external application may leverage a function to be triggered upon the creation of a manifest file to process all the files referenced by the manifest. The manifest file includes details such as content hash value, file size information etc that assist in confirming that file content is completed and has not been tampered with prior to processing the files.

The following sections provide additional information about manifest files.

The Manifest Option Batch Parameter

Manifest file creation is supported on certain base product extract related batch controls only. These batch controls include the **Manifest Option** batch parameter that controls whether a manifest file should be created or not upon successful completion of the batch process. You may use the Batch Control Query portal to find all batch controls supporting this option.

Manifest File Information

Manifest file content is provided in JSON format and includes the following information:

- The version of the manifest details structure.
- The batch control code, run number and rerun number identifying the batch run producing the files
- Total number of files created by the batch run.
- Total number of records processed by the batch run.
- The manifest creation timestamp in ISO format.
- The previously completed batch run number, if any.
- The manifest file produced by the previously completed batch run, if any. This may be used to ensure files are processed in a proper order and assist in detecting potential situations of missing files.
- A list of files created by the batch run that includes the following details for each file: the file's name, its size in bytes and the SHA-256 hash value of the file's content.

The manifest file name is constructed as follows:

```
[batch control]_[batch run number]_[batch rerun number]_manifest.json
```

The following is an example of the manifest file structure.

```
{
  "version": 1,
  "batchCode": "HD-PDE",
  "batchRunNumber": 106,
  "batchRerunNumber": 0,
  "totalFiles": 3,
  "recordsProcessed": 10,
  "timeStamp": "2020-05-02T16:55:43.000353Z",
  "previousBatchRunNumber": "105",
  "previousManifestFileName": "HD-PDE_105_0_manifest.json",
  "fileDetails": [
    {
      "fileName": "SOME_FILE_NAME_001.json.gz",
      "fileSize": 1543,
      "hashAlgorithm": "SHA-256",
      "hashValue": "ff7d4e466f93cad4a18ab009080916baff631e03b728e2f2684c4a4f92ccbe1"
    },
    {
      "fileName": "SOME_FILE_NAME_002.json.gz",
      "fileSize": 1182,
      "hashAlgorithm": "SHA-256",
      "hashValue": "78869e7ce971f28a70f5b35693a05726ba66109fecf492edb60291a62ae1ba9f"
    },
    {
      "fileName": "SOME_FILE_NAME_003.json.gz",
      "fileSize": 1182,
      "hashAlgorithm": "SHA-256",
      "hashValue": "78869e7ce971f28a70f5b35693a05726ba66109fecf492edb60291a62ae1ba9f"
    }
  ]
}
```

Verifying The Manifest File

The **Verify Manifest File** web service may be used by an external system to validate that the manifest file it has received for a specific batch run is not corrupted or tampered with. The service returns the manifest file name and the hash value of its content for the requested batch run allowing the caller to compare their file details with the returned values.

Sharing Customer Exported Data

Some data export related batch processes support an option that streamlines the process by which customer extracted data may be routed to and shared with Oracle so it can be uploaded to Oracle's data lake for analytic purposes. These batch controls include the **Copy to Oracle** batch parameter that controls whether a copy of the exported file should be sent to Oracle's data lake. You may use the Batch Control Query portal to find all batch controls supporting this option.

Note: The batch parameter is set to not share any content by default. Customers may opt in to share their data with Oracle by submitting such a batch process with the parameter explicitly set to do so.

Note: This option is only available in a cloud installation.

Processing Errors

When a background process detects an error, the error may or may not be related to a specific object that is being processed. For example, if the program finds an error during batch parameter validation, this error is not object-specific. However, if the program finds an error while processing a specific bill, this error is object-specific. The system reports errors in one of the following ways:

- Errors that are not object-specific are written to the error message log in the [Batch Run](#).

- Some batch processes create entries in an "exception table" for certain object-specific errors. For example, an error detected in the creation of a bill in Oracle Utilities Customer Care and Billing may be written to the bill exception table. If an error is written to an exception table, it does not appear in the batch run tree. For each exception table, there is an associated to do entry process that creates a To Do Entry for each error to allow a user to correct the problem on-line.
- For some background processes, errors that do not result in the creation of an exception record may instead generate a To Do entry directly. For these processes, if you wish the system to directly create a To Do entry, you must configure the To Do type appropriately. Refer to [To Do entry for object-specific errors](#) for information about configuring the To Do type. If the background process detects an object specific error and you have configured the system to create a To Do entry, the error is not written to the batch run tree. If you have configured your To Do type to not create To Do entries for certain errors, these errors are written to the [Batch Run](#).

Note: Some processes create exceptions and To Do entries. It is possible for a background process to create entries in an exception table and create To Do entries directly, depending on the error. Consider batch billing in Oracle Utilities Customer Care and Billing; any conditions that cause a bill or bill segment to be created in **error** status result in a record added to the bill exception table or the bill segment exception table. However, any object-specific error that is not related to a specific bill or bill segment or any error that prevents a bill or bill segment from being created may result in a To Do entry for the object-specific error.

Error Post-Processing Logic

The product supports executing one or more algorithms when a batch process encounters an error that causes execution to stop. This allows for some special processing to occur to handle the failure of the batch job. Algorithms for this plug-in spot receive the batch control, batch run number, batch processing business date, number of threads and the list of the ad hoc parameters of the batch job.

Note: This plug-in spot is available for all Java based batch programs. For programs of type **Java (converted)**, the individual batch programs need to explicitly support this plug-in spot. Unless otherwise noted, assume that a **Java (converted)** program does not support it.

The following are some examples of functionality that may be executed when a batch job fails:

- Another object or record that is monitoring the batch job may have its status updated to reflect the batch status.
- An outbound message service may be invoked to perform a task related to the failure.

Note that the units of work for all threads are committed prior to executing the error post-processing logic.

Post-Processing Logic

The product supports executing one or more algorithms after all the threads of a given batch job have completed. This allows for some special processing to occur at the end of a batch job. Algorithms for this plug-in spot receive the batch control, batch run number, batch processing business date, number of threads and the list of the ad hoc parameters of the batch job.

Note: This plug-in spot is available for all Java based batch programs. For programs of type **Java (converted)**, the individual batch programs need to explicitly support this plug-in spot. Unless otherwise noted, assume that a **Java (converted)** program does not support it.

The following are some examples of functionality that may be executed at the end of a batch job:

- Another dependent batch job can be kicked off. Note that this use case is only needed when the multiple dependent jobs are not part of a scheduler (which can also detect the successful end of one batch job so as to submit the next job).
- Statistics for the batch run may be analyzed and based on results, a To Do Entry may be sent to an administrator.
- If the current batch job is processing a large number of child records in multiple threads, a parent record could be updated to a different status or with some other audit information.

Note that the units of work for all threads are committed prior to executing the post-processing logic. The algorithm should perform standard error handling. If an error occurs in one of the post-processing algorithms, the overall batch job's status is set to Error so that it can be re-submitted to retry the logic in the finalize step.

Timed Batch Processes

Most batch jobs are submitted via a batch scheduler. In the absence of a scheduler, a batch control may be configured as “timed” triggering the framework to monitor and schedule these batch jobs as defined by the timer interval. The timer interval defines the desired interval between starts (in seconds). The system schedules new batch runs at each interval if the last instance of the job has completed.

When configuring a batch control as “timed”, other default information must be provided, including the User ID and Language to use for submitting the job and the email address for notification, if desired.

Timed batch controls also include an Active setting, allowing for an implementation to temporarily stop further executions of the batch job (but retain the other timer settings).

Timed jobs are controlled by the default threadpool and not by a scheduler. When the **DEFAULT** threadpoolworker starts it will start executing any job for a Batch Control configured as **Timed** with the Timer Active set to **Yes**. This is whether the batch daemon or batch server is enabled or not.

Monitor Background Processes

In many areas of the system, functionality is driven from business object configuration as a BO driven record progresses through its lifecycle. Refer to [Business Object Lifecycle](#) for details. As part of that functionality, it is possible that a background process, called a [monitor batch process](#), is used to execute functionality for the record. A single program is provided for the BO monitor functionality. The product also provides a batch control template (**F1-MNTPL**) that should be used as a starting point. Parameters are used to limit the records processed by maintenance object and other optional parameters that may further limit the records. The product typically provides at least one monitor batch control for each maintenance object that supports a configurable lifecycle on its business object.

This topic highlights the parameters supported by the monitor batch job. Not all parameters are applicable to all maintenance objects and therefore may not be configured on a given base monitor batch control.

| Parameter Name | Description | Comments |
|---------------------------------|-----------------------------|--|
| maintenanceObject | Maintenance Object | For most base delivered batch controls, this parameter is delivered already populated with the value of the maintenance object value. Note that it is supported to leave this value blank, at which point, the program will determine the maintenance object (objects) to process by looking for an MO that refers to this batch control record as an option. |
| isRestrictedByBatchCode | Restrict by Batch Code | Set this to true to indicate whether the process should only select records that explicitly refer to this batch control on its current BO state. This is also referred to as "deferred" mode. If set to false , the program includes all records that refer to the current batch control in its BO state <u>and</u> records that don't refer to any batch control in its current state (but monitor algorithms exist in the current state). This is commonly referred to as "periodic" mode. Note that if the value is not set at all, the program will determine whether to run it as "deferred" or "periodic" based on whether the batch code is configured on the MO option as a State Monitor Process (“deferred”) or a Periodic Monitor Process . |
| restrictToType | Restrict by Related Type | This parameter is only applicable to maintenance objects that have a related 'type' object and the maintenance object has configured an option indicating the field for the related type column. This parameter may be used to limit the processing to records that are in the indicated type. |
| restrictToBusinessObject | Restrict by Business Object | This parameter may be used to limit the processing to records that are in the indicated business object. |
| restrictToBOStatus | Restrict by Status | This parameter may be used to limit the processing to records that are in the indicated status. |

| Parameter Name | Description | Comments |
|---------------------------|----------------------|---|
| restrictToDate | Restrict By Date | Enter a valid date on the record's primary table to limit processing to records that have a value in this field that is on or before the batch business date. Optionally, enter "+" or "-" followed by a number to shift the comparison date to the batch business date plus or minus the given number. For example, entering REVIEW_DT -3 will retrieve all records whose review date is on or before the batch business date minus 3 days. |
| sampleRecordNumber | Sample Record Number | This is not a commonly used parameter. It is only applicable when the monitor is used for a business use case that supports processing a subset of the records during a testing phase. For example, if the process is validating a large number of records, it may be an option to only validate every 100 records to determine if there are repeated validation errors that may indicate a common problem that may be solved to fix many errors. |

Also note that when submitting a monitor process with multiple [parallel threads](#), the program will use a **Thread Level SQL Select** strategy unless any of the following are true (in which case it will use the **Job Level SQL Select** strategy:

- The input maintenance object is left blank and the program finds more than one maintenance object that refers to this batch control in its options.
- A single MO is applicable but it has a multi-part primary key.
- A single MO is applicable and it has a single primary key, but it is a user defined key instead of a system generated key.
- The sample record number parameter is populated.

Plug-in Driven Background Processes

Although the product is delivered with a rich library of background processes, implementations may have business requirements that require new processes to be introduced. It is possible for an implementation to write a background process from scratch using a base process as a template. However, the product also provides base background processes that call algorithms to do the work that is needed. These are called plug-in driven background processes. There are three major types of plug-in driven batch processes:

- Processes that act on records that are stored in the database in the system. These types of processes require SQL to select the records along with the logic to process the records.
- Processes that extract information to a file. These types of processes require SQL to select the records along with the logic to select the information and return it such that the process can write the information based on various settings.
- Processes that import data from a file and store new records in the system as a result. These types of processes require an algorithm that is able to map the data from the file to appropriate new records in the system

The subsequent sections provide more detail about the three types of plug-in driven background processes.

Ad-hoc Processes

A process that retrieves records in the system and does some action on them requires an algorithm to select the records to be processed and another algorithm to process the records. We refer to this type of process as an Ad-hoc Process. The base batch control Plug-in Driven Generic Template (**F1-PDBG**) may be used as a template.

The base processes implement standard background process functionality including parallel background process logic and the ability to create To Do entries for errors. This allows for an implementation to take advantage of the pre-built support and provide plug-ins that include the logic that is unique to the specific use case.

The following sections provide more information about the functionality for ad-hoc processes. Note that extract processes share some of the same functionality. Refer to [Extract Record Processing](#) for additional information specific to extract processes.

Select Records Algorithm

The first important algorithm to design when implementing a plug-in driven batch process is the Select Records algorithm, plugged in on the [batch control](#) page. This algorithm type must define the first parameter as the SQL. The batch job will directly access the SQL parameter value in the metadata (rather than invoking the algorithm). All other parameters are available for the algorithm to use for its own logic.

In addition, when invoking the algorithm, it must return the strategy to use (**Thread Level SQL Select** or **Job Level SQL Select**). Refer to [parallel background processes](#) for more information about the two strategies and when to use each. When choosing the **Thread Level SQL Select** strategy, the algorithm should return the name of the primary key in the Key Field parameter. In addition, the SQL should include a **BETWEEN** clause that includes the bind variables for the low and high ID for the ranges. See below for the bind variable syntax.

If the SQL statement includes variables that are determined at execution time, it must use bind parameters. Bind parameters are referenced in the SQL statement using a colon and a parameter name (for example **:parameter**). There are some variables provided by the system that are populated by the batch job at execution time. These have **fl_** as its prefix.

The system supports the following pre-defined bind parameters:

- **:fl_lowID** and **:fl_highID** - these should be used in the **BETWEEN** clause for the **Thread Level SQL Select** strategy. They should be selecting data from the Key Field that is returned as part of the Select Records algorithm. The batch job will substitute the appropriate ID range as required.

Note: The table where this key field is selected from should be the first table in the FROM clause.

- **:fl_batchCode** and **:fl_batchNumber** - these are common attributes of the batch control that are referenced on a record for selection purposes. Note that the batch run number is set according to whether the batch job is a re-run of a previous run or not.
- **:fl_businessDate** - the batch job will populate the input batch business date, if populated otherwise the current date.

Note: The system supports both "fl." and "fl_" as a prefix for the bind variables. However, the "fl." prefix will result in an error if the SQL security property setting is turned on. As such, the underscore syntax is recommended. The period syntax remains for backwards compatibility.

For any other custom parameters, the Select Records algorithm may return one or more sets of field name / variable name / value where the variable name matches a bind variable in the SQL. The field name provides information about the length that assists the SQL binding logic to properly substitute the values. Note that the variable name cannot start with **fl.** as its prefix. The batch job will use the value returned by the algorithm to set the bind parameter in the SQL statement. Also note that the logic binds all variables as a string, so for date variables the SQL must include the "TO_DATE" function.

The plug in spot receives a list of the ad hoc parameters for the batch job as name / value pairs. If the list includes parameters whose values are to be used in selecting records, your algorithm may be used to identify the relevant batch parameter passed as input and populate the field name and output bind variable appropriately.

The product provides a base algorithm type for this plug-in spot that simply defines a parameter for the SQL. It also includes parameters for the strategy and the key field name. This algorithm type may be used by any custom batch process where the SQL does not rely on any special bind variables that must be determined. Simply create an algorithm for the algorithm type and provide the appropriate SQL. Refer to the algorithm type Select Records by Predefined Query (**F1-PDB-SR**) for more information.

Process Records Algorithm

The other important algorithm to design when implementing a plug-in driven batch process is the Process Record algorithm, plugged in on the [batch control](#) page. This algorithm is called for each record selected for the process. It receives all the information that was selected from the Select Records plug-in.

For the ad-hoc processing batch process, algorithms plugged into this spot are responsible for doing the work for each record based on the desired logic.

For the extract batch process, algorithms plugged into this spot are responsible for returning the data that should be written to the file. Many of the parameters for this plug-in spot are only applicable to extract processes. Refer to [Extract Record Processing](#) for more information on the functionality specific to extract processes.

Also note that algorithms for this plug-in spot will be passed two Booleans, `isFirst` and `isLast`, to indicate if the current work unit is the first and/or last for that thread. This allows for the plug-in to do additional work if needed. Note that the `isFirst` indication is available for both types of batch processes, ad-hoc and extract. However, the `isLast` indication is only applicable for the file extract batch. For the ad-hoc batch process this value will always be set to **false**. Extracts will always execute in a single database transaction. In a single transaction run, any error causes the run to be aborted so that it restarts from the beginning when resubmitted. This is done to avoid partial files being written along with inaccurate setting of the `isLast` element.

Configuring a New Process

The following points summarize the steps needed to implement a new background process that acts on records in the system using plug-ins for the specific functionality:

- Verify the SQL that the background process should execute. Keep in mind that all the data selected in the SQL is available to pass to the plug-in that processes the records. If the performance of the background process is important, be sure to consult with a DBA when designing the SQL.
 - If the SQL does not require any custom variables to substitute at runtime, create an algorithm for the base algorithm type **F1-PDB-SR** and configure the SQL. In addition, configure the strategy and the primary key name (for the **Thread Level SQL Select** strategy).
 - If the SQL requires custom variables, a new [plug-in script](#) must be designed and coded to populate the variable names and values using the algorithm entity **Batch Control - Select Records**. Besides defining the variables, the algorithm must also indicate the strategy and the primary key name (for the **Thread Level SQL Select** strategy). Define the algorithm type for the newly created script. The first parameter of the algorithm type must be the SQL as illustrated in the base algorithm type. Note that the other parameters are available for use by this algorithm type if needed. Define the algorithm, populating the SQL as appropriate (using the custom variables).
- Design the logic required to process each record. If your edge product does not deliver a suitable plug-in, create a [plug-in script](#) where the algorithm entity is **Batch Control - Process Record**. Note that the plug-in receives all the information selected in the SQL defined in the Select Records plug-in. For an ad-hoc process, the algorithm should perform whatever process is required based on the business use case. Note that the background process is responsible for committing the records.

In either case, if a new processing script is required, define the algorithm type and algorithm for the newly created script.

- Create a batch control by duplicating the base template **F1-PDBG**. Plug in the algorithms created above and configure the parameters as appropriate. Note that you may configure custom ad hoc parameters on the batch control if required. Both base and custom batch parameter values are available to the Select Records and Process Records plug in algorithms.

Extract Record Processing

A process that selects records and produces output for each record to write to a file to integrate with external systems is called an Extract Process. The base batch control Plug-in Driven Extract Template (**F1-PDBEX**) may be used as a template.

Fastpath: Please read the topic [Ad-hoc Processes](#). Its information about the Select Records plug-in and some of the information about the Process Record plug-in apply to extract processes. This topic focuses on aspects that are unique to extract processes.

The system provided process includes parameters to configure the file path and file name for the created file. The file path supports all the functionality described in the topic [Referencing URIs](#). The file name supports system substitution variables, such as run number, thread number, user and date / time. The process also supports compression if an appropriate extension is used. Refer to the File Name parameter description in the batch control for more information.

Note: Refer to [Flexible File Name / Writing Multiple Files](#) for information about support for substituting a business value into the file name.

For extract processes, the Process Record algorithm is responsible for returning the data that should be written to the file in one or more XML instances along with the schema name(s) that describes the XML instance(s). The program will write the data to the file as per the format indicated in the File Format batch parameter. By default the service uses the OUAF format for date and time. To override this and use XSD format, configure the Date Time Format batch parameter to 'XSD'.

If an existing schema satisfies the output requirements, it may be used. Otherwise, you should define a data area to indicate the output format of the records as appropriate. Note that you should define an appropriate Field for each element in the schema. This is needed for the fixed position File Format, but is good practice for any output format. Refer to **F1-PDBGenProcExtractRecord** for an example of a data area with fields defined for each schema element.

There are two options for designing and configuring the Process Record algorithm:

- Create a specific **Process Record** algorithm type that encapsulates the extract logic. The product provides a base algorithm type that illustrates the basic technique to follow. Refer to the algorithm type General Process - Sample Process Record Extract (**F1-GENPROCEX**) for more information.
- Create a file integration type that defines the records to be included in the extract and configure a plug-in driven batch control that references that integration type. Refer to [Extract Using File Integration](#) for more information about implementing this type of functionality.

Your specific edge product may provide other Process Record algorithm types out of the box. Use the algorithm type query and search for records for this algorithm entity.

Grouping by Record XML Node

When configuring an extract process that should produce the output in XML format, your Process Record plug-in may return multiple schemas with information that is all part of the same overall record. For example, the output could include account information and related service agreement details:

```
<account type="group"
  <accountId>1234567890</accountId>
  ...
</account>
<sa type="group"
  <saId>123457665</saId>
  ...
</sa>
<sa type="group"
  <saId>1234588913</saId>
  ...
</sa>
```

In this case, it may be desired to wrap all that information in a grouping XML tag so that all the information for one record is grouped together. Because the Process Record plug-in could be returning header or footer records that are not part of a given selected record's extract information, the batch process doesn't know what schemas returned by the Process Record plug-in belong together logically. The output parameter 'record XML node' in the schema collection should be used to indicate the outer XML node to use to group related information together. For example:

```
<SchemaInstance>
<recordXMLNode>record</recordXMLNode>
<schemaName>CM-AccountRecord</schemaName>
<schemaType>F1DA</schemaType>
<data><account><accountId>1234567890</accountId>...</data>
</SchemaInstance>
<SchemaInstance>
<recordXMLNode>record</recordXMLNode>
<schemaName>CM-SAInfo</schemaName>
<schemaType>F1DA</schemaType>
```

```

<data><sa><saId>123457665</saId>... </data>
</SchemaInstance>
<SchemaInstance>
<recordXMLNode>record</recordXMLNode>
<schemaName>CM-SAIInfo</schemaName>
<schemaType>F1DA</schemaType>
<data><sa><saId>1234588913</saId>... </data>
</SchemaInstance>

```

All schemas returned from a single call to the Process Record plug-in that have the same record XML node will be grouped in the written output within that XML tag, as per the example below:

```

<root>
<record>
<account>
  <accountId>1234567890</accountId>
  ...
</account>
<sa>
  <saId>123457665</saId>
  ...
</sa>
<sa>
  <saId>1234588913</saId>
  ...
</sa>
</record>
<record>
<account>
  <accountId>987654320</accountId>
  ...
</account>
<sa>
  ...
</sa>
</record>
</root>

```

Multi-threaded Extract

When extracting data, it's possible that the volume of data warrants running the job multi-threaded. In this case, a separate file is produced with the thread number included in the file name. You may proactively include the thread number as a substitution variable when indicating the file name. If not, the system appends the thread number.

As a convenience, the system supports concatenating the extract files produced by the various threads at the end. The system does this by finding files whose file names match except for the thread number. As such, the file name may not contain date or time if the concatenation parameter is true. Please note the following with respect to the concatenation feature:

- The content of each file is concatenated together "as is". If the individual files have header, footer or summary information, there is no logic to consolidate that information in the concatenated file. If you want a single header, footer or summary, you must run the extract single threaded.
- Concatenation is not supported if the file name indicates the zip compression should be used.
- The individual thread files are retained.
- Note that if the file format is XML, the files written for the individual threads will be written with an extension of ".tmp".

Skipping Records

By default, the extract process expects one or more schemas to be returned by each call to the Process Record plug-in. (Ideally when designing any process, the Select Records algorithm only selects records that should be processed and

the Process Record algorithm does not need to confirm whether the record should be part of the processing or not.) If however there is a need to check a condition in the Process Record plug-in and it is found that no data needs to be extracted for this record, the process record algorithm should return the 'is skipped' output parameter to **true** so that the program doesn't write an empty row.

Note that the base process records algorithm for file integration types (**F1-FILEX-PR**) will set the 'is skipped' parameter to **true** if the file integration record extract record algorithm returns no data.

Configuring a New Process

The points documented in the topic related to [configuring a new adhoc process](#) with respect to the Select Records algorithm apply to extract processes.

For the Process Records algorithm, it is responsible for returning one or more schema instances populated with information that should be written to the file. If your edge product does not deliver a suitable plug-in, create a [plug-in script](#) where the algorithm entity is **Batch Control - Process Record**. Note that the plug-in receives all the information selected in the SQL defined in the Select Records plug-in.

Refer to [Configuring an Extract Process Using File Integration Type](#) for information on designing extracts using this configuration.

If a new processing script is required, define the algorithm type and algorithm for the newly created script. Create a batch control by duplicating the base template **F1-PDBEX**. Plug in the algorithms created above and configure the parameters as appropriate. Note that you may configure custom ad hoc parameters on the batch control if required. Both base and custom batch parameter values are available to the Select Records and Process Records plug in algorithms.

Flexible File Name / Writing Multiple Files

By default, the data is written to the File Name defined in the batch parameter. The file name supports several dynamic substitution variables as defined in the detailed description for the batch parameter in the Plug-in Driven Extract Template batch control (**F1-PDBEX**). Also refer to [Extract Record Processing](#) for information about the file name and multi-threaded processes.

The system also supports more advanced file creation for a single batch run. Consider the following use cases

- An extract is for data associated with multiple service providers where each service provider should receive its own file. In this use case, the unit of work is the service provider so a file is produced for each work unit.
- An implementation operates with multiple jurisdictions represented by CIS Division. A certain extract should result in a file per division so that each division only gets its relevant data.
- An extract of Person information should separate individual person data from business person data. In addition, for each person, the contact information should result in a separate file. In this use case, one unit of work includes data to be written to more than one file.

To support the above use cases, the Process Record algorithm supports returning the File Name in the output:

- The file name is included in the output Schema Instance group. You would populate this if you want the data for a specific Schema entry to go to this file name. In the person extract example above, the schema that includes the contact information would indicate the specific contact file.
- The file name is an output field outside the schema list. You would populate this if you don't have different files for different schemas but you still want to override the file name defined in the batch parameter. The service provider and division examples above would populate this parameter with the desired file name. The person extract example could populate this field for all the non-contact information.

The batch process checks the output after each call to the Process Records algorithm. For each schema, if there is a specific File Name associated with the schema, the data for that schema is written to that file. Otherwise, if the output file name is provided, the data is written to that file. Otherwise, the File Name in the batch parameter is used.

Note: Substitution Variables. After the call to Process Records, if there are any system variables in the file name, they are resolved at this time.

Managing File Names

This type of requirements means that the Process Record algorithm needs to provide a file name that has some business value to distinguish the individual files. For example, the service provider or the division or the person type value must be part of the file name. However, the recommendation is not to have the file name entirely determined by the algorithm. Rather the suggestion is that you still allow the user submitting the batch job to provide a desired file name as a batch parameter. That way, it can include any of the supported substitution variables for system information (such as batch run number, or date /time stamp) that ensure your files are unique for a given batch run. The algorithm can designate a substitution variable that it looks for to replace with the business value.

For example, using the files per division use case, imagine the user indicates the file name `EXTRACT_FILE_<DIV>_{BN}_{RN}_{TN}.csv`. The process record algorithm receives this parameter. It knows to look for "`<DIV>`" and replace it with the actual division. Imagine the division code is A100, it would return the file name `EXTRACT_FILE_A100_{BN}_{RN}_{TN}.csv` in its output, along with the data to write to that file for this unit of work.

For the person information use case above, where two files are written, the suggestion is to use the File Name parameter for one of the files, for example the person information file. An additional parameter should be used to define the second file, the contact information file. So the users submitting the batch job would define the following parameters:

| Parameter Name | Description | Value | Comments |
|------------------------|-------------------|-------------------------------|--|
| fileName | File Name | persons_<personType>_{BN}.txt | This is the file name parameter provided with the extract. |
| contactFileName | Contact File Name | contacts_{BN}.txt | This is a special parameter defined by the CM extract batch control. |

The Process Record algorithm would look for the File Name parameter provided as input, find the text "`<personType>`" and replace it with the person type value and return that file name in the output. When building the list of schemas to return in the output, the one that includes the person contact information would include the file name found in the Contact File Name parameter provided as input.

Note: If an extract uses [file integration types](#), the file integration record's extract process algorithm would have the above responsibility for indicating the file name and pass it back to the Process Record algorithm.

Multiple Threads

This functionality works as expected with multiple threads. Based on the use case and the implementation of the Select Records algorithm, each thread could be producing files for the same business value. Let's use the division use case. Imagine an implementation has three divisions: A100, B200, C300. Now imagine that the extract is for financial information for an account. The select records algorithm should be threading by account id so that the data is evenly distributed across the multiple threads. But within each thread, accounts could be in any of the 3 implementation's divisions. So each thread could produce 3 files for each of the 3 divisions.

As described in [Multi-threaded Extract](#), the system supports an option to concatenate, allowing you to consolidate the files such that you have 3 complete files for the 3 divisions. The same features and limitations described in that topic apply for this use case.

Closing Files

An important consideration when using this functionality is that attention should be paid to how many files are open during the batch process. Each open file takes some memory to manage it. As such, the product has imposed a limit of only 10 open files (per thread) during the run of the batch job. When designing a batch to write to multiple files, the product strongly encourages you to design the process so that whenever possible, all the data for one file can be written and that file can be closed before going on to the next file.

Let's look at our examples.

- For the service provider example, the unit of work for the batch process is service provider. In this case, after each call to process records, the data can be written to the file and then the file can be closed.
- For the division example, the data selected should be threaded by the proper unit of work related to the purpose of the extract, such as Account or Asset. But the data should be ordered by division so that all the data for each division is processed before the next division's data. Each division's file can be closed once the next division's data starts getting processed.
- For the person extract example, the contact file is used for all the data so that file needs to remain open throughout the duration of the job. However, the person information gets segregated by person type. The Select Records could order the data by person type so that all the data for one type could be written and then all the data for the other type could be written. However, given that for any run no more than 3 files will ever be open, this use case is one where there is no need to actively manage closing files during the process.

How will the batch program know when to close a file? Since the batch program is agnostic and does not know what type of data is being processed nor when files should be closed, the Process Record algorithm should provide this information.

Note: The batch process will issue an error if Process Records indicates that the file to write to is one that was already closed. Reopening closed files is not allowed. The design of the process needs to be reviewed if this error is received.

To manage this, the batch process provides the Process Record algorithm with the list of open files (with the system substitution variables unresolved) and a Boolean to mark whether the file should be closed.

Note: If an extract uses [file integration types](#), the file integration record's extract process algorithm receives this list of open files and would have the responsibility described here to manage closing files.

To explain further, we'll use our examples.

File Per Division Example

This use case is that there are 4 divisions in the implementation: NORTH, EAST, SOUTH, WEST and that the data (account data) should be grouped in separate files by division.

The recommendation is that the Select Records algorithm selects the data ordered by Division.

The batch process passes to the Process Record algorithm the list of open files (there should be only be zero or one). In this case, the only indication that the data for one division is finished is if the Process Record algorithm sees that its data is for one division and the open file listed is for a different division. Each call should prepare its file name. Then it should see if its file name is in the list of open files. If not, it should indicate that the other open file should be closed. (Note that it doesn't need to add itself to the 'open list'. The batch program is only looking for entries marked as closed. It will ignore entries that are not marked as closed).

Assume the file name in the batch parameter is myFile_<DIV>_{BN}.txt

The data is sorted so that the accounts in the EAST division are processed first. Let's imagine this is a work unit that is also in the EAST division. It receives the file name and the list of open files.

```
...
<hard>
<batchParms>
  <BatchParm>
    <name>fileName</name>
    <value>myFile_<DIV>_{BN}.txt</value>
  </BatchParm>
  ...
</batchParms>
<openFiles>
  <OpenFile>
    <closeFile></closeFile>
    <fileName>myFile_EAST_{BN}.txt</fileName>
  </OpenFile>
</openFiles>
...
```

```
</hard>
```

The algorithm substitutes its division into the <DIV> portion of the file and populates that in the output. It then compares its file name with the current list of open files. It finds its file so it doesn't need to do anything else.

```
<hard>
...
<fileName>myFile_EAST_{BN}.txt</fileName>
...
<openFiles>
  <OpenFile>
    <closeFile></closeFile>
    <fileName>myFile_EAST_{BN}.txt</fileName>
  </OpenFile>
</openFiles>
...
</hard>
```

If we then imagine a call to the process records algorithm where the division is NORTH and it's the first entry for that division, here is what it receives:

```
<hard>
<batchParms>
  <BatchParm>
    <name>fileName</name>
    <value>myFile_{DIV}_{BN}.txt</value>
  </BatchParm>
  ...
</batchParms>
<openFiles>
  <OpenFile>
    <closeFile>true</closeFile>
    <fileName>myFile_EAST_{BN}.txt</fileName>
  </OpenFile>
</openFiles>
...
</hard>
```

The algorithm substitutes its division into the <DIV> portion of the file and populates that in the output. It then compares its file name with the current list of open files and doesn't find its file name. So it indicates that the existing open file should be closed.

```
<hard>
...
<fileName>myFile_NORTH_{BN}.txt</fileName>
...
<openFiles>
  <OpenFile>
    <closeFile>true</closeFile>
    <fileName>myFile_EAST_{BN}.txt</fileName>
  </OpenFile>
</openFiles>
...
</hard>
```

File Per Service Provider Example

In this use case, the unit of work is service provider and each service provider should have its own file. In this case, as the Process Record algorithm is preparing the data and the file name unique to its service provider, it can also indicate

that the file can be closed. There is no need to wait for the next call to Process Record to indicate that the previous file can be closed. Let's assume the file name is MYFILE_<serviceProvider>_{BN}_{TN}.txt. Each call to Process Records will pass the batch parm file name and no open files.

```
<hard>
<batchParms>
  <BatchParm>
    <name>fileName</name>
    <value>MYFILE_<serviceProvider>_{BC}_{TN}.txt</value>
  </BatchParm>
  ...
</batchParms>
<openFiles>
  <OpenFile>
    <fileName></fileName>
    <closeFile></closeFile>
  </OpenFile>
</openFiles>
...
</hard>
```

The algorithm is processing data for service provider A100. It returns the following information related to the file name, namely the single File Name in the output related to this service provider and adds its file to the open file list and indicates that it should be closed. (Note that file-per-work-unit is the only known use case where the algorithm will know that it is the last entry for a file and to close itself.)

```
<hard>
...
<fileName>MYFILE_A100_{BC}_{TN}.txt</fileName>
...
<openFiles>
  <OpenFile>
    <closeFile>true</closeFile>
    <fileName>MYFILE_A100_{BC}_{TN}.txt</fileName>
  </OpenFile>
</openFiles>
...
</hard>
```

Multiple Open Files Example

This example assumes that the file names are defined as per the Managing File Names section above. We'll assume that the algorithm designer chose to not actively close the person information file since there are never more than three files open. Similarly, we'll assume that they chose not to order the data by person type. Here is what is passed in in the middle of the run:

```
<hard>
<batchParms>
  <BatchParm>
    <name>fileName</name>
    <value>persons_<personType>_{BN}.txt</value>
  </BatchParm>
  <BatchParm>
    <name>contactFileName</name>
    <value>contacts_{BN}.txt</value>
  </BatchParm>
  ...
</batchParms>
<openFiles>
  <OpenFile>
    <fileName>persons_P_{BN}.txt</fileName>
```

```

    <closeFile></closeFile>
  </OpenFile>
  <OpenFile>
    <fileName>persons_B_{BN}.txt</fileName>
    <closeFile></closeFile>
  </OpenFile>
  <OpenFile>
    <fileName>contacts_{BN}.txt</fileName>
    <closeFile></closeFile>
  </OpenFile>
</openFiles>
...
</hard>

```

An instance of one call to Process Records algorithm that has details for an individual ("P" person type).

```

<fileName>persons_P_{BN}.txt</fileName>
<fileOutput>
  <listValue>
    <SchemaInstance>
      <recordXMLNode>person</recordXMLNode>
      <schemaName>CM-PersonDetail</schemaName>
      <schemaType>F1SS</schemaType>
      <fileName></fileName>
      <data>LotsOfData</data>
    </SchemaInstance>
  </listValue>
  <listValue>
    <SchemaInstance>
      <recordXMLNode>person</recordXMLNode>
      <schemaName>CM-AddressDetail</schemaName>
      <schemaType>F1SS</schemaType>
      <fileName></fileName>
      <data>LotsOfData</data>
    </SchemaInstance>
  </listValue>
  <listValue>
    <SchemaInstance>
      <recordXMLNode></recordXMLNode>
      <schemaName>CM-ContactDetail</schemaName>
      <schemaType>F1SS</schemaType>
      <fileName>contacts_{BN}.txt</fileName>
      <data>LotsOfData</data>
    </SchemaInstance>
  </listValue>
</fileOutput>

```

This XML example illustrates the following points:

- There is an override file name in the fileName element.
- The first two schemas don't have any value in the fileOutput\listValue\SchemaInstance\fileName so they should be written to the file in fileName. Note that these two schemas also include a Record XML Node. That will ensure that if the output is XML format, the data from both of those schemas will be wrapped by the 'person' XML Node. This is not functionality related to this epic. It's just trying to illustrate multiple features.
- The third schema has an entry in fileOutput\listValue\SchemaInstance\fileName . So that data is written to a separate file.

Extract Using File Integration

The product provides separate configuration that may be used to define how to extract the data and how to format it. This configuration provides more metadata related to defining how to get the data to extract and how to format

the data. You may have many use cases where using this configuration rather than having all the logic directly in the Process Records algorithm is beneficial.

The configuration can support simple extracts, containing a single record type and possibly a header or footer record. It also supports more complex integrations, involving multiple record types and parent/child relationships between the records.

File Integration Type Configuration

The framework supplies two objects that work together to define the processing needed to create a specific type of extract:

- The file integration type which describes and classifies the extract configuration.
- The file integration record where the sequence, format and logic to extract the data required for a given record type are captured.

File Integration Type

The file integration type defines the integration classification. Currently, only **Extract** is supported. In addition, the file integration type can be assigned to a category. The category may be used to identify extracts with a common purpose or target such as collection agency referrals. Your edge product may deliver a number of categories or you may define your own.

The system provides a business object for extract file integration types (**F1-ExtractFileIntegrationType**) that is expected to be used for most use cases

File Integration Record

The file integration record is the object that is responsible for defining a record's format and capturing the record details. A separate integration record must be defined for each record type included in the extract.

The record sequence defines the order that records are processed by the system. The parent sequence defines the record type of which this record is a child. Child records may also be referenced as a parent of lower level child records. The base Process Records algorithm provided by the framework processes all child records of a record type before processing the next record type in sequence.

For extracts that are XML format, the system supports creating a grouping node surrounding all the output that belongs to the same entity. File integration records define a record XML node that will be used as the grouping node. Each record type in the list that belongs within the same group would indicate the same value in the record XML node. Refer to the [Grouping by Record XML Node](#) section for more details.

Note: The system does not support nested record XML nodes. All child records of a record type must define the same record XML node as the parent.

Each file integration record references a data area that defines the extract record's format, allowing the data to be extended. The **Extract Records** algorithms are responsible for populating the data area. The file integration record supports multiple extract processing algorithms so that the custom information can also be populated.

The extract record plug-in also supports the functionality described in the [Flexible File Name / Writing Multiple Files](#) topic.

The system provides a business object for extract file integration records (**F1-ExtractFileIntegrationRec**) that is expected to be used for most extract record use cases.

Configuring an Extract Process Using File Integration Type

The following points summarize the additional steps needed to implement a new extract background process that uses a file integration type to define the specific functionality:

- Choose or create data area objects to define the extract record formats.
- Define the logic required to populate each extract record type. Your edge product may deliver suitable plug-ins or you may need to create a [plug-in script](#) where the algorithm entity is **File Integration Record - Extract Record**.

Note that the Extract Record plug-in receives most of the information defined in the Batch Control - Process Records plug-in.

- Define the algorithm type and algorithm for each newly created script.
- Choose or create a category for the file integration type using lookup **FILE_INT_OBJ_FLG**.
- Create the file integration type and configure the file integration records using the defined data areas and algorithms.
- Create a batch control by duplicating the appropriate base template for an extract background process. Include the File Integration Type parameter (fileIntegrationType) on the batch control and reference the appropriate file integration type.
- Plug in a Process Records algorithm that reads the file integration type configuration and processes the record types. The system provides a base file integration record extraction algorithm (**F1-FILEX-PR**) that is expected to be used for most file integration plug-in extract processes.

Extending a File Integration Extract Process

Your edge product may deliver file integration types and batch controls designed for standard extract processes. However, extending the delivered extracts to add custom data is common practice for most implementations. You can customize the output from a delivered extract by:

- Identifying the record types that need additional details
- Creating a data area that defines the additional details and using that to extend the data area configured on the record type
- Creating a File Integration Record — Extract Record [plug-in script](#), algorithm type and algorithm that populates the extra details
- Adding the algorithm to the integration record's extract algorithms collection

In some cases, you may wish to extend the extract by adding additional record types. To do this, add your custom file integration records to the file integration type, following the steps described in [Configuring an Extract Process Using File Integration Type](#).

Uploading Records

The base product provides a background process to upload data from a file. The batch control Plug-in Driven File Upload Template (**F1-PDUPL**) may be used as a template. The process includes parameters to configure the file path and file name for file to upload along with other parameters to control how to handle missing files and how to rename the file once processed. Refer to the description of the batch control and its parameters for more information.

This background process requires an algorithm plugged into the plug-in spot **File Upload**. This plug-in is called once for a given file. The batch process opens the file and passes to the algorithm the file reader element. The algorithm associated with the batch control is responsible for using provided APIs to read the content of the file and store the data in appropriate table(s) (for example, an appropriate staging table). The base provided process supports uploading multiple files and may be run mutli-threaded to process multiple files. Each file is processed by one call to the File Upload algorithm and supports a single commit for the records uploaded in a given file.

Note: Plug-in scripts written to implement this type of algorithm must use the Groovy script engine version as the APIs are not accessible using the XPath scripting language. Refer to [Additional Coding Options For Server Scripts](#) for more information.

Note that this step in the upload of data is only one part of a typical upload end-to-end process. This step is sometimes referred to in the product as "Process X". The goal of this step is to get records from a file into database records, with minimal validation and processing. The data should be stored in records that are then processed by a second step (often referred to in the product as the "upload" step, for example "Payment Upload"). The second step, independent of the plug-in driven batch process described here, is responsible for validating the data and should be able to be threaded by individual records and have proper error handling for individual records. Note that depending on the type of data being uploaded, the product may already supply appropriate tables that the plug-in driven upload process may populate. These could be staging tables, such as payment upload staging. Or they may be records with business objects that have a lifecycle designed to handle uploaded data, for example Business Flag. In such cases, the product will typically supply out-of-the-box background processes to validate and further process the data and finalize the upload. If the data to upload does not already have a base provided staging table, be sure to work with your

implementation team to identify an appropriate table to use for the plug-in driven batch upload. In addition, confirm the design for the second step that is responsible for the detailed validation and finalization of the data.

The product supplies sample algorithms to illustrate calling the supplied APIs for processing different types of source data: comma delimited, fixed position and XML. In every case, the sample data supported by the upload uses 'degree day' information to illustrate the process. The system provides sample target records (based on the Fact maintenance object) in order to illustrate the step to store records based on the input data. Note that only sample plug-in scripts have been provided. No algorithm, algorithm type or batch control is configured to use the sample plug-in scripts. To view the scripts, navigate to the [Script](#) page, search for a Script Type of **Plug-in Script** and Algorithm Entity of **Batch Control - File Upload** and look for the 'Sample' scripts.

Note that the sample plug-in scripts provided by the product are supplied to illustrate use of the provided APIs. They should not be considered a template for how to implement a plug-in script for a real use case. The following highlight some points to consider when designing a file upload algorithm:

- **Error handling / resolution.** The sample plug-in scripts do some basic error handling related to the data to illustrate error handling. However, any errors found in this step require processing of the whole file to stop. As such, this plug-in should only report errors that are not possible to fix, but where the whole file should be rejected. If there are errors that can be adjusted in the data, then the recommendation is to not check for those errors at this step. Rather, this plug-in should simply populate the appropriate staging tables and let the next step check for validity. As described above, the next step should include the ability to mark individual records in error, allowing for users to fix the data and retry.
- **Target tables.** The sample plug-in scripts use Fact as the target for the resulting insert statements. As mentioned above, the decision of where to store the uploaded data must be carefully considered. There may already be existing tables that are specific to a given use case. If the data being uploaded does not have existing tables to use, review the product to verify what existing tables may be useful, such as Inbound Sync Request or Service Task. Be sure that the tables chosen support error handling, either out-of-the box or via designing an appropriate business object with a lifecycle that supports an error status and the ability to resolve the error. Also note that the Sample Flat File Upload plug-in illustrates a header record / detail record scenario. In this case, the header record is linked to the child record via a CLOB element. This is not the recommended technique. In a real use case, the header record should be linked to the child record via a separate database column to allow for searching.

Configuring a New Process

The following points summarize the steps needed to implement a new file upload background process:

- Verify the details of the data in the upload file and map the data to fields in one or more appropriate tables in the system.
- Design the logic required for reading the record details and identifying each record to properly create the insert statements for storing the data. The sample plug-in scripts provided by the product illustrate using the various APIs available for use. Create a [plug-in script](#) where the algorithm entity is **Batch Control - File Upload**. Create an appropriate algorithm type and algorithm for this plug-in script.
- Create a batch control by duplicating the base template. Plug in the algorithm created above and configure the parameters as appropriate. Note that you may configure custom ad hoc parameters on the batch control if required. Both base and custom batch parameter values are available to the File Upload algorithm.

How to Re-extract Information

If you need to recreate the records associated with an historical execution of an extract process, you can - simply supply the desired batch number when you request the batch process.

How to Submit Batch Jobs

Most batch jobs are submitted via a batch scheduler. Refer to [Batch Scheduler Integration](#) for information about the integration with the Oracle Scheduler.

Batch jobs may be configured as [Timed](#), which means they will automatically be run based on the timer frequency.

You can manually submit your adhoc background processes or submit a special run for one of your scheduled background processes using the online [batch job submission](#) portal.

The system provides a [REST web service](#) (using the inbound web service **F1-SubmitJob**) to create a batch job submission request from an external system. Note that no parameter defaulting occurs when submitting a record using a web service. All the desired parameter values must be provided.

How to Track Batch Jobs

You can track batch jobs using the batch process pages, which show the execution status of batch processes. For a specified batch control id and run id, the tree shows each thread, the run-instances of each thread, and any messages (informational, warnings, and errors) that might have occurred during the run.

Fastpath: For more information, refer to [Tracking Batch Processes](#).

How to Restart Failed Jobs and Processes

Every process in the system can be easily restarted if it fails (after fixing the cause of the failure). All you have to do is resubmit the failed job; the system handles the restart.

Assessing Level of Service

For some background processes, an implementation may wish to supply one or more algorithms that check some conditions to assess whether or not the process is performing as expected. An algorithm could be used to check the performance of the job to see if it is running as efficiently as expected. Or it could analyze the data processed by the background process to assess whether there may be some problem with the quality of the data.

The system provides a Level of Service plug-in spot on [batch control](#) to configure the appropriate algorithms for a given background process, if desired. Each algorithm is expected to return a value to indicate the 'level of service' determined along with a message indicating the reason for the value. The following Level of Service values are supported:

- **Normal.** Indicates that the algorithm did not detect any issues.
- **Warning.** Indicates that the algorithm found some issues that may or may not indicate a problem.
- **Error.** Indicates that the algorithm found some issues that should be investigated.
- **Disabled.** Indicates that the algorithm could not properly execute the level of service logic.

When viewing a [batch control](#) record, if there are any level of service algorithms configured, the logic is executed and the results are displayed. The level of service is also part of the [Health Check](#) service.

Batch Resource Groups

Database resource management tools may be used to prioritize resource allocation between various batch processes. For example, export type of processes may have a lower resource allocation priority relative to billing related processes. These tools allocate resources to groups of consumers, not to an individual batch process. They use rules that are based on certain session variables, to associate a batch process with a resource group.

When applicable, you may use the **Batch Resource Configuration (F1-BatchResourceConfig)** extendable lookup to associate certain batch processes with one of three priority resource groups: 10 (High), 20 (Medium), 30 (Low).

In a Cloud installation, if a batch control is associated with a resource group the latter is included by default as part of the MODULE database session variable as follows: '<batch control>,R=<resource group>'. This allows DBAs to potentially take advantage of this information for resource prioritization purposes. On premise, this feature needs to be explicitly opted in using the **Expose Batch Resource Group** option in the **General System Configuration** feature configuration.

With this configuration enabled, DBAs can set up rules that parse the MODULE variable to identify the resource group for a batch process and apply prioritization rules accordingly. Note that most batch controls may not be associated with a resource groups so default allocation rules should be considered.

Note. This configuration does not include nor enforce the database resource management configuration. It only allows for such tool to be leveraged by DBAs as needed.

Defining Batch Controls

The system is delivered with all necessary batch controls. Implementations may define default values for parameters. In addition, implementations may define their own background processes.

To view background processes, open **Admin > System > Batch Control**.

Use the **Batch Control Query** portal to search for an existing batch control. Once a batch control is selected, you are brought to the maintenance portal to view and maintain the selected record.

Refer to [Background Processing Concepts](#) for more information.

CAUTION: Important! If you introduce a new batch process, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

Description of Page

Enter an easily recognizable **Batch Process** and **Description** for each batch process.

Owner indicates if this batch control is owned by the base package or by your implementation (**Customer Modification**). The system sets the owner to **Customer Modification** when you add a batch control. This information is display-only.

Use the **Detailed Description** to describe the functionality of the batch process in detail.

Enter the **Application Service** that is used to provide security for submission requests for the batch control. The application service must have an Access Mode of **Execute**. Refer to [Granting Access To Batch Submission](#) for more information.

Use **Batch Control Type** to define the batch process as either **Timed** or **Not Timed**. A [Timed batch process](#) will be automatically initialized on a regular basis. A Not Timed process needs to be run manually or through a scheduler.

Use **Batch Control Category** to categorize the process for documentation purposes. The base values provided are as follows:

- **Ad Hoc.** Processes of this type are run on an ad hoc basis, only when needed. For example, if there is a process to do a mass cancel / correction of data, it would only be run when a situation occurs requiring this.
- **Extract.** Extract processes extract information that is interfaced out of the system. Processes of this type typically extract records marked with a given run number. If the requester of the process does not supply a specific run number, the system assumes that the latest run number should be extracted. If you need to re-extract an historical batch, you simply supply the respective run number when you request the batch process.
- **ILM.** [Information Lifecycle Management](#) jobs are crawler background processes that are associated with the ILM based storage solution.
- **Monitor.** Processes of this type are processes related to business objects with a lifecycle state that defines [monitor algorithms](#). The monitor process selects records in a given state and executes its algorithms, which may cause the record to transition to another state or may trigger some other logic to occur. Using configuration, the monitor process may target only specific records. Refer to [Monitoring Batch Processes](#) for more information. Note that these types of background processes can be considered a subset of **Process What's Ready**
- **Process What's Ready.** Processes of this type create and update records that are "ready" for processing. The definition of "ready" differs for every process. For example, a payment upload process creates payments for every record that is **pending**. An overdue event monitor activates pending overdue events that have reached their trigger date.
- **Purge.** Processes of this type are used to purge historical records from certain objects that generate a large number of entries and may become unwieldy over time.
- **To Do Entry.** Processes of this type are used to detect a given situation and create or complete a To Do Entry. Refer to [To Do Entries Created by Background Processes](#) for more information.
- **Upgrade.** Processes of this type are typically run only one time and are used to populate data in a table based on information that can be determined elsewhere in the system. These are processes that could have been done through an upgrade script, but perhaps due to data volume or timing, the upgrade logic warranted a separate stand-alone process.
- **Upload.** Processes of this type are used to upload data from a file into the system.

- The following categories are related to the data conversion / migration processes:
 - **Conversion.** Processes of this type are dedicated to converting or migrating data from external applications into the product.
 - **Object Validation.** Processes of this type are dedicated to validate data within objects for conversion or migration purposes.
 - **Referential Integrity.** Processes of this type are dedicated to validate referential integrity within objects for conversion or migration purposes.

Note: Additional categories may be introduced by your specific product.

If the batch process is Timed, then the following fields are available:

- **Timer Interval** is the number of seconds between batch process submissions. The system will start the next run this many seconds from the start time of the previous run.
- **User ID** is the ID under which the batch process will run.
- **Email Address** is the Email address to be used for notification if the batch process fails.
- **Timer Active** allows you to temporarily switch off the timer while retaining the other settings for the timed job.
- **Batch Language** is the language associated with the batch process.

Use **Program Type** to define if the batch process program is written in **Java** or **Java (Converted)**, meaning that the program has been converted into Java.

Note: Java (Converted) program types are not applicable to all products.

Use **Program Name** to define the Java class / program associated with your batch process.

Note: View the source. If the program is shipped with the base package, you can use the adjacent button to display the source code of this program in the [Javadoc](#)s viewer.

Level of Service shows the output of the [level of service](#) algorithms for the batch control. If one algorithm is plugged into the Batch Control, the level of service lookup value along with a message indicating the reason for the output value is shown. If multiple algorithms are plugged in, the text **See Results for Details** is displayed. There is an icon provided to expand the details returned by each algorithm. If no level of service algorithm is found, then the value **Disabled** is shown with a message indicating that no algorithm is provided for this batch control.

The **Last Update Timestamp**, **Last Update Instance** and **Next Batch Nbr** are used for audit purposes.

Turn on **Accumulate All Instances** to control how this batch control is displayed in the [Batch Run Tree](#). If checked, the run statistics (i.e., "Records Processed" and "Records in Error") for a thread are to be accumulated from all the instances of the thread. This would include the original thread instance, as well as any restarted instances. If this is not turned on, only the ending (last) thread instance's statistics are used as the thread's statistics. This may be preferred for certain types of batch processes where the accumulation would create inaccurate thread statistics, such as those that process flat files and, therefore, always start at the beginning, even in the case of a restart.

The following fields are default values that are used when a batch job is submitted for the batch control:

- Use **Thread Count** to control whether a background process is run single threaded or in multiple parallel threads. This value defines the total number of threads that have been scheduled.
- Select **Trace Program Start** if you want a message to be written whenever a program is started.
- Select **Trace SQL** if you want a message to be written whenever an SQL statement is executed.
- Use **Override Nbr Records to Commit** to define the default number of records to commit. This is used as the default value for timed jobs as well as online submission of jobs that are not timed.
- Select **Trace Program Exit** if you want a message to be written whenever a program is exited.
- Select **Trace Output** if you want a message to be displayed for special information logged by the background process.

For more information about these fields, see [Batch Job Submission - Main](#)

The parameter collection is used to define additional parameters required for a particular background process. The following fields should be defined for each parameter:

Sequence. Defines the relative position of the parameter.

Parameter Name. The name of the parameter as defined by the background process program.

Description. A description of the parameter.

Detailed Description. A more detailed description of the parameter.

Required. Indicates whether or not this is a required parameter.

Parameter Value. The default value, if applicable. Any value entered here is displayed to a user when submitting a job through online [Batch Submission](#). Users may override the value before submitting the job. This includes resetting the value for an optional parameter. Regardless of how a batch job is submitted, if a value is not supplied for a required parameter, the default value defined here, if found, is used. Optional parameters with no value supplied at submission time will not be defaulted to a value defined here. Note that an implementation may define a default value for base provided batch controls.

Security. Indicates whether the system should **Encrypt** the parameter value or not. A value of **Encrypt** means that the parameter value is stored in the database and written to the log files using encryption. In addition, the parameter is written to the log files with asterisks. The setting applies to values entered here as well as in the online [Batch Submission](#). If there is no need to secure the parameter value, use the default setting of **None**.

Owner Indicates if this batch process is owned by the base package or by your implementation (Customer Modification). The system sets the owner to **Customer Modification** when you add a batch process. This information is display-only.

Batch Control - Algorithms

Use this page to maintain a batch control's algorithms. Open this page using **Admin > System > Batch Control** and then navigate to the **Algorithms** tab.

Description of Page

The **Algorithms** grid contains algorithms that control important functions for instances of this batch control. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.
- **Owner** indicates if this is owned by the base package or by your implementation (**Customer Modification**).

The following table describes the **System Events**.

| System Event | Optional / Required | Description |
|------------------------------|---------------------|---|
| Error Post-Processing | Optional | Algorithms of this type are called if the batch process fails to complete due to an error. Multiple algorithms are allowed and are executed in sequence order. Refer to Error Post-Processing Logic for more information. |

| System Event | Optional / Required | Description |
|-------------------------|---------------------|---|
| File Upload | Optional | <p>Algorithms of this type are only applicable to plug-in driven background processes and are used to upload all records for a file.</p> <p>This is a single algorithm plug-in spot. If multiple algorithms are plugged into the batch control, the one with the highest sequence is used.</p> |
| Level of Service | Optional | <p>Algorithms of this type are called to determine the Level of Service provided by a batch control. Multiple algorithms are allowed. Refer to Assessing Level of Service for more information.</p> |
| Post-Processing | Optional | <p>Algorithms of this type are called after all threads are complete. Multiple algorithms are allowed and are executed in sequence order. Refer to Post-Processing Logic for more information.</p> |
| Process Record | Optional | <p>Algorithms of this type are only applicable to plug-in driven background processes and are used to process a specific record.</p> <p>This is a single algorithm plug-in spot. If multiple algorithms are plugged into the batch control, the one with the highest sequence is used.</p> |
| Select Records | Optional | <p>Algorithms of this type are only applicable to plug-in driven background processes and are used to define the SQL to use to select the records to process.</p> <p>This is a single algorithm plug-in spot. If multiple algorithms are plugged into the batch control, the one with the highest sequence is used.</p> |

Note: You can add new system events. Your implementation may want to add additional batch control oriented system events. To do that, add your new values to the customizable lookup field **F1_BATCH_CTRL_SEVT_FLG**.

Defining File Integration Types

This section describes the functionality supported for viewing and maintaining file integration types.

Refer to [Extract Record Processing](#) for an overview of the file integration type functionality provided with [plug-in driven background processes](#).

To view or add a file integration type, open **Admin > Integration > File Integration Type**.

Once a file integration type record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **File Integration Records** zone lists the record definitions for this integration, in hierarchical order. Use the zone actions to add, maintain or view a file integration record. Press the **Record Layout** icon to view a pop-up display of the record's schema.

On-Line Batch Submission

The on-line [batch submission](#) portal enables you to request a specific background process to be run. When submitting a background process on-line, you may override standard system parameters and you may be required to supply additional parameters for your specific background process. After submitting your background process, you may use this portal to review the status of the submission.

The following topics further describe logic available for on-line submission of background processes.

Batch Submission Creates a Batch Run

When you request a batch job to be submitted from on-line, the execution of the desired background process will result in the creation of a batch run. Just as with background processes executed through your scheduler, you may use the [Batch Run](#) portal to view the status of the run, the status of each thread, the run-instances of each thread, and any messages that might have occurred during the run.

Note: Your on-line submission record is assigned a status value so that you may know whether your job has been submitted and whether or not it has ended, however, it will not contain any information about the results of the background process itself. You must navigate to the [Batch Run](#) portal to view this detail.

Jobs Submitted in the Background

When you save a record on the batch job submission page, the batch job does not get submitted automatically. Rather, it saves a record in the batch job table. A special background process will periodically check this table for pending records and will execute the batch job. This background process will update the status of the batch job submission record so that a user can determine when their job is complete.

Note: At installation time, your system administrator will set up this special background process to periodically check for pending records in the batch job submission table. Your administrator will define how often the system will look for pending records in this table.

It should be noted that this special background process only submits one pending batch job submission record at a time. It submits a job and waits for it to end before submitting the next pending job.

Note: If you request a batch job to be run multi-threaded, the special background process will submit the job as requested. It will wait for all threads to complete before marking the batch job submission record as **ended**. Refer to [Running Multi-threaded Processes](#) for more information.

Email Notification

If you wish the system to inform you when the background process completes, you may supply your email address. The email you receive will contain details related to the batch job's output; similar to the job results you would see from your batch scheduler.

The email includes information from the product installation to help users that may be working in and submitting background processes in more than one environment.

- It includes the product name and product version for the product in the [installed products](#) list that is marked as the one to display.
- If a domain name message is configured in the [installation messages](#), this information is also included.

Note: This assumes that during the installation process, your system administrator configured the system to enable email notification. Your administrator may also override the amount of detail included in the email notification.

Note: A batch control parameter may be used to indicate if the email should only be sent in the case of an error or success or both. Refer to [Parameters Supplied to Background Processes](#) for more information.

Running Multi-Threaded Processes

Many of the system background processes may be run multi-threaded. When submitting a background process on-line, you may also run a multi-threaded process. The fields Thread Count and Thread Number on the [batch submission](#) portal control the multi-threaded process requests:

- To run a multi-threaded process, indicate the number of threads in **Thread Count** and enter **0** in the **Thread Number**. If a previous run ended with one or more threads in error, a new submission may be created to restart all the threads that were in error. This submission would result in new Batch Thread Instance records added for each thread that previously ended in error. Note that if the previous run was marked to "Do Not Restart", then a new submission will result in a new Batch Run.
- In the situation where a previous run resulted in one or more threads in error, you may use the Thread Number to indicate a specific thread to restart. This is only valid if there is a previous run found that is not marked "Do Not Restart". This will result in a new Batch Thread Instance created for the specific thread in the previous run.
- To run a process as a single thread, enter Thread Count = **1** and Thread Number = **1** (or **0**). This will execute the background process single-threaded.

Note: When running a multi-threaded process, the special background process will wait until all threads are complete before marking the batch job submission record as **Ended**.

Submitting Jobs in the Future

If you wish to request a batch job to be submitted in the future, you may do so when creating your batch job submission record by entering a future submission date. The special background process, which looks for pending records in the batch job submission table, will only submit batch jobs that do not have a future submission date.

Lifecycle of a Batch Job Submission

The following diagram illustrates the lifecycle of a batch job submission record.

Pending – Records are created in **Pending** status. Records in this state are put in a queue to be submitted.

Started – Once a pending record has been submitted for processing, its status will be changed to **Started**.

Pending Cancel – Users may request the cancellation of a pending record to prevent the batch job from being submitted. In addition, users may request to cancel a started batch job that was not initiated by DBMS scheduler. The

system will look for records in this status and look for batch runs that may need to be canceled for this batch job. Once it is confirmed that any batch runs are stopped, the status changes to **Canceled**.

Ended – When the batch job has finished processing, its status will be changed to **Ended**. Note that batch jobs in **Ended** status may have ended in error. You will need to navigate to the [Batch Run](#) portal to determine the status of the batch run.

Granting Access To Batch Submission

Every batch control must reference an [application service](#). When you link a batch control to an application service, you are granting all users in the group the ability to submit the associated batch job for execution.

Fastpath: Refer to [The Big Picture Of Application Security](#) for information about granting users access rights to an application service.

When the batch control is added to the batch job table, the system checks if both the user submitting the job and the user ID recorded on the batch submission record have access rights. Application security does not apply when viewing a batch control or an associated batch run.

Note: Base batch controls will be associated with base owned application services by default. Implementations will need to ensure the appropriate user groups are linked to these application services.

Submission User and Method

Batch jobs track submission details using the following attributes.

The **Submission User** indicates who initiated the batch job and may differ from the batch user who controls permissions and auditing during the actual execution of the job. This value is not populated for timed batch jobs or batch jobs submitted via a scheduler.

The **Submission Method** indicates how the batch job was initiated. Valid methods include:

- **Online** - populated when a user manually creates or manually duplicates a batch job submission.
- **Generated** - populated by algorithms that submit a batch job and by 'initiator' batch jobs that submit other batch jobs.
- **Scheduled** - populated by the DBMS scheduler. Note that for other schedulers, it is not advised to use this value as there may be logic and validation related to records created with this value that may not apply to other schedulers.
- **Timed** - populated by the batch daemon that submits timed batch jobs.
- **Other** - populated when no other value is provided.

Additional values may be added by your implementation. Refer to the lookup `SUBMIT_METH_FLG` for a list of the submission methods supported by your system.

Batch Job Submission Portal

To view a submitted batch job, use **Menu > Tools > Batch Job Submission**. You are brought to a query portal with options for searching for a Batch Job Submission entry.

Once a batch job submission entry has been selected, you are brought to the maintenance portal to view the selected record.

The inline help provides information about several fields. Refer to [Parameters Supplied to Background Processes](#) for more information about the fields on this page.

Refer to [On-Line Batch Submission](#) on page 407 for detailed explanations about many features of online submission.

Actions

This page has three special actions.

- Using the **Duplicate** button opens a window with the selected batch job submission details displayed. These fields, including the batch parameter values, may be overridden. Pressing **Save** will create a new Batch Job Submission entry.

- Use the **Rerun** button to rerun the selected batch job. A window opens displaying the details of the batch job submission to be rerun. These fields, including the batch parameter values, may be overridden. Pressing **Save** will create a rerun Batch Job Submission entry.

Note: Rerun is only intended to be used for background processes that download information that belongs to given run number. It is typically only required if you need to download an historical run (rather than the latest run).

- **Cancel** is only applicable for batch job submissions that are in **Pending** or **Started** status and do not have a submission method of **Scheduled**. The action is not visible for other statuses. Refer to [Lifecycle of a Batch Job Submission](#) for more information.

Tracking Batch Processes

The topics in this section cover the tools provided for reviewing the status and performance of batch processes. Refer to [Defining Batch Controls](#) for more information on how batch control codes are defined.

Batch Run

The batch run portal shows the execution status of a selected batch process. The information includes thread status summary, details about each thread, its instances, and any error To Do Entries and messages (informational, warnings, and errors) that might have occurred during the run. It also includes information about files that may have been created by the process along with various types of analytical reports.

You can access the portal from the **Main Menu > Tools > Batch Run**. You are brought to a query portal with options for searching for a specific batch run. Once a batch run has been selected you are brought to this portal to view the selected record.

The following points should help understand the concept of threads:

- Many batch jobs cannot take advantage of your hardware's processing power when they are run singularly. Rather, you'll find that a large percentage of the CPU and/or disk drives are idle.
- In order to minimize the amount of idle time (and increase the throughput of your batch processes), we allow you to set up your batch processes so that multiple instances of a given batch job are executed at the same time. For example, in Oracle Utilities Customer Care and Billing when you schedule the **billing** process, you can indicate that multiple parallel instances should be executed (rather than just one instance). You'd do this so that the processing burden of creating bills for your customers can be spread over multiple processes.
- We refer to each parallel execution of a batch process as a "thread".
- Statistics and information messages are displayed in respect of each thread. Why? Because each thread is a separate execution and therefore can start and end at different times.

Refer to [Understanding Background Processes](#) on page 377 for more information.

The following zones may appear as part of the portal's **Main** tab page.

- **Batch Run.** This zone provides information about the selected batch process, including a high level summary of key details such as threads status, processing record counts and more.
- **Batch Jobs.** This zone lists one or more batch job submission records that were used to execute the batch run. Typically a batch run is associated with a single job submission record but multiple may exist when some of the threads needed to be restarted. When a single job record exists the batch parameters specified at submission time are listed on the Batch Parameters zone. When multiple jobs exist, select a job to view its parameters.
- **Batch Parameters.** This zone lists the parameters specified as part of a selected batch job submission. This zone is hidden by default when more than one job exists for the batch run.

The following zones may appear as part of the portal's **Threads** tab page.

- **Batch Run Threads.** This zone allows you to filter and review thread instances information. When an instance is associated with messages, you may click on the message count to review the message in the Batch Instance Message zone.

About Log files:

- **Availability.** The ability to download batch log files depends on whether the application properties file has been configured with the location of the log files and the log files associated with the batch run are still available.
- **Security Access.** Only users that have security access to the **Download** access mode for the batch run application service can download log files.
- **Compression.** The log files are compressed and include a *.gz extension. Different browsers treat this type of file differently. Some browsers may automatically decompress the file as part of the download and they are viewable in any text viewer by changing the extension to one the text viewer recognizes. However, some browsers download the compressed file and a user will need to unzip the file prior to viewing.
- **Batch Run Logs.** The **Download stdout** and **Download stderr** zone action links may be used to download log files at the batch run level. These files may exist for processing that occurs before the thread execution. While the links are always visible, the corresponding file may only be downloaded if available and the user has security rights to download files.
- **Batch Thread Logs.** If the log files associated with a batch thread are still available and the user has security rights to download files, the **Download stdout** and **Download stderr** icons are visible for instances of that thread.
- **Batch Instance Messages.** This zone lists any messages reported by a selected thread instance. The zone is hidden by default. Refer to [Processing Errors](#) for information about these types of errors.

The following zones may appear as part of the portal's **Errors** tab page.

- **Batch Instance Messages.** This zone allows you to filter and review messages across all thread instances. Refer to [Processing Errors](#) for information about these types of errors.
- **Batch Run To Do Entries.** If the background process has been enabled to create [To Do entries for object specific errors](#), information about the To Do entries are displayed in this tab. This zone displays a summary of all To Do entries created by this batch process, grouped by status and error message. The zone is only visible when such entries exist.
- **Sample To Do Entries.** This zone displays a sample of To Do Entries for a specific status and application message selected in the Batch Run To Do Entries zone. The zone is hidden by default.

The following zones may appear as part of the portal's **Files** tab page.

- **Batch Run Files.** This zone lists file names created by the batch process.

The following zones may appear as part of the portal's **Threads Analysis** tab page.

- **Threads Analysis.** This zone includes several analytical reports around thread performance.

The following zones may appear as part of the portal's **History** tab page. This tab is only available when the maintenance object supports lifecycle definition.

- **Previous 20 Runs - Records Per Seconds.** This zone compares the throughput of the previous 20 runs.
- **Previous 20 Runs - Processed Records.** This zone compares the number of records processed by the previous 20 runs.
- **Previous 20 Runs.** This zone lists the previous 20 runs along with key details about each run.
- **Concurrent Batch Runs.** This zone lists other batch processes that ran at the same time as the current batch run. This information is sourced from the batch snapshot tables and is therefore only available when snapshot data is kept up to date.

Actions

The page supports the following special actions:

- **Do Not Attempt Restart.** If the **Run Status** is **Error**, the system will attempt to restart this run when you attempt to execute the Batch Control. In most situations, this is exactly what you want to happen. However, there are rare situations where you do not want the system to execute a given batch run (e.g., if this run is somehow corrupt and you cannot correct the data for whatever reasons). If you want the system to skip the execution of a batch run (and proceed to the next run), click on the **Do Not Attempt Restart** action.
- **Attempt Restart.** Use this action to revert back to the standard restart functionality.

Batch Day Dashboard

This portal provides a high level summary of the status, duration and other details of the batch jobs that ran on a given business date. An implementation may introduce additional zones to this portal as needed.

Use **Menu > Dashboards > Batch Day Dashboard** to navigate to the portal.

Batch Runs By Business Day

This zone provides a summary by business date of the number of batch runs completed, in error, and in progress, together with the earliest start time and latest end time of the jobs on that day. The zone is sorted in descending order by business date.

Note: For performance reasons, the zone is configured to restrict the number of rows retrieved by the query. The 'Results' number will indicate how many rows have been retrieved. Use the Next and Previous buttons to retrieve additional dates or return to a prior set of dates.

The following filters are provided:

- **Batch Business Date** allows you to select a particular business date.
- **Process Date** allows you to restrict the batch runs included in the summary to those where the processing date is within the start and end dates for the run.
- **Exclude Reruns** allows you to exclude batch reruns from the summary.

Note: The values selected in these filters will be applied as hidden filters to the other zones in the portal.

When a specific business date is broadcast from the summary, the following zones will appear as part of the portal's **Main** tab page.

Batch Day By Status

This zone summarizes the batch runs for the business date by their status, displayed in the form of a pie chart. Selecting a specific slice of data on the chart broadcasts its value to the other zones on the portal allowing them to filter their data accordingly. Use the **Reset** action to reset the filter set by this zone.

Batch Day By Category

This zone summarizes the batch runs for the business date by their batch category, displayed in the form of a pie chart. Selecting a specific slice of data on the chart broadcasts its value to the other zones on the portal allowing them to filter their data accordingly. Use the **Reset** action to reset the filter set by this zone.

Batch Jobs Summary

This zone displays details of the individual batch runs for the broadcast business date. The zone is sorted by batch control, batch run number and batch rerun number.

Note: For performance reasons, the zone is configured to restrict the number of rows retrieved by the query. The 'Results' number will indicate how many rows have been retrieved. Use the Next and Previous buttons to retrieve additional rows or return to a prior set of rows.

The following filters are provided:

- **Batch Control** allows you to select a particular batch control to review. This filter supports wildcard searching.
- **From Start Date/Time** restricts the batch runs displayed to those where the start date time is on or after this date and time.
- **To Start Date/Time** restricts the batch runs displayed to those where the start date time is on or before this date and time.
- **From End Date/Time** restricts the batch runs displayed to those where the end date time is on or after this date and time.

- **To End Date/Time** restricts the batch runs displayed to those where the end date time is on or before this date and time.
- **Batch Control Type** restricts the batch runs displayed to the selected type.

The following columns are displayed initially:

- **Batch Control** is the batch control ID of the batch run.
- **Description** is the description of the batch control. Click the hyperlink to navigate to the [Batch Control](#) portal.
- **Batch Run** is the run number of the batch job. Click the hyperlink to navigate to the [Batch Run](#).
- **Status** is the status of the batch run.
- **Start Date/Time** is the start time of the run.
- **End Date/Time** is the end time of the run. The current date and time may be displayed if the batch job is still in progress.
- **Duration** is the time taken for the run, formatted as Days:Hours:Minutes:Seconds.
- **Threads** is the total threads for the batch run.

Click the **Column Configuration** icon  in the zone header to show the [Column Configuration Area](#) in which additional columns can be added to the results. The additional columns include the following:

- **Batch Category** is the category of the batch run.
- **Batch Control Type** is the type of the batch run.
- **Do Not Attempt Restart** indicates whether the run has been marked not to be restarted.
- **Rerun Nbr** is the rerun number of this batch job.

The Big Picture of Requests

Requests enable an implementer to design an ad-hoc batch process using the configuration tools.

An example of such a process might be to send an email to a group of users that summarizes the To Do entries that are assigned to them. This is just one example. The request enables many types of diverse processing.

Request Type Defines Parameters

For each type of process that your implementation wants, you must configure a request type to capture the appropriate parameters needed by the process.

Previewing and Submitting a Request

To submit a new request, go to **Menu > Tools > Request** in add mode. You must select the appropriate request type and then enter the desired parameter values, if applicable.

After entering the parameters, the following actions are possible:

- Click **Save** to submit the request.
- Click **Cancel** to cancel the request.
- Click **Preview** to see a sample of records that satisfy the selection criteria for this request. This information is displayed in a separate map. In addition, the map displays the total number of records that will be processed when the request is submitted. From this map you can click **Save** to submit the request, **Back** to adjust the parameters, or **Cancel** to cancel the request.

When a request is saved, the job is not immediately submitted for real time processing. The record is saved with the status **Pending** and a monitor process for this record's business object is responsible for transitioning the record to **Complete**.

As long as the record is still **Pending**, it may be edited to adjust the parameters. The preview logic described above may be repeated when editing a record.

The actual work of the request, such as generating an email, is performed when transitioning to **Complete** (using an enter processing algorithm for the business object).

To Do Summary Email

The base product includes a sample request process that sends an email to users that have incomplete To Dos older than a specified number of days.

The following configuration tasks are required to use this process:

- Define an Outbound Message Type. The business object usually defined for the Outbound Message Type is **F1-EmailMessage**.
- Define an External System that contains the Outbound Message Type in one of its steps. In the configuration determine if the communication is through SOA, batch, or real-time processing method when sending the email notification. Refer to [Outbound Messages](#) for more information about configuration needed for the different processing methods.
- Create a Request Type that includes the Outbound Message Type and the corresponding External System.
- Create a Request for the created Request Type.

Defining a New Request

To design a new ad-hoc batch job that users can submit via Request, first create a new Request Type business object. The base product BO for request type, **F1-ToDoSumEmailTyp**, may be used as a sample.

The business object for the request includes the functionality for selecting the records to process, displaying a preview map for the user to review, and for performing the actual processing. The base product BO for request, **F1-ToDoSumEmailReq**, may be used as a sample. The following points highlight the important configuration details for this business object:

- Special BO options are available for request BOs to support the Preview Request functionality.
 - **Request Preview Service Script.** This script retrieves the information that is displayed when a user asks for a preview of a request.
 - **Request Preview Map.** This map displays the preview of a request.
- The enter algorithm plugged into the Complete state is responsible for selecting the records that satisfy the criteria and processing the records accordingly.

Setting Up Request Types

Use the Request Type portal to define the parameters to capture when submitting a request. Open this page using **Admin > General > Request Type**.

This topic describes the base-package zones that appear on the Request Type portal.

Request Type List. The Request Type List zone lists every request type. The following functions are available:

- Click a **broadcast** icon to open other zones that contain more information about the request type.
- Click **Add** in the zone's title bar to add a new request type.

Request Type. The Request Type zone contains display-only information about a request type. This zone appears when a request type has been broadcast from the Request Type List zone or if this portal is opened via a drill down from another page. The following functions are available:

- Click **Edit** to start a business process that updates the request type.
- Click **Delete** to start a business process that deletes the request type.
- Click **Deactivate** start a business process that deactivates the request type.
- Click **Duplicate** to start a business process that duplicates the request type.
- State transition buttons are available to transition the request type to an appropriate next state.

Please see the zone's help text for information about this zone's fields.

Maintaining Requests

Use the Request transaction to view and maintain pending or historic requests.

Open this page using **Menu > Tools > Request > Search**. This topic describes the base-package portals and zones on this page.

Request Query. Use the query portal to search for an existing request. Once a request is selected, you are brought to the maintenance portal to view and maintain the selected record.

Request Portal. This portal appears when a request has been selected from the Request Query portal. The following base-package zones appear on this portal:

- **Actions.** This is a standard actions zone.
- **Request.** The Request zone contains display-only information about a request. Please see the zone's help text for information about this zone's fields.
- **Request Log.** This is a standard log zone.

Attachments

Some implementations may require that attachments be available from the application. These attachments can be stored in the Attachment table and then linked to other objects if applicable.

Attachment Overview

The following topics provide additional information regarding attachment functionality.

Attachment Types

The system supports several different attachment content types, for example:

- PDF Document
- Excel Spreadsheet
- Jpeg Image
- Text Document

The attachment data itself may be text or binary. When storing the data in the application however, it is stored as text information only. As a result, the upload of an attachment that is a binary type requires a conversion prior to storing the data. When viewing the attachment, the data is converted again for display.

Each type of attachment is defined using an attachment business object. The business object includes configuration defining the supported file extensions, whether the data is binary or not and the content type that represents the type of data for the attachment.

Note: To view the attachment business objects provided with the base product, navigate using **Admin > System > Business Object > Search** and search for business objects related to the Maintenance Object for Attachments (**F1-ATCHMT**).

Owned Attachments

Attachments can be either 'owned' or 'common'. An owned attachment is one that is related to a specific record. For example, the specific test results for a given device can be uploaded and linked to that device or to its test records. These types of attachments are typically uploaded and maintained via the object that owns it.

Common Attachments

Common attachments are ones that are uploaded independent of any transaction in the system. They can be used for general system or company information. Or they can be linked to more than one transaction. For example, instructions for performing a certain type of task can be uploaded as an attachment and linked to a task type where those instructions are relevant. These types of attachments are uploaded and maintained in the central Attachment portal. Objects that may refer to the attachments may link the attachments via characteristics or some other appropriate mechanism.

Emailing Attachments

The system supports a business service that may be used by system processing to send an email. The business service **F1-EmailService** supports receiving the IDs of one or more attachments as input parameters.

Refer to [Sending Email](#) for more information.

External Reference

Attachment records may be added from an external system in which case, the external system could have a reference ID to capture. The attachment allows for including an external reference ID when adding an attachment internally.

Malware Scan

The system provides a plug-in spot where you can configure a step to scan attachment for malware. If an algorithm is provided, it is called every time attachment content is added.

Configuring Your System for Attachments

In order to link attachments to objects in the system, there may be some configuration or implementation required to support the link. It is possible that one or more objects in your product already support attachments out of the box. Consult the product documentation for the specific object for confirmation. For objects in the system that do not support attachments out of the box, the following sections provide some guidelines for enabling support for attachments. Contact product support for more information.

Supporting Common Attachments

The attachments themselves are created / uploaded using the attachment portal. Refer to [Maintaining Attachments](#) for more information.

If your implementation has a use case where one or more common attachments may be linked to an object (and the object does not already support this functionality), the object may need to be extended to capture the attachments.

- If the object includes a characteristic collection, this is a recommended way to capture attachments. A characteristic type should be defined for each type of attachment. The characteristic type should be a foreign key type and should reference the Attachment FK reference. The characteristic entity collection should include the object that the common attachment will be linked to.
- Most characteristic collections are sequence based characteristics and would support multiple entries for the same characteristic types, if multiple attachments are applicable.
- If the object to support the attachments is governed by a business object, the implementation must extend the business object to define one or more appropriate elements used to capture the attachments. If only one attachment of a certain type is allowed, a single flattened characteristic may be used. If multiple attachments of a certain type are allowed, the BO schema may define a “flattened list” exposing the sequence and the characteristic type.
- If the object is maintained on a “fixed page” with a generic characteristic collection, no additional configuration is needed to allow users to link attachments to that object.

Supporting Owned Attachments

When creating an attachment for a specific record, the attachment itself captures the information about the related record, namely its maintenance object code and its primary key. For these types of attachments, no configuration is needed on the related business object to capture the attachments, as was the case with common attachments.

However, it is recommended to configure the user interface of the related object so that the owned attachments can be viewed and maintained from that page. To do this, you may use the generic attachment zone provided by the product: **F1-ATTCHOWN**.

Note that your product may already have support for viewing and maintaining owned attachments on one or more of its base delivered portals.

Configuring Size Limit

The system allows for configuration of a size limit for uploading attachments. This is optional but the recommendation is to set this to a reasonable value so as to limit the ability to upload unreasonably big files. To configure this, navigate to [Feature Configuration](#). Search for an existing feature configuration with the Feature

Type **General System Configuration**. If one does not exist, create a feature configuration of this type. Select the **Maximum Attachment Size** option and define an appropriate value.

Defining a New Attachment Type

As mentioned, the product provides support for several content types. If your implementation needs to support attachments for a content type not currently supported, create a new business object copying the configuration of an existing attachment business object.

Configure the following option types for the BO:

- **Binary** indicates whether the attachment data must be converted from binary format. Binary attachments are stored in the database as text, and are then converted back to the original format when retrieved.
- **Content Type** represents the browser's mime type of the attachment.
- **Supported File Extension** specifies the valid file extensions for the content type.

Once the business object is defined, it is ready for use.

Supporting File Name Exceptions

By default, the system prevents attachment file names from having special characters. If there is some reason that an implementation needs to define an attachment with special characters, there is a system property setting that may be configured to relax this validation. Contact your system administrator for support.

Enabling Malware Scan

The product provides a malware scan algorithm in the base product that uses ClamAV. ClamAV itself is not provided as part of the product. To use the base algorithm, your implementation needs to get ClamAV and define system properties for the host and port where ClamAV may be called. The algorithm, called **F1-ATCHM-WS** should be plugged into the [installation options - algorithms](#) collection using the system event **Attachment Malware Scan**

If your implementation wants to use a different algorithm for malware scanning, you may deliver your own algorithm and plug it into the installation algorithm collection.

Maintaining Attachments

This section describes the functionality supported for viewing and maintaining attachments.

Navigate using **Admin > General > Attachment**. You are brought to a query portal with options for searching for common attachments.

Once an attachment has been selected, you are brought to the maintenance portal to view and maintain the selected record.

Note: The base search options for the attachments query only support searching for common attachments. Owned attachments may also be viewed on the attachment maintenance portal, but a user may only drill into the attachment maintenance from the maintenance portal of the “owning” entity.

The Attachment zone provides basic information about an attachment, including the ability to upload the file and to view an uploaded file. Viewing an attachment will typically launch a download of the attachment file, following standard browser behavior.

Adding Attachments

Common attachments may be added from the attachments portal (or via the standard menu path). In addition, your product may support attachments associated with specific records (“entity owned attachments”) which may also provide the capability to add attachments.

In both cases, when adding an attachment, you are prompted for the file to upload. Once the file is chosen, the system determines the appropriate business object to associate with the attachment based on the file extension. Typically one and only one business object is found at which point you are prompted to provide the Attachment Name. (Your specific product may also require additional information at this time). Fill in the details and save.

Please note the following:

- If no business object is found for the uploaded file's file type, an error is issued. This type of file is not currently supported as an attachment.
- If multiple business objects are found, the user must choose the appropriate one. This should be rare.

Monitoring and Analytics

This chapter describes various tools provided in the product to support system monitoring including tools related to reporting, monitoring and analytics.

Reporting Tool Integration

This section describes how to configure your third party reporting tool and how to define your reports in the system to enable users to submit reports online.

The Big Picture Of Reports

The topics in this section describe the approach for designing and defining your system reports. Note that the product includes an out-of-the-box integration with BI Publisher. However it is possible to use the reporting objects to integrate with a different third party tool.

Integration with BI Publisher

Your DBMS, your product, and BI Publisher can work together to produce reports. You may choose to use a different reporting tool, but this may not be a trivial effort. This section provides high-level information about some of the business requirements that are being solved with the reporting solution.

Multi-Language and Localization Support

The integration supports a multi-language implementation and supports different localization settings.:

- All labels, headings and messages are defined using field and message meta-data in the application, which support multiple languages.
- The appropriate font, size, and layout are based on the requested report and the user's language.
- Dates and numbers are formatted as per the user's display profile.
- Currency based numbers are formatted as per the currency definition from the product

Requesting Reports from The System

Although reports are rendered in your reporting tool, users must be able to request ad-hoc reports from within the system (assuming users have the appropriate security access).

- The prompts for the input parameters must be shown in the user's language
- Users should be able to use the standard search facilities to find parameter values
- Plug-ins can be optionally used to cross-validate input parameters
- Application security must authorize ad-hoc report requests

Overview of the Data - BI Publisher

The following diagram provides an overview of where data is stored for your reports for integration with BI Publisher.

Figure 5: Application and BI Publisher

The application contains:

- The application data that appears on your reports.
- The language-specific headings, labels and messages on your reports.
- The layout file name to be used for the report.

BI Publisher contains:

- How your reports look.
- Information about scheduled reports and reports that have already run.

The DBMS contains the SQL used to retrieve the data on your reports (residing in database functions).

Note: BI Publisher can be configured to retrieve data via a service call. Because every business object can be read via a service call, elements that reside in an XML based column can be displayed on reports produced using BI Publisher. See your product's *Installation Guide* or *Optional Products Installation Guide* for information on this configuration.

How To Request Reports

A user may request an ad hoc report from within your product:

- A [report submission](#) page enables a user to choose the desired report and enter the parameter values for the report
- The user must be granted security access to the report
- The request is passed to the reporting tool real time. Refer to [Configure The System to Invoke BI Publisher](#) for more information.
- The reporting tool generates the report and displays it in a new browser window

The reporting tools' scheduler creates reports (as per your schedule). This function is entirely within the reporting tool. No scheduling functions reside within your product.

A user can request an ad-hoc report from within the reporting tool. Note, the user's ID must be supplied as a parameter to the report in order for the user's profile to be used to format dates and numbers

Viewing Reports

As described above, ad-hoc reports requested from within your product are displayed immediately after they are generated in a new browser window

If your reporting tools supports it, the [Report History](#) page may be configured to open tool's report execution history page and request a view of this report.

Note: The [Report History](#) page currently does not display historical reports for BI Publisher.

Configuring The System To Enable Reports

Configuring BI Publisher Reports

This section contains topics specific about configuring the product to interoperate with BI Publisher.

Configure the System to Invoke BI Publisher Real-time

The base product provides an [installation algorithm](#) plug-in spot called Reporting Tool. This plug-in spot should contain an algorithm that invokes the third party reporting tool real-time.

For BI Publisher, the system provides an algorithm type called **F1-BIPR-INV**, which invokes BI Publisher.

These algorithms rely on information defined in the [Reporting Options](#) table: the reporting server, reporting folder and the user name and password for accessing the reporting tool. The values in the reporting options should have been set up when the system was installed. Contact your system administrator if there are any problems with the values defined on the reporting options.

To use the algorithm types to invoke BI Publisher, perform the following steps:

- Create an [algorithm](#) for the appropriate algorithm type.
- On the [installation options](#), add an entry to the algorithm collection with an algorithm entity of **Reporting Tool** and indicate the algorithm created in the previous step.

Batch Scheduling in BI Publisher

For many of your reports, you probably want the report to be produced on a regular basis according to a scheduler. The reporting solution relies on the BI Publisher software to provide the batch scheduler functionality. Refer to BI Publisher documentation for details about configuring the batch scheduler.

Defining Reporting Options

The reporting options are provided as a mechanism for defining information needed by your reporting solution. The base product uses the reporting options to define information needed to access the reporting tool from within the system using the algorithm defined on the installation option.

Navigate to this page using **Admin > Reporting > Reporting Options**.

Description of page

Reporting Folder defines the shared folder where reports are stored.

Reporting Server From Browser defines the URL of the web application where the reporting tool is installed. For example, using BI Publisher, the format is: `http://<BI Publisher Server>:<port>`.

Note: Customize Options. The reporting options are customizable using the Lookup table. This field name is **RPT_OPT_FLG**. The reporting options provided with the system are needed to invoke the reporting tool. If your implementation requires other information to be defined as reporting options, use the lookup table to define additional values for the reporting option flag.

Where Used

This information is used by the reporting tool algorithm on the [installation option](#) to invoke the reporting tool software.

Implementations may use reporting options to record other information needed for their reporting tool.

Defining Report Definitions

For each report supplied by your installation, use the report definition page to define various attributes of the report.

Report Definition - Main

Navigate to this page using **Admin > Reporting > Report Definition**.

CAUTION: Important! If you introduce new report definitions, you must prefix the report code with **CM**. If you do not do this, there is a slight possibility that a future release of the application could introduce a new system report with the name you allocated.

Description of page

Enter an easily recognizable **Report Code** and **Description** for each report. Use the **External Reference ID** to define the identifier for this report in your external reporting tool.

Define an [application service](#) to enable users to request submission of this report online or to view report history for this report. Once you define an application service for each report, use [Secured Objects and Application Services](#) on page 22 to define which users may access this report.

Note: Access Mode. The access mode for application services related to reports must be set to **Submit/View Report**.

If you have more than one parameter defined for your report and you wish to perform cross-validation for more than one parameter, provide an appropriate **Validation Algorithm**.

Enter a **Long Description** to more fully describe the functionality of this report. This information is displayed to the user when attempting to submit the report online or when viewing history for this report.

For BI Publisher, if you want to use one of the sample reports provided by the system, but with a different layout, indicate the layout to use for the report in the **Customer Specific Font/ Layout** field and BI Publisher uses this information instead. The name for base report layout is <report code>_Base. For example, a base layout for CM_TODO is named CM_TODO_Base.

Report Definition - Labels

Navigate to this page using **Admin > Reporting > Report Definition** and go to the **Labels** tab.

Note: Company name and logo. Note the company name used as a title in the sample reports is defined as a message on the [installation options](#). For information about installing the company logo, refer to your product's *Installation Guide* or the *Optional Products Installation Guide*.

Description of Page

In order to provide multi-language capability for each report, the labels used for the report must support multiple language definitions. For each label used by your report, indicate a unique **Sequence** and the **Field** used to define the **Label**. The label defined here should be the same label that is defined in your report layout defined in the external reporting tool.

When rendering an image of the report, the external reporting tool retrieves the appropriate label based on the language used for the report.

Report Definition - Parameters

Navigate to this page using **Admin > Reporting > Report Definition** and go to the **Parameters** tab .

Description of Page

The **Parameters** scroll contains one entry for every parameter defined for the report. The following fields display:

Parameter Code is the identifier of the parameter. This must correspond to the parameter definition in the reporting tool.

Required indicates that a value for the parameter must be defined when submitting the report.

Sort Sequence must match the parameter order defined in the reporting tool's report. It is also used when displaying the list of parameters on the [report submission](#) page.

Characteristic Type indicates the characteristic type used to define this parameter.

Default Value is option and if populated is displayed to the user when the report is chosen on the [report submission](#) page.

Description is a brief description of the parameter. This description is used when displaying the parameter on the [report submission](#) page.

Long Description is a detailed description of the parameter. This description is used on the [report submission](#) page when the user requests more information for a given parameter.

Sample Reports Supplied with the Product

Depending on your specific product, there may be sample reports provided that your organization may use as they are or as a starting point for creating a [new report](#). The following sections provide an overview of the sample reports along with instructions on how to use one of the sample reports in your implementation environment.

How to Use a Sample Report Provided with the System

If you would like to use any of the sample reports, you need to perform some steps to be able to execute them in an implementation environment. This section walks you through the steps needed.

Steps Performed at Installation Time

Refer to the *Installation Guide* or *Optional Products Installation Guide* for instructions for setting up and configuring your product and reporting tool to use the sample reports provided with the system. The following steps are described there.

- Setting up the stored procedures used by the sample reports.
- Defining the company title and logo used by the sample reports. Note the company name used as a title in the sample reports is defined as a message on the [installation options](#).
- Defining a user for integration with your product.
- Publishing the sample reports in BI Publisher.

Contact your system administrator to verify that the above steps have occurred.

How To Define A New Report

Use a Sample Report as a Starting Point

- Make a copy of the report and save it in an appropriate directory. Prefix the new report name with **CM**.
- Review the stored procedure(s) used for this report. Refer to the installation guide for information about where the stored procedures should be defined. If you want to change the data that is being accessed, copy the stored procedure, prefixing the new stored procedure with **CM**. Make the appropriate changes in the new version of the stored procedure. Contact your database administrator to find out the procedure for creating a new stored procedure.

Note: Performance considerations. When designing a stored procedure, you must consider the performance of the report when executed. Consult your database administrator when designing your database access to ensure that all issues are considered.

Note: Defining Messages. The stored procedures provided with the system use messages defined in message category 30. If your new stored procedures require new messages, use message category 90000 or greater, which are reserved for implementations.

- Review the parameters used by the report. Make appropriate changes to the parameters required by the report. This affects how you define your report. Refer to [Designing Parameters](#) for more information.
- Determine whether or not you require cross validation for your report parameters. If any cross validation is necessary, you should design an appropriate validation algorithm to be executed when requesting a report in your product. Refer to [Designing Validation Algorithms](#) for more information.

Note: Cross Validation for On-line Submission Only. The cross validation algorithm is only executed for ad-hoc report submissions via your product. If you submit this report through your reporting tool, this algorithm is not executed.

- Review the labels used by the report. Labels and other verbiage are implemented in the sample reports using a reference to the field table in the system. This enables the report to be rendered in the appropriate language for the user. For any new report label you require, you must define a new field entry. Refer to [Designing Labels](#) for more information.
- Review the layout of the report and make any desired changes based on your business needs.

When you have finished designing and coding your new report in your reporting tool, you must do the following in order for it to be usable:

- Publish the report in BI Publisher. Refer to the documentation for this products for details about publishing a report. Refer to [Publishing Reports in BI Publisher](#) for configuration information specific to publishing a report for integration with your product.
- Define the report. Refer to [Designing Your Report Definition](#) for more information.

Publishing Reports in BI Publisher

Please refer to the documentation for BI Publisher for more information about publishing a report in this system. The remaining topics in this section provide information about settings needed to ensure that the report is accessible using BI Publisher.

BI Publisher Database Access

When publishing a report in BI Publisher, you are asked for database logon information. The logon user name and password must be the user name and password that has access to the database functions related to this report in your database.

Verify BI Publisher User Access Rights

To verify the user's access rights to folders in BI Publisher:

- Open the BI Publisher Enterprise Security Center.
- Check that the role for the user has access to the appropriate report folders.

For more information, refer to the "Understanding Users and Roles" section in the Oracle Business Intelligence Publisher User's Guide.

Designing Your Report Definition

When adding a new report, you must define it in the system to allow users to request ad-hoc reports from on-line and to take advantage of the multi-language provisions in the system. The following topics illustrate the steps to take to correctly configure your report definition.

Designing Main Report Definition Values

Refer to field description section of the [report definition](#) main page for information about defining general information about the report.

For the validation algorithm, preliminary steps are required. Refer to [Designing Validation Algorithms](#) for more information.

For the application service, preliminary steps are required. Refer to [Designing Application Services](#) for more information.

Designing Characteristic Types

The parameter tab on the report definition page uses [Characteristic Type](#) to define the report parameters. For each report parameter that you plan to use, you must define a characteristic type.

You do not need a unique characteristic type for each report parameter. For example, if Start Date and End Date are parameters your report, only one **Report Date** characteristic type needs to be defined. This characteristic type would be used on both date parameters.

Each characteristic type to be used as a report parameter must indicate a characteristic entity of **Report**.

To illustrate the characteristic type definitions, let's look at the sample report Tax Payables Analysis. It needs the following parameters: From Date, To Date, GL Account Type Characteristic Type and Account Type value.

Note: Account Type Parameters. The tax payables report must find general ledger entries that have posted to a certain distribution code. In order to find the appropriate distribution code, the report expects each distribution code to be defined with a characteristic indicating its GL account type (for example, **Revenue**, **Asset**, etc.) The report needs to know the characteristic type used to define this entry.

To support the required parameters, the following characteristic types are needed.

| Char Type | Description | Type | Valid Values | Char Entities |
|-----------|---------------------|--------------|---|---------------|
| CI_DATE | Date Parameter | Ad-hoc | (Uses validation algorithm to validate proper date entry) | Report |
| CI_CHTYP | Characteristic Type | FK Reference | CHAR_TYP | Report |

| | | | | |
|----------------|-----------------|-------------|--|---------------------------|
| CI_GLTY | GL Account Type | Pre-defined | A- Asset, E- Expense, LM- Liability/miscellaneous, LT- Liability/taxes, R- Revenue | Distribution Code, Report |
|----------------|-----------------|-------------|--|---------------------------|

Highlights for some of the above settings:

- We have defined a characteristic type for defining a characteristic type. This is to allow the user to indicate which Char Type on the Distribution Code is used for the GL account type. This is an FK reference type of characteristic.
- The GL account type characteristic type is referenced on both the Distribution Code entity and the report entity.

Designing Parameters

Your report definition parameters collection must define a unique parameter entry for each parameter sent to the reporting tool. The sequence of your parameters must match the sequence defined in your reporting tool.

Continuing with the Tax Payables Analysis report as an example, let's look at the parameter definitions.

| Parameter Code | Description | Char Type | Default Value |
|-------------------------|--|-----------|--------------------|
| P_FROM_DT | From Date | CI_DATE | N/A |
| P_TO_DT | To Date | CI_DATE | N/A |
| P_CHAR_TYPE | Account Type Characteristic | CI_CHTYP | CI_GLTY |
| P_TAX_ACCTY_CHAR | Account Type Char Value for Tax Related GL Account | CI_GLTY | LT-Liability/taxes |

Highlights for some of the above settings:

- The from date and to date parameters use the same characteristic type.
- The characteristic type parameter is defined with a default value pointing to the GL account type characteristic type.
- The GL account type parameter defines the liability/taxes account type as its default value.

Note: User Id. The sample reports provided by the system pass the user id as the first parameter passed to the reporting tool. It does not need to be defined in the parameter collection for the report.

Designing Validation Algorithms

When designing your report definition, determine if cross validation should occur for your collection of parameters. In the Tax Payables Analysis report, there are two date parameters. Each date parameter uses the characteristic type validation algorithm to ensure that a valid date is entered. However, perhaps additional validation is needed to ensure that the start date is prior to the end date. To do this, a validation algorithm must be designed and defined on the report definition.

The system provides a sample algorithm **RPTV-DT** that validates that two separate date parameters do not overlap. This algorithm should be used by the Tax Payables Analysis report.

If you identify additional validation algorithm, create a new [algorithm type](#). Create an [algorithm](#) for that algorithm type with the appropriate parameter values. Plug in the new validation algorithm to the appropriate report definition.

Designing Application Services

[Application services](#) are required in order to allow a user to submit a report on-line or to view history for a report. Define an application service for each report and define the user groups that should have submit/view access to this report.

Update [report definition](#) to reference this application service.

Designing Labels

The system supports the rendering of a report in the language of the user. In order to support a report in multiple languages, the verbiage used in the report must be defined in a table that supports multiple languages. Some examples of verbiage in a report include the title, the labels and column headings and text such as "End of Report".

The system uses the [field](#) table to define its labels.

Note: Report Definition. This section assumes that your new report in the reporting tool has followed the standard followed in the sample reports and uses references to field names for all verbiage rather than hard-coding text in a single language.

For each label or other type of verbiage used by your report, define a field to store the text used for the verbiage.

- Navigate to the field page using **Admin > System > Field**.
- Enter a unique **Field Name**. This must correspond to the field name used in your report definition in the reporting tool and it must be prefixed with **CM**.
- Define the **Owner** as **Customer Modification**.
- Define the **Data Type** as **Character**.
- **Precision** is a required field, but is not applicable for your report fields. Enter any value here.
- Use the **Description** to define the text that should appear on the report.
- Check the **Work Field** switch. This indicates to the system that the field does not represent a field in the database.

Update the [report definition](#) to define the fields applicable for this report in the **Labels** tab.

If your installation supports multiple languages, you must define the description applicable for each supported language.

Service Health Check

The system provides a plug-in spot on [Installation](#), called Health Check. The algorithms plugged in here are used to check various system conditions and return details to help assess the health of the system.

What Information is Checked?

Each algorithm is responsible for checking one type of health check condition. The condition should be defined as a valid health component type (as defined in the **HEALTH_COMP_FLG** lookup). The algorithm may check conditions across many records (referred to as Health Components) and return a status and details for each health component. For example, if the algorithm is checking the level of service for batch programs in the system, the batch control is the health component in this case. The algorithm should gather the level of service results for each batch program and return the collection of information to the calling program.

The algorithms for the plug-in spot should return the following information for each health component.

- The **Health Component Detail** should be populated with information specific to the object that was checked. For example, if the algorithm is checking batch control level of service, this will have the Batch Control code. In addition, for enabling display for details of each health component type, the algorithm should populate the maintenance object code and primary key field and value details along with the navigation option.
- The **Health Component Status Flag** and **Health Component Status Description** should be populated with a valid status code and description appropriate for the condition being checked. This information could differ based on the health component type as each health component type may have its own unique status values.
- The **Health Component Status Reason** is meant to provide supporting information about the health component's status value. For example, if the component provides an error type of status, this could have the status reason.
- The **Health Component Response** is used to map the status value of the health component to a standard value defined in the lookup **HEALTH_RESPONSE_FLG**. The values are a subset of HTTP response codes. The supported values are **All Checks Successful** (200); **Non-Critical Function Degraded** (203), **No Content** (204) and **One or More Critical Functions Degraded** (500).
- The **Response Details** list is provided for health components that check several conditions as part of the health check. Each condition could return its own status. In this situation, the algorithm should use the response details

list to record the individual responses and populate the overall Health Component Status Flag, Description and Reason with summary information. The suggestion is to do the following:

- Set the status flag and response based on the details of the individual responses. Refer to the batch level of service information below for an example of this logic.
- When the response list is populated, the health check user interface will show the overall Status Reason text along with an icon to expand the details. The suggestion is to populate this field with text like "See Results for Details".

The system provides an algorithm that checks the **Batch Level of Service** health component type. This health component type finds all the batch controls that are configured with at least one [level of service](#) algorithm and invokes the algorithms for each batch control. The business service populates the output for this health service for each batch control as follows:

- The **Health Component Detail** is populated with the Batch Control code and description. In addition, the navigation information for being able to drill into the batch control are provided and used to build the column as hypertext.
- The **Status** is populated based on whether the batch control has one algorithm or multiple. If there is one algorithm, the Level of Service lookup value returned by the algorithm is returned. If there are multiple, the system determines an overall status based on the detailed status values from each algorithm. If any algorithm returns Error, that value is returned. Otherwise, if any return a Warning, that value is returned. Otherwise Normal is returned.
- The **Status Reason** is populated based on whether the batch control has one algorithm or multiple. If there is one algorithm, the expanded text of the status reason returned by the algorithm is returned. If there are multiple, the text from message category / message number 11002 / 22001 is returned (**See Results for Details**)
- The **Response** is populated based on the value of the overall Level of Service status. It is set to **All Checks Successful** (200) when the Level of Service is **Normal** or **Disabled; Non-Critical Function Degraded** (203) when the Level of Service is **Warning** and **One or More Critical Functions Degraded** (500) when the Level of Service is **Error**.

How are the Algorithms Called?

These algorithms are called by a business service provided by the product **F1-HealthCheck**.

That service calculates an overall Health Response value based on all the details returned by all the algorithms. The values described above for the **HEALTH_RESPONSE_FLG** are the ones used.

Also note that the system provides [Inbound Web Services](#) for this business service for both SOAP and REST service calls allowing external systems to use a web service to retrieve this information.

Health Check Configuration

To enable your system to display health check information, navigate to the [Installation Options - Algorithms](#) collection and add an entry for the **Health Check** system event for each health check algorithm provided by the product that your product would like to include in your system health check assessment.

Viewing Health Check Results

The product provides a portal that allows a user to view the detailed results of the [health check](#) business service.

Navigate using **Admin > System > Health Check** to view this portal.

The zone on the portal displays the following:

Overall Response is the HTTP response code returned by the business service.

The grid displays the detail of each individual component checked as part of the system health check. Refer to [Service Health Check](#) for more information about the details returned.

Introducing Health Check Conditions

If your implementation would like to check a condition for system health that is not already provided by your product, here are the steps required:

- Define a new value in the Health Component Type lookup (**HEALTH_COMP_FLG**).
- Provide a new algorithm type, plug-in script and algorithm for the Health Check system event that checks the condition that you wish to check. Refer to the [Service Health Check](#) topic for the information that each algorithm should be supplying for the condition. Note that if you follow the pattern of the system delivered Batch Control - Level of Service algorithm, your algorithm may be designed to check conditions across many records of the same type and gather all the results.
- Plug this new algorithm into the [Installation Options - Algorithms](#) collection using the **Health Check** system event.

Measuring Performance

Many implementations need the ability to track and view the performance of key system processes against a defined target level. The framework provides objects to allow an edge product or an implementation to calculate and display performance measures against a desired target for one or more use cases. The topics in this section provide information about what is supplied in the framework and guidelines for implementing a specific use case for batch processes. Your product may supply out of the box support for additional use cases. Refer to your product documentation for more information.

Understanding Performance Targets

The following are examples of use cases that would be well suited for tracking as performance targets:

- Track and view the duration of key batch processes, either individually or as a group, and how they relate to a defined target.
- Monitor used and free space on a database against critical levels.
- Check the performance of individual user interface zones against a defined performance expectation
- Compare the number of web service requests made to an application against a threshold where performance may be of concern.

Framework provides functionality to define and categorize performance targets and link them to objects such as business services, zones and portals. This supports the calculation and display of the metrics against desired results.

In addition, Framework supplies out of the box support for batch process performance targets. Individual edge applications may supply more specific functionality for other use cases, if applicable.

Ideally, users should have the ability to view these performance targets on a dashboard that groups related measures. Framework provides the necessary components to achieve this for batch process performance targets.

The following sections highlight functionality supported for performance targets in the framework. Refer to the edge application product documentation for more details of other supported use cases.

Performance Target Objects Overview

The setup of a performance target involves a unique combination of configuration data and processing logic that calculates and displays a specific measure.

The framework performance target functionality is supported by a combination of inter-related objects, as shown below. Some of these objects will be generic for use in all performance targets while some are specific to a functional area such as batch processes.

- **Maintenance Objects** for capturing performance target types and performance target instances.
- **Extendable Lookups** to define performance target categories and performance target metrics.
- **Business Services** to calculate known metrics for a group of performance targets, such as for batch processes.
- **UI Maps** to interpret the performance calculation results and display them in charts that show the comparison to the target.
- A **Zone** that serves as a template for system duplication to create specific zones related to each performance target. The zone invokes a business service to perform calculations and display performance measures in the related UI map.
- **Business Objects** to capture configuration data for a specific performance target instance and its related objects.
- Functionality to create **Zone instances** for specific performance targets based on the associated template zone.

Each edge application will deliver the following to compliment the objects delivered by the framework:

- **Portals** to group related performance target zones.
- Specific entries for the performance target category **Extendable Lookup** .

The following sections describe the combined use of these objects for performance targets in more detail.

Calculating and Displaying Performance Targets

Performance targets are intended to be displayed in a portal using an explicit object zone. The zone parameters define both the business service used to calculate the performance metrics and the UI map that displays the results. While an individual performance target needs to reference a zone with a unique configuration that calculates a particular metric, those zones will be based on a template zone which defines the core parameters.

Framework provides a base Batch Performance Target Metric Template zone (**F1-PERFBA**) for batch process performance targets. Refer to this zone and its parameters for more information about the batch performance zone configuration and the related business service and UI map.

Performance Target Metrics and Metric Types

The framework supports two types of metrics for performance monitoring:

- **Value based metrics** are used to record results against a specific numeric target.
- **Time based metrics** are used to track the results against a specific date and time target.

The list of valid metrics for a given performance target category and its associated performance target types is maintained using an extendable lookup. Framework uses the base business object Batch Performance Target Metric (**F1-BatchPerfTargetMetric**) to define batch process metric values. Refer to this lookup for the supported batch process metrics.

Note: While users are not prevented from adding new values to the lookup, the list is not intended to be extendable as new values will not be recognized by the business service that performs the base batch performance calculation logic.

Your edge product or implementation may supply other extendable lookup business objects for additional performance measurement use cases, if applicable.

Performance Target Categories and Types

There are key configuration details required by all performance targets. These are defined on two related objects.

Performance Target Categories

Target categories define the template zone and security setting for a group of performance measures. The list of valid categories is maintained using an extendable lookup.

The framework product supplies the business object Performance Target Category (**F1-PerformanceTargetCategory**) for this functionality. Refer to the business object description and configuration for more information.

Performance Target Types

Target types define the related performance target business object and the display portal for a group of performance measures. In addition, a target type references a target category which defines the associated zone details.

The framework product supplies the business object Performance Target Type (**F1-PerformanceTargetType**) for this functionality. Refer to the business object description and configuration for more information.

The framework does not deliver any standard type or category values for batch processing performance targets. Refer to your specific edge application products to verify if any standard values are delivered for the batch processes within your applications. Edge applications may also supply standard categories and types for additional performance target use cases.

Performance Targets Define Specific Metrics

Although the types of measures and the business services and UI maps that govern how they are calculated and displayed are defined using separate objects, a **performance target** record defines the additional configuration needed to measure a specific metric and compare the result to a desired value.

There are key configuration details required by all performance target instances. These include a reference to the metric being measured, the desired target value or time, the desired result for the target and the unique zone by which this performance target will be monitored.

Note: The performance target maintenance object has a direct foreign key link to the extendable lookup business object and value that define the performance metric. This is an unusual pattern as extendable lookup values are normally recorded only in an object's schema. The pattern has been adopted to allow the description of the metric to be displayed in the performance target maintenance portal.

A given **performance target type** may require additional details for its calculations. For example, the framework batch process performance target defines additional details to restrict the measurement to specific batch processes that have executed within a given time frame. These details are configured on the performance target business object. Refer to the embedded help text on the business objects supplied by the framework and your edge applications for more information.

The **performance target type** also defines the business object to use when creating the resulting performance target record.

Objects Linked to a Performance Target

Some performance measures such as batch process metrics, derive the data for the calculation from objects within the system. The performance target can be linked to one or more related objects to define the specific data sources included in that target metric. For example, when creating a batch process performance target, the framework supports linking specific batch codes to the performance target to indicate the group of batch processes that are included in the measure.

The performance target business object may be configured to allow only relevant objects types to be linked to a performance target record. Refer to the base Batch Performance Target business object (**F1-BatchPerformanceTarget**) for an example.

Creating Performance Target Zones

Once a performance target and its objects have been defined, a unique zone needs to be created to display and monitor the specific target.

The framework functionality for batch performance targets implements the zone creation via the related business object lifecycle. When a performance target is added, status enter plug-ins are responsible for generating the new zone using the template zone and prefix configured on the target category (or the override values) and adding the zone to the portal configured on the target type. When a performance target is inactivated, an enter plug in is responsible for removing the zone from the portal.

Note: While the template zone associated with the performance target category may be overridden, the zone generation algorithm makes certain assumptions about the zone type and parameters. In particular, the logic expects to configure a zone parameter that references the performance target code as input to the business service responsible for calculating the metrics.

Refer to the base Batch Performance Target business object (**F1-BatchPerformanceTarget**) for details of the lifecycle and the enter plug-ins responsible for performance target zone creation.

Setting Up Performance Target Configuration

The following topics highlight the general configuration steps required to use performance target functionality. Your particular product or implementation may supply additional functionality to support specific use cases for performance targets. Refer to your product's documentation and the library of business objects supplied for performance target in your system for more information.

Performance Target Category Lookup

Refer to [About Performance Targets](#) for an overview of performance target functionality.

Each Performance Target Type is associated with a unique Performance Target Category. The categories are defined as an extendable lookup.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Performance Target Category** business object. Define values that are appropriate to the categories your implementation is assigning for the performance target types in use. In some cases, an edge application may already have delivered the appropriate performance target category for your use

Refer to the embedded help for more information about configuring this object.

Defining Performance Target Types

Refer to [About Performance Targets](#) for an overview of performance target functionality.

To maintain the performance target types applicable to your product or implementation, open **Admin > Reports > Performance Target Type**.

This is a standard [All-in-One portal](#).

The information captured on the performance target type depends on the business objects supported by your product or implementation. Refer to the embedded help text for more information.

Maintaining Performance Targets

This section describes the functionality supported for viewing and maintaining performance targets.

Refer to [About Performance Targets](#) for an overview of performance target functionality.

Navigate using **Main > Reporting > Performance Target**. This is an [All-in-One portal](#) and includes the standard List and display zones for a performance target.

For information about the data defined on the performance target, refer to embedded help.

Capturing Statistics

The product provides objects to allow for an edge product or an implementation to periodically calculate and capture statistics for one or more use cases. The topics in this section provide information about what is supplied in the framework and guidelines for implementing specific use cases.

Understanding Statistics

There are two objects that work together to capture the statistics related to a given business use case:

- The statistics control record which defines configuration related to capturing statistics. It also defines a category that is used to group similar types of statistics together.
- The statistics snapshot is the record where the actual calculated statistics are captured.

Statistics Control

The statistics control record defines whether or not statistics are automatically calculated and how frequently. In addition, you may control the retention policy of snapshot records. You may indicate that only the most recent snapshot is kept or all snapshot records are kept or that they are retained for a defined number of days.

The system provides a business object for statistics control (**F1-Statistics**) that is expected to be used for most use cases. Its lifecycle includes the support for periodic capturing of statistics snapshot records as well as on demand capture.

Statistics Snapshot

The statistics snapshot object is the object that is responsible for calculating and capturing the statistics details. A separate business object must be defined for each use case. The schema of the business object defines the details that are captured. In addition, it must include an algorithm as an enter plug-in on the **Complete** state that is responsible for capturing statistics.

The system provides a 'root' business object for statistics snapshot (**F1-SnapshotRoot**) which includes the lifecycle that statistics snapshot business objects should follow. No explicit statistics snapshot use case is provided by the

Framework. Your specific product may supply some out of the box support for certain use cases, in which case specific statistics snapshot business objects are provided. Refer to your product specific documentation for more information.

Viewing / Reporting Statistics

The product provides the mechanism for defining statistics control and statistics snapshot records and viewing the data in basic format. If your product has provided support for specific use cases, there may also be additional portals used to display the statistics in a meaningful format. For example, the statistics snapshot may be capturing data that can be presented in graphical format. Additionally, if multiple historical statistics snapshot records are retained, a zone may be defined to graph changes over time.

Configuring Your System for Statistics

If your product provides statistics use cases that you are planning to implement, all that you need to do is configure the appropriate statistics control record and define the appropriate configuration for your business requirements. Refer to [Defining and Monitoring Statistics](#) for more information.

If your implementation has identified an additional use case where you would like to capture statistics, the following points highlight the steps needed to configure the system to support the use case.

- Determine whether an additional Statistics Category value is needed. This is captured on the statistics category record. Navigate to the [Lookup](#) page. Search for and select the **STAT_CATEGORY_FLG** field. Review the values and determine if additional values are needed.
- Define a new statistics snapshot BO. This should be a child BO of the base delivered BO (**F1-SnapshotRoot**). Its schema should define elements for the specific information that is captured by the statistics calculations. The schema should be designed in conjunction with an appropriate Enter Status algorithm for the **Complete** that calculates the statistics as appropriate for the business requirement.
- Once the snapshot business object is designed and implemented, configure the appropriate statistics control record.

Defining and Monitoring Statistics

Refer to [Understanding Statistics](#) for an overview of the statistics functionality.

To define and maintain statistics control records and view a list of the current snapshot records, open **Admin > Reporting > Statistics Control**.

This is an [All-in-One portal](#) and includes the standard List and display zones for a statistics control.

For information about the data defined on the statistics control, refer to embedded help.

Statistics Snapshot

If there are any Statistics Snapshot records for the statistics control, the **Statistics Snapshot List** zone displays a list of the most recent records. A user may drill into any of the records to view more detail. You are brought to a maintenance portal where you may view details about the calculated statistics. The information captured will be unique to the particular use case. Refer to the embedded help for more information.

Creating Cube Views

Many implementations require the ability to extract and analyze complex sets of data in a way that is simple to visualize and supports business or organizational decision making. A common model for performing this type of analysis is a multi-dimensional array, often referred to as a data cube. Cube views allow data to be represented in a way that provides the user with multiple perspectives of the results.

Although called a "cube", a cube view can have two, three or a higher number of dimensions. Each dimension represents some attribute in the database and the cells in the data cube represent a measure or value. For example, a cell could contain a count of the number of times that attribute combination occurs in the database, or the minimum, maximum, sum or average value of data related to that attribute. Queries are performed on the cube to retrieve information.

The framework provides objects to support the definition of data cubes and a flexible means of viewing them. The topics in this section provide information about what is supplied in the framework to assist in implementing a cube view. Your product may also supply out of the box support for relevant use cases. Refer to your product documentation for more information.

Understanding Cube Viewer

The framework provides a cube viewer portal which is intended to be used for most implementations of cube views. It supports a number of common actions and data representations.

Note: The choice of appropriate menu for the Cube Viewer portal will differ from product to product. Refer to your product specific documentation for more information on how to access the viewer.

The following sections describe the basic concepts and features of the cube viewer.

Cube Viewer Components

The base Cube Viewer interface is comprised of the following main areas:

1. The Toolbar
2. The Settings Area
3. The Filters Area
4. The Views Area

| | DECU 101 | | | | | | | |
|-------------------|------------|-------|-------------|-------|------------|-------|-------------|-------|
| | GS | | | | RS | | | |

The next topics provide more information about each component.

The Toolbar

This following features are available on the Cube Viewer toolbar.

Settings and Filters Buttons

Click the **Settings** and **Filters** toggle buttons to collapse and expand the respective [Settings](#) or [Filters](#) areas.

Apply Button

Click the **Apply** button to apply any changes to the settings and display the new results in the views.

Details Button

Click the **Details** button to open a dialog box in which additional attributes of the current cube view can be viewed and updated. Refer to [Cube View Details](#) for more information about the attributes displayed.

Cube View Dropdown

Click the **Cube View Dropdown** to open a list of cube views, of the same type as the current view, to which you have access. Selecting a cube view from the list will open that view. Use the search box to search for a view within the list using the cube view description.

Save, Save As and Delete Buttons

Click the **Save** button to save the current settings for the cube view. Click the **Save As** button to create a copy of the current cube view. Click the **Delete** button to delete the current cube view.

Cube View Details

Clicking the **Details** button on the cube viewer **Toolbar** allows you to maintain the following information for the cube view:

- The short **Description** for display in the viewer header and a more **Detailed Description** for capturing additional information about the cube view.
- An **Access Type** of shared, private or public.
- The **Access Group** that defines the group of users with access to the cube view. This field is only visible if the access type is shared.
- A specific **User** who has sole access to the cube view. This field is only visible if the access type is private.
- The **Row Functions** text box in which the functions to be applied to the values across the rows in the data grid are defined. Clicking anywhere in the box will display a list of supported functions to choose from.
- The **Column Functions** text box in which the functions to be applied to the values in the columns in the data grid are defined. Clicking anywhere in the box will display a list of supported functions to choose from.
- An **Inactivate** button. Click this button to deactivate this cube view.

The **Fixed Parameters** for the cube view are displayed but cannot be updated here. Refer to [Configuring Cube Types](#) for more information on cube view parameters.

The Settings Area

The Settings Area contains a number of sections whose inputs control various aspects of the current cube view.

Selection Criteria

Open the **Selection Criteria** section to enter filter values for the user parameters defined on this cube type. User parameters that have been configured as 'Save with Cube View' on the cube type will be saved when the cube view is saved.

Compare

Open the **Compare** section to enter one or more sets of criteria that are used to retrieve data sets for comparison to the data retrieved by the main Selection Criteria. Use the Add and Delete buttons to add or remove a set of criteria. The comparison values will be displayed side by side with the main cube values in the data views. Note that the pseudo dimension **Dataset** must be included as a dimension column in order to display comparison views.

View Options

Open the **View Options** section to access buttons that toggle on and off the display of the supported data view types. The buttons can be used to change the order in which the views are displayed, using drag and drop. Any changes made to the default button settings will be saved when the cube view is saved. Refer to the [Views Area](#) topic for more information on the available data views.

Dimensions

Open the **Dimensions** section to view the list of dimensions defined on this cube type, as well as the pseudo dimension **Dataset** and the date/time filter, if applicable. Use drag and drop to move a dimension into the list of **Columns** or **Rows** displayed in the data views. Moving a dimension into the **Unassigned** list will remove it from the data views.

Format

Click the Edit button on the **Format** section to open a dialog box in which conditional formatting, such as background or text color, can be defined for the values in the data grid. Refer to [Defining Conditional Formatting](#) for more information about the formatting controls.

Note: Changes made to the settings will only be reflected in the views when the **Apply** button is pressed, with the exception of the **View Options**, where changes are reflected immediately upon toggling or rearranging the buttons.

Defining Conditional Formatting

Clicking the **Edit** button in the **Format** section of the **Settings** area allows you to define formatting rules for the display of values in the cube view data grid. The rules are based on mathematical expressions or formulas which use the cube view values as variables.

The formulas must be expressed using the field names of the values for the cube, as used in the cube view query zone. A list displaying the **Column Name** and associated **Label** for each value configured in the cube view is provided, to assist in defining the formulas.

The following attributes need to be defined for each rule:

- The **Sequence** defines the order in which the formatting rules are evaluated.
- The **Active** check box indicates whether the rule should be applied or not.
- The **Formula** defines the mathematical expression that is evaluated to determine whether the formatting should be applied. The expression variables should reference the **Column Name** of the value.
- **Format** defines the formats to be applied to cells whose value meets the condition expressed in the formula. The formats include the **Background** and **Text** colors and whether the text should be in **Bold**.
- The **Stop If True** check box indicates whether to stop evaluating the remaining formulas in sequence if this formula evaluates to true.

The Filters Area

The Filters Area provides the ability to select and apply dimension filters to the current view.

The **Tree** section displays a hierarchical view of the dimension values in the current cube view. Clicking a value will cause it to be displayed in the **Filters** section and immediately applies that filter to the data in the currently selected views. To remove a dimension from the filters, click on the value in the **Filters** section.

The **Hierarchical Filtering** icon, , is used to toggle between hierarchical and non-hierarchical selection mode. In hierarchical mode, clicking a dimension value at any level in the tree will automatically populate the filters with the related higher level dimension values. In non-hierarchical mode, only the selected dimension value is added as a filter.

Use the expand and collapse icons, , to quickly expand the tree, one level at a time, below the currently selected dimension value or collapse the entire level.

The Views Area

This section describes the types of views supported by the Cube Viewer.

Data Grid

The **Data Grid** displays the cube view data set in the form of a pivot table. The fields that appear as rows and columns in the table are defined in the **Dimensions** section of the [Settings](#) area. The default aggregation function used for the values is sum. Additional functions can be defined in the details of the cube view. Refer to the description of the **Details** pop-up window in the [Toolbar](#) area for more information.

Raw Data

The **Raw Data** view displays the cube view data set as a flat table.

Line Chart

The **Line Chart** displays cube view data in a chart with a time sequence as the X-axis and value intervals as the Y-axis. Each line corresponds to a specific combination of the selected dimensions. This view is only visible if the cube view includes at least one date/time filter in the selection criteria. If the criteria include more than one date/time field, the first date/time filter in order is chosen for the time sequence.

Bar Chart

The **Bar Chart** also displays cube view data in a chart with a time sequence and value intervals. Each bar corresponds to a specific combination of the selected dimensions. This view is only visible if the cube view includes at least one date/time filter in the selection criteria. If the criteria include more than one date/time field, the first date/time filter in order is chosen for the time sequence.

Cube Configuration Components

Cube views are supported using a number of standard configuration components.

The system provides a business object for cube views (**F1-CubeView**) which is used to capture access controls and the settings, such as user parameter values, for a cube view instance. The business object also defines the portal navigation and the base display UI Map (**F1-CubeViewDisp**) and accompanying display map service script (**F1-CubeViewD**). The display map and service script together drive the functionality supported in the cube viewer.

Note: The system also supplies a UI map fragment (**F1-CubeViewProc**) which is used to display a cube view in a process flow panel. Refer to [Process Flows](#) for more information.

The system provides a portal for cube views (**F1CUVWM**) that can be configured on the appropriate menu item or other navigation path for your implementation. The portal is linked to the base cube view zone (**F1-CUBEVIEW**).

In addition, the system supplies a simple query by cube view information (**F1-CUBVIWQ1**) that is the single entry on a base multi-query zone (**F1-CUBVIWQ**). The multi-query zone is not linked to the base portal as the expectation is that implementations will need to create searches tailored to their specific use cases for cube views. The base multi-query provides a quick means of configuring a cube view search while in development mode.

Configuring Cube Types

Cube Types are used to capture the details that define the sourcing of the data for a cube view and parameters that control certain features of the cube viewer. These details include:

- The business service whose associated zone defines the query used to select and filter the data for the cube view.
- The user parameters that correspond to the filters for this cube type's business service and zone.

- The user parameter settings that determine whether a given filter value should be saved with the cube view and whether the value should be populated from global or portal context, if applicable.
- The fixed parameter values to be applied as hidden filters for cube views of this type.
- The results from the business service and zone to be used as dimensions in the cube view and those that are the cube view values.
- The dimension settings that determine the order in which the dimensions are displayed in the data grid, which dimensions are to be used as filters in the cube view and which dimensions are to be included in the cube view tree.
- The values settings that determine the default sequence in which the values are displayed in the data grid.
- The FK Reference used to navigate from the data grid to the underlying source data.

If your product provides business services that support cube views you plan to use, all you need to do is configure the appropriate cube type records. Refer to [Maintaining Cube Types](#) for more information.

If your implementation has identified additional cube views you need for data analysis, you will need to create a zone and business service that use specific techniques for defining the SQL to derive the source data for the view and for mapping the results. Refer to [Cube Type Advanced Topics](#) for more information

Maintaining Cube Types

Refer to [Creating Cube Views](#) for an overview of the cube viewer functionality.

To define and maintain cube type records, open **Admin > Analytics Configuration > Cube Type**.

This is an [All-in-One portal](#) and includes the standard list and display zones for a cube type.

For information about the settings defined on the cube type, refer to [Configuring Cube Types](#) and the embedded help.

Cube Type Advanced Topics

The following topics describe the technical models that need to be followed when creating a new cube type.

Designing Your Cube Type SQL

In order to support the base cube viewer, the SQL used in your cube type data explorer zone needs to be constructed with two main components. The first component creates a view of the data and its dimensions in a form that supports a tree-like structure and allows for the dynamic use of filters. The second component queries the filtered data set to provide the values to be displayed for each dimension.

The first component should contain the following queries:

- A sub-query constructed using a 'with' clause that builds a tree-like view of the cube's dimensions and optionally other columns used in the main SQL. This portion of the SQL must be enclosed within `/*>tree*/` and `/*<tree*/` hints and use the table alias **C_TREE**. The combination of the dimension columns should form a unique 'key' in the **C_TREE** data. Both the 'with' clause and the 'tree' portion within it may contain other supporting sub-queries.
- A sub-query which is the placeholder for filtered queries on the 'tree' data. It must use the table alias **C_FILTER** and take the form `'C_FILTER as (select * from C_TREE where 1=1 and ROWNUM <= n)'`. The value of 'n' should be set to limit the rows returned to a number that is manageable within the cube viewer.

The second component is the main query that retrieves the measures for the cube view dimensions. This query references **C_FILTER** as the subset of the **C_TREE** and joins with other tables if required to retrieve the numeric values. The first date or date/time result column of the main query (as specified in the zone configuration) designates a time-series column, which forms the time-series 'key' with the dimensions columns.

Defining Your Cube Type Business Service

The business service that identifies the zone for a cube type is also used to provide additional configuration options.

The business service schema should define meaningful element names for the parameters, dimensions and values. It should also define labels for those elements to be used by both the cube type and cube viewer user interfaces. The labels can be derived by mapping the element to a meta-data fields or by using the `'label='` syntax to define a text string directly in the schema definition. The `'required=true'` syntax can be used to require a value to be entered for a user parameter on the cube viewer or for a fixed parameter on the cube type.

The user parameter elements are expected to be defined within a group in the schema called 'input' and the fixed parameters within a group called 'hidden'.

Product Use Metrics

The Product Use Metrics portal includes a zone (or zones) that are used to perform a business review of your organization's implementation of the product to confirm licensing / subscription compliance. The information visible on this portal will depend on the product or products installed by your organization.

To view this portal, open **Main > Dashboards > Product Use Metrics**.

For more information about what each zone on the portal is reporting, refer to the embedded help.

External Messages

This section describes mechanisms provided in the product that enable an implementation to configure the system to communicate with an external application.

Incoming Messages

This section provides information about support for incoming messages.

Inbound Web Services

Inbound web service functionality is provided to support receiving web service requests from an external system.

Understanding Inbound Web Services

The system supports communicating with the system via RESTful services or via SOAP services. In both cases, the system uses an object called inbound web service (IWS) to store the configuration. A web service class is used to distinguish whether the IWS is used for REST or SOAP. There is also a distinct business object for each web service class value because there is different configuration for each type of IWS.

For both types of inbound web service, the system supports the configuration of one or more operations per web service. Each operation defines the schema-based object to invoke to perform the desired function. An operation may refer to a Business Service, a Business Object, or a Service Script. If the IWS supports multiple operations, each operation can refer to the same or a completely different schema-based object from other operations within the IWS.

REST APIs may be secured by OAuth client credentials grant in a cloud installation. Refer to the Identity and Access Management chapter in the *Oracle Utilities Cloud Services Administration Guide* for more information.

The following topics provide more information about the different configuration of IWS based on whether it is SOAP or REST.

Inbound REST Web Services

This topic provides more information about the product's support of REST services using IWS.

The REST engine checks the Accept-Language header and attempts to find a supported language whose locale matches the referenced language. If found, the web service response returns any translatable data in that language. Note that if no supported language is found for the languages provided in the Accept-Language header, the system uses the language of the user that submitted the request.

IWS REST records are marked with a REST engine version of 1.0 or 2.0. Version 2.0 is the version used for new services. Version 1.0 is introduced for backward compatibility. Some of the system behavior differs based on the version of the REST service. The sections below highlight cases where this occurs.

HTTP Method and Parameters

When defining operations for inbound REST web services, the product supports the HTTP methods of Get, Patch, Post, Put, and Delete. Note that the product's support of these various HTTP methods are a means of communicating the purpose of the web service to the outside world. However, the actual behavior of the REST web service is driven by the behavior of the underlying schema based object (business object, business service or service script). For example, you may configure the HTTP Method of "Put" for an operation that references a service script that just

retrieves a record. The product is not able to detect this type of discrepancy. Configuration users should carefully consider the correct method to use based on the logic of that service.

For operations that reference a business object, the transaction type must be provided. The REST syntax doesn't support defining the transaction type at runtime. There are some basic validation checks in this case related to the transaction type and the HTTP method. For example, a Get method only makes sense with the Read transaction type.

Note: Using the transaction type **Change** requires all values to be passed in. Using the transaction type **Update** allows the web service to pass only the primary key and the values to be updated. All other elements will retain their existing values.

You may additionally define parameters. For each parameter, you define an external reference to the element, which is how this parameter is exposed to the external callers and is defined in the API specification. Each of these parameters is mapped to the XPath of the schema element from the underlying business object, business service or service script. For each parameter, you indicate if it is a **Path** parameter or a **Query** parameter.

- Path parameters are parameters that are part of the endpoint and are required. Each path parameter must be included in the operation's URI component surrounded by curly brackets.
- Query parameters are optional. They are not part of the endpoint but rather are included in the endpoint URL after a question mark, followed by name value pairs.

Refer to the URL section below for examples of path and query parameters in the sample URLs.

URL Composition

When building the endpoint URL for a REST service, there are three main parts that make up the full URL.

- The first part is the one that is environment specific. This will differ for an on premise implementation as compared to a cloud implementation. Both will have the host and the port and then additional components that identify the environment.
- The second part is a hard coded path designated by the product, namely `"/rest/apis"`.

These two parts of the URL are defined in the substitution variable **F1_REST_BASE_URL**. This is defined when initializing your environment. Refer to the Server Administration Guide for more information.

The remaining part of the URL is built dynamically based on configuration for each IWS and its operations. The components are `"/ownerURIComponent/resourceCategoryURIComponent/iwsURIComponent/operationURIComponent"`

- The owner URI component is taken from the owner flag of the inbound REST web service. A special extendable lookup ([Owner Configuration for REST Services](#)) defines this component for each owner flag.
- Each Inbound REST Web Service must reference a [resource category](#). This category is used to associate related web services to a common category of resources. For multiple IWS records linked to the same resource category, external catalogues can use this information to group together related web services. The resource category is an extendable lookup and the URI component is an attribute of this record.
- Each REST IWS record defines a URI component that serves as an external identifier of this IWS record. The value must be unique within a given owner flag.
- Each operation must define the HTTP Method and optionally a URI component. When defining path parameters, the path parameters must be included in the URI component using curly braces.

In all cases, the URI component must begin with a slash (/).

The following are some examples of the dynamic portion of the URL for a REST service. The last example illustrates the use of a query parameter.

| IWS Name URI Component | Owner URI Component | Resource Category URI Component | Operation HTTP Method URI Component | Dynamic URL Component | Run Time Example |
|--|---------------------------|---|--|---|---|
| c1rateCalculation / rateCalculation | C1 /customer | C1-RATES /rates | Post / | ../customer/rates/ rateCalculation/ | ../customer/rates/ rateCalculation/ |
| w1WorkActivity /workActivity | W1 /asset | W1-WORK /work | Get /{activityId} | ../asset/work/ workActivity/ {activityId} | ../asset/work/ workActivity/5798165498 |
| w1WorkActivity /workActivity | W1 /asset | W1-WORK /work | Patch /scheduleWindow/ {externalSystem}/ {activityId}/ {windowStartDateTime} | ../asset/work/ workActivity/ scheduleWindow/ {externalSystem}/ {activityId}/ {windowStartDateTime} | ../asset/work/ workActivity/ scheduleWindow/ MY- COMPANY/5798165498/201901 |
| CM- AccountActivityHistory / accountActivityHistory | CM /cm | CM-ACCT- INFO / accountInformation | Get /{accountId} | ../cm/ accountInformation/ accountActivityHistory/ {accountId} | ../cm/ accountInformation/ accountActivityHistory/ accountActivityHistory/12345678 activityId=5468976 |

Payload Format

REST services support receiving a request payload in XML or JSON format and returns the payload in either XML or JSON. The default format returned depends on the value of the REST Engine Version.

- Version 2.0 services assume JSON format as the default. The default can be overridden by providing an accept header of **application/XML**.
- Version 1.0 services assume XML format as the default. The default can be overridden by providing an accept header of **application/JSON**.

Root Node for JSON Format

Version 2.0 services with the JSON formatted payload do not accept in the request or return in the response any root node around the payload. The following is an example of the response of a REST call for a version 2.0 service:

```
{
  "batchJobId": "string",
  "requestSuccessful": "string"
}
```

Version 1.0 services with the JSON formatted payload expect a root node in the request and return one in the response. The following is an example of the response of a REST call for a version 1.0 service:

```
{
  "FlCnclBatJob": {
    "batchJobId": "string",
    "requestSuccessful": "string"
  }
}
```

The Open API Specification visible on the inbound web service maintenance page displays the expected format based on the record's REST engine version when viewing the specification.

Data Type Format in JSON

In JSON format, strings are surrounded by quotes and numbers and Boolean data do not have quotes. All services for REST engine version 2.0 follow this standard. Originally services that are REST engine version 1.0 were incorrectly treating numbers and Boolean data as strings and returning the data with quotes. This has been corrected.

To accommodate any integration that may have worked around the behavior for version 1.0 services, the system provides the ability to identify inbound web services that are exceptions to this rule. For any inbound web service identified as an exception, the system continues to treat numbers and Boolean data as strings in JSON responses. To add one or more IWS records to the exception list:

- Go to [Feature Configuration](#).
- Look for an existing feature configuration with the feature type **External Messages**. If one does not exist, create one.
- Add an option for the option type **IWS JSON Data Type Exceptions**.
- In the option value, indicate the IWS record that is an exception. Note that multiple options for the option type may be added. Additionally, the option value supports a comma delimited list.

External Facing Schema

By default the schema of the underlying service (for example, service script, business object or business service) is also the schema for the REST inbound web service operation and acts as both its Request and the Response schema. The product provides the ability to define an explicit schema for a REST inbound web service (IWS) operation, allowing a user to adjust the schema for an external facing consumer. The IWS operation schema also supports some special configuration that allows additional features to be defined only for the IWS operation schema.

The operation schema supports the following capabilities:

- Declaring whether an element belongs only to the request schema, only to the response schema, both (default) or excluded altogether. This is used to establish a clear separation between request and response schema definitions.
- Assign a different element name to an internal element. This allows the internal service element name to more closely align to internal references to the element, if needed. The external facing element name can be different allowing for a more readable schema.
- Introduce specialized elements that support links and other types of structural standards in a way that does not impact internal service processing.

Refer to [Web Service Schema Nodes and Attributes](#) for more information.

The REST servlet uses the request and response schemas to map elements to and from the internal schema.

Note: While the caller should only provide elements defined by the request schema, the application does not filter out extraneous elements. Assumption is that the internal service is designed to ignore such elements. However, only elements defined by the response schema are included in the response.

Dynamic Links

There are use cases where the published API includes a "_self" element that contain the endpoint URL of the GET operation related to the data returned in the response. Additionally, response payloads may include foreign keys and for those entities, the response includes a "_link" element that contains the endpoint URL of the GET operation for that entity (if it exists).

Syntax is provided in the REST inbound web service operation schema to support building the runtime endpoint URL for the _self and _link elements. Besides dynamically building the static portion of the URL based on the current environment details, it also builds the dynamic portion of the URL, substituting the URL components for the operation and substituting the path parameters. The syntax allows you to define a specific IWS Operation or allows you to reference a maintenance object and at runtime, the system determines the GET operation for the maintenance object and builds the URL accordingly.

Example of the syntax:

```
<_link getOperation="mo:'TO DO ENTRY';pk1:todoEntryId;"/>
```

Example of the runtime endpoint URL:

```
_link: "http://.../common/toDos/todoEntries/28937296450934"
```

A GET operation may be associated with a maintenance object to denote that this is the default GET operation for the entity. A **GET Operation** option at the Maintenance Object and Business Object level may be used to override this default. If the entity is not associated with a business object or the latter is not associated with such option then the operation associated with the maintenance object (if any) is used.

API Specification Documentation

The following documentation information may be provided for an Inbound Web Service:

- Short and detailed description for each operation.
- Help text may be provided for individual elements. The same text can be shared across multiple elements across all operations of the Inbound Web Service. If an element is not associated with help text then its internal field's label is used instead.
- Sample request and response documents may be provided for each operation.
- Operations may be associated with a sequence number that controls the order in which they appear in the Open API Specification.

Note: Detailed descriptions and element related help text are not translated since the published catalogue for base product APIs is in English language only.

Inbound SOAP Web Services

For inbound SOAP web services, by default the system uses the Schema Name to dictate the Request and Response for the service. The API can be overridden with custom formats by specifying Request and Response XSLs to transform into the relevant schema formats. In addition, if desired, the Request and Response Schemas that document the expected message may be provided.

Note: The Request and Response Schema fields are not supported in a cloud implementation.

Note: The system supports defining the XSLs as a [managed content](#) record. For backward compatibility, the system supports defining the XSL as a file in the file system. This is a system wide setting, defined using a feature configuration option. The feature type is **External Messages** and the option type is **XSL Location**. Set the value to **F1FL** to support XSL in the file system. The file location is configured using a system property. To support the XSL in managed content, no option is needed as this is the default. You may explicitly define the value of **F1MC** if desired.

In addition, note that for business object based operations, when invoking the web service an action is required. This may be passed into the web service as part of the invocation or alternatively, the action may be defined when configuring the operation using the transaction type.

Note: Using the transaction type **Change** requires all values to be passed in. Using the transaction type **Update** allows the web service to pass only the primary key and the values to be updated. All other elements will retain their existing values.

Annotations Used for Security

When preparing to deploy inbound SOAP web services, the security aspects of the service must be decided. The product provides a default security policy that is applied when no other policy is defined: **@Policy(uri="policy:Wssp1.2-2007-Https-BasicAuth.xml", attachToWsd=true)** which requires HTTP Basic over SSL and a WS-Security Timestamp.

If a different security policy is desired, the following options are available:

- Security policies may be attached to the Inbound Web Service via the Java Enterprise Edition (Java EE) Web Application Server. This allows for multiple policies to be attached as supported by the Java EE Web Application

Server. In order to enable this capability, explicit system configuration is required so that the product does not assume the default security policy. See the subsequent bullets for more information.

- Define a system wide security policy using a feature configuration option. Find the [Feature Configuration](#) record for the **External Messages** feature type. (It may need to be defined if it does not exist). Choose the option type **Default security policy** and define an appropriate value. If your implementation wishes for the policies to be attached at the Java EE Web Application Server, define this option type with an option value of **<none>**.
- Attach a security policy to the IWS via a Web Service Annotation. The base product provides annotation types that support the standard WS-Policy (**F1POLICY**) and OWSM Security Policy (**F1-OWSM**). No base annotation is supplied by the product for either annotation type.

If your implementation wishes for the policy of a particular IWS to be attached at the Java EE Web Application Server, define a special annotation for the **F1POLICY** annotation type and configure the **uri** parameter value to **<none>**.

Note: Refer to WebLogic documentation for more information on supported security policies.

Note: In order to use the OWSM Policy, additional system configuration is necessary. Contact your system administrator to confirm if your implementation supports OWSM.

Inbound SOAP Web Service Deployment

A Inbound SOAP Web Service must be deployed to the Java EE Web Application Server in order for it to be available to the Web Service Clients to access the system. Refer to [Deploying SOAP Web Services](#) for more information.

Deploying XAI Inbound Service via IWS

For implementations using XAI inbound services for external messages, the product recommends moving to the inbound web service mechanism, which uses the Java EE Web Application Server to communicate with the product rather than the XAI servlet.

For XAI inbound services that use the **Business Adapter**, it is straight forward to move to IWS because the configuration is similar. In both cases, the service is configured to reference a business object, business service or service script. The associated WSDL for each record is similar. Changing the interface for the incoming message to use IWS instead of XAI inbound services is similar.

However, for XAI inbound services that use the **Core Adapter**, these services reference an underlying "page service" in the product. For these services, the Request and Response schemas for the XAI inbound service were created using the Schema Editor. In order to support calling an underlying "page service" in IWS, first a [business service](#) must be created to reference the page service (if one doesn't already exist). However, the resulting schema for the business service is different from the Request and Response schemas related to the XAI inbound service. Moving this functionality to IWS using business services requires changes to the format of the incoming messages.

Moving all incoming messages over to use IWS instead of XAI is the product recommendation. However, to aid in implementations that have many integrations in place using the XAI inbound services that use the **Core Adapter** (or any adapter whose message class is **BASEADA**), the product provides the ability to deploy these types of XAI inbound services to the Java EE Web Application Server along with the Inbound Web Services.

To take advantage of this capability, you must define a feature configuration option. Under the **External Messages** feature configuration type, the **Support XAI Services via IWS** is used to indicate if this feature is supported. Setting the value to **true** turns on the feature. If no option is defined for that option type, it is equivalent to setting the value to **false**.

When the system is configured to support XAI services via IWS, the [Inbound SOAP Web Service deployment](#) includes XAI inbound services (that are configured with an Adapter that references the **BASEADA** message class). The deployment portal will also include a zone showing the deployment status of these XAI Inbound Services.

Note: There is no support for XAI inbound services via REST, only via inbound SOAP web services.

Configuring Inbound Web Service Options

This topic describes the configuration needed for using inbound web services.

Configuring SOAP Inbound Web Service Options

This topics in this section describes the configuration needed for using inbound SOAP web services.

Technical Configuration

In order to use inbound web services, there are tasks a system administrator must perform.

Refer to the Server Administration Guide for technical details of each of these processes.

Maintaining Web Service Annotation Types

The product provides some base annotation types. Refer to the metadata for more information. If your implementation wishes to define additional annotation types, use the Web Service Annotation Type portal. Open this page using **Admin > External Message > Web Service Annotation Type**.

You are taken to the query portal where you can search for an existing web service annotation type. Once an annotation type is selected, you are brought to the maintenance portal to view and maintain the selected record.

Note: Use of custom policies should only be considered if the policies supplied by the Java EE Web Application Server are not sufficient for your implementation's needs.

CAUTION: Important! When adding new records, carefully consider the naming convention of the web service annotation type code. Refer to [System Data Naming Convention](#) for more information.

The **Web Service Annotation Type** zone provides basic information about the web service annotation type.

Please see the zone's help text for information about this zone's fields.

The system supports the ability for an IWS record to refer to multiple policies. In this situation, the annotation type for the policy should include a reference to a parent annotation type so that the system can properly build the array of annotations.

Maintaining Web Service Annotations

If your implementation wishes to define annotations, use the Web Service Annotation portal. Open this page using **Admin > Integration > Web Service Annotation**.

This is a standard [All-in-One portal](#).

CAUTION: Important! When adding new records, carefully consider the naming convention of the web service annotation code. Refer to [System Data Naming Convention](#) for more information.

Maintaining XAI Inbound Services

XAI Inbound Service is a legacy mechanism for exposing system services to external systems as web services. The current supported mechanism for defining web services is [Inbound Web Services](#), which should be used for any new web service.

Some framework based products and existing implementations may have existing XAI inbound services that may need to be viewed. For these services, the product supports deploying them as SOAP inbound web services for execution. Refer to [Deploying XAI Inbound Service via IWS](#).

The following sections describe basic information about the maintenance pages. Note that some of the information is related to legacy functionality that is no longer supported.

XAI Inbound Service - Main

To view an inbound service, open **Admin > XAI > XAI Inbound Service**.

Description of Page

XAI In Service Name is used in the system to identify the service. The service name is also the first XML element after the <Body> element in the XML request/response document. The **XAI Service ID** serves as the primary key.

Owner indicates if this XAI inbound service is owned by the base package or by your implementation (**Customer Modification**). This information is display-only.

The **Adapter** defines the interface with the target application server.

If adapter for this service invokes a system service, then the appropriate **Service Name** is visible.

If adapter is the **Business Adapter** then **Schema Type** and **Schema Name** reference the object to invoke.

Web Service Category is visible if the XAI inbound service is linked to one or more [web service categories](#).

Use the **Description** and **Long Description** to describe the service.

Check the **Active** switch if this service is enabled and available for execution.

Post Error is not applicable.

Trace is not applicable.

Debug is not applicable.

Schema Definitions

Note: Request Schema and Response Schema are not applicable to services invoking schema-based objects. They do not appear when the **Business Adapter** is used.

The next two properties define the request and response XML schemas. The schemas are SOAP compatible. The schema XML files are expected to be stored in the Schemas Directory on the Web server running the XAI server.

The **Request Schema** is the XML schema defining the service request. The request sent to the server must adhere to the schema definition.

The **Response Schema** is the XML schema defining the service response. The response generated by the XAI server corresponds to the response schema definition.

The same service may perform several actions on a business object. Use the **Transaction Type** to define the default action performed by a service. The transaction type can be provided when invoking a service, by dynamically specifying a transaction type attribute on the Service element of the XML request. This field may take the following values: **Read, Add, Change, Update, Delete, List** and **Search**.

Note: The difference between **Change** and **Update** is that for **Change**, all field values must be passed in with the request. Field values that are not passed in to the request are set to null. For **Update**, you need only pass the primary key field values and the values of the fields to be updated. All other fields retain their existing values.

Services, which perform a Search, may allow searching based on different criteria. When the Transaction Type value is **Search**, use the **Search Type** to define the default search criteria. The possible values are **Main, Alternate1, Alternate2, Alternate3, Alternate4, Alternate5** and **Alternate6**.

Note: This is a default definition only and it may be overridden at run time when the service is invoked. To override the search type at run time, you should specify the searchType attribute on the Service element of the XML request.

XSL Transformation Definitions

Sometimes, the XML request document does not conform to the request schema, or the response document expected by the service requestor is not the one generated by the adapter. In such cases the request and/or the response documents must be transformed. The XAI server supports transformation through XSL transformation scripts. Transformation scripts may be applied to the request before it is passed to the adapter or applied to the response document before it is sent to the service requestor.

The **Request XSL** is the name of the XSL transformation to be applied to the request document before processing it. The transformation is usually required when the incoming document does not correspond to the XAI service request schema therefore it has to be transformed before it can be processed by the adapter.

The **Response XSL** is the name of the XSL transformation to be applied to the response document when the requester of the service expects the response to have a different XML document structure than the one defined by the response schema for the service.

Click the **WSDL URL** hyperlink to launch a separate window that contains the WSDL definition for the inbound service. Note that the server name and port number for the URL are built using a setting in the common properties file using the XAI HTTP Caller URL setting.

Configuring REST Inbound Web Service Options

This topics in this section describes the configuration needed for using inbound REST web services.

Owner Configuration Lookup

Refer to [Inbound REST Web Service](#) for an overview of REST IWS functionality.

When generating the URL for a REST web service, part of the URL is taken from the owner of the Inbound REST Web Service record. The component to add to the URL is defined in this lookup using the URI Component field. The values are provided by the product.

To view the values, navigate to the [Extendable Lookup](#) portal. Search for and select the **Owner Configuration for REST Services** business object.

Resource Category Lookup

Refer to [Inbound REST Web Service](#) for an overview of REST IWS functionality.

Each Inbound REST Web Service is associated with a Resource Category. The categories are defined as an extendable lookup. The REST URL is built using a component from the IWS record's resource category.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Resource Category** business object. Define values as needed. Typically the category is related to a logical grouping of entities, or maintenance objects, referred to as a 'resource' in REST nomenclature. In some cases, an edge application may have already delivered appropriate resource categories for your use.

Populate the appropriate URI component to include when building the URL for IWS records linked to this resource category.

Maintaining Inbound Web Services

[Inbound Web Services](#) are used to define a specific message that your implementation will receive from an external system and provides configuration needed to process the inbound message.

The product provides support for REST and SOAP services and provides several inbound web services out of the box.

For inbound SOAP web services, by default no annotations are defined for the base inbound web services. You may modify the message options or the annotations for any base IWS record. In addition, you may define additional IWS records for other incoming messages supported by your implementation.

To view an inbound web service, navigate using **Admin > Integration > Inbound Web Service**. You are brought to a query portal with options for searching for inbound web services.

Once an inbound web service has been selected, you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Important! When adding new records, carefully consider the naming convention of the inbound web service code. Refer to [System Data Naming Convention](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Inbound Web Service.** This zone displays the configuration information for the record and its operations.
- **Operations.** This zone lists the operations defined for the selected inbound web service. The zone is only visible for a REST inbound web service. You may navigate to the Inbound Web Service Operation portal to further describe the operation's web service schema.
- **Help Text Fields.** This zone maintains help text information for fields across all operations of the selected inbound web service. The zone is only visible for a REST inbound web service.

Refer to [Inbound SOAP Web Services](#) for specific information about Operations for SOAP records.

Refer to [Inbound REST Web Services](#) for specific information about Operations for REST records.

Note that in addition to standard actions available on this portal, there is also a special **Add to Category** button in the page action area. Click this button to link an inbound web service to one or more [web service categories](#).

Maintaining Inbound Web Service Operations

This portal is used to maintain a REST inbound web service operation. You can access the portal from the **Operations** zone on the Inbound Web Service portal for a REST service.

Refer to [Inbound REST Web Services](#) for specific information about Operations for REST records.

The following zones may appear as part of the portal's **Main** tab page

- **IWS Operation.** This zone provides information about the selected operation.
- **Schema.** This zone describes the request and response schema as defined by the operation's web service schema. The zone is only visible when an operation schema is explicitly defined.
- **Schema Extensions.** This zone manages web service schema extensions that correspond to extensions made to the operation's internal schema. This zone is only visible if the underlying schema was extended using dynamic data area extension functionality. Each owner that extended the internal schema may provide web service schema information for their extension elements.
- **Options.** This zone lists various options for the operation such as request and response samples. The zone is visible when such options exist for the operation. Note that options are maintained as part of operation record.

The following zones may appear as part of the portal's **References** tab page

- **IWS Operation References.** This zone lists references to the current web service operation. The list includes other inbound web service operation records that reference the current operation via their web service schema. For a GET operation, the list also includes the maintenance object or business object that explicitly references the operation using a **GET Operation** option.

Web Service Schema Nodes and Attributes

A REST inbound web service (IWS) operation invokes a single schema based object, either a Business Object, a Business Service or a Service Script. The object has one schema which by default acts as both the Request and the Response schema. The product provides the ability to define an explicit schema for a web service operation that represents a view of the underlying internal schema for an external facing consumer. Note that the operation schema is a strict view of the internal schema and as such does not introduce structural changes.

While optional, defining an operation schema has the following benefits:

- Declaring the **usage** of an element as to whether it is part of the Request schema, Response schema, both or neither.
- Assigning an **external element name** to an internal element. Useful to avoid cloning of internal services for this purpose only.
- Better management and visibility of **GET operation** references.
- Support HATEOAS style structures outside of the internal schema. This allows for seamless internal processing.
- Providing help text for individual elements.

The following documentation is a complete list of the attributes available to you when constructing an IWS operation schema.

Operation Schema Definition

The following attributes defines the external facing operation schema that establishes the request and response schema for the operation.

| Mnemonic | Valid Values | Description | Examples |
|--|--------------|---|--|
| <code>usage="REQ"</code> | | <p>Indicates that the element should be included in the request schema only.</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p> | <pre><customerName usage="REQ" /></pre> |
| <code>"RESP"</code> | | <p>Indicates that the element should be included in the response schema only.</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p> | <pre><customerId usage="RESP" /></pre> |
| <code>"BOTH"</code> | | <p>Indicates that the element should be included in both request and response schema definitions. This is the default value</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p> | <pre><customerName usage="BOTH" /></pre> |
| <code>"EXCL"</code> | | <p>Indicates that the element should not be included in either the request or the response schema definitions.</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p> | <pre><httpMethod usage="EXCL" /></pre> |
| <code>mapTo="internal element name"</code> | | <p>Maps a web service element to an internal element. By default the internal element name is assumed to be the same as the web service element name. Use this attribute to assign an external facing element name in the operation schema and map it to a corresponding internal element.</p> <p>Note that this is not an XPath expression but rather a reference to a valid element name that corresponds to the structure of the expanded internal schema.</p> <p>The owner of the element must be the same as the owner of the web service schema. If an operation's underlying schema was extended (using dynamic data area extension) then the extending owner may only reference their elements on their web service schema extension for the operation.</p> | <p>Internal schema element:</p> <pre><todoPriority .../></pre> <p>Operation schema element:</p> <pre><priority mapTo="todoPriority"></pre> |

| Mnemonic Values | Description | Examples |
|---------------------|--|--|
| role= "FKGP" | <p>Establishes a group structure that represents a foreign key to an entity.</p> <p>The element itself does not exist in the internal schema. It groups together the foreign key value element(s) along with a corresponding _link element that at run time provides the endpoint URL of that entity's GET operation. Consumers of the web service may use the link to get the data for the entity.</p> | <p>Internal schema element:</p> <pre data-bbox="1162 264 1463 323"><user .../></pre> <p>Operation schema group:</p> <pre data-bbox="1162 401 1463 552"><user role="FKGP"> <user> <_link getOperation="mo:' > </user></pre> |

| Mnemonic | Valid Values | Description | Examples |
|---|----------------------|---|--|
| | <p>"COLL"</p> | <p>Establishes a group structure that represents a collection of entities that corresponds to an internal service list.</p> <p>The element itself does not exist in the internal schema. It groups together the internal list mapped to a _data element along with a corresponding _link element that at run time provides the endpoint URL for the collection's GET operation. Consumers of the web service may use the link to get a more detailed set of information for each entity in the list.</p> <p>By default all the elements in the referenced list are included in the operation schema. You may explicitly reference and define attributes for specific elements as needed.</p> | <p>Internal schema element:</p> <pre data-bbox="1161 262 1494 514"><alerts type="list"> <alert/> <startDate / > <endDate /> <version /> </_data> </ alerts></pre> <p>Operation schema group:</p> <pre data-bbox="1161 598 1620 829"><alerts role="COLL"> <_link getOperation="... > <_data mapTo="alerts"> <version usage="EXCL > </_data> </alerts></pre> |
| <p>getOperation="expression"</p> <p>Expression components:</p> <ul style="list-style-type: none"> • mo:'<maintenance object>'; • pk1:<relative xpath to an element in the internal schema>; • pk2:...; • pk3:...; • pk4:...; • pk5:...; <p>Parameters pk2–5 are required to match the maintenance object's prime key definition.</p> | | <p>Only valid on _self and _link elements. The attribute is used to reference the default GET operation for an entity as defined by its maintenance object or business object.</p> <p>The application determines the GET operation to use as follows:</p> <ul style="list-style-type: none"> • If the entity's business object references an operation using the GET Operation option then it is used. • If the entity's maintenance object references an operation using the GET Operation option then it is used. • If a GET operation is found that references the maintenance object then it is used. <p>If a GET operation cannot be determined for the entity a standard text indicating that a link is not available is returned instead.</p> | <pre data-bbox="1161 882 1620 955"><_link getOperation="mo:'TO ></pre> |
| <p>"expression"</p> <p>Expression components:</p> <ul style="list-style-type: none"> • iws:'<inbound web service name>'; • operation:'<operation name>'; • parms:[<external reference as defined on the GET operation record>:<relative xpath of an element name in the internal schema that holds the | | <p>Only valid on _self and _link elements. The attribute is used to reference a specific GET operation along with the information needed to compose its path parameters.</p> | <pre data-bbox="1161 1522 1620 1648"><_self getOperation="iws:'F1 ToDoEntry'; operation:'getTo [ToDoEntryId:ToDoEntryId;]"/ ></pre> |

Specialized Elements

The operation schema definition makes use of specialized element names in the style of the Hypermedia as the Engine of Application State (HATEOAS) standard. These elements should only be defined by the operation schema as they are not relevant to nor should be managed by the internal operation service.

The following list describes each element and how it is used.

| Element Name | Description | Examples |
|---------------------------------|--|--|
| <code><_self .../></code> | <p>Response payloads may include a "_self" element that contains the endpoint URL of the GET operation related to the entity returned in the response.</p> <p>This is an optional element and only one may exist in an operation schema.</p> <p>Refer to getOperation= schema definition attributes for more information.</p> | <pre><_self getOperation="mo:'TO DO ENTRY'"> </_self></pre> |
| <code><_link .../></code> | <p>Response payloads may include foreign keys and for those entities, the response includes a "_link" element that contains the endpoint URL of the GET operation for that entity (if it exists).</p> <p>Refer to role= and getOperation= schema definition attribute for more information.</p> | <pre><_link getOperation="mo:'TO DO ENTRY'"> </_link></pre> |
| <code><_data .../></code> | <p>Provides a standard reference to a list of entities in the internal schema.</p> <p>Refer to role="COLL" schema definition attribute for more information.</p> | <pre><alerts role="COLL"> <_link getOperation="mo:'TO DO ENTRY'"> </_link> <_data mapTo="alerts"> </_data> </alerts></pre> |

Documentation Attributes

The following attributes provide additional documentation for individual elements that is included as part of the web service's Open API specification.

| MnemonicValid Values | Description | Examples |
|---|--|---|
| helpText= “help text field name” | <p>Associates an element with a specific help text record defined for the Inbound Web Service. If the element is included in both request and response schema the same help text is used in both.</p> <p>If this attribute is not specified, and a single Help Text Field record exists for the Field associated with the internal element, that help text record is used. If more than one such Help Text Field record exists the one where the help text name is the same as the Field name is used.</p> <p>Note that an internal element is associated with a Field name via the mdField= attributes, if any, else via the mapField= attribute.</p> <p>No valid for <code>_self</code> and <code>_link</code> elements.</p> | <pre><ToDoEntryId usage="BOTH" helpText="TD_ENTRY"></pre> <p>In this example the inbound web service defines a help text field name “TD_ENTRY” that provides help text for this element. The same help text is included for the element in both request and response schema.</p> |
| helpTextResponse= text field name” | <p>Associates an element that is included in both request and response schema with a specific help text record to be used in the context of the response schema.</p> <p>Follows same rules as the helpText= attribute.</p> | <pre><ToDoEntryId usage="BOTH" helpText="TD_ENTRY"></pre> <p>In this example the inbound web service defines the following help text records:</p> <ul style="list-style-type: none"> • Help text field name “TD_ENTRY” describes the element sent in the request schema. • Help text field name “TD_ENTRY_RESP” describes the element populated in the response schema. |

Deploying Inbound SOAP Web Services

Once an Inbound SOAP Web Service is defined it is not automatically available to the Web Service Clients to access the system. The Deployment Status and the Active flag (set to true) indicate whether a Web Service is available or not. The last step is to deploy the Inbound SOAP Web Services to the Java EE Web Application Server. This deployment phase has a number of steps that are automatically performed when a deployment is initiated:

- The Web Service files are generated and policies are attached.
- The WSDL is generated with appropriate annotations and enumerations.
- The necessary Java stub code to implement the Web Service in the Java EE Web Application Server is generated and compiled.
- The Web Services are built into a valid Web Application Archive (WAR) file.
- Optionally, the newly created Web Services WAR file is deployed to the Java EE Web Application Server. This can also be done manually for clustered deployments, if desired.

There are two methods available for deploying inbound SOAP web services:

- Deployment at the command line using the **ivwsdeploy[.sh]** command as outlined in the Server Administration Guide. This method is recommended for native installations and production implementations.

- Deployment using the Inbound Web Service Deployment portal. This method is only supported in development (non-production) environments.

Inbound Web Service Deployment Portal

To use the online Inbound Web Service Deployment portal, navigate using **Admin > Integration > Inbound Web Service Deployment**.

The following sections describe the base zones that are provided on the portal.

Deploy Inbound SOAP Web Services

The Deploy Inbound SOAP Web Services zone provides information about the last deployment. If the region is a development (non-production) region you may use the **Deploy** button to deploy or re-deploy inbound web services. All inbound web services whose Active switch is Yes will be deployed. All whose active switch is No will be undeployed.

Note: When an Inbound SOAP Web Service is deployed, the value of its service revision field is captured. Certain changes to configuration will require re-deployment to take effect. When any of the following changes occur, the IWS service revision value is incremented. This will cause the deployment status to show **Needs Deployment**.

- Active switch is changed
- An Annotation is added or removed
- An Operation is added or removed.
- The Operation Name, Schema Type / Schema Name, Request or Response Schema, Request or Response XSL for an Operation is changed.

Note: In addition, if the implementation supports XAI services deployed through IWS, the appropriate XAI inbound services will also be deployed or undeployed as required.

Deployment Status

The Deployment Status zone displays a list of inbound SOAP web services in the product, including the deployment status.

The deployment status is determined by comparing the internal Service Revision field on each IWS against the value captured at the time of deployment.

- **Deployed.** Indicates that the IWS has been deployed and no changes have been detected to the configuration.
- **Needs Deployment.** Indicates that the IWS has never been deployed or has been deployed but in the meantime, changes have been detected to the configuration that require redeployment.
- **Undeployed.** Indicates that the IWS is marked as inactive and the IWS is not found to be deployed at this time.
- **Needs Undeployment.** Indicates that the IWS is marked as inactive but the IWS is found to be deployed at this time.

If the IWS has been deployed, the View column will include a **WSDL** link allowing you to launch a separate window to view the WSDL definition.

Note: For cloud installations, the system supports defining the WSDL URI via a substitution value defined for the token URI: `@F1_BASE_IWS_URI@`. The system will use this value per the functionality described in [URI Substitution](#). When no value is defined, the system uses a default URL, which is the appropriate URL for on-premise installations.

Use the broadcast button adjacent to any of the inbound web services listed in the zone to view the details of the IWS record. This causes the **Inbound Web Service** zone to appear. It is the same zone that appears on the [Inbound Web Service](#) maintenance portal.

XAI Inbound Service Deployment Status

The XAI Inbound Service Deployment Status zone is only visible if the feature configuration option **Support XAI Services via IWS** is configured on the **External Messages** feature type or if the system detects that there are XAI inbound services that have been deployed. (The latter condition is checked for the case where an implementation has

XAI inbound services deployed and then chooses to discontinue using this functionality. After changing the feature configuration option to false, one more deployment is required to "undeploy" the XAI services.) The zone displays a list of XAI inbound services in the product that are related to page services. Refer to [Deploying XAI Inbound Service via IWS](#) for more information.

The deployment status is determined by comparing the record's Version field against the value captured at the time of deployment.

- **Deployed.** Indicates that the XAI inbound service has been deployed and no changes have been detected to the configuration.
- **Needs Deployment.** Indicates that the XAI inbound service has not been deployed or has been deployed but in the meantime, changes have been detected to the configuration.
- **Undeployed.** Indicates that the XAI inbound service is marked as inactive or the **Support XAI Services via IWS** is not set to **true** and the XAI inbound service is not found to be deployed at this time.
- **Needs Undeployment.** Indicates that the XAI inbound service is marked as inactive or the **Support XAI Services via IWS** is not set to **true** but the XAI inbound service is found to be deployed at this time.

XAI inbound service does not have the equivalent of a Service Revision field that inbound web service has, which is only incremented when changes are made to the record that impact deployment. For XAI inbound service, the version number on the record is used. This field is incremented when any changes are made, even ones that may not impact deployment. As a result, some XAI Inbound Services may indicate "Needs Deployment" in cases where a redeployment may not be necessary. The recommendation when this occurs is to simply Deploy again to be safe.

If the IWS has been deployed, the View column will include a **WSDL** link allowing you to launch a separate window to view the WSDL definition.

Guaranteed Delivery

There are alternatives for sending messages to the system besides using inbound web services. An external system may be able to send messages to the system in a generic manner where a new web service does not need to be defined for every new type of message. These types of messages may provide a payload (the message) and the service script or business service to invoke. An example of this type of communication is a message sent from a mobile application using RESTful operations.

The external system may have no mechanism for retrying failed messages. For this situation, the product provides an algorithm that may be used to capture incoming messages that should 'guarantee delivery'. A servlet processing this type of message may invoke the [installation algorithm](#) - Guaranteed Delivery, passing the details of the message and an indication if a response should be returned. The algorithm is responsible for storing the message information in a table so that it can be subsequently processed.

Outgoing Messages

"Outgoing messages" is the term used to describe messages that are initiated by our system and sent to an external system. Messages may be sent real time or near real time. The system provides the following mechanisms for communicating messages to external systems.

- **Outbound Messages.** This method allows implementers to use configurable business objects to define the message format and to use scripts to build the message. If sent near real-time the message is posted to the outbound message table waiting for Oracle Service Bus to poll the records, apply the XSL and route the message. If sent real time, the message dispatcher routes the message immediately.
- **Web Service Adapters.** Using a web service adapter, an implementation can consume a WSDL from an external system and create an "adapter" record that references the URL of the external system and creates appropriate request and response data areas to expose the payload information in a format understood by configuration tools. A script may then be written to build the request information and initiate a real-time web service call from within the system.
- **Send Email.** The system supplies a dedicated business service that may be used to send an email real-time from within the application.

All these methods are described in more detail in the following sections.

Outbound Messages

Outbound messages provide functionality for routing XML messages to an external system real-time or in near real time. In addition the functionality supports collecting related messages into a batch to then be sent to an external system as a consolidate XML message.

For each outbound message that your implementation must initiate you define a [business object](#) for the outbound message maintenance object. Using the business object's schema definition, you define the fields that make up the XML source field. These are the fields that make up the basis for the XML message (prior to any XSL transformation).

Each outbound message requires the definition of its schema by creating a business object whose schema describes the information that is provided to the external system. An XSL transformation may then be performed when routing the message to an external system.

For each external system that may receive this message, you configure the appropriate message XSL and routing information.

Because the outbound message type is associated with a business object, your implementation can easily create outbound message records from a script using the [Invoke business object step type](#). Such a script would do the following:

- Determine the appropriate [outbound message type](#) and [external system](#) based on business rules
- Access the data needed to populate the message detail
- Populate the fields in the schema and use the **Invoke business object** script step type for the outbound message type's business object to store the outbound message.
- The resulting outbound message ID is returned to the script and the scriptwriter may choose to design a subsequent step to store that ID as an audit on the record that initiated this message.

The following topics provide more information about functionality supported by outbound messages.

Polling Outbound Messages Using OSB

If the outbound message that needs to be sent to an external system can be sent as an asynchronous message (in 'near real time'), the process initiating the outbound message should create a record in the outbound message staging table. Oracle Service Bus (OSB), is the recommended tool to use to process outbound messages in near real-time.

Outbound messages that should be processed by OSB should be configured with a processing method defined as **SOA** for the external system / outbound message type. No other information is required for defining outbound message types that are processed by OSB.

For the OSB part of the processing, the product provides a custom transport: OUAF Outbound Message that may be used by an implementation to define messages to process and how to process them. This transport processes outbound messages in order of the priority defined on the outbound message type.

This section provides an overview of steps required to develop OSB integrations for outbound messages created by your product.

Before developing OSB integrations, a developer should be familiar with OSB development such as creating proxy services, business services, and message flow/routing. These terms are defined as follows:

Proxy Service: In OSB, a Proxy Service is the entity that processes a given type of message and routes it to a Business Service. A separate proxy service should be defined for each type of outbound message. If a given outbound message type may be routed to different external systems, it is the responsibility of the proxy service to query the external system defined on the outbound message and invoke the appropriate business service (see below). If any transformation is required prior to routing a message to a business service, it is the proxy service's responsibility to perform the transformation.

Business Service: In OSB, a Business Service is an entity that receives a message from OSB and routes it to the appropriate destination. This should not be confused with the Business Service object provided in the product in the configuration tools.

Fastpath: Refer to the technical reference paper *OSB Integration* for more information.

Batch Message Processing

Your implementation may be required to send messages to the same destination as a single XML file with multiple messages include. The following points describe this logic:

- The individual messages that should be grouped together must have a processing method of **batch** on the external system / outbound message type record. The appropriate batch code that is responsible for grouping the messages must also be provided.
- A separate "consolidated message" outbound message type should be configured for the external system with a processing method of **SOA**.
- When outbound message records are created for the individual messages, the batch code and current batch run number are stamped on the record.
- When the batch process runs it is responsible for building the XML file that is a collection of the individual messages. This batch process should include the following steps:
 - Format appropriate header information for the collection of messages
 - Apply the individual message XSL to each message before including the message
 - Insert a new outbound message for the external system with the "consolidated message" outbound message type.
- The consolidated message is ready to be processed by Oracle Service Bus.

Note: No process provided. The system does not supply any sample batch job that does the above logic.

Real Time Messages

The system supports the ability to make web service calls, i.e. sending real time messages, to an external system.

The system supports special functionality for sending an Email message real-time. Refer to [Sending Email](#) for more information.

For other types of real-time messages, the system also uses outbound message type and external system configuration to format and route the message. When defining the configuration for real time messages, an additional step is required to define the mechanism for routing the message using a message sender. The system supports routing messages via HTTP and via JMS. Note that for HTTP routing, the system also supports sending the message using a JSON format.

Just like near real-time messages, initiating a real-time outbound message may also be done from a script. When a real time message is added, the system immediately routes it to the external system. If the external system provided a response message back, the system captures the response on the outbound message. If the outbound message type for the external system is associated with a response XSL it is applied to transform the response. In this case the system captures the raw response as well on the outbound message. Note that the outbound message BO should be configured to capture a response XML in its schema.

Any error (that can be trapped) causes the outbound message to be in a state of **Error**. It is the responsibility of the calling process to check upon the state of the outbound message and take a programmatic action. When the outbound message state is changed back to **Pending** the message will be retried.

The base package provides two business services: Outbound Message Dispatcher (**F1-OutmsgDispatcher**) and Outbound Message Mediator (**F1-OutmsgMediator**) that further facilitate making web service calls. Both business services are similar, allowing the calling script to configure the following behavior (with differences noted):

- Whether or not exceptions encountered while sending the message are trapped. Trapping errors allows the calling script to interrogate any errors encountered and take some other programmatic action.
- Whether or not the sent message is persisted as an actual outbound message record.
 - If a persisted message is desired, the recommendation is to use the Outbound Message Dispatcher. This business service creates the message using standard BO processing, relying on the outbound message logic to route the message and store the record. The message is routed after the BO pre-processing algorithm and after the record is persisted but before the BO post-processing and audit plug-ins are executed. If you need to send

the outbound message ID as part of the message, refer to [Capturing the Outbound Message ID in the Message](#) on page 456 for more information.

- If the message should not be persisted, then the recommendation is to use the Outbound Message Mediator. As mentioned, the Outbound Message Dispatcher creates the outbound message record, relying on the outbound message logic to route the message. If it should not be persisted, it is subsequently deleted. In contrast the Outbound Message Mediator executes the BO pre-processing algorithms and then routes the message explicitly without creating a message record. It is more efficient for scenarios that don't require persistence. Note that the Outbound Message Mediator also supports persistence, but it does so by creating the records without using BO processing. This is not recommended. The Dispatcher is the better option if persistence is desired.

Refer to the descriptions of the two business services for more information.

Designing the System for Outbound Messages

The following sections describe the setup required when using [Outbound Messages](#) to communicate with an external system. The configuration walks you through the steps to configure a single external system and all its messages.

Define the Outbound Message Business Object and Type

The product supplies many outbound message Business Objects along with Outbound Message Types for out of the box functionality.

In addition, implementations may need to define configuration for custom outbound messages. For each outbound message that must be sent to an external system, create a [business object](#) for the outbound message maintenance object. Using the business object's schema definition, your implementation defines the elements that make up the XML Source field (XML_SOURCE). These are the elements that are the basis for the XML message. XSL transformations may be applied to this XML source to produce the XML message.

If your integration is real-time and a response is expected, the Outbound Message business object should also map to the XML Response field (XML_RESPONSE).

- You may decide to capture the response as is and define the element as “raw”. For example

```
<responseDetail mapXML="XML_RESPONSE" type="raw"/>
```

In this scenario, a Response XSL may or may not be needed.

- Alternatively, if the details of the response are needed, you may define specific elements for the response. For this option, depending on how the integration is designed, a Response XSL may be needed to transform the response into the expected XML format.

Once you have your business object and schema, define an [outbound message type](#) for each unique outbound message.

Referencing an XSL

The system supports defining the XSLs as a [managed content](#) record. For backward compatibility, the system supports defining the XSL as a file in the file system. This is a system wide setting, defined using a feature configuration option. The feature type is **External Messages** and the option type is **XSL Location**. Set the value to **F1FL** to support XSL in the file system. The file location is configured using a system property. To support the XSL in managed content, no option is needed as this is the default. You may explicitly define the value of **F1MC** if desired.

Capturing the Outbound Message ID in the Message

If your integration would like to use the system generated Outbound Message ID as a unique identifier with the external system, the following configuration is needed:

- Define an element within the XML Source that should be populated with the system generated outbound message.
- Configure a BO Option on the outbound message's business object using the Option Type **Outbound Message ID XPath** and set the Option Value to the XPath of the element defined to capture the ID.

Note: This functionality is only applicable if the outbound message is persisted.

Support for Dynamic URLs

The product supports the ability to build a dynamic URLs. These are cases where the URL requires information determined at runtime. This is supported with a combination of BO schema definition, URL configuration and appropriate code when creating the outbound message. The following points highlight the steps needed to support this functionality.

- When defining the [Message Sender's](#) URL, use the syntax `${pathParms}` in the location of the URL where runtime information must be inserted. For example: `http://[SERVER_NAME]:1000/rest/services/${pathParms}`
- Include the data area **F1-OM-DynamicConfig** (Outbound message dynamic configuration) in the schema of the business object for the outbound message. This data area includes elements for **pathParms** and **queryParms**.
- In the code that creates the outbound message, populate the **pathParms** and if applicable **queryParms** elements with the appropriate information. The system will build the URL by plugging in the **pathParms** element value followed by a question mark, followed by the **queryParms** element value into the `${pathParms}` location in the URL.

The following is an example of run time values.

```
<dynamicConfiguration>
  <pathParms>job/1234</pathParms>
  <queryParms>firstName=John&lastName=Doe</queryParms>
</dynamicConfiguration>
```

Add SOAP Header Parameters at Runtime

The product supports the ability to add SOAP header parameters to an external message at runtime. The following points highlight the steps needed to support this functionality.

- Include the data area **F1-OM-DynamicConfig** (Outbound message dynamic configuration) in the schema of the business object for the outbound message. This data area includes the element **soapHeaders** .
- In the code that creates the outbound message, populate the **soapHeaders** element with the self contained XML to add to the SOAP header section of the outgoing SOAP request.

Real-Time Message Configuration

Messages are routed to an external system real-time using the outbound message dispatcher or using the real-time send email business service. The system supports routing messages using HTTP and routing messages using JMS. In addition, there is a special type of message sender used for sending emails. The following sections highlights the supported real-time communication and the configuration needed for each.

Email Messages

For sending emails, the following configuration is needed:

- Define a [message sender](#) configured for email. Senders of this type should be configured with the **RTEMAILSNDR** class. The sender context is used to configure the connection information for the connecting to the SMTP server.
- This sender may be defined as the default email sender on the [message option](#) table. Alternatively, the message sender can be provided to the business service as input. Refer to [Sending Email](#) for more information.

Outbound Messages

For other outbound messages that are routed using the real-time outbound message dispatcher, a [message sender](#) must be configured to define how to route the message. The following points highlight more detail related to this configuration.

Determine the communication mechanism prior to configuring the sender.

- When routing the message using JMS, the following configuration must be defined
 - Define an appropriate [JNDI Server](#) that indicates where the JMS resources are located.
 - Define a [JMS Connection](#) to define additional configuration needed for the connection.
 - Define the [JMS Queue](#) or [JMS Topic](#) to define the queue or topic to use.
- When communicating using a JSON format, determine the method to use to convert the XML to JSON. The desired method is driven by how the request should be sent.
 - If choosing the **Base JSON Conversion** method, if XSL transformation needs to be applied prior to the conversion to JSON, then the target XML Request Schema must be defined (using a data area) so that the conversion logic knows the format of the XML it is converting. The XSL is applied to the outbound message's XML Source, resulting in the defined XML Request Schema, which is then converted to JSON. If XSL transformation is not required, then the outbound message's XML Source is converted to JSON.
 - If choosing the **Rootless JSON Conversion** method, the group element mapped to the XML source field is removed by the conversion, resulting in a rootless JSON request document.
 - If the XML source on the outbound message can be converted to JSON using an XSL, then the **XSL Transformation** method may be chosen.
 - You may also choose to convert the XML Source to JSON via the **Standard API Conversion** method (using a Jettison library). With this method, an XSL may optionally be provided. The conversion will be performed on the transformed XML.
 - For the response, if the outbound message BO defines detailed elements for the XML Response field, then the JSON should be converted to this format.
 - If your conversion method is **Base JSON Conversion**, then if the JSON response cannot be converted directly to the XML Response elements on the outbound message BO, then define a Response Schema (data area) that represents the results for the base JSON conversion. In addition, define an XSL that can transform the response from the converted XML to the XML format expected on the BO.
 - If your conversion method is **Rootless JSON Conversion**, the response document is assumed to be rootless. The group element mapped to the XML response field is added by the conversion process, resulting in a well formed XML response document.
 - If the conversion method is **Standard API Conversion** or **XSL Transformation**, the standard API is used to convert JSON to XML. An XSL may be defined to convert the response to the XML Response if needed.
 - If the outbound message BO defines a "raw" element to capture the response, then a response schema and XSL are not necessary. In this case, the system will perform a JSON to XML conversion using the **Standard API Conversion** method (regardless of the conversion method defined) and the result is captured in the XML response.
- For HTTP senders including JSON senders, the system provides the following support for sending messages secured by OAuth authentication:
 - Using Oracle Web Services Manager (OWSM). The system provides a pre-configured set of policies for OAuth (**F1-OAUTH**) using a special extendable lookup. Note that the values of this policy set defines a specific CSF key repository that the implementation should use for capturing its CSF keys. In addition, there is a substitution value defined for the token URI: `@F1_OAUTH2_URI@`. Configure the appropriate URI for this implementation as described in [URI Substitution](#). By default the system does not support additional policy sets to be defined. If your implementation requires a different policy set, contact support.
 - You may provide OAuth related settings as part of the [message sender](#) configuration for a REST API.

Define a [message sender](#) configured for each appropriate routing method. The invocation type should be configured as **Real-time**. For routing via HTTP, use the **RTHTTPSNDR** - HTTP sender class. For routing via HTTP with SOAP format automatically applied, use the **SOAPSNDR** - HTTP SOAP sender class. For routing via HTTP using JSON format, use the **RTJSONSNDR** - JSON sender class. For routing via JMS, use the **RTJMSQSNDR** - JMS queue sender class or **RTJMSTSNDR** - JMS topic sender class and configure the JMS Connection and JMS Queue or JMS Topic. Use the sender context to configure the required values for connecting to the appropriate destination.

Note: Refer to [Support for Dynamic URLs](#) for configuration needed to support dynamic URLs when sending an outbound message. There is specific configuration expected when defining the URL on the Sender in order to support dynamic URLs.

Configure the [external system](#) / outbound message type collection. The processing method defined for the external system / outbound message type must be **Real-time**.

Define the External System and Configure the Messages

Define an [external system](#) and configure the valid outgoing messages and their method of communication (processing method). Refer to [Outbound Messages](#) for more information.

Outbound Message Schema Validation

The outbound messages that are generated by the system should be well formed and valid so that they do not cause any issues in the external system. To ensure this validity you may configure the system to validate messages before they are routed to their destination. Note that the validation is applied just before communication with the sender and therefore after any Request XSL has been applied.

- Define a directory where the valid W3C schemas are located using the Message option **Outbound Message Schema Location**.
- Each [external system](#) message must indicate the appropriate W3C schema to use for validation.

You may turn on or off this validation checking using the Message option **Schema Validation Flag**.

This feature is not supported for cloud implementations.

Configuring the System for Outbound Messages

The following sections describe the setup required when using [Outbound Messages](#) to communicate with an external system.

JNDI Server

If using JMS to communicate outbound messages, define a new JNDI Server. Open **Admin > Integration > JNDI Server**.

Description of Page

Enter a unique **JNDI Server** and **Description**.

Indicate the Provider URL to indicate the location of the JNDI server. A variable may be used in place of all or part of the URL. The variable must be predefined in the substitution variable property file. The value here should enclose the variable name with @. Refer to [Referencing URIs](#) for more information.

Indicate the **Initial Context Factory**, which is a Java class name used by the JNDI server provider to create JNDI context objects.

JMS Connection

To define a JMS Connection, open **Admin > Integration > JMS Connection**.

Description of Page

Enter a unique **JMS Connection** and **Description**.

Indicate the **JNDI Server** to be used. Refer to [JNDI Server](#) for more information.

Use the **JNDI Connection Factory** to indicate the lookup keyword in the JNDI server used to locate the JMS connection.

Where Used

JMS Queue

To define your JMS Queue values, open **Admin > Integration > JMS Queue**.

Description of Page

Enter a unique **JMS Queue** and **Description**.

Enter the **Queue Name** as defined in the JNDI server. This is the JNDI lookup name identifying the queue.

Use the **Target Client Flag** to indicate whether or not the target client is **JMS** or **MQ**.

Select the **JNDI Server** where the queue is defined. Refer to [JNDI Server](#) for more information.

JMS Topic

To define your JMS Topic values, open **Admin > Integration > JMS Topic**.

Description of Page

Enter a unique **JMS Topic** and **Description**.

Select the **JNDI Server** where the topic is defined. Refer to [JNDI Server](#) for more information.

Enter the **Topic Name** as defined in the JNDI server. This is the JNDI lookup name identifying the topic.

Message Sender

The topics in this section describe the maintenance of a message sender

Message Sender - Main

To define a new sender, open **Admin > Integration > Message Sender**.

Description of Page

Enter a unique **Message Sender** and **Description**.

CAUTION: Important! When adding new records, carefully consider the naming convention of the message sender code. Refer to [System Data Naming Convention](#) for more information.

Set **Invocation Type** to **Real-time**.

Indicate the **Message Class** for this sender, which indicates the method used to route the message. The valid sender classes are as follows:

| Message Class | Description |
|--------------------|-------------------|
| RTEMAILSNDR | Email sender. |
| RTHTTPSNDR | HTTP sender. |
| RTJMSQSNDR | JMS queue sender. |
| RTJMSTSNDR | JMS topic sender. |
| RTJSONSNDR | HTTP JSON sender. |
| SOAPSNDR | HTTP SOAP sender. |

Indicate whether or not this sender is currently **Active**.

For JMS related senders, indicate whether the **MSG Encoding** is **ANSI message encoding** or **UTF-8 message encoding**. (Note that for all other types of senders, the Character Encoding context type is used to configure encoding.)

If the Message Class is one that connects to a JMS Queue or JMS Topic, indicate the appropriate **JMS Connection**

Fastpath: Refer to [JMS Connection](#) for more information.

If the Message Class is one that connects to a JMS queue, indicate the name of the **JMS Queue** to define where the message is to be sent.

Fastpath: Refer to [JMS Queue](#) for more information.

If the Message Class is one that connects to a JMS topic, indicate the name of the **JMS Topic** to define where the message is to be sent.

Fastpath: Refer to [JMS Topic](#) for more information.

Message Sender - Context

The sender may require context information to define additional information needed by the system to successfully send outgoing messages. Open **Admin > Integration > Message Sender** and navigate to the **Context** page.

Description of Page

Define the **Context Type** and **Context Value**, which contain parameters for senders when more information is required. See below for the supported context values for different types of senders.

Email Sender Context

The email sender is used by the business service that [sends email messages real-time](#).

An email sender must point to the Message Class **RTHTTPSNDR**. In addition, the following context records should be defined for senders of this type.

| Context Type | Description |
|-------------------|---|
| SMTP Host name | The SMTP server host name. |
| SMTP Username | The user ID used to access the SMTP server. |
| SMTP Password | The password used to access the SMTP server. |
| Response Time Out | The amount of time the system should wait for a real time response. |

HTTP Sender

An HTTP sender is one that sends messages to an HTTP server using the HTTP protocol. HTTP senders should reference a Message Class of **RTHTTPSNDR**, **RTJSONSNDR** or **SOAPSNDR**.

Various parameters are required to establish a session with the target HTTP server. You specify these parameters by defining a collection of context values for the sender. A set of context types related to HTTP variables is provided with the product. The following section describes the context types and where appropriate, indicates valid values.

Before defining the HTTP sender, you need to find out how the HTTP server on the other side expects to receive the request, and in particular, to answer the following questions:

- What is the address of the HTTP server?
- Is the HTTP server using a POST or GET HTTP method?
- If the server is using POST, how are message contents passed? Does it use an HTTP FORM or does it pass the data in the body of an XML message?

| Context Type | Description | Values |
|-----------------------|---|-----------------------------------|
| HTTP URL1 - URL9 | <p>Used to construct the URL of the target HTTP server.</p> <p>Since the URL may be long and complex, you can break it into smaller parts, each defined by a separate context record. The full URL is built by concatenating the values in URL1 through URL9.</p> <p>You may use substitution variables when entering values for URL parts. Note that the substitution string @XMLMSG@ may be used for GET calls if an XSL has been applied to convert the message into HTTP GET parameters. It is useful if the HTTP Form is not applicable to the type of message.</p> <p>Refer to Support for Dynamic URLs for configuration needed to support dynamic URLs when sending an outbound message.</p> | |
| HTTP Method | <p>The HTTP method used to send the message.</p> <p> Note: The SOAP sender message class SOAPSNDR only supports the POST method.</p> | POST or GET |
| HTTP Transport Method | <p>Specifies the type of the message. You can either send the message or send and wait for a response.</p> | Send or sendReceive |

| Context Type | Description | Values |
|---------------------|---|--------|
| HTTP Form Data | <p>Used when the message is in the format of an HTML Form (Content-Type: application/x-www-form-urlencoded).</p> <p>This context specifies the form parameters (data) that should be passed in the HTTP message. Since a form may have multiple parameters, you should add a context record for each form parameter.</p> <p>The value of a form parameter takes the format of $x=y$ where x is the form parameter name and y is its value.</p> <p>If y contains the string @XMLMSG@ (case sensitive) then this string is replaced by the content of the service response XML message. The @XMLMSG@ string can be used in the HTTP Form Data or in the HTTP URL, but not in both.</p> <p>If a context record of this type is defined for a sender, the sender uses the HTML Form message format to send the message even if @XMLMSG@ is not specified in one of the context records.</p> <p>If a context record of this type is not defined for a sender, then the XML is sent with Content-Type: text/plain. When using POST it is put in the HTTP message body.</p> <p>Always required when using the GET method. If you are using the GET method and do not specify a Form Data context record, no message is transferred to the HTTP server.</p> <p>You may use substitution variables when entering values for Form Data.</p> | |
| HTTP Login User | <p>The HTTP server may require authentication. Add a context record of this type to specify the login user to use.</p> | |
| HTTP Login Password | <p>The HTTP server may require authentication. Add a context record of this type to specify the login password to use.</p> | |

| Context Type | Description | Values |
|------------------------|---|--|
| HTTP Header | <p>Sometimes the HTTP server on the other side may require the addition of HTTP headers to the message.</p> <p>For each HTTP header that has to be specified you should add a context record with a value having the following format <i>x:y</i> where <i>x</i> is the header name and <i>y</i> is the value for the header</p> | |
| HTTP Time Out | Indicates the amount of time to wait for a connection to be established with the remote system. | |
| Character Encoding | Indicates if the message should be encoded. The sender will add to the HTTP's content type header the string <code>; charset=x</code> where <i>x</i> is the value of this context and when sending the message it will encode the data in that encoding. | UTF-8 or UTF-16 |
| Response Time Out | The amount of time the system should wait for the remote system to send a response. | |
| Sender Security Type | Indicate the desired security type to apply. (Note that additional security types are applicable only to the SOAP Sender. See below for more information.) | BASIC (HTTP Basic), TEXT (Username Token plain text), DIGEST - Username Token Digest, OWSM - OAuth Security via OWSM, OAUTH - OAuth Security. |
| OWSM Policy Set | Applicable only if the Sender Security Type is OWSM . Defines the policy set to apply. | Enter a valid value for the extendable lookup Set of Policies (F1-SetOfPolicies). The product provides the value F1-OAUTH that may be used here. |
| OAuth Grant Type | Applicable only if the Sender Security Type is OAUTH . Defines the OAuth specification method for acquiring an access token. | client_credentials |
| OAuth Access Token URL | Used to construct the URL of the target authorization server. You may use substitution variables to construct the URL. | |
| OAuth Client ID | The generated identifier for the current application in the external system's authorization server. | |
| OAuth Client Secret | The secret paired with the OAuth Client ID as provided by the external system's authorization server. | |

| | | |
|-------------------------------------|---|--|
| OAuth Key Ring | Defines the key ring used to store the OAuth Client ID and secret provided by the external system's authorization server. If a key ring is specified, the OAuth Client ID and OAuth Client Secret context entries are not allowed. | |
| OAuth REST API Scope | The authorization level granted by the end point. | |
| OAuth Token Request Details in Body | By default, the authorization token request includes the Client ID and Secret information in the message header. This context type may be used to indicate that this information should be sent in the body of the request instead. | Set this to 'Y' to send the Client ID and Secret information as part of the body of the authorization token request. |

Real-time HTTP Sender

The following context type is only applicable to senders with the **RTHTTPSNDR** message class.

| Context Type | Description |
|--------------|---|
| Content Type | Populate a value here to override the Content-Type attribute in the HTTP header, which defaults to text/xml . |

SOAP Sender

A SOAP sender is an HTTP sender that automatically adds support for the SOAP format. For this type of sender (message class of **SOAPSNDR**), besides the context values listed above, the following context entries may also be supplied.

| Context Type | Description | Values |
|------------------------------------|--|--------|
| Message Namespace URI | Used to indicate a specific namespace to be included in messages for this sender. Note that this value is used only when the External Message link to this sender is configured with a Namespace Option of Configured on Sender . | |
| SOAP Insert Timestamp | Indicate whether a timestamp should be added. Default value is 'N'. | Y or N |
| SOAP Expiration Delay (in seconds) | Indicate an expiration delay to add to the timestamp. The default value is 60. | |

| Context Type | Description | Values |
|----------------------|---|---|
| Sender Security Type | Additional security types are supported for SOAP senders for specific third party integrations. | CIM - Uses an appropriate namespace and adds security information in the SOAP header specific to Landis+Gyr, MS_V30 - Uses an appropriate namespace and adds security information in the SOAP header specific to MultiSpeak v3.0, MS_V41R - Uses an appropriate namespace and adds security information in the SOAP header specific to MultiSpeak v4.1. ITRON - Uses appropriate SOAP header information security information in the SOAP header specific to Itron. |

Note: Refer to [Add SOAP Header Parameters at Runtime](#) for information about dynamically including SOAP Header parameters when sending a message.

JMS Sender

A JMS sender is one that sends messages to a JMS queue or JMS topic. JMS senders should reference a Message Class of **RTJMSQSNDR** or **RTJMSTSNDR**, respectively.

The following parameters are used to connect to the JMS resource.

| Context Type | Description | Values |
|-------------------------------------|---|----------------------|
| JMS Message Type (Bytes(Y)/Text(N)) | Indicates whether the data is sent as a bytes message or as a text message. | Y or N |
| JMS User Name | Enter the user name to connect to the JMS resource. | |
| JMS User Password | Enter the password to use to connect to the JMS resource. | |
| JMS Header | <p>If JMS header values are required for the message, use this context type.</p> <p>For each JMS header that has to be specified, add a context record with a value having the following format <i>x:y</i> where <i>x</i> is the header name and <i>y</i> is the value.</p> | |

Application Variables

Some APIs may require application identifying variables to be included in the message payload. These values are typically available at provisioning time and need to be captured in relation to these API configurations.

Note: This type of context is not involved in the process of orchestrating and routing the API call. It needs to be incorporated into the payload by the application logic that composes the message using the "Get Application Variables (FIMsgVars)" service script.

The following parameters may be used to capture application variables.

| Context Type | Description | Values |
|----------------|--|--|
| Application ID | Identifies the current environment for this API. | Determined at provisioning time by the API provider. |
| Tenant ID | Identifies the current tenant for this API. | Determined at provisioning time by the API provider. |

Defining Outbound Message Types

Refer to [Outbound Messages](#) for an overview of this functionality.

Use this page to define basic information about an outbound message type. Open this page using **Admin > Integration > Outbound Message Type**. You are brought to a query portal with options for searching for outbound message types.

Note: This page is not available if the **External Message** module is [turned off](#).

Once an outbound message type has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Outbound Message Type** zone provides basic information about an outbound message type. Besides the code and description, the outbound message type captures the outbound message business object and the relative priority of the outbound message. The priority is only applicable if the [outbound message is processed using OSB](#). In addition, if the outbound message type is linked to any web service categories, they are displayed.

CAUTION: Important! When adding new records, carefully consider the naming convention of the outbound message type code. Refer to [System Data Naming Convention](#) for more information.

Note that in addition to standard actions available on this portal, there is also a special **Add to Category** button in the page action area. Click this button to link an outbound message type to one or more [web service categories](#).

The **External System Links** zone is visible if the outbound message type is linked to any external systems.

External Systems

Use this page to define an external system and define the configuration for communication between your system and the external system.

External System - Main

Open this page using **Admin > Integration > External System**.

Note: This page is not available if both the **External Message** and the **Open Market Interchange** modules are [turned off](#).

Description of Page

Enter a unique **External System** and **Description**.

CAUTION: Important! When adding new records, carefully consider the naming convention of the external system code. Refer to [System Data Naming Convention](#) for more information.

Use the field **Our Name In Their System** to specify the identity of your organization (i.e., your external system identifier) in the external system.

Note: The workflow process profile and notification download profile are only applicable to products that support workflow and notification. They are not visible in the product if the **Open Market Interchange** module is [turned off](#).

If this external system sends inbound communications through notification upload staging, the type of workflow process that is created is controlled by the sender's **W/F (Workflow) Process Profile**.

If you send notifications to this external system, select a **Notification DL (download) Profile** that is used to define the configuration of the outgoing messages.

Note: The remaining fields are not visible if the **External Message** module is [turned off](#).

Set **Usage** to **Template External System** for external systems whose outbound message type configuration is inherited by other external systems.

If the outbound message type configuration should be inherited from a template external system, define the **Template External System**. If this field is specified, the outbound message type collection displays the data defined for the template system as display-only.

The **Outbound Message Type accordion** contains an entry for every type of outbound message defined for this external system. For each type of outbound message identify its **Outbound Message Type**.

Define the **Processing Method** for messages of this type. Valid values are **Batch**, **Real-time**, **SOA** and **XAI**.

Define an appropriate **Message Sender** if the processing method is **XAI** or **Real-time**.

Namespace Option is used when your message should include a namespace in the resulting XML. The valid options are **Standard Namespace** and **Configured on Sender**. If the value is Standard Namespace, the system will generate a namespace for the resulting WSDL with the following value: http://ouaf.oracle.com/outbound/AAA_BBB, where AAA is the external system code and BBB is the outbound message type code. If the value is Configured on Sender, then the value of the namespace is taken from the sender context with context type **Message Namespace URI**.

Define an appropriate **Batch Control** if the processing method is **Batch**.

If the message sender is one with a message class of **RTJSONSNDR**, indicate the **JSON Conversion Method**. The valid values are **Base JSON Conversion**, **Standard API Conversion** and **XSL Transformation**. Refer to [Real Time Message Configuration](#) for more information about these methods and the additional configuration that may be applicable.

If the **JSON Conversion Method** is **Base JSON Conversion**, the **Request Schema** is enabled. Populate a data area that defines the schema for the XML format to convert the outbound message's BO schema to prior to performing the JSON conversion. Refer to [Real Time Message Configuration](#) for more information.

The **Message XSL** is the schema used to transform information from the format produced by the system to a format understood by the sender, who receives a message of this type. This is not applicable for Processing Method of **SOA**. Refer to [Referencing an XSL](#) for information about configuring where the XSL is defined.

Enter the file name of the appropriate **W3C Schema** if you want to validate the message built for outbound messages for this external system / outbound message type prior to being routed to their destination. Refer to [Outbound Message Schema Validation](#) for more information. This is not applicable for Processing Method of **SOA**. This feature is not available for cloud implementations.

If the **JSON Conversion Method** is **Base JSON Conversion**, the **Response Schema** is enabled. Populate a data area that defines the schema for the XML format that the JSON message is initially converted to. The XML is then converted to BO XML. Refer to [Real Time Message Configuration](#) for more information.

Response XSL will only be displayed when the processing method is **Real-time**. Refer to [Real Time Messages](#) for more information on how it is used. Refer to [Referencing an XSL](#) for information about configuring where the XSL is defined.

External System - Template Use

If you are viewing an external system whose usage is a **Template External System**, use this page to view the other external systems that reference this one. Open this page using **Admin > Integration > External System** and then navigate to the **Template Use** tab.

Description of Page

The tree shows every external system that references this external system as its template.

Message Option

The Message Option page defines various system settings used by the system when processing external messages.

To define options for your environment, open **Admin > Integration > Message Option**.

Description of Page

The following options are supported.

| Option | Description | Option Name |
|----------------------------------|--|------------------------------------|
| Default Email Sender | This is the default Message Sender used for sending e-mails when no explicit Message Sender is specified. | defaultEmailSender |
| Default User | The default user is used by the system to access your product when no other user is explicitly specified. | defaultUser |
| Email Attachment File Location | This is the default location of e-mail attachment files. If not specified, the e-mail service provided with the product assumes a full path is provided with each attachment file. | emailAttachmentFileLocation |
| Email XSL File Location | This is the default location of e-mail XSL files. If not specified, the e-mail service provided with the product assumes a full path is provided to an XSL file as part of an e-mail request. | emailXSLFileLocation |
| Messages Language | The default language to use for the messages. | language |
| Outbound Message Schema Location | Enter the full path of the virtual directory where valid W3C schemas are stored if your implementation wants to validate outbound message schemas . For example: http://localhost/cisxai/schemas . | xaiOuboundSchemaLoc |
| Schema Validation Flag | Enter Y to turn on schema validation for outbound messages . Enter N to turn this off. | xaiSchemaValidationCheck |

Note that the following options are no longer applicable.

| Option |
|---|
| To Do Type for Inbound JMS Message Errors |
| To Do Type for Outbound Message Errors |
| XSD Compliance |

Managing Outbound Messages

Use this page to view information about outbound messages.

Outbound Message - Main

Open this page using **Menu > Integration > Outbound Message**.

Description of Page

Outbound Message ID is the system-assigned unique identifier of the outbound message. These values only appear after the outbound message is added to the database.

The **Processing Method** indicates whether this record will be processed by a **Batch** extract process or **Real-time**. (The value of **XAI** is no longer supported). The value defined on the external system / outbound message type collection populates this value.

When records are created with a processing method of **Batch**, the system sets Extract to **Can Be Extracted**. Change the value to **Not to be extracted** if there is some reason that processing should be held for this record.

For records with a processing method of **Batch**, **Batch Control** indicates the process that will extract this record. This value is populated based on the on the external system / outbound message type's value. **Batch Number** indicates in which batch run this record was extracted or will be extracted.

The **Retry Count** is no longer applicable..

The **Creation Date** indicates the date that this record was created.

The status is no longer applicable.

Outbound Message - Message

Use this page to view the XML source used to build an outbound message. Open this page using **Menu > Integration > Outbound Message** and then navigate to the **Message** tab.

Description of Page

The **XML Source** is displayed.

If a message XSL is defined on the external system / outbound message type record linked to this outbound message, the **Show XML** button is enabled. Click this button to view the XML that is a result of applying the Message XSL to the XML source.

Outbound Message - Response

Use this page to display the XML response. Open this page using **Menu > Integration > Outbound Message** and then navigate to the **Response** tab.

Description of Page

The **XML Response** and optionally the **XML Raw Response** is displayed.

XML Response displays the response data from the system called by the real-time message. If a response XSL is defined on the external system / outbound message type record linked to this outbound message, a transform is performed and the XML Raw Response displays the original, unchanged response.

Web Service Adapters

The base product provides a configuration object called Web Service Adapter that is used to help build configuration objects to allow for functionality in the system to initiate a web service call from within the system. A Web Service Adapter provides the following functionality:

- WSDL (web service description language) import. An implementer can use the WSDL import functionality to read the details of a WSDL into the system
- Internal API generation. The system generates internal data areas that have two main purposes: they provide the API for custom code to define the appropriate input and they provide output data for the web service call using Oracle Utilities Application Framework schema language. In addition, the web service dispatcher uses element mapping defined in the data areas to transform the internal XML into the structure expected by the external system as described in the WSDL.
- Defines the URL needed to perform the web service call at runtime.

Understanding Web Service Adapters

The following topics describe the system functionality in more detail.

Importing a WSDL

Configuring a Web Service Adapter starts by identifying the WSDL (the web service description language document used to define the interface) that will be provided by the external system. The following steps describe the base product functionality provided to allow a user to import a WSDL.

- Navigate to the **Web Service Adapter** page in add mode and select the appropriate base business object.
- Enter a meaningful Web Service Name and appropriate descriptions.
- Provide the URL of the given WSDL.
- Click **Import** to retrieve the details of the WSDL. The system then parses the WSDL details and populates the WSDL Service Name, WSDL Source, WSDL Port, URL and a list of Operations (methods) defined in the WSDL.
- Determine which Operations should be **active** based on the business requirements for invoking this web service. **Active** operations are those that the implementation is planning to invoke from the system. These require appropriate request and response data areas generated for them. The following section provides more information about that.
- Specify the appropriate Security Type to configure the type of security to use when invoking this web service.
- Click Save.

At this point, a web service adapter record is created in pending status. The next step is to generate the request and response data areas for the operations configured as active.

Generating Request and Response Data Areas

Each **active** operation for the web service adapter requires a pair of data areas, request and response, that represent the request and response XML messages for the operation.

The base product provides steps to generate the data areas as follows:

- As described in the Importing a WSDL section above, the operations listed in the WSDL are generated for the web service adapter and the implementer should indicate which operation to activate.
- After saving the **pending** web service adapter, the display lists all the active operations and for each one includes a **Generate** button.
- After clicking **Generate** for an operation, a window appears where the names of the new Request and Response Data Areas may be defined. Click **Save** to generate the data areas.

The generated data areas provide the API for the implementer to use when implementing the web service call in an appropriate algorithm or service in the system. The data areas contain the appropriate mapping from the elements that the implementer works within the code that invokes the web services and the WSDL definitions.

To facilitate generating the request and response data areas, the base product invokes a special business service used to create the appropriate mapping. The business service is defined as a BO option on the Web Service Adapter business object. This allows an implementation to provide a custom business service to further enhance the request and response mapping where appropriate.

Note:

Generated data areas. It is possible to edit and modify the generated data areas after they are created. An implementer can change element names or remove unneeded elements if desired. Manually changing the generated data areas must be done only when absolutely necessary. This is because the system is not able to validate manual changes and issues with the data areas would only be detected at run time.

Activating Web Service Adapters

The business objects provided by the base package for web service adapters include a simple lifecycle of **Pending** and **Active**. Configure the web service adapter and its data areas while in **Pending** status and activate it when it is ready to be implemented in the appropriate system functionality.

Invoking Web Services

To make a call to a web service using a web service adapter, the system has provided a Web Service Dispatcher business service (**F1-InvokeWebService**) to submit a web service call. The calling program is responsible for retrieving all the information to correctly populate the request data required by the web service call before invoking the business service.

Note:

Refer to the detailed description of the business service for more information.

Limitations

The following points highlight limitations associated with the types of web services that the system supports:

- It is possible for one WSDL document to contain definitions for several web services. The system currently supports only one port or service per WSDL document.
- It is possible for a WSDL to support multiple message patterns. The system currently supports only request / response.

Setting Up Web Service Adapters

Use the Web Service Adapter portal to define the configuration needed to communicate with an external system using a web service call. Open this page using **Admin > Integration > Web Service Adapter**. You are brought to a query portal with options for searching for web service adapters.

Once a web service adapter has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Web Service Adapter** zone provides basic information about the web service annotation type.

Please see the zone's help text for information about this zone's fields.

Fastpath: Refer to [Understanding Web Service Adapters](#) for information about common web service adapter functionality.

Sending Email

The framework provides the ability to initiate an email from within the system. The following topics highlight the functionality available.

- Sending email "real time" using a specific business service. The framework provides a business service **F1-EmailService** that supports sending an email. The schema supports elements for all the information required to create an email real time. The SMTP information (host, user name and password) may be provided or may be defined on a message sender, that may be provided as input. In addition, the business service supports using a default message sender defined as a [message option](#). Review the business service schema for information about the input elements.

Note: Retry setting. An option in the system properties file allows your implementation to configure the number of times to retry (if any) if the SMTP server is unavailable. Refer to the server administration guide for more information.

- The business service supports sending attachments. The may either reference attachments from the file system (file name and content ID) or reference attachment records captured in the system's attachment table. Note that attachments in the file system are not supported in a cloud implementation.

Note: Validating attachments. If a Validate Email Attachment algorithm is plugged into the [installation record](#), it is called to validate the attachments supplied, if applicable.

- Using an outbound message to send an email. This option allows for different variations as described in [Outbound Messages](#).
 - Some emails may be created en masse (for example a large group of emails routed to users for a given set of To Do entries). In this case, the records can be created in the staging table for processing using OSB.
 - Messages may still be sent real time using one of two business services described in [Real Time Messages](#). This option is an alternative to the dedicated email service described above when aspects of the outbound message

functionality are needed, such as the ability to instantiate a record as an audit or to include additional logic via BO plug-ins as part of sending the email.

Web Service Category

The product provides the ability to categorize web services that are defined in the system. The term web services refers to Outbound Message Types, Inbound Web Services, and for those implementations where they are applicable, XAI Inbound Services.

A given web service may be linked to more than one category. The product supplies web service categories and most base delivered web services are configured with appropriate categories. Implementations may define new categories and may link custom web services to base delivered categories or to custom categories. In addition, implementations may link additional categories to base delivered web services. However, implementations may not remove base delivered web services from base delivered categories.

If your implementation uses the [Integration Cloud Service Catalog](#), the integration provides the categories for each web service that is sent to the catalog.

The web service category portal supports adding and removing web services from the category. In addition, the [Outbound Message Type](#) portal and [Inbound Web Service](#) portal each provide a page action button to **Add to Category**.

Defining Web Service Categories

Refer to [Web Service Category](#) for an overview of this functionality.

Use this page to define basic information about a web service category. Open this page using **Admin > Integration > Web Service Category**. You are brought to a query portal with options for searching for web service categories.

Note: This page is not available if the **External Message** module is [turned off](#).

Once a web service category has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Web Service Category** zone provides basic information about a web service category.

CAUTION: Important! When adding new records, carefully consider the naming convention of the web service category code. Refer to [System Data Naming Convention](#) for more information.

Once a web service category exists, an **Add Web Services** zone is provided to find and select web services to link to the web service category.

When viewing a category that already has web services linked to it, they are visible in the zone **Included Web Services**. This zone allows a user to remove a customer owned web service from the list.

JMS Message Browser

The JMS Message Browser portal allows you to select a JMS queue and view messages currently in the queue.

In order for a JMS queue to be available on the portal, a [message sender](#) must be defined that is configured for the appropriate JMS queue with the credentials to connect to the queue.

- If your organization sends real-time outgoing messages to a JMS queue, this configuration would exist as per the details in [Real-Time Message Configuration](#).
- If inbound web service messages are routed to the system via a JMS queue, no configuration is needed in the system. However, if you would like to view the messages in the queue in the JMS message browser portal, configuration for the JMS queues as described for outgoing messages is required.

Navigate to the portal using **Main > Integration > JMS Message Browser**.

The JMS Senders zone provides a list of configured message senders eligible for selection.

The JMS Message List zone is visible for the JMS Sender broadcast from the first zone. This zone supports selecting one or more records to delete from the queue. Use the message selector to limit the results to messages that satisfy the

message selector. This uses standard JMS API message selector functionality. Refer to the zone embedded help for information about the supported syntax.

The JMS Message Details zone displays a message broadcast from the list zone.

Oracle Integration Cloud Catalog

Oracle Integration Cloud (OIC) is an offering that serves as integration infrastructure for Oracle cloud solutions. The product provides an adapter for OIC to streamline integration between your edge application and OIC.

The product provides a mechanism (referred to as an adapter) for OIC to retrieve the REST catalog and another to retrieve the SOAP catalog from a given product. The expectation is that a given implementation would use either REST or SOAP and not both, but for those implementations that do support both classes of web services, OIC can retrieve both catalogs.

For the SOAP catalog, the adapter retrieves the name, the source system, the WSDL location and namespace for each web service.

For the REST catalog, the adapter retrieves the name, the source system and the OpenAPI Specification for each web service.

It is possible that not every web service supported by an edge product is managed by OIC. In order to only include the appropriate web services in the adapter, configuration is needed to identify which web services to include.

The web service catalog is used to identify the records that should be retrieved by the adapter. Separate catalogs exist for REST and for SOAP

- For SOAP inbound messages, the system supports both the use of [inbound web services](#) and XAI inbound services that are [deployed via IWS](#). Each IWS or XAI inbound service that should be included in the catalog must be flagged in the SOAP catalog. Note that only [deployed](#) services are returned to the catalogue.
- For REST inbound messages, each IWS that should be included in the catalog must be flagged in the REST catalog.
- For outbound message, the system requires the creation of an External System that includes each outbound message type that the external system receives. For outbound messages that are integrated through OIC, the external system itself will represent OIC. Rather than identifying each outbound message type to include in the catalog, only the external system needs to be flagged. The adapter will return web service information for all the outbound message types configured for the external system. If an implementation supports both REST and SOAP, separate external systems should be created to separately group the REST and SOAP outbound messages.

Note: The subordinate catalog functionality is no longer applicable and will be removed in a future release.

Fastpath: Refer to [Maintaining the Web Service Catalog](#) for more information.

Web Service Catalog Configuration

The topics in this section describe the configuration needed in your edge application to integrate with OIC.

Web Service Catalog Master Configuration

The **Service Catalog Configuration** ([master configuration](#)) record defines several system wide settings related to integrating with the service catalog.

It includes configuration for the WSDL base URL for the SOAP catalog. Note that this element supports the functionality described in [Referencing URIs](#). Note that for the REST catalog, the system will use the URL defined in the substitution variable **F1_OPEN_API_BASE_URL**

The subordinate server section is no longer applicable and will be removed in a future release.

For more information about specific fields in the master configuration, refer to the embedded help.

Maintaining the Web Service Catalog

Refer to [Oracle Integration Cloud Catalog](#) for an overview of web service catalog functionality.

To add or remove services that are reported to the OIC catalog, navigate to the portal using **Admin > Integration > Web Service Catalog**.

The Catalog by Class zone provides the list of classes (REST and SOAP). Broadcast the web service class that you want to work with.

The Catalog zone provides a list of services that are currently in the catalog based on the web service class chosen. Users may use this zone to remove services from the catalog.

The Candidate Services zone provides a list of external systems and inbound web services that are not currently linked to the catalog. Users may use this zone to add services to the catalog. The inbound web services will be limited to those with the same web service class as the one broadcast. All external systems are shown regardless of the web service class because there is no web service class configuration on external systems.. The expectation is that implementers will create the external system to include either only REST or only SOAP services and will know which external system to include in which catalog. For the SOAP web service class, if XAI inbound services are applicable, they are also visible.

Note: For inbound SOAP web services and XAI inbound services, they may be selected for the SOAP catalog at any time. However, only **deployed** services are returned to the catalog by the OIC adapter.

XAI Documentation Note

The XAI functionality is legacy functionality and not recommended for new implementations. The help topics are no longer provided.

Integrations

This chapter provides high level information about product integrations supported for all products that use Oracle Utilities Application Framework.

Creating Application Links in External Applications

When integrating Oracle Utilities applications with other external applications, you can create links from external applications to specific portals and pages within the Oracle Utilities applications (also known as "deep linking"). These links typically leverage Business Process Assistant (BPA) scripts to help navigate the user to the appropriate target portal or page and to make provided parameter values available for use on the portal or page.

Note: This technique may also be used within the product to launch a new browser tab from within the application when it's important to maintain the current screen. For example, launching the GIS Viewer in Oracle Utilities Work and Asset Management by creating a new browser tab.

To do this, parameters are added to the application URL by appending a question mark (?) to the end and using the syntax "key=value". If you require more than one parameter, use an ampersand (&) to separate each key=value pair. There are several predefined parameter key values recognized by the application. In addition, specific parameters understood by the script may be provided. The following list highlights the predefined parameters.

- **location**=<navigation key> - If the exact page to launch is known, the navigation key value of that page can be part of the URL using 'location='. For example, if an approval process has sent an email to a user to approve an adjustment, the link configured in the email may include the adjustment's navigation key.
- **script**=<BPA script name> - In almost every use case, a script is needed to help navigate to the correct page and display the correct information. Even if a location is known and provided in the URL, if there is context data provided as a parameter, it is the responsibility of a script to move that parameter data from the URL into the page data model, so that the page can access the information and display the correct record. In cases where the target page is dynamic based on information provided by parameters, the script may be used to determine what page to launch.
- **portal=true** - When using the location parameter where the target page is a portal page and passing context data, use this parameter. The allows the system to know that the parameter data must be pushed into portal context.
- **initNav=false** - By default, if a script is provided but the location attribute is not provided, the system navigates to the user's home page prior to executing the script. If the script itself includes a step to navigate to a target page as one of its initial steps, the navigation to the home page is unnecessary and may degrade performance. This optional attribute may be included in the URL to bypass the home page.

Note: The system still requires a page to be launched for technical reasons. A blank portal with no zones is used for this purpose. Users may see this portal (called **Launching Application**) briefly before the navigation initiated by the script. In addition, this is the portal that the user will remain on if there are any errors in the script or if the script does not navigate anywhere.

- **minSidebar=true** - This option minimizes the sidebar area as part of launching the application. (The user will be able to maximize the sidebar themselves if needed). You would use this option to potentially improve the speed at which the application is launched. Whether this is useful will depend on the use case. If the reason for launching the application is to bring the user to a specific record to view details about that record, the sidebar may be providing valuable information about the record. In this case, it may be correct to display the sidebar by default (and not include this parameter in the URL). On the other hand if the use case is that a user is already in the application and clicks a link that opens a new browser tab to show the user specific detail about a chosen record, while keeping the original page open on the first tab, the sidebar may contain the same information already visible on the original tab. In this case, minimizing the sidebar may be beneficial.

Note: For backward compatibility, the system still supports the original parameter **minDashboard=true**, which has analogous functionality.

For example, the following URL illustrates launching the script **CM-StopAutoPay** for a given account, assuming the application URL for launching the system is `http://system-server:1234/cis.jsp`:

- **`http://system-server:1234/cis.jsp?script=CM-StopAutoPay&ACCT_ID=1234512345&location=accountMaint`**

It doesn't matter in which order the parameters are provided. The system processes them in the correct order. For example, the following examples are processed by the system in the same way:

- **`http://system-server:1234/cis.jsp?ACCT_ID=1234512345&script=CM-StopAutoPay&location=accountMaint`**
- **`http://system-server:1234/cis.jsp?ACCT_ID=1234512345&location=accountMaint&script=CM-StopAutoPay`**

These parameters are kept in a common area accessible by any script for the duration of the session. To use these parameters on a script you may reference the corresponding **%PARM-<name>** [global variables](#). In this example, after the system is launched any script may have access to the above account ID parameter value by means of the **%PARM-ACCT_ID** global variable. Also note, these parameters are also loaded into temporary storage (to continue the example, there would also be a temporary storage variable called **ACCT_ID** that holds the passed value).

Determining the Application URL

When building the link from within application logic, the service script **F1-EnvURL** may be used to retrieve and build the application URL information.

Navigate to a Given Record's Maintenance Portal

The product provides a script **F1-GotoPrtl** (Navigate to portal for an MO and key values) that may be used for any use case that simply navigates to the maintenance page for a given record and displays that record. This script is only applicable to records that are governed by a business object (and define a navigation option as a BO option). It requires the parameters **mo=** with the maintenance object code of the record and the parameters **pkValue1=** through **pkValue5=** for providing the key values. It looks up the appropriate portal navigation option from the record's BO, populates keys into the 'page data model' and navigates to the portal.

It is also recommended to include the **initNav=false** attribute when building a URL with this script. The example below navigates to the appropriate Migration Data Set portal for the given ID's business object.

- **`http://system-server:1234/cis.jsp?script=F1-GotoPrtl&pkValue1=1234512345&mo=F1-MIGRDS&initNav=false`**

LDAP Integration

Organizations commonly use a Lightweight Directory Access Protocol (LDAP) security repository as a source of security credentials. The system provides support for importing users and groups from an external LDAP repository into the product to populate Users and User Groups in the system. Once imported, all user and group functions are available. You can resynchronize your LDAP users and groups at any time.

Note: Import only. The system currently supports importing LDAP information. Exporting users and groups from the system to LDAP is not provided.

Note: Additional configuration. When importing new users and / or groups, additional configuration is needed in the base product. For example, after importing a new user group and its users, the user group configuration should be updated to define the valid application services for the user group. After importing a new user, additional configuration may be needed on the user such as valid To Do Roles, valid Home Page, etc.

Fastpath: Refer to [Users and User Groups](#) on page 19 for more information about the application security and what it controls.

This section the functionality provided in the framework application that supports LDAP. Refer to the *LDAP Integration* technical reference paper for more information about typical steps related to the full integration.

LDAP Integration Overview

This topic provides a high level overview of the integration process.

At a high level, the base product provides a process to import user group and / or user definitions from and LDAP repository. This is a one way integration.

- When importing a user, if it is not already found in the system, it will be added; otherwise its attributes will be updated according to the imported information.
- When importing a user group, if it is not already found in the system, it will be added; otherwise its attributes will be updated according to the imported information.
- When importing a user, its user group links will be updated as per the information in the import file. In addition, if there are any user groups linked to the user that are not found in the system, they will be added (however, the other users linked to that group in the LDAP repository will not be added as part of this step).
- When importing a user group, its user links will be updated as per the information in the import file. In addition, if there are any users linked to the user group that are not found system, they will be added (however, the other user groups linked to that user in the LDAP repository will not be added as part of this step).
- The import will not cause any deletions of the User or User Group to occur.

A Batch Process Initiates the Import

A batch process is used to initiate the import of information from the LDAP repository. **F1-LDAP** may be submitted ad hoc or may be set up in a scheduler to periodically re-sync the information from the LDAP repository into the application.

The batch process uses parameters to define how to connect to the LDAP repository. In addition, parameters are used to indicate which user or group is being imported.

Adjusting Data to Import

The system provides several mechanisms for adjusting data that is being added to the system:

- There is an **LDAP Import Preprocess** algorithm plug-in spot on the [installation](#) record. Algorithms plugged in here are called by the batch process prior to the add or update of any records. It may be used to make adjustments to the data before doing updates in the application.
- Specifically for creating or updating Users, the **F1-IDMUser** business object is used to add and create the user. The standard BO Preprocessing algorithm plug-in spot may be used to adjust data prior to creation. Note that the system does not support defining a characteristic to support a template user that can aid in populating

configuration for a new user. However, this integration can take advantage of using a default template user as an algorithm parameter. Refer to [Template User](#) on page 20 for more information.

- The LDAP mapping file supports some attributes to perform simple modifications to data.
 - The **transform** attribute supports values to truncate values or to convert data to upper case.
 - The **autoGenerate** attribute is specific to the User ID field. Setting this to true will trigger code that will automatically populate the User ID based on the user's name. Refer to [LDAP Mapping](#) for more information.

Performing Additional Processing After Import

The system provides a plug-in spot on the [installation](#) record called **LDAP Import**. Algorithms plugged into this spot are called after users or user groups have been added or updated. It may be used to perform any extra processing that may need to be executed.

Configuring LDAP Integration

To interface the LDAP based security repository with the authorization component of the Oracle Utilities Application Framework product the following must be performed:

- The location and port number of the LDAP based security repository must be defined to in the JNDI Server.
- The LDAP based security repository must be mapped to the Oracle Utilities Application Framework security model. This mapping is expressed as an XML file containing the LDAP query, rules and defaults used in the transformation.
- The mapping file must be configured on the **F1-LDAP** batch job.

Define the JNDI Server

The first step in the configuration process is to define the location of the LDAP based security repository server so that the interface can connect to the physical attributes of the interface. This is done by creating a [JNDI Server](#).

Note: The LDAP server is strictly not a JNDI source but is treated as a JNDI source for the integration.

Enter a reasonable JNDI Server name and description.

Populate the **Provider URL** using the format **ldap://<hostname>:<portnumber>** where **<hostname>** is the host of the LDAP server and **<portnumber>** is the port used for the interface.

For the **Initial Context Factory**, the interface uses the standard **com.sun.jndi.ldap.LdapCtxFactory** provided with java for the LDAP interface. If your vendor supplies a custom context factory it may be used. Refer to the documentation provided with your LDAP based security repository for further information.

Define Mapping

The critical component of the interface is a file that describes the mapping between the LDAP based security repository and the system's security model. This file contains the mapping, rules and queries used by the LDAP batch program to provide the interface. The LDAP batch job includes the reference to the mapping file as a parameter. Refer to [LDAP Mapping](#) for more information on defining the mapping file.

Configure LDAP Batch Process

At this point, many parameters for the **F1-LDAP batch control** can be updated with system wide configuration.

- JNDI Server, User and Password may all be configured appropriately. Note that it is recommended that the **Security** setting for the Password be set to **Encrypt**.
- The **LDAP Configuration File** should be populated with the name and location of the LDAP Mapping file.
- If the LDAP service has any limitation to the number of objects that may be imported, configure the **LDAP Query Page Size** parameter to enable querying.

Note: Group and User Parameters. The assumption is that the Group or User input parameters are specific to a given import request and as such would not be populated as part of a configuration step.

Note: L2 Cache. The LDAP Import batch process requires the L2 Cache to be disabled since it needs to perform some updates in the outside of the worker threads. Any environment using LDAP Import must set **spl.runtime.batch.L2CacheMode=OFF** in the **threadpoolworker.properties** file. It is recommended to run the LDAP import in its own dedicated threadpoolworker.

LDAP Mapping

An LDAP repository consists of multiple entries. Each entry represents an object in the directory that is identified by a Distinguished Name (DN) and may contain one or more attributes. In a typical LDAP repository there is usually an entry for users and an entry for groups. The connection between users and groups may be implemented in two different ways:

- The users belonging to a group are defined in a special multiple-value attribute on the Group entry.
- The groups to which a user belongs are defined in a special multiple-value attribute on the User entry.

The mapping between LDAP security objects and base security objects is stored in an XML document that can be processed by the LDAP import batch job. As part of setting up your system for LDAP import, you need to define this mapping. The base package provides a sample mapping file called **ldapdef.xml** that can be used as a starting point and changed per your business requirements and your particular LDAP repository.

Once you have defined the mapping XML document, this is configured as a parameter in the **F1-LDAP** batch job.

The XML structure:

- The **LDAPEntry** element maps the LDAP entries to system objects (User or Group). The mapping file must contain one and only one LDAPEntry element for User and one for Group.
- The **LDAPCDXAttrMapping** element within the LDAPEntry element maps attributes in the LDAP entry to attributes in the system object.
- The **LDAPEntryLinks** element describes objects linked to the LDAP entry. When mapping the user entity you need to describe how the groups the user belongs to are retrieved. When mapping the group entity you need to describe how the users contained in the group are retrieved.

The following table describes the attributes to define for each element.

| Element | Attribute | Description |
|-----------|--------------|---|
| LDAPEntry | name | The name of the LDAP entry: - Group - User |
| | baseDN | The base distinguished name in LDAP for this entry. |
| | cdxEntity | The name of the base product entity to which the LDAP entry is mapped: - Group - User |
| | searchFilter | An LDAP search filter that is used to locate LDAP entries. A %searchParm% string in that filter is replaced by the value from the user or group parameter from the F1-LDAP batch job submission. |
| | Scope | Sets the scope of the search. Valid values are: - onelevel (the value normally used) - subtree |

| Element | Attribute | Description |
|--------------------|--------------------|--|
| LDAPCDXAttrMapping | ldapAttr | The name of the LDAP attribute to be mapped. Note that this may be referenced more than once to allow one LDAP element to map to multiple base product elements. For example, if an email address should be used both for the Login ID and the Email Address. |
| | cdxName | The name of the base product attribute to be mapped. For User, this is the element within the F1-IDMUser business object. For Group, this is either the 'group' or the 'description'. |
| | default | The default value that will be assigned to the element referenced in the cdxName attribute when one of the following occurs: - The LDAP attribute contains a null or empty value - The LDAP attribute does not exist or is not specified. Default values are applied only when creating a new entity and are not applied to updated entities. |
| | autoGenerate | Set this to true in order to turn on auto generation of the user ID. If this is true, the system will define the user id as <first initial of first name>+<last name> all uppercase, to a maximum of 8 digits. If an existing user is found for the generated ID, a number will replace the eight digit (or be appended to the end). The system will increment the number until a unique ID is found. |
| | transform | Use this attribute to indicate if a transformation of the data should occur. Valid values: uppercase truncate . Note that this attribute should not be used in conjunction with the autoGenerate attribute. |
| LDAPEntryLink | linkedToLDAPEntity | The name of the linked entity (User or Group). Use User when describing the Group entity. Use Group when describing the User entity. |
| | linkingLDAPAttr | The multiple-value attribute name on the LDAP entity that contains the linked entity. |

| Element | Attribute | Description |
|---------|---------------------|---|
| | linkingSearchFilter | <p>The search filter to be applied to retrieve the list of linked objects, for example:</p> <p>(&objectClass=group)(memberOf=%attr%)</p> <p>The search filter may contain the string % attr % that acts as a substitution string and is replaced at run time by the value of the attribute named "attr" of the imported entity. If the LDAP entry you are describing is a Group and the string is %name %, it is replaced by the value of the "name" attribute of the group you are importing. If the LDAP entry you are describing is a User and the string is %dn%, it is replaced by the "dn" attribute of the User you are importing.</p> |
| | linkingSearchScope | <p>Sets the scope of the search. Valid values are:</p> <ul style="list-style-type: none"> - onelevel (the value normally used) - subtree |

Sample Mapping

The following XML describes a sample mapping. The example makes the following assumptions:

- The base product attribute **displayProfileCode** is defaulted to "NORTHAM" when adding a new user.
- The LDAP Group entry contains the list of users belonging to the group in the **departmentNumber** attribute.
- The groups to which a user belongs are retrieved by applying a search filter.

```

<LDAPEntries>
  <LDAPEntry name=" User" baseDN="ou=people,dc=example,dc=com" cdxEntity="
    user" searchFilter=" (&(objectClass=inetOrgPerson) (uid=%searchParm
    %)) ">
    <LDAPCDXAttrMappings>
      <LDAPCDXAttrMapping ldapAttr="uid" cdxName=" user" />
      <LDAPCDXAttrMapping ldapAttr="cn" cdxName="externalUserId" />
      <LDAPCDXAttrMapping cdxName="language" default=" ENG" />
      <LDAPCDXAttrMapping ldapAttr="givenName" cdxName="firstName"/>
      <LDAPCDXAttrMapping ldapAttr="sn" cdxName=" lastName"/>
      <LDAPCDXAttrMapping cdxName="displayProfileCode" default="NORTHAM" />
      <LDAPCDXAttrMapping cdxName="toDoEntriesAge1" default="30" />
      <LDAPCDXAttrMapping cdxName="toDoEntriesAge2" default="90" />
      <LDAPCDXAttrMapping cdxName="userEnable" default="ENBL"/>
    </LDAPCDXAttrMappings>
    <LDAPEntryLinks>
      <LDAPEntryLink linkedToLDAPEntity="Group" linkingLDAPAttr="departmentNumber" /
    >
    </LDAPEntryLinks>
  </LDAPEntry>
  <LDAPEntry name="Group" baseDN="ou=people,dc=example,dc=com" cdxEntity="
    Group" searchFilter=" (&(objectClass=organizationalUnit) (ou=
    %searchParm%)) ">
    <LDAPCDXAttrMappings>
      <LDAPCDXAttrMapping ldapAttr="name" cdxName="Group" />
      <LDAPCDXAttrMapping ldapAttr="description" cdxName=" Description" default="Unknow
    >
    </LDAPCDXAttrMappings>
    <LDAPEntryLinks>
      <LDAPEntryLink linkedToLDAPEntity="User" linkingSearchFilter="

```

```
(&amp; (objectClass=inetOrgPerson) (departmentNumber=%distinguishedName
%)) "
  linkingSearchScope="onelevel" />
</LDAPEntryLinks>
</LDAPEntry>
</LDAPEntries>
```

Oracle Identity Manager Integration

The *Oracle Identity Manager* product allows a site to centralize their user definitions and password rules to manage and deploy across the enterprise set of products. When an employee joins an organization, changes their name or departs an organization their security presence across an enterprise must be appropriately managed. Oracle Identity Manager allows for users to be provisioned and managed in a central location.

An integration is provided to allow the ability to create, maintain and remove users in the identity management product and sync those changes to the users defined in the application. The following sections provide additional details about the integration with respect to configuration steps required in an Oracle Utilities Application Framework based product. For more information about the configuration required in the identity management product, refer to the *Identity Management Suite Integration* technical reference paper.

In order to use this functionality, [feature configuration](#) options for the **External Messages** feature type must be configured.

- Set option type **Support SPML Deployment in IWS** to **true**.
- Set option type **Default SPML service security policy** to an appropriate value per your implementation rules.

Template User Functionality

The user object in this product captures configuration used to control access but also preferences. The identity management product allows for extending the configuration to capture user configuration that is specific to this product. However, it does not support providing searches or dropdowns to select valid values. For example, to define the user's Home Page requires the reference to a navigation option. To set up your business process such that the home page is configured when defining the user in the identity management product dictates that the security user types in the correct navigation option reference.

On the other hand, to define a minimal amount of user information in the identity management product may result in a two step process for defining users: first define them in the identity management product with the basic authentication details and setting system defaults for some important fields, then after submitting the new user to be added to this product, navigate to the [user](#) page in this product and fill in all the configuration that is specific to this product.

The product provides support for defining a template that can facilitate the definition of users and reduce some of the challenges listed above. Refer to [Template User](#) on page 20 for information about defining template users along with other details around this functionality.

Once you have template users defined, you should look at extending the configuration in the identity manager product.

- Map the information that is unique to a user and in addition, define a field for the template user. For example, you may choose to only capture the Name (first and last), Email address and User IDs for the user along with its Template User (which is mapped to a user characteristic). Additional fields may be included for capture in the identity management product when defining new users as per an implementation's business needs. For example, if the organization covers multiple time zones, perhaps it is easier to define the user's time zone when defining the user in the identity management product.
- When the new user is uploaded to the system, the algorithm used by the system to create the user looks for the existence of a template user sent as a characteristic of type **F1-TMUSR**.
- Once the new user is created, its configuration can now be adjusted, if applicable.

Note: There is configuration needed in Oracle Identity Management to capture the template user and any other information that the implementation has chosen to define in the identity management product when provisioning a new user. Refer to the *Identity Management Suite Integration* technical reference paper for more information.

Provision Users with SCIM Open Standard

The product provides a REST web service **F1-SCIMUser** (SCIM User Provisioning) that supports adding, changing or viewing details of a user where the API follows the SCIM standard.

The following points highlight some of the mapping between the SCIM API and the application's user record.

- The user record in the application supports only first name and last name. The SCIM standard supports additional detail such as middle name, suffix and prefix. These elements are ignored when adding or updating a user.
- The SCIM standard supports a collection of email addresses. The application only supports one email address. As such, only the first email address is used when adding or updating a user.
- The integration relies on the use of a Template User so that the user is created with appropriate application configuration associated with each user. The system copies application settings from the template user to the new user being provisioned. If the external system is able to support referencing a template user such that it can be provided with the payload, the integration expects the user type element in the API to reference the template user. If it's not possible to provide a template user ID in the user type element, you should define a default template user using an algorithm parameter. Refer to [Template User](#) on page 20 for more information.

Refer to the web service definition for more information about the supported integration.

Template User Functionality

The user object in this product captures configuration used to control access but also preferences. The identity management product allows for extending the configuration to capture user configuration that is specific to this product. However, it does not support providing searches or dropdowns to select valid values. For example, to define the user's Home Page requires the reference to a navigation option. To set up your business process such that the home page is configured when defining the user in the identity management product dictates that the security user types in the correct navigation option reference.

On the other hand, to define a minimal amount of user information in the identity management product may result in a two step process for defining users: first define them in the identity management product with the basic authentication details and setting system defaults for some important fields, then after submitting the new user to be added to this product, navigate to the [user](#) page in this product and fill in all the configuration that is specific to this product.

The product provides support for defining a template that can facilitate the definition of users and reduce some of the challenges listed above. Refer to [Template User](#) on page 20 for information about defining template users along with other details around this functionality.

Once you have template users defined, you should look at extending the configuration in the identity manager product.

- Map the information that is unique to a user and in addition, define a field for the template user. For example, you may choose to only capture the Name (first and last), Email address and User IDs for the user along with its Template User (which is mapped to a user characteristic). Additional fields may be included for capture in the identity management product when defining new users as per an implementation's business needs. For example, if the organization covers multiple time zones, perhaps it is easier to define the user's time zone when defining the user in the identity management product.
- When the new user is uploaded to the system, the algorithm used by the system to create the user looks for the existence of a template user sent as a characteristic of type **F1-TMUSR**.
- Once the new user is created, its configuration can now be adjusted, if applicable.

Note: There is configuration needed in Oracle Identity Management to capture the template user and any other information that the implementation has chosen to define in the identity management product when provisioning a new user. Refer to the *Identity Management Suite Integration* technical reference paper for more information.

User Redirection

The product allows an implementation to support the ability for a customer to authorize a customer service representative (CSR) to view the customer's account information in a customer facing portal (Digital Self Service), to see exactly what the end customer is seeing/experiencing.

When the request for the CSR to view the customer information is received, the following steps occur:

- The security server for the customer facing portal is contacted to obtain a temporary grant code.
- The redirection response returns the grant code and the URL of the target customer facing portal.
- The browser redirects to the user to this URL with the grant code, which is further authenticated and automatically exchanged for an authorization token, allowing the CSR to log in.

Standard security measures with private/public key encryption using JSON Web Tokens (JWT) ensures that only the implementation's enterprise application is allowed to communicate with the implementation's customer facing portal server. The system also provides a plug-in spot to allow for additional information, such as the customer's name and email address, to be included in the call to the security server.

This feature works in conjunction with functionality provided by the enterprise customer application. Refer to the documentation for that product for information about how this feature is supported.

Note: The product has been designed to potentially support other types of redirection besides the mentioned use case by adding another entry in the Redirection Target lookup (F1_REDIRECTION_TARGET_FLG). However, the internally provided services work specifically for the Digital Self Service use case. There is no guarantee that they would work for a different redirection use case. Please contact product support if your implementation would like to implement a different redirection scenario.

Redirection Security Context Plug-in

The product supports a plug-in spot to allow for the system to populate additional keys and values to add to the JWT (JSON Web Token) when calling the external security service.

In addition, the product provides an Extendable Lookup BO **Redirection Security Context (F1-RedirectionSecurityContext)** to define the key mnemonic values. For an enterprise product or implementation to populate additional keys, use the extendable lookup to define the key mnemonics. Then provide an algorithm that uses the available information about the customer and populates the security context keys and values by determining the related data in the system.

Master Configuration

The master configuration **Redirection Targets Configuration (F1-RedirectionTargetsConfig)** defines the information needed to contact the security server to obtain a grant code. It also defines the redirection URL.

Build an Anchor Hyperlink

The service script **Return a Hyperlink to the Redirect Servlet for a given Target (F1TargetLink)** is provided to allow for a link to be placed on a UI map or in a zone to initiate the redirection request. Refer to the service script detailed description in the metadata for more information.

Batch Scheduler Integration

The Oracle Database includes an enterprise wide scheduler to simplify the scheduling of background processes. The scheduler is implemented by the *DBMS_SCHEDULER* package. The product provides an integration with the Oracle Scheduler to facilitate scheduling background processes shipped with the product.

At a high level, the integration with the Oracle DBMS Scheduler supports the following entities:

- **DBMS Program.** A program should be defined for each Batch Control that needs to be scheduled by the DBMS scheduler. A program would typically invoke a batch job, but it could be configured to set certain options instead.
- **DBMS Chain.** A Chain defines a series of steps with dependency rules between them. A step references a program, with the program performing the actual work for that step. A rule is attached to each step to identify its dependent steps and the condition for when that step should be executed. For example, in a chain consisting of STEP_A and STEP_B, where STEP_B can only start if STEP_A was successful, the rule for STEP_B to start would specify a condition of "STEP_A SUCCEEDED".
- **DBMS Schedule.** A predefined frequency for jobs that need to be run periodically, for example, nightly jobs.
- **DBMS Job.** Defines a plan to perform a specific program or a chain periodically on a specific schedule or ad-hoc.

The product provides a set of business services to maintain these entities as well as submit jobs, manage submissions and report on past submissions. Refer to business services that start with the prefix "F1-DBMS" for more information.

Note: For details on the integration, refer to the *Server Administration Guide* which contains the API. In addition, refer to the technical reference paper *Oracle Scheduler Integration* that provides guidelines for using this integration.

Data Synchronization

Your implementation may need to communicate certain data to external systems. This may be part of a data warehousing requirement or an integration effort. The synchronization process has two main parts. First, the change to the data must be detected and captured. Once that is accomplished, the next step is to manage the communication of that change to the external systems involved. The changes must be captured in chronological order so as to avoid systems going out of sync.

Understanding Data Synchronization

The product supports various options for managing an ongoing synchronization of an entity to an external system. While each integration involves unique business rules, in many cases the process is quite similar and involves the following overall steps:

- When an entity is added, changed or deleted logic determines whether the change is eligible for synchronization and if so a sync request record is initiated to manage the synchronization process. The base product uses the **Audit** plug-in spot on the maintenance object to allow for such logic to be performed when a change is detected to a record for that MO. The framework calls the algorithm defined on this plug-in spot in the event a change to the MO has been detected. Refer to the description of the plug-in spot on [Maintenance Object - Algorithms](#) for more information about when this plug-in is called.
- The processing of the sync request is deferred to batch so that the communication with the external system does not impact the updating transaction. It also ensures that the data being shared with the external system is fully committed to the database.
- When processed, sync request logic manages the following aspects of the process:
 - Determines whether the synchronization is still needed and if not discards the request.
 - Prepares the outbound message with the entity's synchronization details and sends it to the external system.
 - Manages errors and retry attempts as needed.

The following sections describe the various data synchronization options supported by the product.

Accumulative Data Synchronization

The product supports a data synchronization method by which several changes made to an entity may be accumulated and sent together as a single message to the external system.

The following points describe the functionality at a high level:

- When an entity is added, changed or deleted, a snapshot of the entity's data from before the change is captured on one or more sync requests, one for each external system the data needs to be interfaced to. The before-update snapshot is used as a base line for detecting all changes made since then at the time of sending the message to the external system.
- Sync requests are processed by the next monitor batch process.
- The processing of the sync request typically involves business rules that compare the before-update snapshot with the current content of the entity to detect all change made. If changes were made, logic may decide to proceed with the sending the synchronization message otherwise the request is discarded. These rules are also responsible for handling any errors encountered while communicating with the external system and manage retry attempts as needed.

This functionality is supported by logic supplied in the base business object Sync Request (**F1-SyncRequest**). Note that each edge application delivers an appropriate child business object for this BO for each specific synch scenario supported in that product. Some of the functionality below is accomplished using configuration on the parent BO delivered by the framework while other functionality may be delivered by the child BO. In addition, there may be more complex use cases supported by your specific product integration. Refer to your specific application's library

of Sync Request business object along with the documentation related to your specific product integration for more information.

The following sections describe key aspects of this data synchronization approach.

Capturing the Change

The base product provides a change data capture (MO Audit) algorithm **F1-GCHG-CDCP** that may be used by maintenance objects that need to be synchronized by this method. This algorithm creates a Sync Request record for the changed record, capturing the MO code and the primary key, if it doesn't find an existing sync request for the same record (and the same business object) in the initial state. The sync request business object used is the one defined in the **Sync Request BO** option on the MO for the record that was changed. If more than one such option exists then multiple sync requests are created.

Your specific product may also introduce additional Audit algorithms to cater for more sophisticated examples.

When creating the sync request record, typically the Sync Request BO will have a pre-processing plug-in that captures a snapshot of the record's data prior to its change. This will be used in subsequent steps to verify that the external system needs to be notified of the change.

Confirming that a Sync is Needed

Once a sync request is captured, there are several steps performed prior to any information being sent to the external system.

Note: This section only highlights key steps. Please refer to the business object configuration, its lifecycle and algorithms for a thorough picture of the full functionality..

- When a Sync Request record is created, its initial state (**Pending**) is configured to be processed by a batch monitor. That way, records are added to the sync request table throughout the day but all are processed together. The MO audit algorithm ensures that a new synch request is not created if a Pending record already exists for a given MO / PK combination (for the same business object). However, it is possible that a record for that MO / PK exists in a subsequent “non-final” (such as **Awaiting Acknowledgement**). This state includes a monitor algorithm to check for that condition and to skip transitioning if another record exists. This is done to ensure that the existing record is fully processed before this new record is processed.
- The next state of the lifecycle is **Determine if Sync Needed**. This step uses an algorithm to take a snapshot (called the ‘final snapshot’) of the data and compare it against the initial snapshot taken when the record was created. Based on the logic of the algorithm, it may decide to proceed (transition to **Send Request** or to discontinue (transition to **Discarded**).

Communicating to the External System

Once it is confirmed that the sync should occur, a message must be sent to the external system. The following points highlight the basic functionality.

- An algorithm linked to the **Send Request** state. The expectation is that this algorithm creates an outbound message that routes the information to the external system appropriately. The algorithm must determine the external system and outbound message type to use. Business objects for Sync Request support BO options to define the external system and outbound message type to use for this algorithm.
- Once the outbound message is triggered, the record transitions to the **Awaiting Acknowledgement** status. This state is used to hold the sync request from further state transitions until an acknowledgement is received from the external system. Note that this step relies on implementation of a response mechanism from the external system. It is recommended to implement a response as this helps control the chronological flow of information. The product supplies the business service **F1-UpdateSyncRequest** that transitions the sync request to either the next default state (in this case the **Synchronized** state) if a positive acknowledgement is received; or the state associated with the Rejection transition condition (in this case the **Error** state) if a negative acknowledgement is received. In addition, this state may be configured with a monitor algorithm that detects that a timeout limit has been reached.

- For records that enter the **Error** state, it is recommended to configure an algorithm that creates a To Do entry to alert someone of the problem. Refer to the integration documentation for more information. The state is already preconfigured with an algorithm to complete To Dos when exiting the state.
- The final state **Synchronized** is used to mark the successful synchronizations. However, for more complicated use cases, this state may be used to trigger some additional action. Refer to the documentation for your specific product integration for more information.

Generic Data Synchronization

The product supports a generic data synchronization method by which each change to an eligible entity triggers a synchronization flow that communicates details about the entity to one or more external systems.

The following points describe the functionality at a high level:

- The integration of a specific entity (maintenance object) and an external system is enabled and configured using a **Data Synchronization Control** (F1-DataSyncControl) extendable lookup record.
- Rules supporting the integration reside in a **synchronization script** referenced on the control record.
- When an entity is added, changed or deleted, a sync request may be initiated for each integration according to business rules defined by the corresponding synchronization script.
- Sync requests are processed by the next monitor batch process.
- When the sync request is processed, data is synchronized to the external system according to business rules defined by the corresponding synchronization script.

This functionality is supported by logic supplied in the base business object Generic Data Sync Request (**F1-GenericDataSync**). This business object does not need to be extended to support specific integration rules as these rules reside in the synchronization script associated with each integration's data synchronization control record.

The following sections describe key aspects of this data synchronization approach.

Data Synchronization Control

The **Data Synchronization Control** (F1-DataSyncControl) extendable lookup defines the configuration needed to support an ongoing data synchronization of an entity to an external system. The configuration defines the entity's maintenance object, the external system it is synchronized with and references a synchronization script that manages the specific synchronization rules for this integration. An integration is considered enabled when its corresponding control record is in active status.

The data synchronization script is called in the following modes:

- When the entity is added, changed or deleted, the script is called in **Check** mode to determine whether a sync request should be created for the changed entity and a specific external system.
- When the sync request is processed, the script is called in **Process** mode to prepare and send the outbound message to the external system. Alternatively the script may request to discard the request or indicate that it should be processed later. The latter may be used when there is a need to wait until certain conditions are met before sending the message to the external system.

Note that the configuration for a maintenance object and a specific external system may be overridden by another configuration defined with a higher sequence number.

Confirming that a Sync is Needed

The base product provides a change data capture (MO Audit) algorithm **F1ONGDATASYN** that may be used by maintenance objects that need to be synchronized by this method. The algorithm consults the synchronization script associated with each active integration control record configured for the entity as to whether the external system needs to be notified for this change. Once confirmed, the algorithm creates a Sync Request record for the changed record, capturing its MO code and the primary key, along with the corresponding external system.

Note that the decision as to whether to create a sync request or not is controlled by the integration specific synchronization script while the creation of the sync request is the responsibility of the audit algorithm. As such, the same sync request BO is used for all integrations, with no provision for capturing integration specific details.

It is recommended to design the synchronization script to only approve the creation of a synchronization request when it is needed. This prevents unnecessary creation of sync requests that would otherwise be discarded when eventually processed.

Managing the Synchronization Process

Once a sync request is captured, there are several steps performed prior to any information being sent to the external system.

Note: This section only highlights key steps. Please refer to the business object configuration, its lifecycle and algorithms for a thorough picture of the full functionality..

- When a Sync Request record is created, its initial state (**Pending**) is configured to be processed by a batch monitor. That way, the changes that triggered the request are fully committed before being communicated to an external system.
- When the sync request record is processed, a monitor algorithm calls the synchronization script associated with the corresponding integration's control record to manage the synchronization process. The synchronization script may indicate either of the following:
 - The request is not yet ready to be processed, i.e. it should remain in its current status and get processed again by the next batch run.
 - The request should be canceled. This indication results in the transition of the record to the **Canceled** status.
 - The request was successfully processed. The synchronization script has prepared the outbound message and routed the information to the external system appropriately. This indication results in the transition of the record to the **Sent** status.
- If an error occurs while processing the request, a To Do Entry is raised to capture the error details and the record is set to the **Error** status. Retry processing of the sync request continues with each batch process until the request is either sent or canceled.

Communicating to the External System

Typically the communication with an external system is finalized when the message is successfully sent and successfully processed by the external system. Depending on the specific integration, the message may not be processed right away by the external system but rather queued and processed later. In this situation, the sync request may need to be further acknowledged as successfully processed (set to the **Acknowledged** status) upon an explicit response mechanism from the external system. The product supplies the web service **F1-UpdateAndTransitionSyncRequest** that may be used to process such acknowledgements.

Maintaining Sync Requests

The system provides a Sync Request portal that is used to view the in progress or completed sync request records.

The menu location of the portal depends on your specific edge product. It may be in a Data Synchronization menu or perhaps in the Batch menu. You are brought to a query portal with options for searching. The options may differ based on your specific product.

Once a sync request has been selected, you are brought to the maintenance portal to view and maintain the selected record.

An **Actions** zone may appear to display specific actions. Alternatively, the actions may be displayed directly in the display area of the **Sync Request** zone.

The **Sync Request** zone provides basic information about the sync request record.

Depending on your specific product additional zones may appear.

Operational Analytics

The framework provides several building blocks and tools that the edge applications may use to implement analytic reports directly from the operational application using Oracle Utilities Analytics Visualization product (referred to in this section as the analytics visualization product). The following sections provide more information about this functionality.

Understanding Operational Analytics

The following sections describe the type of configuration supported in your product to integrate with the analytics visualization product. Refer to the Oracle Utilities Analytics Visualization documentation for more information.

Direct Data Access

The analytics visualization product's canvases report directly off of the operational system (with the exception of batch run analytics) thus eliminating the need of an ETL process. Selected tables and views have been designated as dimensions and facts for the purpose of generating the Start Schemas used by these canvases.

Batch Run Analytics

There is a high volume of batch run data in the operational system that changes frequently and is recorded in a complex set of relationships. The product provides snapshot tables to capture only the batch run and thread data required for analytics. Using these tables for batch subject area views both improves performance and supports extracting the data for upload to other environments.

The snapshot tables are populated in increments. The **Batch Run Analytics Snapshot Update** and the **Batch Thread Analytics Snapshot Update** processes are run on an ongoing basis; each snapshot update selects only the batch runs and threads not yet included in the snapshot. Parameters are supplied to restrict the selected data based on a range of days from the current date, to support the initial uptake of data. It is recommended that batch run data is updated before the batch thread data, as only threads with corresponding records in the batch run snapshot will be added. Refer to batch controls **F1BRANSN** and **F1BTANSN** for more information.

The **Batch Run Analytics Data Export** and **Batch Thread Analytics Data Export** processes are provided to extract the batch data in increments for upload to other environments. These processes assume that a **Data Export Control** exists for each of the snapshot maintenance objects, to capture the date of the previous extract as a reference point for selecting the next set of records. Refer to batch controls **F1BRANEX** and **F1BTANEX** for more information.

Calendar and Time Dimensions

Analytic reports rely on calendar and time dimensions to support various hierarchical grouping by date and time.

The Calendar dimension provides a level-based definition of the standard calendar and fiscal calendar in a flattened representation that is commonly used in data warehouses. This is necessary to enabling customers to group by calendar week, months, quarter and fiscal calendar period, quarter and fiscal year etc. Note that fiscal information about a specific date is optional and sourced from your edge application specific accounting calendar

In the same way, the Time dimension provides a level-based definition of each minute in a day, supporting reports that group by hours, AM/PM etc.

Note: Calendar dimension records are generated by a batch process; one record for each date in a specified period of time. You need to run the **Generate Calendar Dimension** batch process on an ongoing basis to cover the standard and accounting calendar days needed to support your business. Refer to **F1-BICDD** batch control for more information.

Note: Time dimension records are also generated by a batch process; one record for each minute in a day. You need to run the **Generate Time Dimension** batch process once to generate all the records. Refer to **F1-BITMD** batch control for more information.

Bucket Configuration

The analytics visualization product provides support for defining a set of ranges, each representing a bucket for which extracted measures can be grouped and classified under the relevant bucket. The framework product provides support for viewing and defining the buckets. Refer to [Bucket Configuration](#) for more information.

Analytics Attribute Mapping

The product supports mapping of characteristics to user defined fields associated with dimensions in the analytics visualization product. Each characteristic table that is associated with a dimension table is provided with pre-

generated user defined fields identified by unique column sequence numbers in the analytics visualization product. The mapping of characteristics to dimension user defined fields is maintained directly on the dimension portal. You may also review these mappings using the [Analytics Attribute Mapping](#) portal.

Logical Dimension

The Element Name of a foreign key field to a dimension represents a distinct logical version of the dimension. This allows for different logical dimensions to be based on the same dimension table. For example, a "Location" dimension may be referenced as a "Main Location" on one fact and also as an "Alternate Location" on the same or other fact. While both elements refer to the same dimension as foreign keys, each represent a distinct logical dimension via their element names. In the same way, while each date field is implicitly considered as a foreign key to the Calendar dimension, each distinct element name establishes a unique logical dimension. For example, a "Start Date" element name and an "End Date" element name are distinct logical dimensions of the underlying Calendar dimension.

Some logical dimensions may represent an aggregated or summarized form of another logical dimension. They are also known as "shrunk" dimensions. For example, the "Calendar Month Dimension" view is an aggregated dimension of the Calendar dimension. Establishing a link between a summarized dimension and its detailed dimension allows the analytics visualization tool to drill from one fact to another for performance reasons when they are indirectly linked via the same logical dimension but at different aggregation levels. For example, "Fact A" represents daily records and "Fact B" aggregates the same measures at a monthly level. Associating the "month" field in "Fact B", which is a foreign key to the "Calendar Month Dimension" view, with the logical dimension name of the "date" field in "Fact A" allows analytic queries to use "Fact B" for queries at the monthly level or above which perform better than performing them on the more granular "Fact A".

Analytics Configuration

Depending on which product or products you have installed, there may be some configuration needed for the analytics visualization product. Refer to [Defining Analytics Options](#) for more information.

Calendar and Time Dimensions

This portal is used to view generated calendar and time dimension records.

Refer to [Understanding Operational Analytics](#) for an overview of operational analytic functionality.

Navigate using **Admin > Analytics > Calendar and Time Dimensions**.

The following zones may appear as part of the portal's **Main** tab page:

- **Calendar Dimension.** This zone lists most recent calendar dimension records. You may filter the list to review records generated up to a specific date.
- **Calendar Date.** This zone provides information about a selected calendar date.
- **Time Dimension.** This zone lists all time dimension records.

Maintaining Bucket Configurations

Several key performance indicators in the analytics product look at measurement values (for example: the age of an asset or the age of debt) classified into a number of pre-defined groups also known as buckets. The overall metric can then be reported by the different buckets and allow various analyses.

For example, the age of an asset can be classified into the following buckets:

- Less than 6 Months
- 6-12 Months
- One Year and Older

The age of debt, also known as arrears can be classified onto the following buckets:

- 0-30 Days
- 30-60 Days
- 60-90 Days
- 90+ Days

The definition of the buckets is extracted to the Business Intelligence data warehouse, to be used as dimensions.

Bucket Definition Considerations

Each type of bucket is defined using a bucket configuration Business Object. The bucket definition considerations and/or rules will vary based on the bucket configuration business object used. The business objects available are driven by your specific product. For a list of available bucket configurations business objects, navigate to the business object page and view the business objects for the Bucket Configuration maintenance object.

Setting Up Bucket Configurations

To maintain the bucket ranges for the bucket configuration(s) applicable to your product, open **Admin > Analytics Configuration > Bucket Configuration**.

You are taken to the query portal where you can search for an existing bucket configuration. Once a record is selected, you are brought to the maintenance portal to view and maintain the selected record.

Note: Your specific product may also include an Analytics Configuration portal that displays the list of existing and potential bucket configuration records, allowing you to drill into this page to view the record in detail.

The **Bucket Configuration** zone provides basic information about the bucket configuration.

For more information about the elements supported refer to the zone's help or to the relevant analytics integration documentation for your product.

Defining Analytics Options

Refer to [Understanding Operational Analytics](#) for an overview of the operational analytics functionality.

Your specific product may require some system wide configuration to be defined when using operational analytics.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Analytics Options** business object.

Use the embedded help to review information about the options to define.

Defining Analytics Tables

This portal is used to search for Analytics Table definitions. An Analytics Table record exists for each table or view in the operational system that represent dimension and fact tables in the Operational Analytics product.

Refer to [Understanding Operational Analytics](#) for more information.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Table**. You are brought to a query portal with options for searching for a specific record. Once a record has been selected you are brought to its maintenance portal to view and maintain the selected record.

Defining Analytics Dimensions

This portal is used to maintain metadata for Analytics Dimension tables. A dimension record exists for each table in the operational system that represents a dimension table in the Operational Analytics product.

Refer to [Understanding Operational Analytics](#) for more information.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Table**. You are brought to a query portal with options for searching for a specific record. Once a dimension record has been selected you are brought to this portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page

- **Analytics Table.** This zone provides information about the selected dimension record.
- **Fields.** This zone lists all the fields that define the dimension table. Fields may be selected from the dimension's underlying operation table using the **Excluded Fields** zone or added as computed fields.
- **Dimensions.** This zone lists dimension tables that this dimension references via foreign key constraints.
- **Referenced By.** This zone lists dimension and fact tables that reference this dimension via foreign key constraints.

- **Characteristic Mapping.** This zone manages characteristic mapping extensions for the dimension. Refer to [analytics attribute mapping](#) for more information.
- **Excluded Fields.** This zone lists fields from the dimension's operational table that are not included in the dimension table.

Note: The ability to introduce custom analytics dimensions is currently not supported.

Defining Analytics Facts

This portal is used to maintain metadata for Analytics Fact tables. A fact record exists for each table or view in the operational system that represents a dimension table in the Operational Analytics product.

Refer to [Understanding Operational Analytics](#) for more information.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Table**. You are brought to a query portal with options for searching for a specific record. Once a fact record has been selected you are brought to this portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page

- **Analytics Table.** This zone provides information about the selected fact record.
- **Fields.** This zone lists all the fields that define the fact table. Fields may be selected from the fact's underlying operation table or view using the **Excluded Fields** zone or added as computed fields.
- **Dimensions.** This zone lists dimension tables that this fact references via foreign key constraints.
- **Excluded Fields.** This zone lists fields from the fact's operational table or view that are not included in the fact table.

Note: The ability to introduce custom analytics facts is currently not supported.

Defining Analytics Attribute Mapping

This portal maps extensions to user defined fields provided for tables associated with an analytics dimension table that capture well defined extension data. A common example of this type of data are characteristics.

These mappings may be directly maintained on the operational [Analytics Dimension](#) portal. Refer to [Understanding Operational Analytics](#) for more information.

If your system is integrated with the Oracle Utilities Analytics product refer to [Understanding Analytics Integration](#) for more information about ETL based characteristic mapping.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Attribute Mapping**. You are brought to a query portal with options for searching for a specific mapping record. Once a record has been selected you are brought to the this portal to review the information for the selected record.

The **Analytics Attribute Mapping** zone on the portal's **Main** tab page provides information about the mapping record.

Note: For characteristic mapping, only **Adhoc** and **Pre-defined** characteristic types are supported.

Note: For the product provides support for identifier mapping for operational analytics in this release but only the metadata definition is supported. The support for these types of attributes in the operational analytics product is in a future release.

Analytics Integration

The framework provides several building blocks and tools that the edge applications may use to implement integration with the Oracle Utilities Analytics product (referred to in this section as the analytics product). The following sections provide more information about this functionality.

Understanding Analytics Integration

The following sections describe the type of configuration supported in your product to integrate with the analytics product. Refer to the Oracle Utilities Analytics documentation for more information.

Master Configuration

Edge applications that include an integration to the analytics product typically include a master configuration record that captures information needed for the extract, load and transformation step, such as extract parameters. These records are provided by the specific edge products and may be viewed and maintained on the [master configuration](#) portal.

Note that your specific edge application may deliver an **Analytics Configuration** portal that displays the information from the master configuration record along with other analytics related configuration.

Bucket Configuration

The analytics product provides support for defining a set of ranges, each representing a bucket for which extracted measures can be grouped and classified under the relevant bucket. The framework product provides support for viewing and defining the buckets. Refer to [Bucket Configuration](#) for more information.

ETL Based Characteristic Mapping

The product provides objects to allow mapping configuration of characteristics in the product to user defined fields on dimensions in the analytics product. The mapping is used by the extract process to populate target user defined columns with corresponding characteristic data.

This type of mapping relies on configuration in the Allowed Target Dimensions [extendable lookup](#). The extendable lookup is used to define each Target Table in the analytics product that has one or more user defined fields that may be populated with characteristic values. It also defines the valid characteristic entities that may act as the source for the characteristic data.

Note: The framework does not provide any values in this lookup, but edge products that support mapping provide values in this lookup. Please refer to your specific product's integration chapter and refer to the Oracle Utilities Analytics documentation for more information.

Refer to [Defining Analytics Attribute Mapping](#) for more information.

Change Data Capture Using Sync Request

Depending on the specific edge application and version you are using, there may be components of the integration that use Sync Request for the change data capture step. If that functionality applies to your implementation, the following points highlight how to get more information:

- Refer to the administration guide for Oracle Utilities Analytics to confirm if your product integration is using Sync Request for any change data capture functionality.
- Review the Sync Request Business Objects provided by your product for analytics integration.
- Refer to [Data Synchronization](#) for a high level understanding of the process.

Business Flags

It is possible that information detected in one product may be useful or even critical to share with another product. The framework provides functionality for receiving information from an external system that acts as a type of flag or alert that may need investigation. This allows any system to store detected business flags in a common way and share that information with one or more other systems.

Understanding Business Flags

The following is an example of a use case for business flags. Imagine that DataRaker highlights potential theft of service at a certain location. That product may initiate a business flag alert to various products owned by the implementation with a recognized "standard name" for the business flag, such as "TAMPER".

- If Oracle Utilities Meter Data Management receives this business flag, it may initiate a service investigation monitor.
- If Oracle Utilities Mobile Workforce Management receives this business flag, it may initiate a service investigation activity.
- If Oracle Utilities Customer Care and Billing receives this business flag, it may initiate a hold on billing for that location.

Note that the framework product supplies basic functionality to support logic that is common to all edge applications that implement business flag functionality. However it is the individual edge applications that supply more specific functionality (business objects and algorithms) for specific use cases, if applicable.

The following sections highlight functionality supported for business flags in the framework. Refer to the edge application product documentation for more details for supported use cases.

Standard Name

To ensure that Business Flags are universally understood across all edge applications and to simplify integration each Business Flag will have a Standard Name. This is a name that is used by all the products when sending information to each other. That way, if DataRaker product sends Oracle Utilities Meter Data Management a "TAMPER" business flag, it should result in the same functionality as when Utilities Customer Care and Billing sends a "TAMPER" business flag.

Standard Names are defined using an extendable lookup. In addition to common extendable lookup fields, the standard name also references a category and a class. The lookup also supports defining one or more external names, for cases where information is communicated from an external system that does not send the expected Standard Name.

The framework delivers the class values but does not deliver any standard names or category values. Refer to your specific edge application products to verify if any standard names or categories are delivered. Your implementation may configure appropriate standard names and categories based on your business rules.

Business Flag Type Defines Behavior for a Standard Name

Although the definition of the business flag standard names should be universally understood by the various integrated products that support them, each individual product defines what should occur when a business flag with a given standard name is created. This is configured using a business flag type. Only one active business flag type may exist for a given standard name. Business flags that are received from an external system will define the standard name, but will not have knowledge of the specific business flag types defined. The business flag type is determined based on the standard name.

The business flag type defines the business object to use when creating the resulting business flag record. The business object defines the lifecycle of a resulting business flag record.

Business Flag Type Algorithms

The business flag type includes support for algorithms. This allows for an implementation to define a common business object that may be used for different business flag types (if a common lifecycle is followed) but allow for different functionality to kick in depending on the business flag type.

The product supplies a plug-in spot for **Additional Processing** that may be invoked by a business flag that enters the Additional Processing state. Refer to your product's library of business objects to determine if there is an Additional Processing state that supports calling algorithms on the business flag type.

Objects Linked to a Business Flag

There are two types of links between an object in the system and a given business flag.

Affected Entity

Each business flag is associated with a single record in the system that is considered the "affected entity" or the entity that the business flag is associated with. The affected entity is defined by the specific business objects designed for the use cases supported by your edge product. For example, many utility base products may configure service point as the affected entity for its business flag use cases. Each business flag created is linked to a specific service point. Linking a specific entity to each business flag allows for algorithms to trigger functionality for that entity such as

an investigation order. In addition, algorithms may be implemented in other business process areas that look for the existence of a business flag and act accordingly.

Related Objects

The business flag supports linking one or more related objects to a business flag to make it easier to trigger functionality or for impacted business processes to look for business flags. For example, when creating a business flag for a given service point, it may be useful to link all the accounts that are currently linked to the service point. Then, if an account oriented process should check for a business flag, it can look directly for a business flag linked to the account in its related object.

Impacted Business Process

The product supplies support for associating one or more impacted business processes to a business flag type. This configuration is used when functionality for that business process is impacted in some way based on the existence of a business flag of a given type. For example, maybe some process is put on hold when a certain type of business flag exists.

Note that configuring a business process on business flag type is not enough to trigger any impact on that business process when a business flag exists. There must also be some logic implemented in the business process functionality itself that knows to look for a business flag for a given record that is configured to impact the business process.

The definition of the business process is at the discretion of the edge application that supplies functionality to support this. For example, the business process could be defined as something broad such as “billing” or could be something more granular such as “billing estimation”. The system supplies an extendable lookup to use for configuring the supported business processes. Refer to the values of the business process extendable lookup in your edge application or to the edge application specific Business Flag documentation for more information about supported business processes.

Dates

A business flag supports two dates: a Business Flag Date/Time and a Business Flag **End** Date/Time

- The business flag date / time is required for all business flags. For some types of business flags only one date is needed.
- For business flags that have a start and end period, the business flag date/time acts as the start date and the other field is the end date.

For a business flag that has a date range, it may be important for functionality implemented for [impacted business processes](#). How the process treats the date will depend on its functionality.

- For some processes, the business flag is essentially expired after the end date has passed. This applies to impacted processes that are only looking at the current status of data in the system. For example, collection processing could be held if there is a business flag currently in effect (where the current date is within the date range). It would never look at historical business flags.
- For some processes where historical data may be relevant, a business flag effective during that same historical period may impact the process. For example if a business flag denotes an outage event for a given time period, perhaps estimated consumption should never be calculated for that time period.

Note that because business flags have a status, the design for the lifecycle of the business objects for the above effective dated use cases must carefully consider the states. For business flags that are considered expired after the end date passes, the BO lifecycle may be designed to transition to a final state after that date such that the record is no longer included in active processing. For business flags that continue to impact processing for a historic period, the BO lifecycle may be designed to remain in a non-final state such that it is clear that the record is still applicable.

Creating Business Flags

Business flags may be created in a system for one of the following reasons:

- A message is received from an external system that initiates the creation of a business flag. In this case, logic in the external system has detected some situation that this product is being alerted about.
- Business logic in this product detects a situation that should be investigated or should act as a flag. In this scenario, there may not be any integration needed depending on the business rules.

- Business logic in this product detects a situation that another integrated product should be alerted about. In this scenario, the business flag record is used to send out information to the integrated product.
- A user manually creates a business flag based on knowledge of the affected entity. For example, a customer service representative may create a business flag as a result of contact with the customer.

Creating a Business Flag from a Web Service

The system supplies both a REST and SOAP inbound web service that may be used for an external system to initiate (or update) a business flag. The REST service is **F1-BusinessInsights**. The SOAP service is **F1-BusinessFlagSync**. In both cases, the web service invokes a "driver" service script whose ultimate responsibility is to determine the appropriate Business Flag Type based on the standard name or external standard name, and therefore the appropriate business object for the new business flag. Because different products may have different logic related to creating a business flag, the service script calls another service script linked to the maintenance object using the Business Flag Sync MO option.

The "driver" service script includes a "contextData" group, which in turn references the data area **F1-BusinessFlagContext**. This data area is to allow for an external system to provide additional information for a given business flag use case. For any integration that requires additional information to be passed in from the external system, a separate data area should be used to define the additional elements; and that data area should refer to **F1-BusinessFlagContext** as its extended data area.

The framework does not supply a Business Flag Sync service script, however individual edge applications supply a service script based on the use cases it supports out of the box.

Note: For products that are continuing to use XAI for external messages, the product also includes an XAI inbound service for the same Business Flag Sync Driver service script. Note that the product recommendation is to discontinue use of XAI and use [inbound web services](#) instead.

Error Handling

If there is a problem in trying to create a business flag based on incoming information, the Business Flag Sync Driver service script creates a special business flag record using the Business Flag Error Business Object. This is also configured on the maintenance object as an option. The framework product supplies the business object Business Flag Error (**F1-BusinessFlagError**) for this functionality. Refer to the business object description and configuration for more information.

Confidence

There may be use cases where a condition is suspected, but not confirmed. The originating system should be able to assign a "confidence" level to the business flag.

For example, Oracle Utilities Analytics Insights or other machine learning platforms will aggregate and analyze large amounts of data to identify potential insights that need investigation. These platforms can initiate a business flag with a **Suspected** confidence.

An application receiving this business flag may adjust the confidence to either **Confirmed** or **Rejected**.

- Setting the confidence to **Confirmed** is the equivalent of a true positive.
- Setting the confidence to **Rejected** is the equivalent of a false positive.

Note that the application that receives a business flag is responsible for acting on the value based on business rules. Any updates to the confidence can be communicated to the other products that received the same business flag, if desired.

Additionally, creating a business flag in the application with a confidence of **Missed** provides a way to denote a missed insight. This is the equivalent of a false negative.

Because a utility implementation may have multiple applications installed that support business flags, the following guidelines are suggested for designing where the confidence flag should be updated.

- If Oracle Utilities Service Order Management is implemented, it has the responsibility of updating the confidence flag and communicating the update to other products.

- Otherwise, the assumption is that Oracle Utilities Customer Care and Billing owns field work orchestration and that it will have the responsibility for updating the confidence flag and communicating the update to other products.

No product logic is provided to enforce the above suggestions, however, the business objects supplied by the different edge applications will support the recommended implementation.

Business Flag Updates from External System

When the product that is responsible for updating the Confidence flag makes a change, it should initiate an outbound message to alert other products. On the receiving side, the same inbound web service and Business Flag Sync service script is responsible for the update. Refer to [Creating Business Flags](#) for more information.

Setting Up Business Flag Configuration

The following topics highlight the general configuration steps required to use business flag functionality. Your specific product may supply additional functionality to support specific use cases for business flags. Refer to your specific product's documentation and the library of business objects supplied for Business Flag in your product for more information.

Standard Name Category Characteristic Type

Define one or more categories for grouping your standard names into logical business groupings.

Navigate to the [Characteristic Type](#) page. Search for and select the Business Flag Category characteristic type (**F1–BUSFC**).

Define desired category values and descriptions to be used for the standard names.

Standard Name Lookup

Navigate to the [Extendable Lookup](#) portal. Search for and select the **External Insights Standard Name** business object.

Define values that are recognized in the external systems that your implementation is receiving business flag details from.

Define a **Category** for the standard name that is appropriate for your product. Note that the category does not have to be in sync with standard name definitions in external products.

Select a **Class** for the standard name that is appropriate for its usage.

Refer to the embedded help for more information about configuring this object.

Business Process Lookup

If your specific product supports configuring business processes that may be impacted by the existence of a business flag, they are defined as an extendable lookup.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Business Process** business object.

Integration Configuration

The following points highlight configuration required to support receiving business flag information from an external source:

- Define a record for each [External System](#) that the product may be receiving business flag records from. This should be a value known by the external system and provided when new business flags are sent to this product.

When this product should initiate business flag information to be sent to an external system, configure one or more [Outbound Message Type](#) records. For each one, update the External System to configure how each outbound message type is communicated to the external system.

Defining Business Flag Types

Refer to [About Business Flags](#) for an overview of business flag functionality.

To maintain the business flag types applicable to your product, open **Admin > Integration > Business Flag Type**.

This is a standard [All-in-One portal](#).

The information captured on the business flag type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Maintaining Business Flags

This section describes the functionality supported for viewing and maintaining business flags.

Refer to [About Business Flags](#) for an overview of business flag functionality.

Navigate using **Main > Integration > Business Flags**. You are brought to a query portal with options for searching for business flags.

Once a business flag record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Business Flag** zone provides basic information about a business flag. Refer to the embedded help for more information.

Market Transaction Management

This section describes various entities and aspects involved in the configuration and maintenance of market transactions. The framework product supplies basic functionality to support the objects related to market transaction management. However more specific functionality (business objects and algorithms) for specific use cases are supplied by the edge applications.

Understanding Market Transaction Management

Several objects are provided to support market transaction management.

- **Market Message Type.** This object is used to define the different types of market messages, both inbound and outbound and to define the appropriate market message Business Object to use when creating objects of this type.
- **Inbound Market Message.** This object captures the instance of a market message received from an external source.
- **Outbound Market Message.** This object captures the instance of a market message that will initiate a message to an external source.
- **Market Process Type.** This object is used to define configuration related to processes that may be initiated to support steps that should be execute to support an inbound or an outbound market message. It defines the market process Business Object to use when creating market processes of this type. It may also define one or more market process event business objects to initiate events that are generated to support steps within the market process.
- **Market Process.** This object captures the instance of a market process that may be created to carry out business logic related to a specific inbound or an outbound market message.
- **Market Process Event.** This object is used to orchestrate individual events that may occur to support steps in a given market process.
- **Market Configuration.** This object may be used to capture configuration needed to support market transactions. Each type of configuration should use a Business Object to define what information needs to be captured. Each type of configuration may define up to five key fields that may be used to uniquely identify an individual configuration instance.

Configuring Market Transaction Management

The following sections describe market transaction management configuration options.

Defining Market Configurations

Each market configuration is used to define one or more options for a given type of configuration (based on a delivered business object).

The product defines a generic set of portals, described here, that may be used to define any type of market configuration. However, it may be that your implementation includes more specific configuration portals for certain types of market configurations.

Open this page using **Admin > Market Transaction Management > Market Configuration**.

You are brought to the **Market Configuration Query** where you need to search for the market configuration (i.e., its business object).

Once you have found the appropriate market configuration, select the value and you are brought to a standard [All-in-One](#) portal that lists the existing values for the market configuration. The standard actions for an All-in-One portal are available here.

Defining Market Message Types

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Admin > Market Transaction Management > Market Message Type**.

This is a standard [All-in-One](#) portal.

The information captured on the market message type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Defining Market Process Types

This page is used to define market process types which control behavior of the resulting market processes and the valid market process events that could be triggered as a market process progresses through its lifecycle.

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Admin > Market Transaction Management > Market Process Type**.

This is a standard [All-in-One](#) portal.

The information captured on the market process type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Maintaining Market Transactions

The following sections describe various pages available to view and work on market transactions.

Maintaining Market Processes

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Main > Market Transaction Management > Market Process**. You are brought to a query portal with options for searching for market processes.

Once a market process record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Market Process** zone provides basic information about a market process. Refer to the embedded help for more information.

Related Objects

The related object tab includes several zones that display various objects that may be related to the market process.

Related Market Messages and Processes

This zone displays any entries in the related object collection that are outbound market messages, inbound market messages or market processes.

Related Processes

This zone displays market processes that are linked to this market process using the explicit related process table. The market processes linked here are marked either as a parent, a child or a sibling market process.

Other Related Objects

This zone displays market process events linked to this market process. In addition, the zone displays any miscellaneous objects that are linked to the market process in the related objects collection, besides outbound market messages, inbound market messages and market processes.

Maintaining Market Process Events

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

You can view this page when drilling into a market process event from the [Market Process](#) related objects tab.

Once a market process record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Market Process Event** zone provides basic information about a market process. Refer to the embedded help for more information.

Related Objects

The related object tab includes a zone that displays all entries in the market process event's related object collection.

Maintaining Market Messages

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Main > Market Transaction Management > Market Message**. You are brought to a query portal with options for searching for market messages. Both inbound market messages and outbound market messages may be queried here.

Once a market message record has been selected, you are brought to the appropriate maintenance portal (inbound market message or outbound market message) to view and maintain the selected record. The inbound market message portal and the outbound market message portal have similar portal tabs and zones.

The **Market Message** zone provides basic information about the market message. Refer to the embedded help for more information.

Related Objects

The related object tab includes several zones that display various objects that may be related to the market process.

Related Market Messages and Processes

This zone displays any entries in the related object collection that are outbound market messages, inbound market messages or market processes.

Other Related Objects

This zone displays any miscellaneous objects that are linked to the inbound / outbound market message in the related objects collection, besides outbound market messages, inbound market messages and market processes.

Content Migration Assistant (CMA)

This chapter describes the Content Migration Assistant (CMA), a facility to enable the export of data from one environment to another.

CAUTION: This chapter is intended for users responsible for creating environments for testing.

Understanding CMA

The Content Migration Assistant (CMA) provides implementers with a flexible, extensible facility for migrating data from one environment to another (e.g., from a development environment to a production environment). Data is exported from the source system to a file. The file can then be checked in to a version control system for reuse, or can be immediately imported into the target system and applied.

Note: As used in this chapter, *source* systems are those on which export-related activities are conducted and *target* systems are those on which migration updates are to occur.

The following points highlight some common use cases for using this tool:

- Seeding a newly created environment with configuration data. For example, if you are creating test environments, you can import configuration data from a development environment. In this case, you will probably set up a "copy all configuration" type of migration. Another use case is if you want to troubleshoot an issue in production, you may want to copy all production configuration to a test environment.
- Updating an existing test environment with new configuration or updates to configuration from a development environment. In this case your set of objects will be more targeted and you are doing more of an incremental migration.
- Promoting tested configuration to your production environment.
- Migrating selected master and transaction entities from one environment to another for testing purposes.

Here are key aspects of the import process that apply to all cases:

- When records exist in both the target and the source, the CMA tool will fully **replace** the object with the version from the source. Special consideration should therefore be given to records whose **primary key is system generated** to ensure the correct entity is being replaced.
- While typically the source version of an object is applied directly onto the target environment, CMA does provide a way to **Adjust Imported Data**.
- The import process **does not handle deletion** of records in the target environment. When importing records from a source environment to a target environment, the import process for the migrated records is able to identify objects to add and objects to change. There is no mechanism for indicating that records in the target environment should be deleted. The absence of those records in the import is not enough because the migration may be only importing a subset to add or update. If data on the target system must be deleted, users must delete the records in the target accordingly. Note that CMA does orchestrate the deletion of child rows of an object as a result of a comparison. This is only applicable to child records that are owned by the implementation.

Note: You may review and delete previously imported configuration entities using the **Configuration Deletion** on page 538 portal.

Configuration steps are mainly used to define the data to migrate at the source system but also involve tasks to be performed at the target environment. Note that the products provide base delivered configuration that may be used as is or used as a template for building more specific configuration for a given implementation. At a high level, configuration tasks involve the following entities:

- System wide settings are defined in the **Migration Assistant Configuration** master configuration record.
- Each type of record that may be copied requires a **Migration Plan**. The migration plan is used to identify the maintenance object (MO) for the record (using a business object) and allows for instructions to specify related records that may be included in the migration.
- A **Migration Request** is used to define the data to include in a given migration export.

Refer to **CMA Configuration** for more information.

Once you have a migration request defined to include desired data to export, the next steps are to export from the current environment and import to the target.

- The **Export** process includes all the steps needed to select records to be exported from the source environment and create the export file. For more information, refer to **Exporting a Migration**.
- The file created by the export, which is a BINARY file, needs to be transferred from the export directory to the import directory. The transfer needs to be done in such a way as to preserve the file structure. Refer to **Additional Migration Considerations** for more information.
- The **Import** processes include all the steps needed to read an imported file, compare the data in the file to the data in the target, review the proposed changes and apply the updates. For more information, refer to **Importing and Applying a Migration**.

The topics in this section provide a general understanding of the Content Migration Assistant (CMA) tool.

Types of Migrations

The Content Migration Assistant is used for two general types of migrations: wholesale and targeted. The following topics provide some additional information about these concepts.

Wholesale Migrations

Wholesale migrations are used when migrating all the configuration and/or administrative data from one environment to another. For example, a wholesale migration might be used when migrating administrative data from a development or test environment to a production environment.

A wholesale migration may be comprised of one or more migration requests that in total include all the administrative data to move. Migration plans used in wholesale migrations may be designed to omit subordinate instructions related to explicit foreign keys that are identified through constraints as they are not needed, assuming that the data they are referring to will also be included in the migration.

With the ability to group migration requests, the expectation is that implementations follow these guidelines:

- Multiple migration requests using the Criteria-based or Entity List migration request classes are used to group information logically together to allow for more reuse.
- A Group migration request is used for the export. This allows for one data set to export and one data set on the import side, simplifying the process. Note that depending on the amount of data, this may be a large import set to process. An implementation may find it easier to create multiple migration requests that break down the process into several steps.

You should consider that the framework product provides base migration requests and your specific edge product may provide base migration requests as well that may or may not include framework migration plans. Using the product provided migration requests is beneficial with respect to maintenance. As features are added to the product (including new administrative maintenance objects), any impact on CMA should be included in the product owned migration requests. If your implementation introduces new custom administrative maintenance objects that should be included in CMA, then custom migration plans and a custom migration request should be added. Your implementation can build a Group migration request that includes the base migration request and your custom migration requests to have a consolidated export.

Note: Refer to [Framework Provided Migration Objects](#) for information about migration requests provided in the framework product. Refer to your specific product's documentation for information about addition base provided migration requests.

Targeted Migrations

A targeted migration refers to migrating a specific subset of data from one environment to another. Migration plans used in targeted migrations are designed to be self-sufficient and include all necessary subordinate instructions needed to ensure that the exported entity can be imported without encountering referential integrity errors. With this type of migrations, any relationship explicitly excluded from the migration plan assumes the related entity already exists in the target environment. Examples of targeted migrations include:

- Migration of a new portal, its zones, and its application service.
- Migration of all outbound message types.
- Migration of selected accounts and their related master and transactional entities to a lower environment for testing purposes.

Migrating Configuration Data

A main use of CMA is to migrate configuration data, where the source environment is considered a kind of system of record and the target environment is getting updates based on changes to the source environment. Alternatively, you may be seeding a new environment. The expectation is that the target record is updated to look like the source record.

Configuration data may include a mixture of records that have an owner flag and ones that do not. The comparison step of the import process will generate appropriate insert or update SQL statements for the following data found in the export:

- Configuration data in a maintenance object with no owner flag. This is purely implementation data.
- Configuration data in a maintenance object with owner flag, where the owner is **Customer Modification**. For example, implementer-specific business objects.
- Configuration data in a maintenance object with owner flag, where the main record is owned by the product but where a child record exists with an owner of **Customer Modification**. For example, implementer-specific algorithms added to a base owned business object.
- Customizable fields in a record that is owned by the product. For example, the priority of a based owned To Do type.

Migrating Business Data

CMA may be used to perform a targeted migration of selected master entities and their related transactional data from one environment to another. For example, migrating a subset of accounts and their related data for testing purposes.

The following points highlight key differences between business data and configuration data that call for special considerations when designing your business data migrations:

- Migration of business data typically involves a much higher number of records in a data set compared with a configuration-only data set. While there is no explicit limit to the size of a data set, some reasonable limit has to be assumed.

- Having large sets of entities depend on relatively few entities in the same data set significantly slows the import process. This situation occurs when mixing configuration data, master data and high volume transaction data in a single migration. We therefore recommend designing separate migrations for these data classes. Refer to the **Reduce Dependency Between Migration Objects** section below for more information.
- All business entities have a system generated key. Refer to [Data with System Generated Primary Keys](#) on page 506 for more information.

The following sections expand on topics and concepts related to business data migration.

Reduce Dependency Between Migration Objects

CMA leverages the application's referential integrity and business rules to ensure entities remain compliant and valid when imported into another environment. These rules are there to prevent an entity from being imported when any of the entities it references do not exist in the target environment. When both the referencing entity and the entity it references are part of the same data set they establish a **dependency** that dictates the sequence in which these entities should be processed in order to be successfully imported. Note that the tool supports even the more complex and rare situations wherein the dependency between entities is cyclical, i.e. entity A (directly or indirectly) refers to entity B while entity B (directly or indirectly) refers back to entity A, for which sequential processing is not enough to guarantee a successful import.

The tool uses foreign key relationships between entities in the same data set to identify sets of dependent entities and group them into separate migration transaction records. Note that these foreign keys are defined in the application's [data model](#) repository and not at the database level for greater flexibility. The larger the migration transaction the more complex the process is to successfully import all its objects. So while the tool is designed to support all types of dependencies (sequential and cyclical), handling very large sets of dependent objects may incur a significant performance cost.

While configuration entities tend to be highly inter-dependent, the total number of entities that comprise the entire set of configuration objects is relatively small. Therefore, the impact on performance such dependencies have when importing a configuration-only data set is negligible. On the other hand, configuration entities tend to be referenced on many master and transaction entities as they control many aspects of the latter's business rules. As such, mixing configuration and business data in the same data set is likely to form extremely large sets of business entities that dependent on a small number of configuration entities. It is therefore strongly recommended to import or set up configuration data in the target environment prior to importing business data into it.

In a similar way, some transactional data tends to be of a much higher volume compared to the master data entities they reference. Here too, it is strongly recommend to migrate master data entities prior to their high volume related transactional data. For example, many interval measurement records (transaction data) reference the same measuring component (master data). Migrating a large volume of measurement data along with their measurement component would result in a very large migration transaction that may take long to import. Importing the measurement components prior to migrating their interval measurements will eliminate unnecessary dependencies within the measurements only data set and significantly improve the performance of the overall process.

Reasonable Data Volume

The overall volume of all business entities to migrate in a single data set should be reasonably sized. For example, importing several hundreds of accounts and their related master and transactional data is considered a reasonable size. Migrating too much data may reach physical and performance limitations of the tool.

You may use any supported migration request methods for describing the entities to export. If you opt for an Entity List migration request, consider using the [Collect Entity](#) zone to build the list of entities as you browse them on their respective portals.

Single Source of Data

CMA uses an entity's prime key to determine if it is new to the target environment and therefore should be added or refers to an existing record and therefore needs to be replaced with the new version. All business entities have system generated keys, which are environment specific. It is therefore possible to have different entities in separate environments having the same prime key. When migrating entities whose keys are system generated, it is strongly

recommended to migrate data to a target environment from a single source environment and avoid creating such entities in the target environment using the application. This practice ensures that prime keys for an imported entity are always in sync with their source environment. Refer to [Data with System Generated Primary Keys](#) on page 506 for more information and considerations.

No Deletion

CMA does not handle deletion of entities of any kind, whether they are configuration or business entities. If a test needs to be repeated using an initial snapshot of the data, you should restore your target environment to a backup taken before test data was imported and import the latest version of the test data. If there is no need to delete previously imported entities, you may keep reloading test data from a single source environment as needed.

Bulk Import Mode

By default, the import process creates a migration object for each imported entity. This allows for granular reporting and error handling at the entity level. When importing a high volume data set of business entities, this granular management has a performance toll. In this situation, you may want to use the **Bulk Import** option on the migration data set import request. In this mode, a single migration object record is created for multiple entities of the same maintenance object. In the same way, a single migration transaction record is created for multiple logical transaction groups. Using this option reduces the migration object management effort throughout the process and thus results in better performance.

Note that each entity is still individually compared and validated, as in regular import processing, but if one entity is invalid the entire migration object is not applied hence impacting all entities grouped together with it. Bulk import mode is useful when importing a large set of data from a validated data source such that almost no errors are anticipated.

This option is only supported for master and transaction maintenance objects, i.e. it is not applicable to configuration migrations.

Insert Only Mode

By default, the comparison step of the import process needs to determine whether the imported entity is new and therefore should be added, represents a change to an existing entity and should be updated or the entity is unchanged. When importing a high volume data set of business entities that are all new to the current environment, this check is time consuming and can be avoided. In this situation, you may use the **Insert Only** option on the migration data set import request to indicate that all imported entities are assumed to be new additions to the current environment. By doing so, the import process avoids unnecessary steps to determine whether the entity should be added or updated and thus contributes to a faster import process.

This option is only supported for master and transaction maintenance objects, i.e. it is not applicable to configuration migrations.

Separate Batch Processes for Managing Business Migration Objects

By default, the same import related batch processes manage configuration and business data migrations. Typically, business data migrations involve high volume of records compared to much lighter configuration data sets. Processing them together by the same batch process may slow down the performance of configuration migrations, preventing them from completing faster and more frequently. The issue mainly affects test-like environments where mixed data class migrations are more common: configuration data is imported from a lower environment and large test data is imported from a higher environment. You may adjust the base product's configuration in such environments to benefit from separating the import processes for configuration and business data.

Note that the ability to separate import processes applies to migration objects only because of their volume. Migration data set and transaction records are of low volume and as such remain managed by the same batch processes.

Designated batch processes are provided for importing migration objects containing business data but they are not used by default:

- F1-MGOPB - Migration Object Monitor (Business)

- F1-MGOAB - Migration Object Monitor (Business) - Apply

Follow these steps to use these separate designated batch processes for business data:

- Update the **Migration Object Business Data** (F1-MigrObjectBus) business object to reference the business data related batch controls on the following statuses:
 - **Pending, Error Applying, Needs Review** - Migration Object Monitor (Business) - F1-MGOPB
 - **Approved** - Migration Object Monitor (Business) - Apply - F1-MGOAB
- If your organization uses event driven job submissions for CMA batch processes then refer to [Running Batch Jobs](#) for additional configuration steps.

Data with System Generated Primary Keys

For records with system generated keys, there is an issue if the target environment already has a record with the same key but doesn't represent the same record. The tool shouldn't be just updating that target record with the view of the source in case this will break foreign key relationships that exist in the target.

The tool provides support for administrative data with system-generated primary keys. The logic relies on the maintenance object to use a method that looks at other attributes of the record (considered a "logical key") to detect whether the record being migrated already exists in the target region or not. The examples in this section are based on the Attachment maintenance object. Common attachments are considered administrative data. The attachment MO uses the file name and the creation date as the "logical key".

Imagine a common attachment for the "standard rate codes" file exists in a source region with the key 123456789. The table below highlights possible situations at the target region and actions supported in CMA.

| Scenario | Target Situation | Action | Comments |
|----------|--|--|---|
| 1 | No matching record | Record can be added with key 123456789. | |
| 2 | Record exists with key 123456789 and logic confirms that it is also the "standard rate codes" attachment. | Record can be updated. | |
| 3 | Record exists with key 123456789, but logic detects that it is not the "standard rate codes" attachment. | Record is not updated. An error is issued. | The system cannot update this record because it's not the right attachment record. |
| 4 | The system detects that another attachment record exists for the "standard rate codes" attachment with a different ID. | Record is not updated. An error is issued. | Assumption is that the record was created directly in the target or was copied from a different source. |

The use cases described in scenarios 3 and 4 above would require key mapping to keep track of the id from the source to the id in the target so that any other records from the source that reference this key as a foreign key would be updated as part of the migration. This functionality is not supported.

Scenarios 1 and 2 above are supported for maintenance objects that use the method to detect the logical key.

Note: If a maintenance object with a system generated key does not supply a method to detect the logical key, CMA will update an existing record with the same ID. For maintenance objects in the framework that provide this method, refer to [Framework Provided Migration Configuration](#). For your specific edge application, refer to the CMA addendum for information about support for data with system generated keys.

The product recommends that an implementation establishes a migration strategy such that records with system generated keys are always created in the same region and always follow a standard migration path for promoting the data from this source region to other regions. Following this strategy, you would minimize or eliminate the possibility that a record for the same logical key is created in multiple places such that different IDs would be generated as described by scenario 4 above.

MOs with a Mixture of Administration and Non-Administration Data

There are some MOs that contain a mixture of master or transaction data and administrative data. The Attachment is an example of this. The product supports common attachments and owned attachments. Owned attachments are records that are specific to its owner. The owner could be master or transaction data and its attachments are therefore considered master or transaction data. Owned attachments are not candidates for migration using CMA. Common attachments on the other hand are considered administrative data and may be candidates for migration using CMA. For these use cases, an implementation may follow the suggested strategy of only creating the administrative data in one region so that IDs for common attachments are not reused. However, it is reasonable and expected that owned attachments are being created in the target region and may receive a system generated key that matches the key of a common attachment from the source region.

To try to minimize this issue, the system includes special logic to be used by any MO that may contain administrative data mixed in with master or transaction data. This special logic generates the key of an administrative record with a zero (0) in the middle of the key and ensures that the keys for master and transaction data do not include a zero in this spot. For maintenance objects in the framework that use this method, refer to [Framework Provided Migration Configuration](#). For your specific edge application, refer to the CMA addendum for information about additional maintenance objects that may be in this category.

Importing Data that References a User

Although the tool supports copying users from one environment to another, the assumption is that it will be more common for implementations to define their valid users for each environment separately. In fact, the default CMA configuration for copying security configuration assumes that users are not being copied.

There may be times where a record is being copied from one environment to another where a user is referenced on the record but that user is not valid in the target environment. For example, if a batch control is configured as Timed with a user referenced, if this batch control is copied to another environment, what should happen if that user is not found? You may not want that user defined in the target environment. To handle this, the product provides support for a Default User that you can define in the [migration assistant configuration](#). If this default user is configured then any time the CMA import process recognizes that a record references a User and the user does not exist in the target environment, it updates the record to instead refer to the default user.

Note: Please note that if you are trying to copy entities that includes valid users, you should ensure that all the users are copied to the target environment first. Otherwise, the entity will be updated to refer to the default user, which may not be your intention.

Note: If you copy records that reference a User within an XML field or CLOB, the CMA input tool is not able to detect that. A pre-compare algorithm is recommended if this use case exists in your implementation.

Additional Considerations

The following sections describe some additional considerations for CMA.

File Transfer Considerations

When moving the export file between systems, use the binary transfer option of whatever tool you use to move the file so that line-end characters are not converted from Linux-style to Windows-style or vice versa.

It is recommended to avoid using 'txt' for the export file's extension (defined in the [master configuration](#)). That file extension by default implies a non-binary file and tools that perform file transfer may treat this as a non-binary file unless explicitly stated. The recommendation is to define 'cma' as the extension. This is not a recognized file extension and most file transfer tools will transfer the file as is.

Note that if the file gets converted, there are two likely outcomes - either a numeric conversion error, or a buffer under-run error may be received when attempting to import the file.

Multi-Language Environment Considerations

If your implementation uses a language other than English, it means that migrated administration objects may have multiple language rows (because English is always enabled). There are some important points with respect to multiple languages and CMA:

- As described in [User Language](#), there are steps to follow when supporting an additional language. The steps outlined in that topic highlight that for system data, translation of the strings may be provided via a language pack provided by the product or may be the responsibility of your implementation. In either case, this effort is non-trivial and will have its own established plan. The expectation is that the translation of the system data is applied for each region at your implementation site. CMA should not be used to create a new language in a target region.
- For administrative / control data that your implementation develops as part of your project, the expectation is that descriptions for your supported language are entered in the region that is considered the source region used to promote changes to regions in the "chain". For example, control data is entered in a development region and promoted to a test with the supported language enabled in both regions.
- What if you export data from a region with more languages enabled than your target? This scenario is perhaps a case where the source region is a type of test or playpen region where the additional language is enabled for other purposes. In this case, if the language code doesn't exist at all in the target region, the import will produce an error given that the code is invalid. If the language code exists but is not enabled, this will cause the extra language rows to be inserted in the target region, but will not cause any issues. They are simply ignored.
- What if you export data from a region with fewer languages enabled than your target? In this situation, the import process will only create language rows for the languages that were copied from the source. It will not automatically create language rows in the target as part of the import. For this situation, the recommendation is to run the **New Language** batch program (**F1-LANG**) that creates any missing language entries.

Versions and CMA

This topic addresses two separate version related topics with respect to using CMA between two environments.

- Different versions of the application
- Different CMA file format versions

Different Versions of the Product

CMA was developed with the main requirement of copying data between two environments that are on the same version of the product. For example, copying configuration data from a development environment to a test environment on the same product version.

In general, there isn't anything about how CMA functions that would limit your ability to copy data between two different versions of the product. However, it's possible that your product has enhanced the functionality of a specific object to add or remove columns or change the type of data captured in those columns or has changed the validation around how data should be captured.

Our products follow strict standards for upgrading clients to ensure backward compatibility. Upgrade scripts in the blueprint process know what was changed from one release to another and update the data accordingly where applicable. When using CMA to move data from one version of the product to another, you are bypassing these upgrade scripts. It means your data is not being adjusted as expected. It's not recommended unless you are certain that the data of an object from one version is compatible in the other version. The following points highlight this in more detail.

- For objects whose structure and rules have not changed between the two versions, there should be no issues.
- For objects that have changed between the two versions, there are scenarios that may cause additional steps.
 - If the target environment is a later version and includes a new optional column on an object that was not present in the source, the import should go through without any issues.
 - If the target environment is a later version and includes a new required column on an object that was not present in the source, a 'pre-compare' algorithm could be used to populate the new required value. Your implementation can provide this algorithm to populate the data according to your business rules.
 - If the target environment is an earlier version than the source, we cannot guarantee that there won't be specific issues encountered with specific objects.

File Format Version

If your implementation has decided that you are going to use CMA across product versions, given all the cautions described in the previous section, this section provides information on the rare case where CMA has a change in who it writes the export file.

When creating the export file, the format of the file is specific and the CMA import step knows how to read the file. It is rare, but there are times when the product makes an enhancement to CMA that requires a change in the structure of the export file at which point the 'version' of the CMA file is incremented.

The CMA file format version has no impact to migrations that are exported and then imported into the same version of Oracle Utilities Application Framework. However, if your implementation has different environments on different versions of the product where the CMA file format is also different, then the system has functionality to cater for these differences.

- If you are exporting data from a lower file format version to a higher file format version, there is nothing special that you need to do. The export step captures the file format version and the import step reads this information and processes the file accordingly.
- If you are exporting data from a higher file format version and the product currently supports exporting to a lower file format version, at export time you are prompted for the earlier file format version. You may indicate that you want the earlier file format version when creating the migration data export.

Note: The product supports exporting to an earlier file format version for a reasonable amount of time, but not in perpetuity. If you don't see any option in the user interface to export to an earlier file format, it means that it is not supported in that release.

CMA Configuration

The following sections describe tasks required for CMA configuration.

Master Configuration - Migration Assistant

The **Migration Assistant Configuration** [master configuration](#) record defines system wide configuration used in both the source environment and the target environment.

As described in [Importing Data that References a User](#), if you have records being imported that may reference a user does not exist (and shouldn't exist) in the target environment, define a Default User here.

In both the source environment and the target environment, the system needs to know the location of the export directory and the import directory along with the expected file suffix. For these fields, implementations may also rely on the system defaults. If no Migration Assistant Configuration record is found, the system assumes that there is an entry defined in the system's substitution variable list for **F1_CMA_FILES**. Further it defaults the values as follows:

- Export directory is the value for this variable plus "**\export**".
- Import directory is the value of this variable plus "**\import**".
- File suffix is set to **cma**

Refer to [Referencing URIs](#) for more information about the substitution variable list.

For additional information about specific fields in the master configuration, refer to the embedded help.

Note: This record can be updated at any time to change details. The new configuration takes effect on all subsequent exports and imports.

Migration Plans

A migration plan defines one or more types of objects that are eligible for migration. It is essentially a set of instructions describing how the data to be exported is structured, allowing objects to be migrated together as a logical unit to ensure consistency and completeness.

The migration plan is always related to a given maintenance object, defined using its primary instruction. Multiple migration plans may exist for a given maintenance object if there are different requirements for migrating records in that MO under different circumstances. For each migration plan, you decide if additional data should be included as part of an object using subordinate instructions. For example, when copying a single algorithm type, should

the system only copy that algorithm type record, or should it also copy all its algorithms and its related script (if applicable)? Refer to [Types of Migrations](#) on page 502 for more information.

The following topics describe defining a migration plan as well as other topics for a migration plan.

Defining a Migration Plan

To view or define a migration plan, navigate using **Admin > Implementation Tools > Migration Plan**.

Use the **Migration Plan Query** portal to search for an existing migration plan. Once a migration plan is selected, you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Important! If you introduce a new migration plan, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The following points provide information about defining **Instructions** for a migration plan.

The **Instruction Sequence** uniquely identifies the instruction. The recommendation is to use increments of 10 to allow insertion of other instructions in the future.

Select **Primary** for the first **Instruction Type**. All migration plans must contain one and only one primary instruction. All subsequent instructions require a **Subordinate** instruction type. In this case, the **Parent Instruction Sequence** must be entered. This number, used to maintain the defined relationships in the exported data, must match an instruction sequence number at a higher level in the hierarchy.

The instruction **Description** provides a business description of the instruction.

Select a **Business Object (BO)** to define the type of object from which data will be derived.

Note: Though BOs are specified in each instruction, it's important to understand that each BO is used only for filtering purposes. The migrated data set comprises the complete contents of the *maintenance object* that the business object structure is defined against. For a more detailed explanation of this, see [Understanding the BO Filtering Process](#).

Note: Refer to [Identifying Tables to Exclude From Migrations](#) for information about defining child tables to always exclude from a migration.

Traversal Criteria is used to define the relationship between each of the objects in a migration plan. The system provides three options to define how the child object is connected to the parent object so the system knows how to traverse from one object to another. **Traversal Criteria Type** options are **Constraint**, **SQL** and **XPath**. The following points explain each option:

- **Constraint** allows you to select a table constraint that represents a given record's relationship to another record in the system via a foreign key constraint defined in the meta-data. If **Constraint** is selected, the following additional fields are enabled:
 - **Constraint ID** is a unique identifier for the constraint. The search will show the valid table constraints for the MO of the instruction's BO and the MO of the parent instruction's BO.
 - **Constraint Owner** is used to define the owner of the constraint. This is populated automatically when selecting a constraint from the search.
- **SQL** lets you specify SQL join criteria between the parent instruction's object and the child object in the **SQL Traversal Criteria**. The syntax of the the traversal criteria is a WHERE clause (without including the word WHERE). When referring to a field on the parent instruction's object, use the syntax `#PARENT.TABLE_NAME.FIELD_NAME`. When referring to a field on the current instruction's object, use the syntax `#THIS.TABLE_NAME.FIELD_NAME`. For example, the following statement is used on a migration plan for Business Object, where the parent instruction is the BO and the subordinate instruction is used to reference the UI Map that is referred to as a BO option with the option type "F1DU":
`#PARENT.F1_BUS_OBJ_OPT.BUS_OBJ_OPT_FLG = 'F1DU' AND @trim(#THIS.F1_MAP.MAP_CD) = @trim(#PARENT.F1_BUS_OBJ_OPT.BUS_OBJ_OPT_VAL)`
- The **XPath** option lets you apply syntax in an XPath expression referencing elements in the instructions' referenced business objects. This is entered in the **XPath Traversal Criteria**. For example, the display map collection statement in the SQL example noted above would be written as follows in XPath: `#this/mapCd = #parent/businessObjectOption/businessObjectOptionValue AND #parent/`

`businessObjectOption/businessObjectOptionType = 'F1DU'`. This technique allows foreign key references that are mapped inside an XML column to be referenced.

Note: The `#parent` expressions may access elements that are stored in an XML column and described using `mapXML` and `mdField`. However, the `#this` expressions must refer to fields available in the business object using the `mapField` reference.

Defining **Next Migration Plan** provides the ability to indicate that in addition to copying the object defined in the instruction, any additional instructions included in that referenced migration plan will also be included in an export.

The **Algorithms** grid contains algorithms associated with each instruction. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the Sequence in which they should execute.

| System Event | Optional / Required | Description |
|--------------------|---------------------|--|
| Pre-Compare | Optional | Algorithms of this type may be used to adjust the data after it is moved to the target system. These may only be defined on the primary instruction. Refer to Adjusting Imported Data for more information. |
| Import | Optional | Algorithms of this type are no longer supported. |

Understanding the BO Filtering Process

Migration plan instructions require the definition of a business object to provide CMA with information about the record related to the instruction.

If the business object is the physical business object for the maintenance object, then CMA assumes that the instruction applies to all records that satisfy the traversal criteria. CMA recognizes the physical BO by comparing the BO to the value defined in the maintenance object option. If the business object defined is not the physical BO, then CMA will limit the records in the instruction to those that explicitly reference this BO or reference a child of this BO as its [identifying BO](#) value. (In other words, this BO must be in the parentage hierarchy of the records to be included in the instruction.)

Note: Unlike Bundling, CMA does not use the BO schema to drive what data is copied for a given record. The BO is only used as a filtering mechanism for selecting records. Refer to [Identifying Tables to Exclude from Migration](#) for information about how to ensure a child table is not included in a migration.

For example, if you define a migration plan for Master Configuration and use the physical business object for the instruction (**F1-MstCfgPhysicalBO**) then all master configuration records are considered for the instruction. If instead the business object you define is Migration Assistant Configuration (**F1-MigrationAssistantConfig**) then only the record related to this business object is included in the instruction.

Migration Plans for Objects with XML-Embedded Links

When migrating objects where foreign key references are captured in the object's XML based field, subordinate instructions are needed to define the foreign key references in order for CMA to understand the relationships. This is in contrast to direct foreign keys where CMA can determine the relationships using constraints. The instructions provide two purposes. Defining instructions ensures that the related objects are included in the migration, if appropriate. If you know that the related objects are included because of other criteria, the instructions allow CMA to group related objects into transactions. This helps in the apply process at import time to ensure that related objects

are grouped together. However, the apply process includes iterative steps to try to overcome dependencies like this so defining the instructions is not critical for this purpose.

The following are options for creating migration plans with XML-embedded links:

- One option is to use the specific logical (business) BO in the primary instruction to define the object you are copying. With this option, the subordinate instructions may use XPath criteria to define the related foreign key. When this approach is used, a separate Migration Plan must be created for each logical BO. (Refer to [Understanding the BO Filtering Process](#) for more information.) This option would only be used in isolated cases.
- Another option is to create a migration plan that uses the Physical BO as the primary instruction, and then include a subordinate instruction for the real logical BO, using SQL Traversal to join the object to itself by its primary key. Note that with this technique, the records that reference the logical BO will still only be included in the export file once. At this point further subordinate instructions may use XPath notation to define the foreign key data. Using the physical BO as the primary instruction ensures that all records in the MO are considered. The subordinate instructions with the logical BO and XPath notations will only apply to the records that are applicable to that BO. This option is useful for MOs that have a small number of logical business objects with disparate foreign keys.
- Another option is to use the physical BO in the primary instruction and use raw SQLs in the subordinate instruction's traversal criteria to identify the foreign keys using substring commands. A separate Subordinate Instruction is needed for each SQL corresponding to each element occurrence. Using this technique has the same advantages of the previous in that all records for the MO are included in the migration. However, this technique may be useful for maintenance objects with a larger number of business objects expected where each has one or more foreign keys. It's especially useful if many business objects reference the same foreign key. Then only one instruction is required for that foreign key. Note that a single migration plan may use this technique and the XPath technique for different elements.

A migration request may have multiple migration plans for the same maintenance object. That allows for some flexibility and long term maintainability in that the above techniques may be used in multiple migration plans. Consider the following example:

- A product provides base business objects with foreign keys defined in the XML field and provides the appropriate migration plan with instructions. An implementation extends this business object or perhaps creates their own business object for the same maintenance object and includes different additional foreign keys in the XML. Rather than duplicating the base migration plan and adding additional instructions for the additional foreign keys, the implementation can create a second migration plan for the MO with the additional foreign keys defined. A migration request should be defined to include both migration plans. In this case if the implementation has only one custom BO, they can choose to use the custom BO as the primary instruction as described above in the first option.

Defining a Migration Request

Migration Requests are used to define the data to be included in a migration. To view or define a migration request, navigate using **Admin > Implementation Tools > Migration Request**.

Use the **Migration Request Query** portal to search for an existing migration request. Once a migration plan is selected, you are brought to the maintenance portal to view and maintain the selected record.

There are three types or classes of migration request. The system provides a base business object for each along with a migration request class, which matches the business object. The subsequent sections provide more information about each class of migration request.

Note that all migration requests support defining a Category, which allows implementers to categorize the migration request.

In addition, all classes of migration request include the following zones:

- **Migration Request** This zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.
- **Referencing Migration Requests** This zone is only visible if the displayed migration request is included in a Group migration request. It lists each group migration request that includes it.

Other zones may appear for specific classes of migration requests. See the following sections for more information.

Criteria-based

This type of migration request defines a set of entities to be logically included together as part of a migration. For each migration instruction, selection criteria is defined to indicate which records for each MO should be included. Selection may be defined using SQL, an algorithm, an entity tag or explicit primary key values.

- For selection using SQL Statement, refer to the embedded help for examples.
- For selection using Algorithm, the algorithms that are eligible to be plugged in here are those valid for the **Migration Request - Select** system event.
- For selection using Entity Tag, reference a tag name. The entities linked to the tag at export time would be included in the export file.
- For selection using Specific Keys, the primary key (1 through 5) must be explicitly specified. Multiple rows are allowed.

Entity List

This type of migration request allows the user to choose explicit MO / prime keys. The MOs that are eligible are those that are configured with a **Default Migration Plan** option. Although the user is managing MO / PKs, the migration instructions are still defined with a migration plan. The system maps the migration instructions in a similar way to a **Criteria-based** migration requests that use a Specific Key selection type. Note however that it will create a separate migration instruction for each MO / PK combination. It does not try to group all PKs for the same MO / migration under one migration instruction.

For this type of migration request, a user adds a migration request record with its description and other main information. Then, a special zone **Add Entities** is provided to find and select records based on a selected maintenance object and add to the migration request. The user is prompted to provide a reference and comments, if desired. If the category selected is one that requires a reference, then this will be validated. Alternatively, you may also use the [Collect Entity](#) zone to add specific entities as you review them on their respective maintenance portals.

When maintaining a migration request with existing entities, they are visible in the zone **Migration Request Entities**. This zone allows a user to remove the entity from the list.

Group

This type of migration request points to other migration requests. This allows you to define separate migration requests that represent logical groupings of migration plan instructions for ease of maintenance, but to combine all the separate migration requests into a single "grouped" migration request for streamlined export / import purposes.

The CMA export process will build an extract that includes the union of all the objects that qualify for the export and group them together based on their relationships.

Identifying Tables to Exclude From Migrations

Some maintenance objects that are eligible to be migrated may include child tables that should not be included in the migration. For example, if an object includes log tables, the entries in the log should reflect the actions on the object in that system, and will be different between the source system and the target system. If you have a custom Maintenance Object that includes tables you don't wish to migrate (such as a log table), use the **Non-Migrated Table** option on the MO to specify this table. All child records for this table will also be ignored during migration.

Another use case to consider is a child "many-to-many" table that connects two administrative objects and exists in the maintenance object of both tables. The child table may be in both MOs for convenience sake, but it may be that one MO is considered more of a "driver" object and the other more of a subordinate. If you are doing a migration where you want to copy a subset of objects, you may want to only copy the driver object and its children and their data but not their children. For example, a To Do Type includes a collection of valid To Do Roles and in turn the To Do Role refers to its To Do Types. If an implementation wants to copy a single To Do and include all its related information, including its To Do Roles, it does not want the migration of each To Do Role to in turn copy all its To Do Types (and their data).

Note: The MO option must be set in both the Source and Target systems for a given MO.

Configuring Custom Objects for Migration

During the implementation and extension of the product, new custom administrative maintenance objects may be introduced. If your implementation would like to migrate records in those maintenance objects using the Content Migration Assistant, additional steps must be performed, which are highlighted in the following sections.

Physical Business Object

As described in [Understanding the BO Filtering Process](#), the migration plan requires a business object for its instruction. The business object is used to identify the records eligible for inclusion in the migration. Assuming your custom tables use one or more "logical" business objects for their processing, your implementation must decide if these business objects are appropriate for use by the migration plans, or if a physical BO is warranted. If so, [create an appropriate physical BO](#).

Review MO Option Configuration

The following points highlight maintenance object (MO) configuration that should be reviewed or updated to support CMA:

- If a physical BO was created (above), link it to the MO as an option using the appropriate option type.
- Be sure that your MO defines an appropriate [FK Reference](#) and includes an Option on the MO that identifies the FK Reference. This is used by various portals and zones for CMA when showing detail about records being imported into the target region. Also be sure that this FK reference defines an Information program.
- As described in [Identifying Tables to Exclude From Migrations](#), an MO option is used to identify child tables for an MO that should never be included in a migration. If your custom maintenance object includes a standard Log table, then the recommendation is to list that table as an excluded table. Depending on the specific design of the maintenance object, there may be other child tables to define.

Characteristic Type Configuration

The CMA import process will attempt to create a log record for any administrative object that includes a log table. If your implementation has introduced any custom administrative tables that you plan to include in a migration request and it includes a log table, you must, to ensure that the log creation is successful, add your log table as a valid characteristic entity to the characteristic type **F1-MGO** (Migration Object).

Navigate to [Characteristic Type](#) and select the characteristic type **F1-MGO**. Navigate to the **Characteristic Entity** tab and add a row to include the characteristic entity for your custom maintenance object's log table.

Standard CMA Configuration

Create one or more migration plans for the new object, depending on the type of data in the maintenance object and the types of migrations you envision:

- If you have implemented only one "logical" business object used to define the data in the MO, then a single migration plan that references the this BO (or the maybe the MO's physical BO) is appropriate.
- If you have implemented more than one "logical" business object, would the data for multiple business objects get copied together? Then perhaps a single migration plan that references the MO's physical BO is appropriate.
- Are there additional foreign keys defined using mapXML in the business object(s) for the MO? If so, then it is recommended to include sub-instructions to define the links. At this point, if multiple "logical" BOs exist, your implementation may choose to define all the additional elements in the same migration plan or choose to define separate migration plans for each logical BO.
- Your implementation may decide to define more than one migration plan for the same type of record based on the types of migrations you plan to include. For example, you may decide to include a migration plan that copies only the records in this maintenance object. You may decide to define another migration plan that copies the records in this MO along with related records in another MO (for a special type of migration). Having said that, be sure to design the migration plan with reuse in mind to minimize maintenance efforts.

In order to support **Entity List** migration request, a default migration plan must be defined as an option on the maintenance object. This should be a single migration plan that supports all types of business objects for the MO.

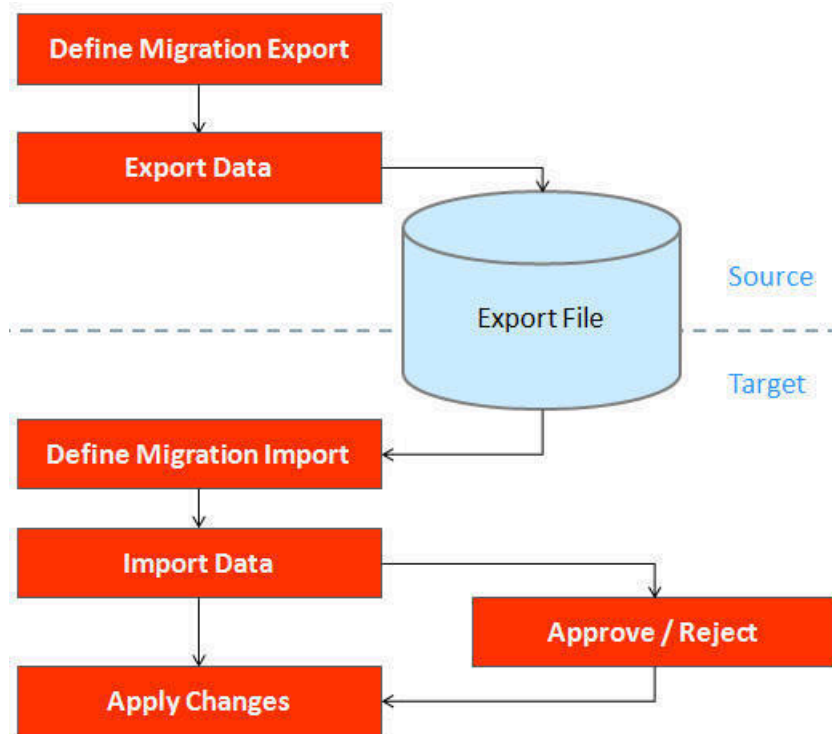

If your implementation has a template migration request to use for migrations, include the new migration plan(s) as appropriate.

CAUTION: Important! New migration plans and migration requests should follow naming conventions. Refer to [System Data Naming Convention](#) for more information.

The CMA Execution Process

The following diagram illustrates a high-level view of the Content Migration Assistant execution process. The subprocesses illustrated here are described in more detail in the following sections.

Exporting a Migration

The migration export process begins in the source environment by defining a **Migration Data Set Export**, which specifies a defined **Migration Request** and provides a file name and description for the export file. After the data set is defined and saved, the **Migration Data Set Export Monitor** batch job can be submitted generate the export file. The lifecycle of the Migration Data Set Export business object includes algorithms that select the appropriate records according to the migration request, determine dependencies between records to build groupings of related objects and create the export file.

The following topics provide more detail about this process.

Migration Data Set Export

To migrate data from one region to another, define a **Migration Data Set Export**. This establishes the export file name and identifies the migration request.

To view an existing migration data set export, navigate using **Admin > Implementation Tools > Migration Data Set Export**. Use the query criteria to locate the desired data set.

Note that you can also initiate the creation of an export data set from the [Migration Request](#) portal using the **Export** button.

The export requires the name of an existing **Migration Request**.

Enter a unique **File Name** for the export. Do not use spaces in the name, and do not enter the file extension or a path. The output location and file extension of the intended export file, which should appear in the **Export Directory** and **File Suffix** labels, are defined as described in the topic [Migration Assistant Configuration](#).

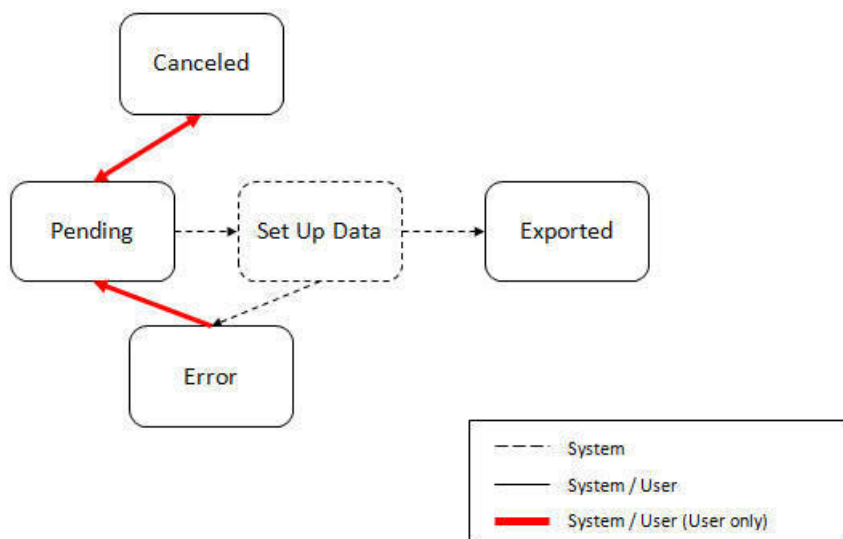

Enter an **Export Description** to provide information about the purpose of the export. Note that this field is not language enabled.

The **Source Environment Reference** is for information purposes. It should be populated with text that provides a meaningful description of the source environment. The default value is the URL of the source environment.

The **Migration File Version** is only visible if the product currently supports creating a file in an earlier [file format version](#). If this element is visible and you are planning to import the file in a target environment that uses an older migration file format version, indicate the lower file format version that you wish the export to use.

Export Lifecycle

The following diagram describes the lifecycle of a Migration Data Set Export (data set).

The following points describe the lifecycle.

- The data set is created in **Pending** status.
- A user may choose to temporarily **Cancel** a pending data set to prevent it from being processed. The user can later return it to the Pending state when desired.
- The record remains in Pending until its monitor batch job is submitted. The **Migration Data Set Export Monitor** (F1–MGDPR) selects pending records and transitions them to **Set up data**. Refer to [Running Batch Jobs](#) for more information.
- Set up data is a transitory state that includes the algorithm that does the work of determining the objects to include in the export and group related objects together into a transaction. If everything is successful, the export file is written to the appropriate file location and the record transitions to **Exported**. If an error is detected, the process stops and the record transitions to **Error**.
- If a record is in error and it is possible to correct the error, the record may be transitioned back to Pending to try again.

When the process is marked as **Exported**, the export file can be imported into the target system.

Note: The export process creates a file, providing the benefits of having a standalone file. It can be stored in a version control system for audit purposes or provided to others for import purposes.

CAUTION: Under no circumstances should exported data files be edited manually. Doing so could cause data corruption when the file content is applied to the target environment.

Note: The export functionality is supported using the business object **Migration Data Set Export** (F1-MigrDataSetExport). The expectation is that implementations will use the delivered base business object and its logic and will have no reason to implement a custom business object for the CMA export process.

Importing and Applying a Migration

The import process is broken down into four general steps: Import, Compare, Approve, Apply. The following points provide an overview of the steps.

- **Import.** The first step covers importing the file and creating appropriate Migration Import records in the target environment to facilitate the subsequent steps.
- **Compare.** The compare step reviews each object that is in the import file and compares the object in the import against the equivalent record in the target environment. The comparison step results in noting which objects are unchanged, which are new (and the appropriate SQL to insert them) and which objects are changed (and the appropriate SQL to update them). Based on user configuration at import time, the objects that qualify for the import may be in a state that requires review or may be pre-approved.
- **Approve.** Once the comparison is complete, the user should review the results. There may be records marked for review. All of these records must be approved or rejected before the import can proceed. Users may choose to

suppress individual SQL statements for a given object that is approved. When the user is satisfied with the results of the comparison and has completed the review, the import is marked to proceed to the Apply step. Optionally, a migration import may be configured to automatically apply.

- **Apply.** This is the final step and is the step where the records in the target environment are added or updated. Because of potential high volumes of data and because of possible dependencies between records, this step supports two levels of attempting to apply the records. There is an apply step at the object level and an apply step at the transaction level. This will be described in more detail below.

Import Step

The import process starts with verifying the import directory configured as described in the following topic [Master Configuration - Migration Assistant](#) and ensuring that the exported file is located in that directory. Then, in the target environment, a **Migration Data Set Import** record should be created. The user indicates the file name.

In addition, the user decides what the default status should be for resulting objects.

- The **Default Status for Add** sets the default status for objects that are determined to be *new* during the import comparison process. The default is to automatically set new objects to **Approved** status. Other options are to set any new objects to **Rejected** or **Needs Review** status.
- The **Default Status for Change** sets the default status for objects that are determined to be *changed* during the import comparison process. As with new objects, the default for changed objects is **Approved**, with **Rejected** or **Needs Review** options available.

The user may also configure the **Automatically Apply** flag to **Yes**. This allows for use cases where the migration is repetitive and has been tested and the user feels that there is no need for manual approval. Note that when configuring this setting, neither of the Default Status values may be set to **Needs Review** and at least one must be set to **Approved**.

The file to import contains a list of all the objects included in the export. Any objects that the export step determined to be related have been grouped into “transactions”. Once the Migration Data Set Import is created, the next step is for the system to read in the file and create Migration Transactions and Migration Objects.

By default, the import step creates a Migration Object for each entity in the file. When importing a high volume data set of business entities, the user may request to import entities in bulk mode for performance reasons. In this mode, a single Migration Object record may contain multiple entities from the file. If at least one of the entities included in the migration object record is new and the remaining ones are either new or unchanged then the **Default Status for Add** setting applies to it. If at least one included entity is determined to be changed then the **Default Status for Change** applies to the record. Refer to [bulk import mode](#) for more information.

The following is a portion of the Migration Data Set Import lifecycle as it pertains to the import step.

The following points describe the lifecycle.

- The data set is created in **Pending** status.
- The record remains in Pending until its monitor batch job is submitted. The **Migration Data Set Import Monitor** (F1-MGDIM) selects pending records and transitions them to **Ready to Compare**. Refer to [Import Process Summary](#) and [Running Batch Jobs](#) for more information.

The Ready to Compare state has an algorithm that is responsible for reading the related import file and creating the migration transactions and migration objects. The data set remains in this state until the comparison step is complete.

Note: A user may choose to **Cancel** a data set. Refer to [Cancelling a Data Set](#) for more information.

The following diagram highlights the relationships of the resulting migration import records.

The migration transaction and migration object each have their own lifecycle that will help manage the subsequent compare and apply steps. At the end of the import step, the status values of the three types of records are as follows:

- Migration Data Set Import is in the **Ready to Compare** state.
- Migration Transaction is in the **Pending** state.
- Migration Object is in the **Pending** state.

Note: The import functionality is supported using business objects supplied by the base product. The expectation is that implementations will use the delivered base business objects and their logic and will have no reason to implement a custom business objects for the CMA import process. The base business objects are **Migration Data Set Import** (F1-MigrObjectImport), **Migration Transaction** (F1-MigrTransactionImport) and **Migration Object** (F1-MigrObjectImport).

Compare Step

The import step results in the creation of one or more migration objects. Typically, one migration record is created for each record selected in the export based on the export's migration request and its configuration. Related objects are grouped together in migration transactions.

When importing a high volume data set of business entities, the user may request to import entities in bulk mode for performance reasons. In this mode, a single Migration Object record may contain multiple entities from the file. Refer to [bulk import mode](#) for more information.

The next step in the import process is the Comparison step. In this step, the data captured by the import file for each object is compared to the view of that object in the target environment.

To cater for a possible large volume of objects, the comparison is done via a batch monitor. To aide in performance of the process, the monitor is performed on the migration objects so that it can be run multi-threaded. Once the objects are finished with the comparison, the migration transactions and the migration data set should be updated with an appropriate overall status before continuing to the next step. As a result, the comparison actually requires three steps: Migration Object Comparison, Migration Transaction Status Update and Migration Data Set Export Status Update. The steps are explained in detail in the following sections.

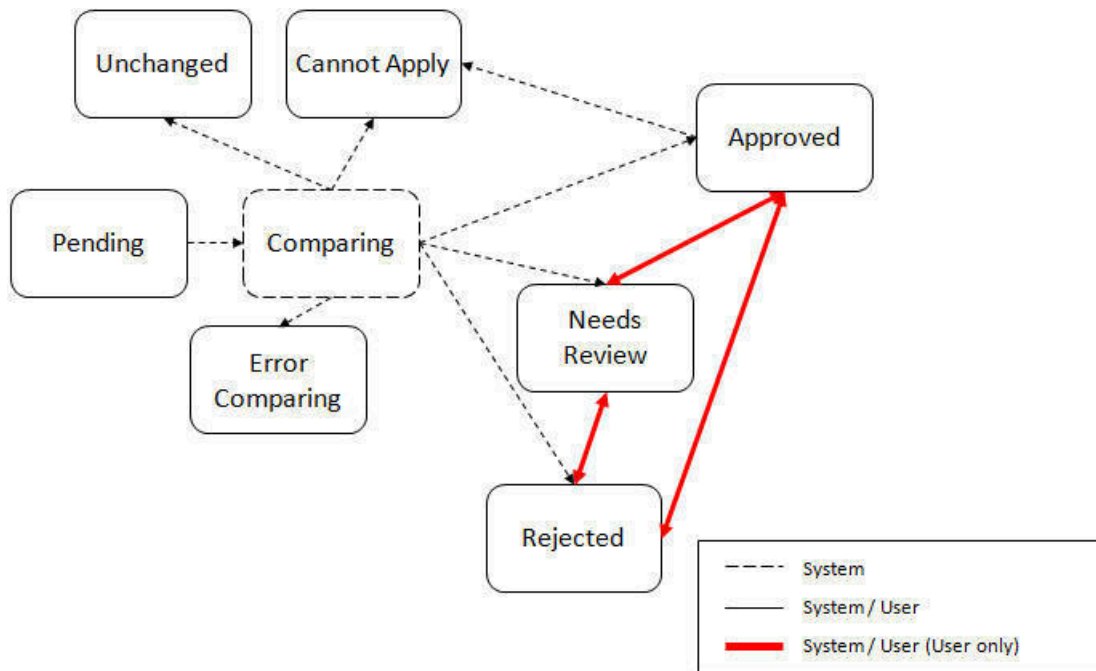

Note: Refer to [Running Batch Jobs](#) for more information about streamlining the various steps in the process.

Migration Object Compare

This is the main step of the comparison. The **Migration Object Monitor** (F1-MGOPR) selects pending migration object records and transitions them to **Comparing**. This is a transitory state that includes the algorithm that does the work of comparing. There are various possible outcomes that could occur based on the logic in the algorithm. The following diagram illustrates a portion of the migration object lifecycle that pertains to comparison.

Note: When using [separate batch processes for business data](#) the **Migration Object Monitor (Business)** process (F1-MGOPB) works in the same way to compare business migration objects.

The following points describe the lifecycle.

- When **Pending** records are selected by the monitor batch job, it transitions to **Comparing**. If the migration object refers to one or more pre-compare algorithms, they are executed to [adjust the data prior to comparison](#). Then algorithm will determine the appropriate next state by comparing the source data to the target data.
- Entity related notes:
 - If the record in the migration object is found in the target environment and the data is exactly the same, the record transitions to **Unchanged** (with the object action value also set to **Unchanged**).
 - If the record in the migration object is found in the target environment and the data is different, the algorithm sets the object action value to **Change** and generates the appropriate SQL to be used later in the Apply step to update the record. It then transitions to **Approved**, **Needs Review** or **Rejected** based on the Default Status For Change setting captured on the Data Set.
 - If the record in the migration object is not found in the target environment, the algorithm sets the object action value to **Add** and generates the appropriate SQL to be used later in the Apply step to insert the record. It then transitions to **Approved**, **Needs Review** or **Rejected** based on the Default Status For Add setting captured on the Data Set.
 - When the import is performed in [bulk mode](#) each included entity is compared separately but the overall status of the record is set as follows:
 - If all included entities are unchanged then the migration object record transitions to **Unchanged** (with the object action value also set to **Unchanged**).
 - If all included entities are either unchanged or changed then the object action value is set to **Change**, corresponding SQLs are generated for the changed entities only and the migration object transitions based on the Default Status For Change setting captured on the Data Set.
 - If all included entities are either unchanged or new then the object action value is set to **Add**, corresponding SQLs are generated for the new entities only and the migration object transitions based on the Default Status For Add setting captured on the Data Set.
 - If some of the included entities are new and some changed then the object action value is set to **Mixed Actions**, corresponding SQLs are generated for the each entity and the migration object transitions based on the Default Status For Change setting captured on the Data Set.

- If there is any issue with attempting to parse the object data from the import, the record transitions to **Error Comparing**.
- If there is any reason that the imported object is not valid for import, the record transitions to **Cannot Apply**. The log will be updated with the error that caused the record to transition to this state. An example is that perhaps the record was exported in a different version of the product and has additional elements that are not recognized in this version.

Note: Refer to [Cancelling a Data Set](#) for information about cancelling a data set and its impact on its related objects.

Migration Transaction Status Update

After the import step, the migration transaction remains in the Pending state until all its objects have completed the comparison step. At that point, the status of the transactions should be updated based on the results of their objects. The **Migration Transaction Monitor** (F1-MGTPR) selects pending migration transaction records and runs its monitor algorithms. There are various possible outcomes that could occur based on the logic in the algorithms. The following diagram illustrates a portion of the migration transaction lifecycle that pertains to comparison.

The following points describe the lifecycle possible next states after Pending.

- If any related migration object is in the Error Comparing state, the transaction transitions to **Error Comparing**.
- If all related migration objects are in the Unchanged state, the transaction transitions to **Unchanged**.
- Otherwise, the transaction transitions to **Ready to Apply**. This means that at least one object is in an “apply-able” state.

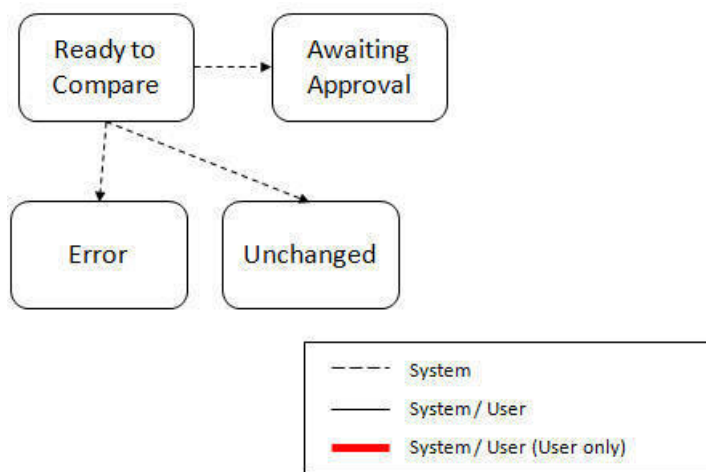

The transaction remains in the **Ready to Apply** state until a user has approved the data set to move to the Apply step and the transaction’s related objects have attempted to apply themselves. This is described in more detail below.

Note: Refer to [Cancelling a Data Set](#) for information about cancelling a data set and its impact on its related objects.

Migration Data Set Import Status Update

Once all the objects and all transactions have been updated via the previous two steps, the migration data set export must be updated based on the results of their transactions. The **Migration Data Set Import Monitor** (F1-MGDIM) selects Ready to Compare data sets and runs its monitor algorithms. Note that this is the same monitor process that is used to select Pending data sets. There are various possible outcomes that could occur based on the logic in the algorithms. The following diagram illustrates the portion of the migration transaction lifecycle that pertains to comparison.

The following points describe the lifecycle possible next states after Ready to Compare.

- If any related migration transactions is in the Error Comparing state, the data set transitions to **Error**.
- If all related migration transactions are in the Unchanged state, the data set transitions to **Unchanged**.
- Otherwise, the transaction transitions to **Awaiting Approval**. This means that there are no errors and at least one object is in an “apply-able” state.

The data set remains in the **Awaiting Approval** state until a user decides that the data set and all its records are ready to progress to the Apply step.

Note: A user can choose to cancel a data set at any time while it is in progress. Refer to [Cancelling a Data Set](#) for more information.

Approval Step

Once the comparison is complete and the data set transitions to the Awaiting Approval state, a user needs to progress the data set to **Apply Objects** to trigger the Apply step. The following points describe steps a user may take during the approval step.

- If the data set configuration for the Default State for Add and Change was set to **Approved**, then any migration object that is determined to be eligible for the Apply step will be in the Approved state. In this situation, a user may want to review the data set and its transactions and objects to see verify that the results make sense. At that time, the user is able to move an object to Needs Review or Rejected as appropriate.
- If the data set configuration for the Default State for Add and Change was set to **Needs Review** for either option, then each migration object in the Needs Review state must be reviewed and the user must either Reject or Approve each object before moving to the Apply step.
- If the data set configuration for the Default State for Add and Change was set to **Rejected** for either option, the assumption is that the rejected records don’t need to be reviewed. But if a user finds a rejected record that shouldn’t be rejected, it may be transitioned to Approved (or Needs Review) as appropriate.

A user has the option to mark one or more SQLs within a migration object to be suppressed. In this case, if the migration object is approved, then only the SQLs that are not marked as Suppressed will be applied. This option is useful when importing a record that has many child records. It may be that the user wants to only include a subset of the child records. This may be done by suppressing the child records that should not be included.

Once the user is comfortable with the data set's results and no more objects are in the Needs Review state, the user should transition the record to **Apply Objects**. This will initiate the Apply step.

Alternatively, if the Automatically Apply flag was set to **Yes** when creating the import record, the import data set will progress from **Awaiting Approval** to **Apply Objects**. Refer to [Import Process Summary](#) for more information.

Note: Refer to [Maintaining Import Data](#) for details about the pages provided to help the user review a data set and its transactions and objects to help in the approval step.

Note: A user can choose to cancel a data set at any time while it is in progress.

Apply Step

The apply step is the step where records in the target environment are added or updated. Like the comparison step, the apply step is actually multiple steps to optimally handle high volume and dependencies between records as smoothly as possible.

Note: Refer to [Running Batch Jobs](#) for more information about streamlining the various steps in the process.

Before explaining the apply steps in detail, the following points highlight the type of data that may be included in a given data set.

1. Records that have no foreign keys and therefore no dependencies on other records. Examples: Message, Display Profile.
2. Records that have foreign keys that may already be in the target. Examples: Algorithms for existing algorithm types, To Do Roles for existing To Do Types.
3. Records that have foreign keys that are new records but also part of the migration. CMA detected the relationship at export time and grouped the objects in the same transaction. Example: Script-based Algorithm Type where the script is also in the migration.
4. Records that have foreign keys that are new records but also part of the migration. CMA did not detect the relationship. This may occur if the referenced foreign key is in a XML or parameter column and the migration plan did not include an instruction to explicitly define the relationship. Example, a Zone that references a visibility script.
5. Records that have circular references where both records are new and are part of the migration. CMA detected the relationship at export time and grouped the objects in the same transaction. Example: plug-in Script for a BO plug-in spot. The script references the BO and the BO references an algorithm for the script's algorithm type. Another example is when the same record is maintained by multiple maintenance objects and therefore exists in multiple migration objects.

To handle high volume data, the first step in the apply process is to perform the apply logic at the migration object level via a multi-threaded batch job. This should result in all records in categories 1 and 2 above being applied successfully.

For records in categories 3 and 4 above, if a record with a foreign key is added or updated before its related record, the validation will fail. However, if the related record is added first and then the record referring to it is added, validation will pass. The tool handles these dependencies as follows:

- Dependency between master and transaction entities is typically hierarchical and in most cases straight-forward. The tool leverages that knowledge to orchestrate the processing of objects in an optimal way that follows their dependency order as much as possible. Note that relationship between entities could be complex and this approach does not eliminate all processing order related errors but rather significantly reduce them.
- Dependency between configuration entities is more complex and inter-twined and therefore migration objects are not ordered, i.e. the multi-threaded batch process may not process records in the desired order.
- To overcome the potential issue of processing order related errors, the Apply step has special functionality, described in detail below.

For records in category 5 above, the circular reference will mean that the apply process at the object level will not successfully add or update these records. The apply process at the transaction level will cover these records. This is described in detail below.

Apply Objects

Once the Data Set is in the state of **Apply Objects**, the **Migration Object Monitor - Apply** process (F1-MGOAP) runs to attempt to apply the objects.

Note:

When using [separate batch processes for business data](#) the **Migration Object Monitor (Business)- Apply** process (F1-MGOAB) works in the same way to apply business migration objects.

The background process in conjunction with the Apply algorithm have special functionality to ensure records in categories 3 and 4 (above) successfully apply during this step:

- The **Migration Object Monitor - Apply** process is a special one that continually re-selects records in the **Approved** state until there are no more eligible records to process.
- When an error is received in the Apply Object algorithm, the algorithm increments an "iteration count" on the migration object record. If the iteration count does not exceed a maximum count (noted in the algorithm), the object remains in the **Approved** state and is eligible to be picked up for processing again. If the iteration count exceeds the maximum defined in the algorithm, the record transitions to the **Error Applying** state.

Note: When submitting this Apply batch job, be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker. Doing this will cause the 'excess' threads to wait for the supported number of threads to finish.

The following diagram is the portion of the migration object lifecycle that pertains to the Apply step.

At the completion of the Apply monitor process, typically the objects will be in the **Applied** state or the **Error Applying** state. The records in the Error Applying state are in that state for one of two reasons.

- They are in category 5 described above where the records have a circular reference with another record. For this scenario, the Apply Transactions step described below should successfully apply the records.
- There is some other error that is unrelated to the records in the current migration. In this case, manual intervention may be required. Refer to the [Resolving Errors](#) section below for more information.

As shown in the diagram, the Apply Objects algorithm may also detect a reason that the object cannot be applied. This may occur if the object in the target environment has been updated since the comparison step, making the SQL captured at that point no longer applicable. If this occurs, after the current migration is fully applied, the original file may be imported again, and new comparisons can be generated and applied.

Apply Transactions

Ideally, after the Apply Objects step, all the objects are **Applied** or are in **Error Applying** due to the "circular reference" situation. The typical next step is to turn over responsibility to the transactions. The migration transactions can then attempt to apply their objects in bulk.

In order to ensure that multiple background processes are not trying to select migration objects to run the Apply step, the Transactions are only eligible to attempt to "apply my objects" if the Data Set is in the **Apply Transactions** state.

A monitor algorithm (executed by the data set monitor batch process) on the Apply Objects state checks to see if all migration objects are no longer **Approved** or the count of records in **Error Applying** does not exceed a configured limit. If so, it automatically transitions the record to the **Apply Transactions** state.

If the number of objects in **Error Applying** exceeds a configured limit, the monitor algorithm does not automatically transition the record. In that case, a user must determine if the large number of errors can be resolved or manually transition to **Apply Transactions** (despite the large number of errors). The [Resolving Errors](#) section below describes alternative steps that the user may take if there are errors.

Once the Data Set is in the state of **Apply Transactions**, the **Migration Transaction Monitor - Apply** process (F1-MGTAP) runs. It attempts to apply the transaction's objects. If no migration objects are in error, the migration transaction simply transitions to **Applied**. If any of the migration objects are in **Error Applying**, the background process and the Apply algorithm have special functionality to try to overcome dependencies in migrated objects:

- The Apply algorithm selects all migration objects in error and performs all their SQL, then validates all the records. If there are objects in the transaction with circular references, they should pass validation at this point.
- Because there may still be some dependencies across transactions, similar error handling described in the Apply Objects step occurs here. When an error is received in the Apply Transaction's Object algorithm for any of the objects in the transaction, the algorithm increments an "iteration count" on the migration transaction record. If the iteration count does not exceed a maximum count (noted in the algorithm), the transaction remains in the **Ready to Apply** state and is eligible to be picked up for processing again. If the iteration count exceeds the maximum, the record transitions to the **Error Applying** state. Note that if any objects in the transaction are in error, none of the objects are applied. They all remain in error.
- The **Migration Transaction Monitor - Apply** process is a special one that continually re-selects records in the **Ready to Apply** state until there are no more eligible records to process.

Note: When submitting this Apply batch job, be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker. Doing this will cause the 'excess' threads to wait for the supported number of threads to finish, erasing the benefit of the iteration processing.

The following diagram is the portion of the migration transaction lifecycle that pertains to the Apply step illustrating the points above.

If at the end of the transaction level Apply process there are transactions in error (and therefore there are still objects in error), a user must review the errors and determine how to fix them. Refer to the [Resolving Errors](#) section below for more information.

Resolving Errors

As mentioned in the previous sections, errors may be received after the Apply Objects process runs. If the number of records in error is below a certain limit (and the data set monitor batch job is submitted to execute the monitor algorithms) the system will automatically transition the data set to the **Apply Transactions**. If the monitor batch job is not run or if the number of objects in error exceeds a certain limit, a user must make the decision after viewing the errors in the Objects in Error zone on the [Migration Data Set Import](#) portal.

- If the errors appear to be dependency related, the user can decide to let the "transactions apply their objects" and transition the data set to **Apply Transactions**, described above.
- If the errors appear to be related to an outside issue that can be manually resolved, the user may choose to fix the issue and redo the Apply Objects step.
- The user may also decide to reject one or more objects to remove them from the migration.

After the Apply Transactions step, if there are still errors, a user must review the records and determine how to proceed. Errors are visible in the **Transactions in Error** zone on the [Migration Data Set Import](#) portal.

- The user may decide to reject one or more objects to remove them from the migration.
- The user may manually resolve an issue external to the migration and then decide to do one of the following:
 - Redo the **Apply Objects** step. This is recommended if there are a large number of Objects still in error and not a large number of dependencies expected. The benefits of running the Apply Objects multi-threaded will ensure that the process runs efficiently.
 - Redo the **Apply Transactions** step.

Because the objects and transactions are in Error Applying, in order to "retry" the Apply step after manually fixing an error, the system needs to move the records back to the state that allows them to be picked up by the appropriate Apply process. For migration objects, records need to be moved back to **Approved**. For migration transactions, records need to be moved back to **Ready to Apply**. The following points describe the Retry logic for migration objects.

- If a user decides to **Retry Objects** (using an action button on the Migration Data Set Import page), the data set transitions to the **Retry Objects** state. At this point the Migration Object monitor must be run.
- The monitor on the **Error Applying** state for the objects detects that the data set is in the state of **Retry Objects** and that triggers the transition back to **Approved**.
- The next step is to transition the data set from **Retry Objects** to **Apply Objects**. This may be done manually or by running the Migration Data Set Import monitor process.
- Now the objects are eligible to be picked up by the object level Apply process.

Analogous logic exists for the migration transactions.

- If a user decides to **Retry Transactions** (using an action button on the Migration Data Set Import page), the data set transitions to the **Retry Transactions** state. At this point the Migration Transaction monitor must be run.
- The monitor on the **Error Applying** state for the transactions detects that the data set is in the state of **Retry Transactions** and that triggers the transition back to **Ready to Apply**.
- The next step is to transition the data set from **Retry Transactions** to **Apply Transactions**. This may be done manually or by running the Migration Data Set Import monitor process.
- Now the transactions are eligible to be picked up by the transaction level Apply process.

The retry logic may also occur when transitioning between the Apply Objects and Apply Transactions depending on whether or not there are errors. The following scenario highlights this point.

- After the **Apply Objects** step there are objects in **Error Applying**. The data set transitions to **Apply Transactions** and the Apply step is done at the transaction level.
- After the **Apply Transactions** step there are transactions in **Error Applying**.

- User chooses to try to apply objects again (by clicking **Retry Objects**). The steps outlined above for retrying objects are followed at this point.
- After the apply objects, user may choose to retry objects again (after fixing errors if applicable).
- At some point the user will transition to **Apply Transactions** again. If there are transactions in **Error Applying**, the system will automatically transition the data set to **Retry Transactions** and the steps outlined above for retry transactions are followed.

Finalize Apply Step

Once all the migration objects for a migration transaction are in a final state (**Applied**, **Rejected** or **Cannot Apply**), the migration transaction transitions to the **Applied** state. Once all the migration transactions are in the **Applied** state, the Migration Data Set record transitions to the **Completed** and the import is complete.

Note: To review the full lifecycle for each record, refer to the Business Object - Summary tab in the application metadata for the base business objects **Migration Data Set Import** (F1-MigrObjectImport), **Migration Transaction** (F1-MigrTransactionImport) and **Migration Object** (F1-MigrObjectImport).

Adjusting Data Prior to Comparing

There are reasons that the data you are importing requires some adjustment before applying it in the target environment. In such cases, an algorithm plugged into the [migration plan](#) primary instruction may be used to adjust the data when importing. This algorithm is executed by the comparison algorithm before any comparison is performed. Algorithms of this system event receive the view of the source record (being imported) and the view of the existing record in the target region, if it exists. The data is provided using the physical BO of the migration plan's maintenance object. The algorithm may make changes and pass a new view of the record that should be used for the comparison. This system event supports multiple algorithms that are executed in sequence. Each algorithm receives the original record's data, the target record's data (if applicable) and the 'new' view of the data (as populated by previous algorithms, if any). The final 'new' view of the data is used for the object comparison. The system includes the algorithms linked to the primary instruction of the migration plan from the source environment. If the system finds any additional pre-compare algorithms linked to the migration plan's primary instruction in the target system, those algorithms are also executed.

Fastpath: Refer to [Base Business Objects](#) for more information about physical BOs.

Some examples of records that may require import algorithms.

- Batch Control references its next batch sequence number along with snapshot information like the last run date / time. This information is only relevant with respect to its environment. The instruction for a batch control can include an algorithm to not overwrite the batch sequence number when copying a batch control.
- Some products include administrative objects that reference a master data object. Master data objects are not copied as part of CMA. An import algorithm may be used to adjust the referenced master data foreign key when importing, for example to reset it (or not overwrite when updating). If the algorithm knows how to find the appropriate master data record to link, that may also be included.
- If you are importing data that from a source environment on a lower version, if the object you are importing has been enhanced in the latest release with a new required field, you may need to provide an algorithm to populate data in that field.

Note that it is possible to use the algorithm to "reset" the source data as a way of indicating that the record should not be imported. For these situations, the migration object comparison step will transition the record to **Unchanged** and will use an object action value of **Canceled**. (Note that object action is a simple lookup value. The record is not transitioned to the **Canceled** BO state as to reserve that status for user initiated cancellations of the object or one of its parent records). This technique not expected to be used often because ideally using appropriate selection criteria at export time should ensure that the only records exported are those that should be imported.

Note: Legacy 'Import' system event. The system originally provided an Import system event / plug-in spot. The purpose of algorithms for this plug-in spot were similar in that they were meant to adjust imported data prior to adding or updating. The algorithms were executed in the Apply step. The logic does not allow for easily interacting with the record using a BO. This makes it difficult to use a plug-in script as the plug-in

type. In addition, it is difficult to update elements in an XML column. The support for the plug-in spot will be removed in a future release. Algorithms to adjust the data should be using the pre-compare system event.

Import Process Summary

The following table summarizes the steps required to complete the import process from start to finish. Note that this section **only a summary** and assumes that you are familiar with the details described in the previous sections. It highlights what steps are manual and what steps are performed by a batch monitor process. For each step, the table highlights the Next Action sequence that would occur. For the Apply steps, there are two parts where multiple next actions are possible based on whether there are errors and the user’s decision on how to resolve the error. Refer to [Resolving Errors](#) for more information. The possible next actions have the same sequence with a letter following the sequence highlighting the action to take based on the results of the previous step.

Note: When running the Apply batch jobs, be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker.

Also note that a sequence and action marked in bold is considered the “normal path”.

When using [separate batch processes for business data](#) any reference to a migration object monitor batch process applies also to the business data related batch controls.

| Step | Seq | Action | Manual / Batch | Portal - Action | Batch Control | Record Impacted - Resulting Status | Next Action Sequence |
|--------|-----------|-----------------------------|----------------|---------------------------------|---|---|----------------------|
| Import | 10 | Create Import record | Manual | Migration Data Set Import - Add | | Migration Data Set Import - Pending | 11 |
| | 11 | Import file | Batch | | F1- MGDIM - Migration Data Set Import Monitor | Migration Data Set Import - Ready to Compare Migration Transaction - Pending Migration Object - Pending | 20 |

| Step | Seq | Action | Manual / Batch | Portal - Action | Batch Control | Record Impacted - Resulting Status | Next Action Sequence |
|---------|-----|--|----------------|-----------------|---|--|----------------------|
| Compare | 20 | Migration Object Compare | Batch | | F1-MGOPR - Migration Object Monitor [When using separate business data processes submit also F1-MGOPB (Migration Object Monitor (Business))] | Migration Object - Approved, Needs Review, Rejected, Unchanged or Error Comparing | 21 |
| | 21 | Migration Transaction status update | Batch | | F1-MGTPR - Migration Transaction Monitor | Migration Transaction - Ready to Apply, Unchanged or Error Comparing | 22 |
| | 22 | Migration Data Set Import status update | Batch | | F1-MGDIM - Migration Data Set Import Monitor | Migration Data Set Import - Awaiting Approval, Apply Objects (if configured for Automatic Apply), Unchanged or Error | 30 |

| Step | Seq | Action | Manual / Batch | Portal - Action | Batch Control | Record Impacted - Resulting Status | Next Action Sequence |
|----------|-----|--|----------------|---|---|--|---|
| Approval | 30 | <p>Review comparison results, approve / reject as needed</p> <p>(This step is skipped if the data set is configured for Automatic Apply)</p> | Manual | Migration Data Set Import, drill in to the Transactions / Objects as necessary. | | <p>Migration Object - Approved or Rejected (no records should be in Needs Review)</p> <p>Migration Data Set Import - Apply Objects</p> | 40 |
| Apply | 40 | Apply Objects | Batch | | <p>F1-MGOAP - Migration Object Monitor - Apply</p> <p>[When using separate business data processes submit also F1-MGOAB (Migration Object Monitor (Business) - Apply)]</p> | <p>Migration Object - Applied or Error Applying</p> | <p>41</p> <p>Appropriate next action is based on error review, if applicable.</p> |
| | 41a | <p>Migration Data Set Import status update - auto transition to Apply Transactions.</p> <p>Only applicable if the number of migration objects in Error Applying is below a threshold</p> | Batch | | <p>F1-MGDIM - Migration Data Set Import Monitor</p> | <p>Migration Data Set Import - Apply Transactions</p> | 42 |

| Step | Seq | Action | Manual / Batch | Portal - Action | Batch Control | Record Impacted - Resulting Status | Next Action Sequence |
|------|-----|--|----------------|--|---------------|--|----------------------|
| | 41b | <p>Migration Data Set Import status update - manual transition to Apply Transactions.</p> <p>Occurs if user reviews errors and determines that they may be resolved in the Apply Transaction step.</p> <p>System detects that all the transactions are in the Ready to Apply state and proceeds to the Apply Transactions state.</p> <p>System detects that there are transactions in the Error Applying state and transitions instead to the Retry Transactions state.</p> | Manual | Migration Data Set Import - click Apply Transactions | | | |
| | | | | | | Migration Data Set Import - Apply Transactions | 42 |
| | | | | | | Migration Data Set Import - Retry Transactions | 45 |
| | 41c | <p>Migration Data Set Import status update - manual transition to Retry Objects.</p> <p>Occurs if user reviews errors and decides to fix an external error and wants to try the batch level Apply again at the object level.</p> | Manual | Migration Data Set Import - click Retry Objects | | Migration Data Set Import - Retry Objects | 44 |

| Step | Seq | Action | Manual / Batch | Portal - Action | Batch Control | Record Impacted - Resulting Status | Next Action Sequence |
|------|-----|---|----------------|---|---|---|--|
| | 42 | Apply Transactions | Batch | | F1- MGTAP - Migration Transaction Monitor - Apply | Migration Transaction - Applied or Error Applying Migration Object - Applied or Error Applying | 43 Appropriate next action is based on error review, if applicable. |
| | 43a | Migration Data Set Import status update - auto transition to Completed Applicable if all transactions are Applied | Batch | | F1- MGDIM - Migration Data Set Import Monitor | Migration Data Set Import - Completed. | N/A |
| | 43b | Migration Data Set Import status update - manual transition to Retry Objects. Occurs if user reviews errors and decides to fix an external error and wants to try the batch level Apply again at the Object level. | Manual | Migration Data Set Import - click Retry Objects | | Migration Data Set Import - Retry Objects | 44 |

| Step | Seq | Action | Manual / Batch | Portal - Action | Batch Control | Record Impacted - Resulting Status | Next Action Sequence |
|------|-----|--|-------------------|---|--|---|-------------------------|
| | 43c | <p>Migration Data Set Import status update - manual transition to Retry Transactions.</p> <p>Occurs if user reviews errors and decides to fix an external error and wants to try the batch level Apply again at the Transaction level.</p> | Manual | <p>Migration Data Set Import - click Retry Transactions</p> | | <p>Migration Data Set Import - Retry Transactions</p> | 45 |
| | 44 | <p>Migration Objects status update from Error Applying back to Approved.</p> <p>Occurs if user chose to Retry Objects.</p> | Batch | | <p>F1- MGOPR - Migration Object Monitor</p> <p>[When using separate business data processes submit also F1- MGOPB (Migration Object Monitor (Business))]</p> | <p>Migration Object - Approved</p> | |
| | | <p>Migration Data Set Import status update from Retry Objects to Apply Objects</p> | Batch | | <p>F1- MGDIM - Migration Data Set Import Monitor</p> | <p>Migration Data Set Import - Apply Objects</p> | 40 |

| Step | Seq | Action | Manual / Batch | Portal - Action | Batch Control | Record Impacted - Resulting Status | Next Action Sequence |
|------|-----|---|----------------|-----------------|--|--|----------------------|
| | 45 | Migration Transactions status update from Error Applying back to Ready to Apply. Occurs if user chose to Retry Transactions or if the user transitions to Apply Transactions and the system detects that there are Transactions in the Error Applying state. | Batch | | F1-MGTPR - Migration Transaction Apply Monitor | Migration Transaction - Ready to Apply | 42 |
| | | Migration Data Set Import status update from Retry Objects to Apply Objects | Batch | | F1-MGDIM - Migration Data Set Import Monitor | Migration Data Set Import - Apply Transactions | 42 |

The following table summarizes the batch monitor jobs that are used in the import process. You can see that there are special monitor processes for the Apply step for both the Object and Transaction. However, for all other states that have monitor logic, the standard monitor process for that MO is used.

| Batch Control | Description | Comments |
|---------------|--|---|
| F1-MGDIM | Migration Data Set Import Monitor | Processes data set records in the following states: <ul style="list-style-type: none"> • Pending • Ready to Compare • Apply Objects • Retry Objects • Apply Transactions • Retry Transactions |
| F1-MGTPR | Migration Transaction Monitor (Deferred) | Processes transaction records in the following states: <ul style="list-style-type: none"> • Pending • Error Applying |

| Batch Control | Description | Comments |
|---------------|---|--|
| F1-MGTAP | Migration Transaction Monitor - Apply | Processes transaction records in the Ready to Apply state where the data set is in the Apply Transactions or Canceled state.  Note: Be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker. |
| F1-MGOPR | Migration Object Monitor | Processes object records in the following states: <ul style="list-style-type: none"> • Pending • Needs Review (check for Data Set cancellation) • Error Applying |
| F1-MGOPB | Migration Object Monitor (Business) Applicable only when separate business data processing is enabled. | Similar to F1-MGOPR (Migration Object Monitor) but restricted to business data migration objects. |
| F1-MGOAP | Migration Object Monitor - Apply | Processes object records in the Approved state where the data set is in the Apply Objects or Canceled state.  Note: Be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker. |
| F1-MGOAB | Migration Object Monitor (Business) - Apply Applicable only when separate business data processing is enabled. | Similar to F1-MGOAP (Migration Object Monitor - Apply) but restricted to business data migration objects. |

Refer to [Running Batch Jobs](#) for more information about managing the batch jobs, including ways to automate the above steps.

Canceling a Data Set

A user may choose to **Cancel** a data set to prevent it from being processed at any point during the process.

If related migration transactions or migration objects have already been created, they will not be canceled as part of the data set getting canceled (due to possible high volumes of related records). They will be canceled the next time an appropriate monitor batch process runs. The child records checks to see if the data set has been canceled prior to any state transition.

Additional Note Regarding Imports

The following points describe miscellaneous comments related to Migration Import.

- CMA relies on the fact that database referential integrity constraints are not in place, and that the SQL statements can be run in any order within the transaction. Any archiving solution that requires referential integrity constraints

(such as Information Lifecycle Management) would not be possible on this data. Given that CMA migrations comprise administrative data and not transactional data, this should be a reasonable exception.

- The validation that is performed is only via the **Page Validate** service. BO validation algorithms are not executed. Page validation does not include validation of the business object against the schema (for example, for required fields, field sizes, etc.).
- If multiple migration requests are exported at the same time, on the import side, you should consider importing, reviewing, and applying an entire file/data set before moving on to the next one. The reason is that if objects are included in more than one file, two sets of "inserts" will be generated, but only the first will succeed. The second will cause the object to transition to "Cannot Apply". If instead you wait until the first file is completed before importing the second, the second data set will not generate any SQL for the object, since it has already been inserted. It's a matter of efficiency: If you first import all files and then try to apply all, you'll have to identify the duplicated object as an error and then mark the object as rejected before applying the transaction. This may also be avoided by using a Group migration request to include all objects in one file rather than multiple files.
- The system provides an algorithm to purge "unchanged" migration objects for a given migration data set. This may be plugged in as a BO exit algorithm on the **Ready to Compare** state for the Migration Data Set Import business object (**F1-MigrDataSetImport**).

The following points describe miscellaneous comments related to importing a business data set in [bulk mode](#).

- The number of entities included in each migration object is captured on the migration object record.
- The comparison step only generates SQLs for new or changed entities. SQLs are not generated for unchanged entities.
- Searching for migration objects based on their included entities is only supported for entities that were determined as new or changed. In other words, this type of search by included entities is only possible after the comparison step is performed.

Caching Considerations

There are two important caching considerations when using CMA to migrate administrative data.

- The "apply" batch processes update data. As described in [Batch Cache](#), if any batch job is updating data marked as "cached for batch" it must be run in a special thread pool. Contact your system administrator and ask for the name of a thread pool that has turned off caching. This thread pool name must be entered in the batch controls used for CMA processing in the **Thread Pool Name** parameter.
- After a successful migration, the target region now has new administrative data which needs to be part of various caches. It is recommended to flush the server cache (which will trigger a 'global' flush of the cache). If the thread pool workers in the target region are configured to refresh their caches when a global flush is requested, then this is the only step required. If not, then the **F1-FLUSH** batch job should also be submitted to refresh the caches used in batch processing.

Fastpath: Refer to [Caching Overview](#) for more information.

Fastpath: Refer to [Running Batch Jobs](#) for more information about running CMA batch jobs.

Maintaining Import Data

This section describes the portals provided to add, view and maintain migration import data.

Migration Data Set Import

Use the Migration Data Set Import portal to view and maintain migration data set import records. Refer to [Importing and Applying a Migration](#) for an overview of the import process.

Navigate using **Admin > Implementation Tools > Migration Data Set Import**. You are brought to a query portal with options for searching for import data sets. In addition, the query provides an option to specifically search for data sets that have either objects in error or transactions in error. Once a data set has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones are visible on the **Main** tab:

- **Migration Data Set Import.** This zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.
- **Entity Summary.** This zone provides a summary count of all migration objects included in the current data set across the various statuses.

The following zones are visible on the **Transactions** tab:

- **Migration Data Set Transactions in Error.** This zone is only visible if there are transactions for this data set in a non-final state that have errors. It indicates the error for each transaction. A user may use this zone to review errors after the monitor batch job to apply transactions completes. The errors received when attempting to apply objects at the transaction level may differ from those received when attempting to apply objects at the object level. A transaction log is created for each object error received and these exceptions are shown in this zone.

Note: Refer to [Apply Step](#) for more information about resolving errors.

- **Migration Data Set Transactions.** This zone is visible once the [Import Step](#) has occurred and lists all the transactions that are related to the data set. To see more information about a specific migration transaction, click the hypertext for its ID. This brings you to the [Migration Transaction](#) portal.

The following zones are visible on the **Objects** tab:

- **Migration Data Set Objects in Error.** This zone is only visible if there are objects for this data set in a non-final status that have errors. It indicates the error for each object. A user may use this zone to review errors after the monitor batch job to apply objects completes. Using the error information shown, the user can choose to drill into the record to transition it to **Error Applying** or choose to manually fix the cause of the errors and click **Retry Objects**. The user may also choose to select one or more records to **Reject**.

Note: Refer to [Apply Step](#) for more information about resolving errors.

- **Migration Data Set Impacted Object Summary.** This zone is visible once the [Import Step](#) has occurred and lists the objects that are related to the data set. To see more information about a specific migration object, click the hypertext for its ID. This brings you to the [Migration Object](#) portal. A user may choose to update the status of one or more records by checking the records and clicking **Approve**, **Reject** or **Needs Review** accordingly.

Migration Transaction Portal

This page appears after drilling into a specific migration transaction from the migration data set portal or from the migration object portal.

Refer to [Importing and Applying a Migration](#) for an overview of the import process.

The following zones are visible on the main tab:

- **Migration Transaction.** This zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.
- **Migration Transaction Objects.** This zone lists the objects that are related to the data set. To see more information about a specific migration object, click the hypertext for its ID. This brings you to the [Migration Object](#) portal. A user may choose to update the status of one or more records by checking the records and clicking **Approve**, **Reject** or **Needs Review** accordingly.
- **Entity Summary.** This zone provides a summary count of all migration objects included in the current transaction across the various statuses.

Migration Object Portal

This page appears after drilling into a specific migration object from the migration data set portal or from the migration transaction portal.

Refer to [Importing and Applying a Migration](#) for an overview of the import process.

The **Migration Object** zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.

The **Migration Object - List of SQL Statements** zone lists the SQL statements that have been generated as a result of the comparison step. A check mark in the Suppressed checkbox indicates that the SQL for that row will not be applied during the apply step.

The **Migration Object - Algorithms** zone displays any pre-compare algorithms that are associated with the migration plan for this migration object.

Configuration Deletion

Use the Configuration Deletion portal to review and delete configuration entities that were previously imported and are no longer needed. Refer to [Importing and Applying a Migration](#) for an overview of the import process.

Navigate using **Admin > Implementation Tools > Configuration Deletion**. You are brought to a portal where you can define a set of import data sets as representing a complete imported configuration and delete entities that were previously imported but not included in the reference set.

The following zones are visible on the **Main** tab:

- **Configuration Summary.** This zone summarizes the number of imported entities by maintenance object that are included in a selected set of import data assets that represent a complete imported configuration. Selecting a maintenance object lists potential entities for deletion.
- **Entities to Delete.** This zone lists potential entities for deletion, i.e. entities of the selected maintenance object that were previously imported but not included in the reference data set. You may select and delete entities from this list.

Running Batch Jobs

There are several batch jobs that are part of the CMA process, especially the import step (which are highlighted in [Import Process Summary](#)). And in some cases, a single batch jobs may process multiple states in the same business object lifecycle. Implementations must decide the best way to manage the batch job submission depending on how they plan to work.

- **Batch scheduler.** If an implementation wishes to put these batch jobs in the batch scheduler, a given job may need to be included several times to manage progressing the records to completion.
- **Timed Batches.** The batch controls can be configured as timed batches so that they run every N minutes based on the setting. This allows for the batch jobs to run periodically and process whatever is ready. A user doesn't have to manually submit a batch request. Navigate to the [Batch Control](#) page and select the appropriate batch controls. For each one, change the Batch Control Type to **Timed**. Fill in the additional information that appears for timed batches.
- **Event Driven.** The system provides BO enter plug-in algorithms and batch control post processing plug-in algorithms that automatically submit the appropriate next batch job for that step in the process. This allows for as much automation as possible for the steps that don't require user input. Note that configuration is required because the BOs / batch controls are not configured for this scenario by default. The following table highlights the BO and status where an algorithm may be plugged in and the name of the algorithm to use.

| Business Object | Status | Algorithm |
|---------------------------|--|---|
| Migration Data Set Export | Pending | F1-MGDPR-SJ (Submit Migration Data Set Export Monitor). |
| Migration Data Set Import | Pending Ready To Compare, Retry Objects | F1-MGDIM-SJ (Submit Migration Data Set Import Monitor). F1-MGOPR-SJ (Submit Migration Object Monitor). When using separate batch processes for business data add also this algorithm: F1-MGOPRB-SJ (Submit Migration Object Monitor for Business Data). |

| Business Object | Status | Algorithm |
|-----------------|---------------------------|---|
| | Apply Objects | F1-MGOAP-SJ (Submit Migration Object Apply Monitor). When using separate batch processes for business data add also this algorithm: F1-MGOAPB-SJ (Submit Migration Object Apply Monitor for Business Data). |
| | Apply Transactions | F1-MGTAP-SJ (Submit Migration Transaction Apply Monitor). |
| | Retry Transactions | F1-MGTPR-SJ (Submit Migration Transaction Monitor). |

The following table highlights the batch controls where an algorithm may be plugged in and the name of the algorithm to use.

| Batch Control | Algorithm |
|--|--|
| F1-MGTPR (Migration Transaction Monitor) | F1-MGDIM-NJ (Submit Migration Data Set Import Monitor). |
| F1-MGTAP (Migration Transaction Monitor - Apply) | F1-MGDIM-NJ (Submit Migration Data Set Import Monitor). |
| F1-MGOAP (Migration Object Monitor - Apply) When using separate batch processes for business data update also this batch control: | F1-MGDIM-NJ (Submit Migration Data Set Import Monitor). |
| F1-MGOAB (Migration Object Monitor (Business) - Apply) | |
| F1-MGOPR (Migration Object Monitor) When using separate batch processes for business data update also this batch control: | F1-MGTPR-NJ (Submit Migration Transaction Monitor). |
| F1-MGOPB (Migration Object Monitor (Business)) | |

- **Manual submission.** The user managing the CMA import process submits the appropriate batch jobs on demand when a particular step is ready. Navigate to [Batch Job Submission](#), select the appropriate batch control and fill in the parameters as needed.

Note that for the CMA batch processes used to migrate administrative data, there are multiple important caching considerations. Refer to [Caching Considerations](#) for more information.

CAUTION: Be sure that the Thread Count set when submitting the batch job does not exceed the number supported by the thread pool. Otherwise the extra threads will wait until the supported number of threads are finished, possibly resulting in a large number of errors in the Apply steps.

Refer to the parameter descriptions in the batch control metadata for more information about filling in the parameters.

For additional details on submission controls, refer to the topic [Batch Job Submission Portal](#) in the Batch Jobs section.

CMA Reference

This section provides additional reference information.

Framework-Provided Migration Configuration

This topic describes special information relating to migration objects provided for use by CMA in the product. Additional objects may be provided by your specific product. Any special information for objects is provided separately in each product's documentation.

The following points highlight some information about Framework-provided migration requests. Navigate to the migration request page in the application to view the details of all provided objects.

- Several base migration requests are supplied to logically group system and administrative tables. For example, there is a migration request for Framework System Configuration **F1-SystemConfig** where most system configuration objects are included. There is another one provided for CMA related configuration objects.
- The system supplies a group migration request **F1-FrameworkConfig** (Framework Configuration), which includes several other migration requests. The expectation is that this migration request includes all the typical objects that are included in a wholesale migration. Your specific product may include this migration request into its own group migration request to support a wholesale migration of all the framework and product administrative tables. An implementation may choose to build a custom group migration request. In this case, review the various migration requests provided by base to see if any may be included as components for the custom migration request. Then any new migration plans added to the base migration request in future releases are automatically included in future migrations.
- There are several different security related migration requests that include different combinations of migration plans to support multiple possible business requirements related to security migration. Note that the security migration request included in the above mentioned group migration request is the one that does not include users. If your implementation wants to copy users to a target environment, refer to [Importing Data that References a User](#) for some considerations.

Note: Refer to your specific product's CMA documentation for its recommendation on which migration requests to use for a full migration of framework and product administrative tables.

The following points highlight some information about the Framework-provided migration plans. Navigate to the migration plan page in the application to view the details of all provided objects.

- Fields and characteristic types are not migrated with an object (like a business object or a data area) unless specifically indicated.
- The **Application Service** used by an object is migrated only if it is CM-owned.
- The **Batch Control** object optionally references a User (for 'timed' batches). Refer to [Importing Data that References a User](#) for some considerations about copying the user. Also note that when running a batch job, snapshot information is captured on the batch control. Updates like this increment the version number. If a batch control record is part of the migration and the comparison step has detected a change to the batch control, the Apply step will error out for this batch control if a batch job is submitted between the compare and apply step.

Note: CMA batch controls that are part of the import step are executing and as such, the system does not include these records in a migration. If your implementation changes default parameters for any of the batch controls, the recommendation is to manually make those changes to the target region.

- The base migration plans for MO and BO include instructions to copy option types that use foreign key references to refer to other objects. Note that the data stored in the options are not validated, so defining these instructions is not required when doing wholesale migrations. However, including subordinate instructions for foreign key references is useful for targeted migrations to ensure that the related data is included in the migration. If you add additional MO or BO option types that use foreign keys and you want to support targeted migrations, you must create custom migration plans and requests for MO and BO, respectively to include these referenced objects in the migration plan. Note that you do not need to duplicate the instructions in the base migration plans. You may define the additional migration plans to only have the additional custom option types. When submitting a migration request for MO or BO you must include both the base migration plans and the custom migration plans in the request.
- For scripts, schema-based objects and zones, the migration plans provided by the product migrate, through constraints, some of the typical associated data with them. However, data specified through alternate formats (such as through **Edit Data** steps in scripts, referenced in schemas for schema-based objects, or data from mnemonics in zone parameters, etc.) are not identified and combined in the same transaction. The iterative processing functionality of the import step should resolve any timing issues that may result in validation errors for these types of objects.
- There are two migration plans for **Scripts**. The migration plan **F1-ScriptOnly** migrates just the script and its **Application Service** (provided the Application Service is CM-owned). The migration plan **F1-Script** includes most related objects, but does not migrate any objects referenced in the edit data area steps. It does not move the

Function maintenance object. It may be included in any appropriate custom targeted migration request where scripts and related data should be migrated.

- If your implementation includes a **Feature Configuration** setting for the **F1_DBCONINFO** entry that will be included in a migration request, be sure that the import user on the target region has the appropriate security rights to this entry (**Administrator** access mode for the Feature Configuration application service (**CILTWSDP**)).
- The common attachments in the Attachment maintenance object may be considered administrative data to include in a migration. Because this MO has a system generated key, as described in [Administrative Data with System Generated Primary Keys](#), it uses a logical key of the file name and the creation date to determine if the record exists in the target environment. In addition, this MO contains administrative data (common attachments) and non-administrative data (owned attachments). To try to minimize the possibility of key "collision", new common attachments receive a generated key that includes a zero in the middle whereas owned attachments receive a generated key that does not have a zero in the middle.
- The Menu maintenance object has a user defined key, however, its menu lines and menu items have system generated keys. To avoid the possibility of overriding a menu line or menu item incorrectly, the menu MO will check the menu line's menu name in the source and target to be sure they match and will check the menu item's menu line in the source and target to be sure they match otherwise an error will be issued in the comparison step.
- For the system messages, the product provides three different migration plans.
 - Message Category and its Messages (F1-MessageCategory). This migration plan is included in the **F1-SystemConfig** migration request.
 - Message Category (F1-MessageCategoryOnly). This migration plan is provided to support a targeted migration where an implementation has created a custom message category and wants to move it but doesn't want to move all its messages.
 - Message (F1-Message). This migration plan is provided to support a targeted migration where only specific messages within a message category should be migrated.
- For lookup values, the product provides two different migration plans.
 - Lookup Field and its Values (F1-Lookup). This migration plan is included in the **F1-SystemConfig** migration request.
 - Lookup Value (F1-LookupValue). This migration plan is provided to support a targeted migration where only specific lookup values within a lookup field should be migrated.
- There are some system data objects where no information in a base delivered record may be modified by an implementation. For these records, the base delivered migration requests include selection criteria to only select CM-owned records (because the base records will always exist in the target region assuming both regions have the same release). An example is Algorithm Type. The **F1-SystemConfig** migration request only includes CM-owned algorithm types. However, many system data objects support custom changes to one or more fields, for example the Zone object allows an implementation to override the zone text or certain parameters. Other system data objects support custom additions to a collection. For example, the Maintenance Object allows an implementation to add algorithms or options. For the migration plans related to these system data objects, all records are included in the base delivered migration requests to allow for any customized configuration to be migrated. It means that during the Import / Compare step many base delivered objects that are not customized will be marked **Unchanged**.
- Many of the integration related maintenance objects that include references to environment-specific data, such as Message Senders. This data should be migrated with extreme care. When appropriate, consider taking advantage of URI substitution. Refer to [Referencing URIs](#) for more information.

Facts

Fact is an optional configuration tool for simple workflow-type business messages or tasks. The base package does not provide a dedicated Fact user interface because fact is generic by design. Implementations configure their own user interface to visualize the desired custom business process. The topics in this section describe the generic Fact entity and how it can be customized.

Fact Is A Generic Entity

The Fact maintenance object is a generic entity that can be configured to represent custom entities and support automated workflows for a variety of applications. Each fact references a business object to describe the type of entity

it is. A status column on the fact may be used to capture its current state in the processing lifecycle controlled by its business object.

The maintenance object also supports a standard characteristic collection as well as a CLOB element to capture additional information.

Fact's Business Object Controls Everything

A fact's business object controls its contents, lifecycle and various other business rules:

- Its schema defines where each piece of information resides on the physical Fact maintenance object.
- It may define a lifecycle for all fact instances of this type to follow. Each fact must exist in a valid state as per its business object's lifecycle definition.
- It may define validation and other business rules to control the behavior of facts of this type.

Fastpath: For more information about business objects, refer to [The Big Picture of Business Objects](#).

Fact Supports A Log

The Fact maintenance object supports a log. Any significant event related to a Fact may be recorded on its log. The system automatically records a log record when the fact is created and when it transitions into a new state. In addition, any custom process or manual user activity can add log entries.

Fastpath:

Refer to [State Transitions Are Audited](#) for more information on logging.

Conversion

This section describes the overall conversion process and the tools provided to support it.

Understanding The Conversion Process

When you're ready to convert data from your legacy system, you will have analyzed your processing requirements according to your business and organizational needs and set up the control tables accordingly. After the control tables are set up, you are ready to load data into the system from your legacy system.

There are two table owners in the system database. We refer to the first owner as **staging** and the second owner as **production**. The staging owner is linked to the tables into which you insert your pre-validated data. The production owner is linked to the tables used by your production system.

Note: It's important to notice that **control tables exist only in production**. In staging, they exist as views to the production schema. Refer to [Multiple Owners In A Single Database](#) for more information about table ownership.

The conversion effort involves several steps as illustrated in the following diagram:

The following points briefly outline each of the above tasks:

- **Load Legacy Data.** During this step, your legacy data is loaded into the system. Notice that you are not migrating this data directly into production. Rather, your rows are loaded into tables that are identical to the production tables; they just have a different owner. Mapping legacy data into the system is probably the most challenging part of the conversion process because the system is a normalized database (and most legacy applications are not).
- **Validate Staging.** During this step, the system validates the data you loaded into the staging tables. Note that validation rules validate your staging data using the control tables that have been set up in production.
- **Assign Production Keys.** During this step, the system allocates random, clustered keys to the rows in the staging database.
- **XML Resolution.** During this step, the system resolves legacy keys that may be mapped to an XML storage field with new values that were assigned in the key assignment step.
- **Insert Rows Into Production.** During this step, the system populates your production tables with rows from the staging. When the rows are inserted, their prime keys and foreign keys are reassigned using the data populated in the key assignment and XML resolution steps.
- **Validate Production.** During this step, you rerun the object validation processes, but this time against production. We recommend performing this step to confirm that the insertion programs have executed successfully.

Note: Additional steps may be needed to support specific data conversion requirements. Refer to your product's documentation for additional conversion related information.

This section further discusses concepts and guidelines related to the conversion process.

Conversion Entities

Conversion is enabled for selected master and transaction maintenance objects. In the same way, only a subset of a maintenance object's tables are enabled for conversion.

The following is provided for each maintenance object that supports conversion:

- An [entity validation](#) batch control. This batch process validates data in staging and can also be run to validate data in production.

- A [key assignment](#) batch control for each **table** that is eligible for conversion and has a system-generated key.
- An [XML resolution](#) batch control if the maintenance object has at least one table that includes an XML storage field.
- An [insertion to production](#) batch control for every **table** of the maintenance object that is eligible for conversion.

You may review the conversion configuration provided for an entity and more using the [Conversion Entity Dashboard](#) portal.

Conversion Steps

The following sections provide more details about the steps in the conversion process.

Note: Additional steps may be needed to support specific data conversion requirements. Refer to your product's documentation for additional conversion related information.

Load Legacy Data Into Staging Tables

This section provides some high level discussion about mapping and loading legacy data to the system's staging tables.

Mass Load Utility

Unless in a Cloud installation, you can use any method you prefer to load data from your legacy application. However, we recommend that you investigate your database's mass load utility (as opposed to using insert statements) as the mechanism to load the staging tables. In addition, we strongly recommend that you disable the indexes on these tables before populating these tables and then enable the indexes after populating these tables.

Note: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

Populating Keys

Some tables in the staging database have keys that are system-assigned random numbers. Special consideration should be given when populating these keys. Refer to [A Note About Keys](#) for more information on how to properly populate these tables. Those tables that don't have system-assigned random numbers have keys that are a concatenation of the parent's prime-key plus one or more additional fields.

Populating Characteristic Tables

There are many maintenance objects that include a characteristic table used to capture miscellaneous information about the object. Most of these tables include an indexed column used when searching by characteristic value called Search Characteristic Value. During conversion and depending on the type of characteristic, this column must be populated as follows:

- **Predefined.** Populate search characteristic value with the contents of the characteristic value column converted to upper case.
- **Ad hoc.** Populate search characteristic value with the first 50 bytes of the ad hoc characteristic value column converted to upper case.
- **Foreign key.** Populate search characteristic value by concatenating the values of each foreign key characteristic value column to a maximum of 50 bytes.

Validate Information In The Staging Tables

During the first validation step, the system validates the data you loaded into the staging tables. This section provides some high level discussion about the validation process.

A Batch Process Per Maintenance Object

Each of the maintenance objects that are eligible for conversion must be validated using its respective entity validation conversion batch process. These are classic background processes that can also be run against production data.

These processes are multi-threaded and have no dependency on other processes.

Validation Mode

By default, each entity is fully validated for schema as well as entity validation rules, at the maintenance object and business object level. The batch process performs the same business rules that are used to validate data added by users in your production system. You may restrict the batch process to perform schema validation only or entity validation rules only using a batch parameter. This may be useful in identifying common data issues in preliminary runs.

Random Sample Mode

By default all records are selected for validation. The "Process Every Nth" batch parameter allows you execute this process in a random-sample mode to highlight pervasive errors. In this mode, you are actually telling the batch process to validate every N records.

We strongly recommend validating each entity in the following steps:

- Execute the validation batch process in random-sample mode.
- Review and correct the errors. Note, you can use the base package's transactions to correct an error if the error isn't so egregious that it prevents the object from being displayed on the browser.
- After all pervasive errors have been corrected; re-execute each object's validation batch process in all-instances mode to highlight elusive, one-off errors.

Reported Errors

Errors encountered during validation are logged onto the conversion Validation Error (CI_VAL_ERR) table. Note that at the start of this job, all rows in the conversion error table for the process maintenance object are deleted.

You can view errors highlighted by the validation process using the [Conversion Entity Dashboard](#) portal.

Recommendations To Speed Up Validation

The following points describe ways to accelerate the execution of the validation process:

- Ensure that statistics are recalculated after data has been inserted into the staging tables.
- Execute the process multi threaded.
- Execute shorter running validation processes (e.g., less records) first so that the error data can be analyzed while other processes are busy running.
- Remember that validation can be run in random-sample mode. We recommend running these batch processes using a large sample value for this parameter until the pervasive problems have been rectified.

Note: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

Another use for these programs

In addition to validating your objects after conversion or an upgrade, the validation programs have another use. Say for example, you want to experiment with changing the validation of a business entity and you want to determine the impact of this new validation on your existing records. You could change the validation and then run that entity's validation batch process- it will produce errors for each record that fails the new validation.

Allocate Production Keys

During the key assignment step, the system assigns a new key for each legacy key for a table that its prime-key requires a system-generated random key. The conversion process allocates new prime keys to take advantage of the system's parallel processing and data-clustering techniques in the production system (these techniques are dependent on randomly assigned, clustered keys).

The topics in this section provides some high level discussion about the key assignment process and describe the background processes used to assign production keys to the staging data.

The Old Key / New Key Table

It's important to understand that the system does not overwrite the prime-keys on the rows in the staging database, as this is a very expensive IO transaction. Rather, a series of tables exist that hold each row's old key and the new key that will be assigned to it when the row is [transferred into the production database](#). We refer to these tables as the "old key / new key" tables.

The convention "<1st letter of owner flag>K_<table_name>" is used to denote the old key / new key table name. For example, the old key / new key table for CI_ACCT is called CK_ACCT.

The insertion batch process that transfers the rows into the production database use the new key for the main record of the key along with any other record where this key is a foreign key. In the same way, the XML resolution process resolves conversion foreign keys residing in XML storage fields and replaces them with their corresponding new keys from these table.

A Batch Process Per Table

A key assignment batch process is provided for each table that has a system-generated key and belongs to a maintenance objects that is eligible for conversion. The batch process is responsible for populating the corresponding old key / new key table (i.e., you don't have to populate these tables). These processes are single threaded. Refer to a table's corresponding key assignment batch process for more information.

Key Assignment Dependencies

Most tables with system-generated keys do not inherit part of their key from another table's key. Their corresponding key assignment batch process have no dependencies and can therefore be executed in any order you please.

Some tables inherit part of their key from another table's key. Key assignment batch processes for such tables must be executed in key inheritance order. In other words, the key assignment process for a table should be run after the process that generates keys for the entity it depend on. The [Conversion Entity Dashboard](#) portal displays key inheritance dependency information if any exist for a conversion entity.

Note:

You may run multiple key assignment batch process in parallel as long as they are independent with respect to key inheritance.

Iterative Conversions

Rather than perform a "big bang" conversion (one where all records of an entity are populated at once), some implementations have the opportunity to go live on subsets of their entity base. If this describes your implementation, please be aware that the system takes into account the existing prime keys in the production database before it allocates a new key value. This means when you convert the next subset of customers, you can be assured of getting clean and unique keys.

Key assignment logic creates the initial values of keys by a manipulation of the sequential row number, starting from 1. After any conversion run, a subsequent conversion run will start with that row number again at 1, and the possibility of duplicate keys being assigned will be higher. The key assignment batch process allows you to specify a starting value for that row number. The purpose of this parameter is to increase the value of row number by the given value, and minimize the chance of duplicate key assignment. This parameter is only used if you are performing conversions where data already exists in the tables in the production database.

Run Type

Key assignment is performed in two steps:

- **Initial Key Generation.** The system allocates new keys to the rows in the staging tables (i.e., it populates the respective old key / new key table).
- **Duplicate Key Resolution.** The system reassigns keys that are duplicates compared to production.

By default, both steps are performed at the same run but you have the option to run them separately by indicating which step to run via a batch parameter. The proper use of this parameter will greatly speed up the key assignment step as described under **Recommendations To Speed Up Key Generation** section.

Recommendations To Speed Up Key Generation

The following points describe ways to accelerate the execution of the key generation programs.

- For a non-Cloud installation:
 - Make the size of your rollback segments large. The exact size is dependent on the number of rows involved in your conversion. Our research has shown that processing 7 million rows generates roughly 3GB of rollback information.
 - Setup the rollback segment(s) to about 10GB with auto extend to a maximum size of 20GB to determine the high water mark
 - A next extent value on the order of 100M should be used.
 - Make sure to turn off all small rollback segments (otherwise Oracle will use them rather than the large rollback segments described above).
 - After the key assignment programs execute, you can reclaim the space by:
 - Keep a low value for the "minimum extent" parameter for the rollback.
 - Shrink the rollback segments and the underlying data files at the end of the large batch jobs.
 - Compute statistics on the old key / new key tables after every 50% increase in table size. Key generation is performed in tiers or steps because of the inheritance dependency between some tables and their keys. Although key generation for the inheritance dependency tier currently being processed is performed by means of set-based SQL, computation of statistics between tiers will allow the database to compute the optimum access path to the keys being inherited from the previous tier's generation run.
 - Optimal use of the **Run Type** batch parameter.
 - Before any key assignments, alter both the "old key" F1_CX_ID index and the "new key" CI_ID index on the old key / new key tables to be unusable.
 - Run all key assignment batch processes in tiers, submitting each job to only perform the **Initial Key Generation** step.
 - Rebuild the indexes on the old key / new key tables. Rebuilding the indexes using both the PARALLEL and NOLOGGING parameters will speed the index creation process. Statistics should be computed for these indexes.
 - Run all key assignment batch processes in the current tier that were previously run in initial key generation mode, to perform the **Duplicate Key Resolution** step. This will reassign all duplicate keys.

Note: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

XML Resolution

Most system-generated foreign keys are stored in physical fields and characteristic tables and as such their legacy value is replaced with its corresponding new key as part of the insertion to production process. Rarely, maintenance objects may store system-generated foreign keys in an XML storage field, i.e. a field defined with the data type of CLOB or XML. This step is only applicable to such maintenance objects.

During this step, the system resolves convertible system-generated foreign keys that may reside in XML storage fields you may have loaded into the staging tables. This section provides some high level discussion about the XML resolution process.

The XML Resolution Table

It's important to understand that the system does not overwrite the prime-keys on the XML storage fields in the staging database, as this is a very expensive IO transaction. Rather, a corresponding XML resolution table exists for each table that defines an XML resolution field to capture each row's resolved XML storage content, i.e. the content with all the old keys replaced with the new assigned keys.

The convention "<1st letter of owner flag>R_<table_name>" is used to denote the XML resolution table name.

The [insertion](#) batch process that transfers the rows into the production database replaces each XML storage field with its resolved value from the corresponding XML resolution table.

A Batch Process Per Maintenance Object

Each of the maintenance objects that are eligible for conversion and support XML storage fields is provided with an XML resolution batch process. These batch processes must be run to resolve foreign keys that may reside in these XML storage fields.

These processes are multi-threaded and must be executed after the key assignment step has completed and before inserting data to production.

XML Resolution Eligibility

Not all maintenance objects that support XML storage fields actually store convertible system-generated foreign keys in their XML storage field. If none of the business objects associated with the maintenance object involve mapping of such foreign keys to an XML storage field then XML resolution is not needed for any row in the maintenance object. The XML resolution batch process detects such situation and completes right away without storing any rows in any of the maintenance object's XML resolution tables.

Note: If the XML resolution batch process detects that the maintenance object is eligible, the maintenance object must reference a physical BO. If a product delivered business object supports system-generated foreign keys in an XML storage field, the product should be supplying a physical BO. If your implementation has system-generated foreign keys in an XML storage field in a custom business object for a maintenance object where the product has not supplied a physical BO, you must [create a physical BO](#) and link it to the maintenance object.

Only Resolved Values Are Captured

XML storage fields typically store large amounts of data. To avoid capturing the same XML content redundantly, the system only stores values in the resolved XML storage fields if the resolved value is different than the original value, i.e. at least one key was resolved.

If for a given record the resolved XML content is the same as the original content then the following rules apply:

- If this is the primary table of the maintenance object a record is inserted into its corresponding XML resolution table for that record with no value in the XML storage field.
- If this is a child table of the maintenance object then no record is inserted into the corresponding XML resolution table for that record.

Reported Errors

Errors encountered during XML resolution are logged onto the conversion Validation Error (CI_VAL_ERR) table. Note that at the start of this job, all rows in the conversion error table for the process maintenance object are deleted.

You can view errors highlighted by the XML resolution process using the "Validation Error Summary" page.

Insert Production Data

The topics in this section describe the background processes used to populate the production database with the information in the staging database.

A Batch Process Per Table

An insert to production batch process is provided for each table of a maintenance objects that is eligible for conversion.

The batch process is responsible for transferring to production all the rows from the staging table while replacing all references to old keys with their corresponding new keys as follows:

- Keys residing in prime keys, foreign key fields and characteristics are resolved using the corresponding [old key / new key](#) tables.
- Keys residing in generic foreign key reference tables where each row represents a reference to an entity's maintenance object and prime key values are also resolved using the corresponding [old key / new key](#) tables. Note that all entities referenced this way must either be convertible or view of production. A reference to an entity that is explicitly marked as not convertible is not supported as it cannot be resolved.
- Keys residing in XML storage fields are resolved using the corresponding [XML resolution](#) tables.

Note: Foreign keys residing in any other form of storage are not resolved. For example, any references stored in raw elements, log records, or any other field that is not used as an XML storage field.

All insertion batch processes are independent and may run concurrently. Also note, all insertion batch processes can be run in many parallel threads as described in the next section (in order to speed execution).

Recommendations To Speed Up Insertion

The following points describe ways to accelerate the execution of the insertion batch processes:

- Before running the first insertion batch process:
 - Rebuild the index on the prime key on the old key / new key table.
 - Re-analyze the statistics on the old key / new key table.
 - Alter all indexes on the production tables being inserted into to be unusable.
- After the insertion programs have populated production data, rebuild the indexes and compute statistics for these tables.

Note: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

Validate Production

During this step, you rerun the [object validation batch processes](#), but this time in production. We recommend rerunning these batch processes to confirm that the insertion batch processes have executed successfully. We recommend running these batches in random sample mode (e.g., validate every 1000th object) rather than conducting a full validation in order to save time. However, if you have time, you should run these processes in full validation mode (to validate every object).

A Note About Keys

The prime keys of the tables in the staging database are either system-assigned random numbers or they aren't. Those tables that don't have system-assigned random numbers have keys that are a concatenation of the parent's prime-key plus one or more additional fields. Every table whose prime key is a system-assigned random number has a related table that manages its keys; we refer to these secondary tables as "key tables".

The following points provide more information about the key tables:

- Key tables are used by programs that allocate new keys. For example, before a new key is allocated, the key assignment program checks the corresponding key table to see if it exists.
- Key tables only have two columns:
 - The key of the object.
 - An environment ID. The environment ID identifies the database in which the object resides.
- Key tables are named the same as their primary table with a suffix of "_K". For example: The key table for CI_ACCT is CI_ACCT_K.
- The key table for a table whose prime key is a system-assigned is defined on its table definition record.
- When you populate rows in tables with system-assigned keys, you must also populate a row in the related key table. For example, if you insert a row into CI_ACCT, you must also insert a row into CI_ACCT_K. The environment ID of these rows must be the same as the environment ID on this database's [installation record](#).
- When you populate rows in tables that reference this record as a foreign key, you must use the appropriate key to ensure the proper data relationships. For example, if you insert a row in CI_SA for the above account, the ACCT_ID column must contain the temporary account key.

- When you insert rows into your staging database, the keys do not have to be random, system-assigned numbers. They just have to be unique. A later process, [Allocate Production Keys](#), will allocate random, system-assigned keys prior to production being populated.

Multiple Owners In A Single Database

The conversion process relies on the following table owner configuration in the system database:

- The production owner is linked to the tables used by your production system. These tables have an owner ID of CISADM.
- The staging owner is linked to the tables into which you insert your pre-validated data. These tables have an owner ID of CISSTG.

The staging owner schema is almost identical to the production schema, with the following exceptions:

- Control tables are not actual tables in staging but rather views to the corresponding tables in production.
- Conversion specific tables designed solely to support the conversion process exist only in the staging schema. For example, tables that manage key assignment and XML resolution.

This section provides some high level concepts related to these table owners.

Validation Always Uses Production Control Data

When the validation batch processes run against your staging data, they validate the staging data against the production control tables (and insert errors into the staging error table). This means that the SQL statements that access / update entities needs to use the staging owner whereas the SQL statements that access control tables need to use the production owner. But notice that when these same validation batch processes run against production, the SQL statements will never access the staging owner. Rather, they all point at the production owner.

This is accomplished as follows:

- A separate application server must exist for each owner. Each application server points at a specific database user ID.

Note: In a Cloud installation, the application server may only point to a specific database user ID at any point in time. Refer to the “Data Conversion Support for Cloud Implementations” for more information about switching owners.

- The database user ID associated with the staging owner uses CISSTG as the owner for the master and transaction tables, but it uses CISADM as the owner of the production control tables.
- The database user ID associated with the production owner uses CISADM as the owner for all tables.

You may wonder why we went to this trouble. There are several reasons:

- We wanted to reuse the validation logic that exists in the programs that validate your production data. In order to achieve this, these programs must sometimes point at the staging owner, and other times they must point at the production owner (and this must be transparent to the programs otherwise two sets of SQL would be necessary).
- We wanted to let you use the application to look at and correct staging data. This can be accomplished by creating an application server that points at your staging database with the ownership characteristics described above.
- We wanted the validation programs to be able to validate your production data (in addition to your staging data). Why would you want to validate production data if only clean data can be added to production? Consider the following scenarios:
 - After an upgrade, you might want to validate your production data to ensure your pre-existing user-exit logic still works.
 - You may want to conduct an experiment of the ramifications of changing your validation logic. To do this, you could make a temporary change to user exit logic (in production) and then run the validation jobs on a random sample basis.
 - You forget to run a validation program before populating production and you want to see the damage. If you follow the instructions in this document, this should never happen. However, accidents happen. And if they do, at least there's a way to determine the ramifications.

Only Validation Can Work In Both Owners

While the redirection of owner ID's is a useful technique for the validation batch processes, it cannot be used by the key assignment and production insert batch processes? Why, because these processes have to access the same tables but with different owners at the same time. They also need to reference conversion specific tables that do not exist in production. For example, the batch process that inserts rows into a table in production must select rows from the staging version of that table, resolve keys from the conversion old key / new key mapping tables and insert the resolved records into the production version of that same table

This is accomplished as follows:

- In staging, a view to production exists for each eligible to conversion table. These views have hard-coded the database owner to point to production. For example, there is a view called CX_PER that points at person table in production.
- The key assignment and insertion programs use these views whenever then need to access production data.

Conversion Entity Dashboard

This portal provides an overview of a maintenance object's conversion configuration along with information related to its current status and progress within the overall conversion process.

Refer to [Understanding Conversion](#) for more information.

You can access the portal from the **Admin Menu > Implementation Tools > Conversion Entity Query**. You are brought to a query portal with options for searching for a specific maintenance object that is eligible for conversion. Once a maintenance object has been selected you are brought to the conversion entity dashboard portal to review the information for the selected record.

The following zones may appear as part of the portal's **Main** tab page.

- **Tables.** This zone provides information about tables that belong to the maintenance object and are marked as eligible for conversion.
- **Batch Controls.** This zone lists the conversion batch controls defined for the maintenance object in the order they should be executed within the conversion process along with current execution details if any.
- **Error Summary.** This zone provides a summary of all conversion errors related to the maintenance object.
- **Duplicate Keys.** This zone lists duplicate legacy keys that need to be resolved by the key assignment conversion process.

The **Errors** tab page provides a query zone that allows you to review conversion errors related to the maintenance object by various criteria.

Data Export

This section describes concepts and tools related to the various types of data export methods supported by the product.

Understanding Data Export

The application supports the following classes of export methods for a maintenance object:

- **Generalized.** This method may be used for maintenance objects that are low to medium in volume and update activity. Most maintenance objects are eligible for this method.
- **Specialized.** This method should be used for maintenance objects that are high in volume or very frequently updated.

Note: It is your organization's responsibility for designing the process by which these files are imported to one or more target environments.

This section discusses concepts and guidelines related to data export features.

Generalized Data Export

The generalized data export method provides a file-based export of data in JSON format. Exporting the data of a maintenance object using this method involves an initial export of the entity's entire data followed by an ongoing export of changes as they are made over time. These processes are illustrated in the following diagram:

The overall process involves the following steps:

- Enable entities for export in the [Generalized Export Dashboard](#) portal. You may enable many entities at once. This step also allows you to enable ongoing export of these entities.
- Submit the Generalized Initial Export Initiator (**F1-GEXPI**) batch process to export the current content of all enabled entities. This step submits a separate batch process for each entity you have enabled for export.

Note: A full database export can be used instead. The export file can be imported in the target environment to establish the initial baseline. Cloud customers may contact cloud operations to request such export for on-premise use. This schema export is limited for reporting purposes and is intended for initial extract only.

- Schedule the Generalized Ongoing Export (**F1-GEEEXO**) batch process to run periodically.

The following sections further discuss concepts and guidelines related to the generalized data export method.

Eligibility

While most entities are eligible for generalized data export, not all of them are. Here are a few of the common reasons for that:

- The entity manages extremely high volume of data. Tracking changes to such entity would double the volume of managed data and impact overall performance.
- The entity is updated very frequently. Tracking these events may impact overall performance.
- The entity is used by the product's infrastructure and operational processes. These entities are maintained differently and cannot be subject to the generalized data export methods.

By default a maintenance object is eligible for the generalized data export method unless explicitly marked otherwise by the **Data Export Class** option. The option may be used to mark an entity as either not allowed for any type of export or allowed for a [specialized](#) export only. The lack of such explicit option means the maintenance object is eligible for the generalized export.

CAUTION: If an entity is explicitly marked as not eligible for generalized data export there is a good reason for that and its configuration should not be changed.

One Method Fits All

The generalized data export method is designed to accommodate many eligible maintenance objects in a generic way that must also take performance considerations into account. For this reason this method does not support entity specific filtering options nor custom rules of any kind.

The following rules apply to all entities that may be exported using this method:

- Entire data is exported.
 - All fields on all tables that belong to the maintenance object are exported except for “key” and “log” tables if any.
 - Maintenance object log tables typically do not contain useful business information and as such are omitted from export for performance and data volume reasons. However, there are entities for which log records provide analytical value. When applicable, use the **Export Log Tables** option to explicitly include log tables for a specific maintenance object.
- Same data structure and format is used for all entities. Refer to the **Record Format** section for more information.
- Data is exported to files only. Refer to the **Export To Files Only** section for more information.
- All changes are captured. It is not possible to exclude some changes from being tracked for ongoing export based on custom business rules.
- When data changes, a full snapshot of the data related to that entity is exported to avoid heavy data merging on the target side.
- When the entity is deleted, only the primary key of the entity is exported along with an indication that it is deleted.

Note: Export is not supported for entities that rely on the logical time zone functionality. This type of definition is not commonly used and includes maintenance objects that at least one of their fields is defined as stored in **Logical Standard Time**.

Export To Files Only

The immediate destination of both initial and ongoing export processes are files in a customer specified location. In a Cloud installation files are created in a customer owned Object Storage.

Based on your business requirements you may further consume these files by downstream applications such as data lakes etc.

Enabling Data Export

To enable data export for an eligible maintenance object a **Data Export Control** record needs to be created. The record keeps an indication of whether the initial export for the maintenance object has been completed or not and whether changes made to the entity should be tracked and exported on an ongoing basis. A designated portal allows you to enable the generalized data export for many maintenance objects at once as well as monitor their current export status at a glance. Refer to [Generalized Export Dashboard](#) portal for more information.

CAUTION: Enabling and disabling entities for export should only be made via the Generalized Export Dashboard or the Data Export Control portals to ensure the configuration is valid and complete.

CAUTION: When applicable, ongoing data export should be enabled before submitting the initial export batch process for the entity. This ensures that changes made during the initial export are properly tracked.

Ongoing export options are cached in various online and batch caches. In order for these options to take effect and track entity changes made by any online or batch process, the various caches must be properly flushed when these options are changed. Using the designated portals to enable entities for export triggers a 'global' flush of the caches. If the batch thread pool workers are configured to refresh their caches when a global flush is requested, then this is the only step required. If not, then the **F1-FLUSH** batch job should also be submitted to refresh the caches used in batch processing. Refer to [Caching Overview](#) for more information.

Initial Data Export

Each maintenance object that is eligible for the generalized data export method is associated with an initial data export batch control that is referenced on the maintenance object using the **Export Batch Control** option. The same

common batch program is used by all these batch controls to export the entire data of an entity to files. The process is multi-threaded and produces one file per thread by default. An optional batch parameter allows for multiple smaller files to be generated per thread by setting a limit on the number of records written to each file. Refer to the **File Size** section for more information.

Instead of manually submitting the generalized initial export batch process for each maintenance object you have enabled for export, submit the **F1-GEXPI** Generalized Initial Export Initiator batch process to automatically submit them all at once.

The initial export process for each maintenance object updates the corresponding data export control record for the maintenance object to indicate that the process has started and updates it again upon completion. This allows you to view the overall status of the initial export across all enabled entities on the [Generalized Export Dashboard](#) portal.

Note that the initiator batch process only submits batch processes for enabled maintenance objects that according to their data export control record their initial export has not started yet. If you need to export one or more entities again, reset the initial export status indication on their data export control records and submit the initiator batch process again.

The initial export file name is constructed as follows:

```
INIT_EXPORT[_file prefix(optional)]_[maintenance object]_[batch run]_[thread]_[thread count]
[_file sequence].json.gz
```

The "file sequence" part of the file name is used only when more than one file is created per thread. The sequence suffix is populated starting from the second file as follows 2.

Refer to any of the individual generalized initial export batch controls and the initiator batch control for more information.

Restricting Initial Export By Date

By default, the Initial Data Export batch process exports the entire data for an entity. In some situations, typically around high volume historical data, there may be a need to restrict the export to more recent data, for example the last few months of data.

The initial export batch process supports an optional batch parameter **Restrict By Date** that can be used to limit the scope of data to export. The parameter references a date field and a requested time frame in terms of number of days prior to business date. Refer to the **F1-GEIXP** Generalized Initial Export Template batch control for more information.

CAUTION: Excluding records from export should be carefully considered as this may result in data discrepancies when the excluded data is referenced on other exported entities.

Note: The option is only applicable to specific entities that have a qualifying reference date and the time frame for export may vary for each customer. Therefore, the new parameter is not added to any base product Initial Export batch control aside of the template batch control for documentation purposes. You may clone the base product batch control for a specific entity and add the parameter as per your business needs.

Ongoing Data Export

Data changes are tracked by the Capture Change for Ongoing Export (**F1-MO-REGCHN**) Maintenance Object Audit algorithm. The algorithm records the prime key of a changed entity in a designated **Data Export Update** table that serves as a queue of changed entities to export. The queue is later on consumed by the ongoing data export batch process.

Note: The Maintenance Object Audit plug-in spot is capable of tracking changes made to the entity by any layer of the application. Making changes using direct SQL would bypass this mechanism and therefore should be avoided.

The audit rule is added to a maintenance object when the ongoing data export option on its corresponding data export control record is enabled. In the same way the audit rule is removed from the maintenance object when the ongoing export option is disabled.

Note: The ongoing export option has to be enabled on the data export control record for the entity before it is initially exported. This ensures changes made while the initial export process is in progress are not missed.

Unlike the initial export batch process that requires a batch control to be defined for each eligible maintenance object, a single batch process is used to export ongoing changes made to all entities.

The following describes the ongoing export batch process at a high level:

- All changes queued in the Data Export Update table are exported to a designated ongoing export file. Refer to the **Managing a Large Backlog** section for more information.
- A full snapshot of the data related to the changed entity is exported to avoid heavy data merging on the target side.
- Once exported, records are deleted from the Data Export Update table.

The process is multi-threaded and a separate file is produced for each thread by default. An optional batch parameter allows for multiple smaller files to be generated per thread by setting a limit on the number of records written to each file. Refer to the **File Size** section for more information.

Note: It is important to schedule the ongoing export batch process to run frequently enough to avoid accumulating a high volume of records in the Data Export Update table. The smaller the table is kept the faster it is for the change data capture mechanism to add records to it.

The ongoing export file name is constructed as follows:

```
INC_EXPORT_[batch run]_[thread]_[thread count]_[timestamp]
[_file sequence].json.gz
```

The "file sequence" part of the file name is used only when more than one file is created per thread. The sequence suffix is populated starting from the second file as follows `_2`.

Refer to Generalized Ongoing Export (**F1-GEEXO**) batch control for more information.

File Size

The initial export batch process produces a single file per thread by default. For some high volume entities this may result in files that are too large to manage. To produce multiple and smaller files for a specific entity, limit the number of records written to each file by setting the corresponding parameter on the initial export batch control defined for the entity. The same parameter may be provided when submitting the Initial Export Initiator batch process, in which case the initiator value is used only when a corresponding value has not been defined on the entity's specific batch control record.

In the same way, the ongoing export batch process produces a single file per thread by default. To produce multiple and smaller files, limit the number of records written to each file by setting the corresponding parameter on the batch control.

To avoid the creation of too many files by a single batch run, the system sets a maximum limit of around 500 files per run. When the requested number of records per file is determined to cause the number of generated files to exceed the system limit, the actual value used is adjusted to meet the system limit.

Managing a Large Backlog

When a large backlog of changes accumulates in the ongoing export queue for some reason, the next batch takes longer to export which delays the downstream import step. A better option is for the backlog to be cleared in smaller "chunks", allowing the downstream process to import them as they are made available.

You may limit the number of records the batch process exports using the **Thread Processing Limit** batch parameter. When specified, the number of records exported by each thread is capped by the specified limit, leaving the remaining records to be consumed by subsequent batch runs. Instead of waiting for the next scheduled batch run, a new batch process may be automatically submitted, if explicitly requested to do so using the **Automatic Backlog Clearance** batch parameter.

It is important to ensure that the backlog clears gradually and that the queue resumes its normal size in a timely manner. The processing limit must therefore be set with an appropriate value that would promote proper clearance of

the queue. To do so, at least 20% of the queue, and no less than 100,000 records, must be consumed by each batch run across all threads. If the specified limit does not meet the minimum clearance requirement then the processing limit is adjusted accordingly.

Record Format

Data is fetched and exported directly from the database in bulk read operations for performance reasons. For that reason, the structure used does not reflect the logical data model of the entity but rather its physical list of tables. Data for a given instance is organized by tables followed by rows in each table and for each row its list of fields in JSON format.

The following describes the format and structure used:

```
{
  "OBJ": "<mo name>",
  "TIMESTAMP": "<export time in ISO format for example 2019-07-25T11:06:04.740615Z>",
  "PK1": "<mo pk1 value>",
  "PK2": "<mo pk2 value if any>", ← PK2-5 should only be included when applicable
  "PK3": "<mo pk3 value if any>",
  "PK4": "<mo pk4 value if any>",
  "PK5": "<mo pk5 value if any>",
  "DELETED": true, ← should only be included when the entity is deleted
  "DATA":
  {
    "<MO table name 1>":
    [
      {<name value pairs of all fields in row 1 in that table>},
      {<name value pairs of all fields in row 2 in that table>},...
      {<name value pairs of all fields in row n in that table>},...
    ],
    "<MO table name 2>":
    [
      {<name value pairs of all fields in row 1 in that table>},
      {<name value pairs of all fields in row 2 in that table>},...
      {<name value pairs of all fields in row n in that table>}
    ],...
    "<MO table name n>":
    [
      {<name value pairs of all fields in row 1 in that table>},
      {<name value pairs of all fields in row 2 in that table>},...
      {<name value pairs of all fields in row n in that table>}
    ]
  }
}
```

Notes about field values and formats:

- All fields for a row are included even when the field is empty or null.
- All string values are trimmed of excess trailing spaces but if a field is empty it exported as an empty string "" and not null.
- An empty array is used for a table node when no records exists for the entity in the table.
- Date/time information is converted to UTC time zone and exported in ISO format for example 2019-07-25T11:06:04.740615Z.
- Deletes have an explicit indicator in the header.

Order of Consuming Files

It is important to apply all the initial export files for a maintenance object before applying ongoing change files to ensure data consistency.

The following is a recommended procedure for consuming generalized data export files:

- Apply all initial data export files before ongoing export files.

- Apply initial files for a maintenance object in run number order.
- Apply ongoing export files in run number order.
- If a new initial export is available the file consumption procedure should be changed temporarily as follows:
 - Stop consumption of ongoing export files.
 - Apply the new initial export files.
 - Resume consumption of ongoing export files.

Recover from a Lost Ongoing Export File

The ongoing export batch process keeps a backup of all entity keys, that were exported on a specific batch run, in a designated backup table. In rare situations where an ongoing export file is deleted or becomes corrupted before it gets processed, the backup table may be used to identify the missing changes and export them again.

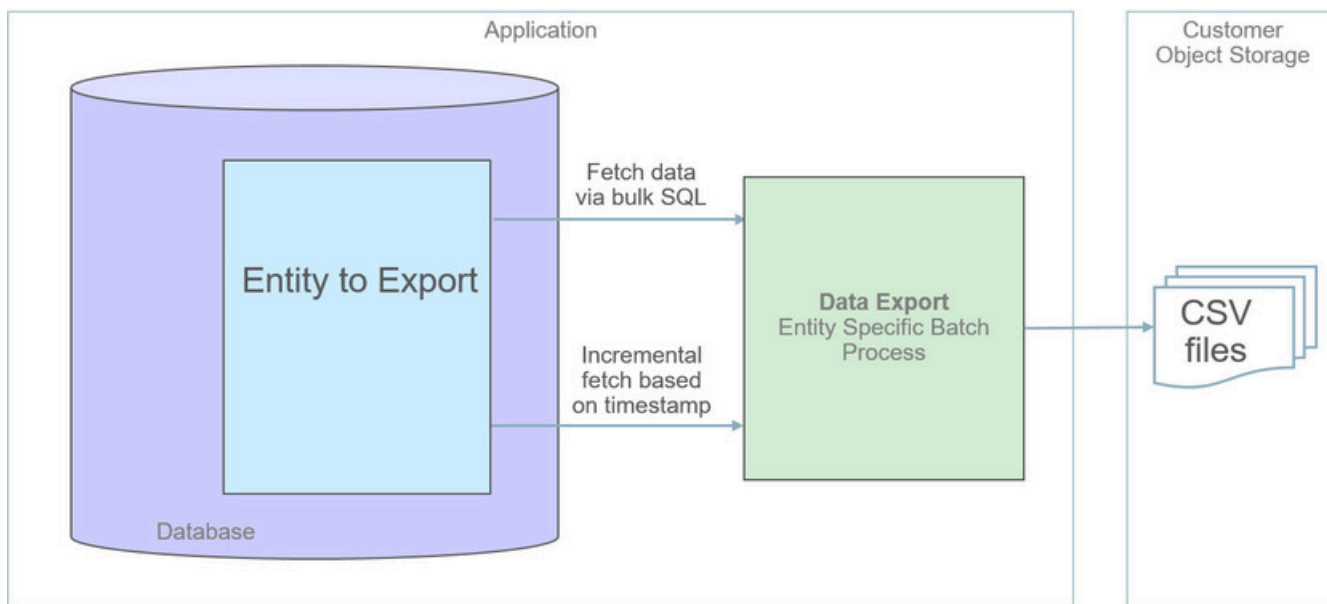

Use the Restore Generalized Export Keys (**F1-GERST**) batch process to recover from this situation. The process identifies the entities that were exported during a specified batch run and adds them back to the ongoing changes queue from the backup table. The entities would then be exported again when the next ongoing export runs. This method does not restore the exact content of the original file that was lost as it cannot be reproduced. Instead, the process ensures that the entities that were included in the lost file would be exported again.

Note: Backup records follow a weekly retention policy for performance reasons. They are meant to support near future situations of file recovery and are not an historical change data capture log.

Specialized Data Export

Several performance considerations are called for when exporting the data of a high volume entity or an entity that is updated in extremely high frequency. The generalized method does not fit such entities and a specific batch process is designed for each, aiming to achieve an optimal export method for the entity. The initial run of the process exports the entity's existing data while subsequent runs of the same process exports data incrementally, i.e. it exports records that were added or updated since the previous run based a timestamp field. The overall process is illustrated in the following diagram:

The following sections further discuss concepts and guidelines related to the specialized data export method.

A Specific Process For Each Entity

A maintenance object that is designed to be exported using the specialized method is explicitly marked as such by the **Data Export Class** option and its specific batch process is defined using the **Export Batch Control** option.

All specialized batch processes are designed to export the data in a CSV format as it produces smaller files in size compared to more verbose formats. Refer to each batch process for more information about specific export considerations and parameters.

Enabling Data Export

To enable data export for a maintenance object a specialized type of [Data Export Control](#) record needs to be created. The record serves as an indication that such entity should be exported and keeps track of the date and time through which data has been exported so far, allowing subsequent export run to only export incremental changes.

Incremental Data Export

The specialized export method tracks changes incrementally from prior export run and does not use a change data capture mechanism. It therefore relies on a timestamp field on the primary table of the maintenance object to indicate when data was added or changed. Only entities that were added or changed since the previous export run are exported with each subsequent run. The date and time through which data has been exported is recorded for each maintenance object on its corresponding Data Export Control record.

Order of Consuming Files

Specialized data export files should be consumed in run number order to ensure a consistent and chronological uptake of data.

Defining Data Export Control

This portal is used to maintain Data Export Control records. These records capture your organization's export settings and current export state for a selected maintenance object. For a generalized export it keeps an indication as to whether the initial export for the maintenance object has been completed or not and whether changes made to the maintenance object should be tracked and exported on an ongoing basis. For a specialized data export it keeps the date/time through which data was exported.

Refer to [Understanding Data Export](#) for more information.

You can access the portal from the **Admin Menu > Implementation Tools > Data Export Control**. You are brought to a query portal with options for searching for a specific record. Once a data export control record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The **Data Export Control** zone provides information about the selected record.

Generalized Export Dashboard

The number of maintenance objects that are eligible for generalized export is large. This portal allows you to easily select and enable export for many eligible entities at once as well as review the current export state of those already enabled at a glance.

Refer to [Generalized Data Export](#) for more information about the generalized data export method.

You can access the portal from the **Admin Menu > Implementation Tools > Generalized Export Dashboard**.

The following zones may appear as part of the portal's **Main** tab page.

- **Export Entities.** This zone lists entities for which generalized data export control settings have already been set.
- **Eligible Entities.** This zone lists entities that are eligible for the generalized data export method and for which such settings have not yet been set.

Customer Care and Billing Administrative User Guide

Defining General Options

This section describes control tables that are used throughout Oracle Utilities Customer Care and Billing.

Defining Installation Options

The topics in this section describe the various installation options that control various aspects of the system that are specific to the Oracle Utilities Customer Care and Billing product.

Fastpath:

Refer to [Installation Options - Framework](#) for options that are common to products on the same framework.

Installation Options - Main

Select **Admin > General > Installation Options** and use the **Main** page to define system-wide installation options.

Description of Page

Use **Quick Add Tender Type** to define the tender type [defaulted on payments added using the Payment Quick Add transaction](#).

Use **Starting Balance Tender Type** to define the tender type of the starting balance recorded on your tender controls (this will almost always be the tender type associated with "cash"). This value is used during tender control balancing as a separate balance is required for each tender type in order to balance a tender control. Refer to [The Lifecycle Of A Tender Control](#) for more information.

Fastpath:

For more information, refer to [Setting Up Tender Types](#).

Turn on the **Create Field Activity Start Stop** if field activities should be created when a start or stop is recorded (as opposed to shortly before the start/stop date). You might want to turn this switch off if it's possible for the state of the service point (or its meter / item) to change between the time service is requested and the actual service date. Why? Because the state of the service point and the state of its meter / item affects the type of field activity that is created. For example, if a customer wants to start service and there is no meter at the metered service point, an "install meter" field activity is created. However, if by the time the install date comes around, a meter has been installed by some other means; this field activity is inappropriate. This is why you might want to setup the system to wait until shortly before the service date to create the field activity (i.e., it reduces the likelihood that an inappropriate field activity is created). Refer to [Starting Service and Field Activities](#) for more information.

Note:

Appointments require field activities. If you don't create field activities when service is started / stopped, you cannot use the appointment scheduling functions. Refer to [The Big Picture of Appointments](#) for more information.

If you use orders to create new customers, define the **Campaign** that should be defaulted on orders created when the order transaction is opened for a new customer. Refer to [Real time Marketing of Services to a New Customer](#) for more information.

Use the **Premise Geo Type** to indicate whether at least one geographic identifier (e.g., GPS coordinate) is Required or Optional on a premise. Refer to [Defining Geographic Types](#) for more information.

The **Alternate Representation** flag should be set to None unless your organization uses multiple character sets for a person's main name and / or a premise's address. Alternate representations are typically only used in countries where multiple character sets are used. For example,

- In Hong Kong, a person's name may be written in both Chinese characters and in English.
- In Japan, a person's name may be written in both Kanji and Katakana.

In both of the above situations, users need to be able to use both representations to find a customer or a premise.

Note:

Spouses. If your organization doesn't use multiple character sets, you might want to consider using this functionality for spousal relationships. For example, rather than setup a person for each party in a spousal relationship, you could simply define one party using the person's main name and the spouse using the alternate name. While this is a bit of a "hack", it might be sufficient for your implementation as it will be much easier for an end user to use.

Alerts that should appear adjacent to a person's name or address. If your organization doesn't use multiple character sets, you might want to consider using this functionality to implement critical person or premise alerts. For example, if you have a customer who's supported by a specific account representative, you could enter the account rep's name as the person's alternate name. If you do this, the account rep's name would appear in parenthesis following the customer's name. In addition, you can search for the customers supported by the account rep on Control Central by entering the account rep's name. This is a bit of a "hack", but it might prove useful for a variety of functions.

If your organization uses alternate representations of person name or address, set this flag to one of the following values:

- Use a value of Address if you only use alternate representations for premise addresses.
- Use a value of Name if you only use alternate representations for a person's primary names.
- Use a value of Name & Address if you use alternate representations for both premise addresses and person names.

The following points describe the ramifications of this flag in the system:

- If you support alternate representations of a person's primary name,
- The name grid on [Person - Main](#) allows you to specify an Alternate name for the person.
- If you use the base package name formatting algorithm, a person's name will be shown throughout most of the system in the format AAA (BBB), where AAA is the person's primary name and BBB is the person's alternate name. Note, this format does not apply to names that appear in search results (i.e., the alternate name is not concatenated to the main name in search results; however you can search for information using the alternate name).
- Most of the system's person name-oriented searches will allow users to use both a person's primary and alternate names to search for information.
- If you support alternate representations of a premise's address,
- A new tab is available on the [Premise](#) page that allows a user to define an alternate address for a premise.
- If you use the base package address formatting algorithm, a premise's address will be shown throughout most of the system in the format AAA (BBB), where AAA is the premise's primary address and BBB is the premise's alternate address.
- Most of the system's premise-oriented searches will allow users to use both a premise's primary and alternate addresses to search for information.

If the CTI Integration flag has been enabled, set the **CTI Integration** flag to Yes if your organization integrates with an external computer telephony integration (CTI) system that supports a "get next caller in the queue" function.

The **Control By CIS Division** flag affects system behavior in many areas. This flag should be set if your business operates in different jurisdictions and CIS Division is used to delineate accounts and premises that users can access. When this flag is set, all users must be associated with at least one CIS division. See [Users and CIS Division](#) on page 593 for more information.

The following system behaviors are affected by this flag:

- On Person, CIS Division is presented and is required when adding an account. Customer class is defaulted after CIS Division is set.
- On Order, CIS Division is presented when a new account is being added and is required. Customer class is defaulted after CIS Division is set.
- On Person, Order, Account and Premise, the list of CIS Divisions that can be chosen is restricted to the CIS Divisions associated with the user. The user's primary CIS Division is defaulted.
- On Account, CIS Division is presented before customer class. Customer class is defaulted after CIS Division is set.

The **Premise/SP Search** flag is used to provide access security to premises and service points that are not linked to an account.

- When the flag is set to Not Restricted, access to premises and service points that are not linked to an account is not secured.
- When the flag is set to Restricted by CIS Division, access to premises and service points that are not linked to an account is secured by the user's CIS Divisions. If the premise has a CIS Division, then only users that have access to that CIS division can access that premise or its service points. See [Users and CIS Division](#) for more information. Premise and service points belonging to premises without a CIS Division are not secured. A Premise Type setting can control whether premises of that type require a CIS Division.

Note: Premises and service points that are linked to an account are secured by the account access group

Warning:

In order to improve response times, installation options are cached the first time they are used after a web server is started. If you change this field's option and you don't want to wait for the cache to rebuild, you must clear the cached information so it will be immediately rebuilt using current information. Refer to [Caching Overview for information](#) on how to clear the system login cache (this is the cache in which installation options are stored).

Installation Options - Person

Select **Admin > General > Installation Options** and use the **Person** page to define person-specific installation options.

Description of Page

Use the **Person ID Usage** to indicate whether or not at least one form of identification is Required or Optional when a new person is added. If required, indicate when the identifier is required based on the person's association with account(s).

Each form of identification has an identifier type. For persons that are humans (as defined by the person type), the system defaults the identifier type defined in **Identifier Type (Person)**. For persons that are businesses (as defined by the person type), the system defaults the identifier type defined in **Identifier Type (Business)**.

The **Use Name Separator** and **Person Name Separator Character** are used when formatting person names for persons (not businesses). The person name format algorithm type (NMFMT-VALFMT) that is provided with the system uses these settings.

Installation Options - Account

Select **Admin > General > Installation Options** and use the **Account** page to define account-specific installation options.

Description of Page

When a new account is added, the system requires it have a customer class. If the main customer linked to the account is a human (as defined by the customer's person type), the system defaults the customer class defined in **Customer Class (Person)**. For persons that are businesses (as defined by the person type), the system defaults the customer class defined in **Customer Class (Business)**. For more information, refer to [Setting Up Customer Classes](#).

In addition to requiring a customer class when a new customer is added, the system also requires a "main customer" (i.e., a reference to a person who is identified as the main customer for the account). Enter the default **Account Relationship Type Code** to be used to define the main customer relationship. For more information, refer to [Setting Up Account Relationship Codes](#).

Enter the default **Bill Route Type** to be used to define how bills should be routed to a customer. For more information, refer to [Setting Up Bill Route Types](#).

Enter the default **Quote Route Type** to be used to define how quotes should be routed to a customer. For more information, refer to [Setting Up Quote Route Types](#) .

If the number of pending start and pending stop service agreements exceeds the **Start Stop Detail Threshold** for an account, it is considered a large account for start stop purposes. Refer to [Start/Stop Maintenance](#) for more information.

Installation Options - Billing

Select **Admin > General > Installation Options** and use the **Billing** page to define billing-specific installation options.

Description of Page

The **Bill Segment Freeze Option** controls when a service agreement's balance and the general ledger is affected by bill segments and certain types of adjustments. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) to understand the significance of this option.

The **Accounting Date Freeze Option** controls how the accounting date defined on financial transactions is populated. Refer to [Forcing The Freeze Date To Be Used As The Accounting Date](#) to understand the significance of this option.

Define the **Rollover Threshold Factor** used by billing to determine if a register's consumption is sensible. This value is used as follows:

- Whenever billing calculates a meter's register's consumption, it compares it to a value equal to X times the register's maximum capacity (where X is the Rollover Threshold Factor).
- If consumption exceeds this value, a bill segment error is generated. If this consumptive value is correct, a user will need to override the consumption value billed on the bill segment (billing will never use such a read).

Define the **Minimum Amount for Final Bill**. If a final bill is less than this amount, the bill is still produced; it's just not printed.

Typically, the system sets a bill's Bill Date equal to the date on which it is completed. If you want to be able to specify a bill's Bill Date when you complete a bill, turn on **User Can Override Bill Date**. You would only want to override the bill date if you are setting up sample bills from historical period whose bill date needs to reflect the respective historical period.

Turn on **Use High Low Failures on Bill** if the system should mark meter reads that fail high / low checks as billable. Turn off this switch if such reads should not be used by billing. Users may override this default value on a specific read. Refer to [Review High / Low](#) for more information.

Base Time is used by interval billing algorithms to determine the effective start and end times for a given period. The **Start Day Option** further defines how to use the base time, indicating whether the base time is for the Current Day or for the Previous Day. Refer to [Start and End Times for Billing](#) for more information.

Turn on **Use Alternative Bill ID** if your implementation uses assigned document numbers or sequential bill numbers. In the **Alternative Bill ID Option** list:

- Select **Document Numbers** if you require a system-assigned document number for each bill in addition to the Bill Id, which is a system-assigned random number used as the bill's primary identifier. Refer to [Document Numbers](#) for more information.
- Select **Sequential Bill Numbers** if you require a system-assigned unique sequential number for each bill in addition to the Bill Id, which is a system-assigned random number used as the bill's primary identifier. Refer to [Sequential Bill Numbers](#) for more information

Note:

Document Number Algorithms. In addition to turning on **Use Alternative Bill ID** and specifying the **Alternative Bill ID Option**, the Document Number and Document Number Details algorithms must be enabled on the [Installation](#) record. These algorithms contain the logic used by the system to assign a document number to a bill.

The **Bill Correction** option lets you control whether your implementation uses Credit Notes or Correction Notes. Select the **Credit Note** option if you require bill segment cancellation details to be presented to the customer on a separate bill (referred to as a credit note). Refer to [Credit Notes](#) for more information. Select the **Correction Note** option if you require bill segment cancellation details and bill segment rebill details to be presented to the customer on a separate bill (referred to as a correction note). Refer to [Correction Notes](#) for more information.

Note:

Credit Notes or Correction Notes. The Bill Correction option on the Installation record controls whether Credit Notes or Correction Notes are allowed. If your implementation uses Correction Notes, the override label on the following should be customized accordingly:

Lookup value CRNT on the customizable lookup field TXN_FLTR_TYPE_FLG (this lookup value is used on the Match Event Page and Account Bill History transactions)

Lookup value CR on the customizable lookup field PYCAN_SYS_DFLT_FLG (this lookup value is used on the Pay Cancel Reason transaction)

Metadata field CR_NOTE_FR_BILL_ID (this field is used on the Bill Search Page)

The **Autopay Creation Option** controls when automatic payments are created, distributed, and frozen. This option allows you to control when automatic payments will affect customer's balances and when their financial impact affects the general ledger. Refer to [How And When Are Automatic Payments Created](#) to understand the significance of this option.

Installation Options - C&C

Select **Admin > General > Installation Options** and use the **C&C** page to define credit and collections-specific installation options.

Description of Page

When you look at an account or service agreement's debt, the system shows the respective age of each piece of outstanding debt. The **Oldest Bucket Age (Days)** defines the debt age after which the system groups all outstanding debt together. For example, if this field is 180:

- The exact age of each element of debt that is less than 180 days old would be shown as a separate line item in the aged debt information.
- All debt older than 180 days would be amalgamated into a single "bucket".

Oldest Bucket Age (Days) also has another use - it defines the age of financial transactions that are considered by the background process that marks old debt as "redundant". This batch process is referred to by the batch code of REDSAAMT.

Warning:

If you change the value of **Oldest Bucket Age (Days)** after debt has been marked as "redundant" by REDSAAMT, the system will NOT re-age the old debt (i.e., once a financial transaction has been marked as "redundant", it is "redundant" forever).

Enter what you consider to be an excellent credit rating in **Beginning Credit Rating**. Collection events can cause an account's credit rating to decrease. When an account's credit rating falls below a certain level, different collection processes may ensue.

Use **Beginning Cash-Only Score** to define the cash-only score for accounts with a perfect payment history (i.e., one without non-sufficient funds). When you cancel a payment tender and use a cancellation reason marked as NSF, the system will cause the account's cash-only score to increase by the value on the payment cancellation reason.

Use **Credit Rating Threshold** to define when an account's credit rating becomes risky. When an account's credit rating falls beneath the Credit Rating Threshold, the system will:

- Assuming you've enabled the Control Central alert algorithm, C1-CRRT-ACCT, an alert displays when an account's credit rating falls below the credit rating threshold on the installation record. This algorithm is plugged-in on the [installation record](#).
- Subject the account's debt to different collection criteria. For more information, refer to [Designing Your Collection Class Control Overrides](#).

Use **Cash-Only Threshold** to define the number of cash-only points a customer must have before the system warns the CSR accepting payments that the account is cash-only.

Installation Options - Financial Transaction

Select **Admin > General > Installation Options** and use the **Financial Transaction** page to define financial transaction installation options.

Description of Page

Use **GL Batch** to define the batch process that is used to interface your financial transactions to your general ledger. The process is snapped on FT download records by the GLS background process.

Use **A/P Batch** to define the batch process that is used to interface your check requests (initiated with adjustments with an adjustment type that reference an A/P request type) to you accounts payable system.

Use **Fund Accounting** to indicate if [fund accounting](#) is Practiced or Not Practiced at your organization.

Use **Alternate Currency** to indicate if your organization accepts customer payments in currencies other than the account's currency.

Fastpath:

Refer to [Alternate Currency Payments](#) to understand the significance of this option.

Installation Options Framework - Algorithms

Select **Admin > General > Installation Options - Framework** and use the **Algorithms** page to define specific system events.

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|---------------------|---------------------|---|
| Account Information | Optional | <p>We use the term "Account information" to describe the basic information that appears throughout the system to describe an account. The data that appears in "account information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the system default "Account information".</p> |

| | | |
|--------------------------|--|---|
| Adjustment Information | Optional | <p>We use the term "Adjustment information" to describe the basic information that appears throughout the system to describe an adjustment. The data that appears in "Adjustment information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the system default "Adjustment information".</p> <p>Note: This algorithm may be further overridden by an "Adjustment information" plug-in on the Adjustment Type. Refer to Adjustment Type for how algorithms of this type are used.</p> |
| Appointment Information | Required | <p>We use the term "Appointment information" to describe the basic information that appears throughout the system to describe an appointment . The data that appears in "appointment information" is constructed using this algorithm.</p> |
| Auto Pay Creation | Required if you allow customers to pay automatically | <p>This algorithm is executed to create automatic payments whenever the system creates automatic payments. Refer to <i>How And When Are Automatic Payments Created</i> for the details.</p> |
| Bill Cycle Selection | Optional | <p>This algorithm is only used if your organization has specific rule for assign a bill cycle to an account. This plug-in spot is invoked by the SA Activate/Stop common routine. The spot is called right after the system has updated the account.</p> |
| Bill Information | Required | <p>We use the term "Bill information" to describe the basic information that appears throughout the system to describe a bill. The data that appears in "bill information" is constructed using this algorithm.</p> |
| Bill Segment Information | Optional | <p>We use the term "Bill segment information" to describe the basic information that appears throughout the system to describe a bill segment. The data that appears in "bill segment information" is constructed using this algorithm.</p> |

| | | |
|--|----------|---|
| Case Information | Optional | <p>We use the term "Case information" to describe the basic information that appears throughout the system to describe a case. The data that appears in "case information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the system default "Case information".</p> <p>Note: This algorithm may be further overridden by a "Case information" plug-in on the Case Type. Refer to Case Type for how algorithms of this type are used.</p> |
| Collection Agency Referral Information | Optional | <p>We use the term "Collection Agency Referral information" to describe the basic information that appears throughout the system to describe a collection agency referral.</p> <p>Plug an algorithm into this spot to override the system default "collection agency referral information".</p> |
| Collection Process Information | Optional | <p>This algorithm displays additional information related to a collection process in a special field on the collection process main page.</p> |
| Control Central Alert | Optional | <p>These algorithms produce the alerts shown on the Alert Zone. Additionally, system-generated alerts can be show on the alert zone if enabled. (See the Alert Zone for more information and the list of system-generated alerts.)</p> |
| Credit Rating 'Created By' Information | Required | <p>The data that appears in the credit rating "created by" information is constructed using this algorithm.</p> <p>Refer to Account - C&C for more information about the credit rating.</p> |
| Credit Rating History Information | Optional | <p>We use the term Credit Rating History information to describe the basic information that appears throughout the system to describe a credit rating history entry.</p> <p>Plug an algorithm into this spot to override the system default "credit rating history information".</p> |

| | | |
|----------------------------------|---|---|
| Digital Signature | Optional | <p>This algorithm is only used if your organization generate and store digital signatures for each bill.</p> <p>Refer to Digital Signatures for the details.</p> |
| Document Number | Optional | <p>If document numbers have been enabled on the installation record, this algorithm type assigns a document number to a bill or payment event.</p> |
| Document Number Details | Optional | <p>If document numbers have been enabled on the installation record, this algorithm type is responsible for returning the details used to construct the document number.</p> |
| Determine Open Item Bill Amounts | Required if you use overdue functionality to collect on bills | <p>This algorithm is responsible for determining the unpaid amount of an open-item bill. It can also be used to return the unpaid amount for a specific SA on a bill.</p> |
| Document Sequence Number | Optional | <p>If document numbers have been enabled on the installation record, this algorithm type is responsible for generating document sequence number only.</p> |
| FA Additional Information | Optional | <p>This algorithm displays additional information related to a field activity in a special field called Additional Info on the field activity main page.</p> <p>For example, contact information linked to the field activity's field order may be displayed.</p> |
| FA Information | Required | <p>We use the term FA information to describe the basic information that appears throughout the system to describe a field activity. The data that appears in "FA information" is constructed using this algorithm.</p> |
| Item Information | Required if you have items | <p>We use the term "Item info" to describe the basic information that appears throughout the system to describe an item. The data that appears in "Item info" is constructed using this algorithm.</p> |

| | | |
|----------------------------|-----------------------------|---|
| Meter Information | Required if you have meters | We use the term "Meter info" to describe the basic information that appears throughout the system to describe a meter. The data that appears in "Meter info" is constructed using this algorithm. |
| Meter Read High Low Limits | Optional | This algorithm is executed to calculate high and low limits for high / low check when a meter read is added to the system (whether through a batch upload or online). |
| Online Bill Display | Optional | This algorithm constructs or retrieves a PDF that contains the image of a bill. This algorithm is executed when the Display Bill button is clicked on the Bill page. Refer to Technical Implementation of Online Bill Display for more information. |
| Online Field Order Display | Optional | This algorithm constructs a PDF that contains the image of a field order. This algorithm is executed when the Display Field Order button is pressed on the Field Order page. Refer to Technical Implementation of Online Field Order Display for more information. |
| Online Letter Display | Optional | This algorithm constructs or retrieves a PDF that contains the image of a letter. This algorithm is executed when the Display Letter button is pressed on the Customer Contactportal . Refer to Technical Implementation of Online Letter Display for more information. |
| Online Quote Display | Optional | This algorithm constructs a PDF that contains the image of a quote. This algorithm is executed when the Display Quote button is pressed on Quote - Main . Refer to Technical Implementation of Online Quote Display for more information. |
| Online Statement Display | Optional | This algorithm constructs a PDF that contains the image of a statement. This algorithm is executed when the Display Statement button is pressed on Statement - Main . Refer to Technical Implementation of Online Statement Display for more information. |

| | | |
|-----------------------------|----------|---|
| Override Proration Factors | Optional | This algorithm is only used if your organization has unusual rate proration requirements that necessitate the overriding of the base package proration logic. For example, you may have certain calculation rules whose charges should never be prorated. Refer to Overriding Proration Factors for more information. |
| Override Seasonal Proration | Optional | This algorithm is only used if your organization has unusual method of determining the seasons for your calculation rules. For example, you may determine the seasonal boundaries for a calculation rule based on the scheduled meter read date associated with the bill cycle. |
| Payment Amount Calculation | Required | This algorithm is executed to calculate the amount of an automatic payment for a bill for an account with an active auto pay option. Refer to How And When Are Automatic Payments Created for more information on automatic payments. This algorithm is also executed to default the amount of a manually added payment. Refer to How To Add A New Payment Event for more information on adding a payment manually. |
| Payment Event Information | Optional | We use the term "payment event information" to describe the basic information that appears throughout the system to describe a payment. The data that appears in "payment information" is constructed using this algorithm. |
| Payment Information | Required | We use the term "payment information" to describe the basic information that appears throughout the system to describe a payment. The data that appears in "payment information" is constructed using this algorithm. |

| | | |
|--------------------------------|----------|--|
| Person Information | Required | In most parts of the system, a person's Main name is displayed to describe a person. However, several transactions do not use this method. Rather, these transactions call the algorithm that's plugged into this spot to construct the person's name. Refer to the description of the Alternate Representation flag on the Main tab for a list of these transactions and for the rationale behind this algorithm. |
| Person Name Format | Required | The format of names entered on Person - Main and Order - Main is validated using this algorithm. |
| Premise Information | Required | We use the term "premise info" to describe the basic information that appears throughout the system to describe a premise. The data that appears in "premise info" is constructed using this algorithm. |
| SA Information | Optional | <p>We use the term "SA information" to describe the basic information that appears throughout the system to describe a service agreement. The data that appears in "SA information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the system default "SA information".</p> <p>Note: This algorithm may be further overridden by an "SA information" plug-in on the SA Type. Refer to SA Type - Algorithms for how algorithms of this type are used.</p> |
| Severance Process Cancellation | Optional | <p>This algorithm is executed to perform additional processing when the system cancels a severance process.</p> <p>Note: This algorithm is executed before the Severance Process Template - Post Cancel Algorithm is executed. Canceling a severance process on-line manually does not execute this algorithm.</p> |
| SP Information | Required | We use the term "SP info" to describe the basic information that appears throughout the system to describe a service point. The data that appears in "SP info" is constructed using this algorithm. |

Defining Customer Languages

As described under [Defining Languages](#), you define the language in which each user see the system. In addition to defining each user's language, the system allows you to define each customer's preferred language. For example, one customer can receive bills in English whereas another customer could receive their bills in Chinese.

Each customer's language is defined by the [language code](#) on their [person record](#). Bills, adjustments and other system-generated records will then be done in the language of the main customer of the account. In addition, the language code is passed on to all customer-facing interfaces, such as letter requests and bill print.

Note:

You can define Rates in multiple languages - when a bill is generated, the line-item descriptions are generated and stored in the account's main customer's language of choice. Anyone who subsequently views these bills can only see the descriptions in that language.

To support bills and other correspondence, you must also provide translations of standard bill stock and letters. This must be handled by your printing software vendor.

Defining Accounting Calendars

Accounting calendars determine the accounting period to which a financial transaction will be booked. The following points describe how the system determines a financial transaction's account period:

- Every financial transaction references an accounting date and its service agreement
- Every service agreement references a service agreement type
- Every service agreement type references a GL division
- Every GL division references an accounting calendar
- The accounting calendar contains the cross-reference between the accounting date specified on the financial transaction and related accounting period in your general ledger

Warning:

This information must be the same as the information in your financial database.

To add or review an accounting calendar, choose **Admin > General > Accounting Calendar > Search**.

Description of Page

Enter a unique **Calendar ID** and **Description** for the calendar.

Enter the **Number Of Periods** for the calendar. Don't count the adjustment period, if you use one, or any special "system" periods.

Specify the **Fiscal Year**, each **Accounting Period** in that year, a **Period Description**, the **Begin Date** and the **End Date**.

When you enter begin and end dates, you can define monthly calendar periods or any fiscal period that matches your accounting calendar (weekly, bimonthly) as long as the begin and end dates of successive periods do not overlap. Every day of the year must be included in a period; do not leave gaps between period dates.

For each fiscal period, enter the **Open From Date** and **Open To Date**. These dates define when that particular business dates are open for posting financial transactions to that fiscal period. For example, you might calculate a bill on Sept 1 for usage recorded on 31 August. To post this financial transaction in the August period, you must keep it open through Sept 1.

As time passes, you will need to return to this transaction to manually enter ensuing years. You can enter several years at a time or incorporate the task into end-of-year system maintenance.

Defining General Ledger Divisions

There are two types of Divisions referenced in the system: a CIS Division and a GL Division. This is a rather powerful structure, but it can be confusing.

- General Ledger divisions typically comprise individual entities (e.g., companies) in your general ledger. You must set up a GL division for each such entity. The GL division's sole purpose in the system is to define the accounting period associated with financial transactions linked to service agreements associated with the GL division (service agreements are associated with GL divisions via their SA type). The system cares about accounting periods in order to prevent a user from booking moneys to closed periods. It also uses accounting periods when it produces the flat file that contains the consolidated journal entry that is interfaced to your general ledger (refer to [The GL Interface](#) for more information).

Note:

When determining how many GL Divisions you need, be sure to consider your general ledger and how your chart-of-accounts is structured. You will typically have one GL division for each "company" in your general ledger.

- A CIS division is typically associated with a jurisdiction. The definition of a jurisdiction is a geographic-oriented entity with unique business rules. For example, if you conduct business in California and Nevada, and each state has different collection rules, you will need a separate jurisdiction for each state. You must set up a CIS division for each jurisdiction in which you conduct business.

Fastpath:

Refer to [Setting Up CIS Divisions](#) for information about CIS Divisions.

To define a general ledger division, select **Admin > General > General Ledger Division**.

Description of Page

Enter a unique **GL Division** for the general ledger division.

Enter a **Description** of this general ledger division.

Define the accounting **Calendar ID** that controls how to convert an FT's accounting date into an accounting period. Refer to [Defining Accounting Calendars](#) for more information.

You may define a **Currency Code** for the GL division.

Note: The GL Download Extract (GLDL) batch process uses the currency code from GL division, by default. For multi-currency support, setting the Use FT Currency Code batch parameter to Y would cause the FT's currency code to be used instead. Refer to the [GLDL Detail Record Layout](#) for more details.

Defining Banks & Bank Accounts

The topics in this section describe how to maintain your implementation's bank accounts.

Bank - Main

To review Banks choose **Admin > Financial > Bank > Search**.

Description of Page

Enter a unique **Bank** and **Description** for the bank.

The **Bank Accounts** collection displays the bank accounts currently linked to this bank code. Use the drill down button to view more details or to modify the bank account details. Alternatively, you may navigate to the Bank Account tab and scroll to the desired bank account.

Bank - Bank Account

To review Bank Accounts for a Bank, choose **Admin > Financial > Bank > Search** and then navigate to the **Bank Account** page.

Description of Page

Use the **Bank Accounts** tab to define the attributes of each bank account. For each account, enter the following information:

- Enter a **Bank Account Key** to identify an Account at a Bank. You may have more than one account at a given bank, and you may have accounts at more than one bank. This code will allow the system to easily identify a specific account.
- Enter a **Description** to appear on prompt lists, inquiries, and reports.
- Enter the **Account Number**, **Check Digit** and if needed, the **Branch ID** of the bank where the account is held.
- Enter the **Currency Code** for the currency in which the account is denominated.
- Use **DFI ID** to define the Depository Financial Institution ID that is interfaced to the automatic payment-processing agent as part of the automatic payment interface.
- Enter the **Distribution Code** to be used for cash GL distributions when a payment is frozen or canceled.

Defining Issuing Centers

This section provides information about defining issuing centers that are used to assign document numbers to bills and payment events. An issuing center should be configured for each location that issues bills. The installation record Document Number and Document Number Details algorithms contain the logic used by the system to assign a document number to a bill. To set up an issuing center, open **Admin > General > Issuing Center > Add**.

Fastpath:

Refer to [Document Numbers](#) for information about document number assignment.

Note:

This section is only relevant for some organizations. The information in this section is only relevant if your organization indicated on the installation record that it uses document numbers as an alternative bill id. If your organization does not use document numbers as an alternative bill id, then no other setup is required.

The topics in this section describe the base-package zones that appear on the Issuing Center portal.

Actions

This is a standard [actions zone](#).

If the issuing center is in a state that has valid next states, buttons to transition to each appropriate next state are displayed.

Issuing Center List

The Issuing Center [List zone](#) lists every issuing center. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent issuing center.
- Click the Add link in the zone's title bar to add a new issuing center.

Issuing Center

The Issuing Center zone contains display-only information about an issuing center, including its current and historic branches. This zone appears when an issuing center has been broadcast from Issuing Center List zone or if this portal is opened via a drill down from another page.

Please see the zone's help text for information about this zone's fields.

Issuing Center Log

This is a standard [log zone](#).

Setting Up Service Types

You will have one service type for each type of service you provide to your customers. If we assume that your organization sells electricity, gas and water, you will need three service types for these services. In addition, you will probably want a catch all service type of Other to put on SA types used for write-offs, payment arrangements and deposits.

Note:

Non Service Point-Oriented Service Types. You may require additional service types if you have non service point-oriented services, e.g., land leases and deposits. Refer to [Service Segmentation](#) for more information.

This page is also used to define valid facility levels for a service type. You may wonder, What is a facility level? Every type of service tends to use a different mapping philosophy to designate the facility hierarchy that supplies service to the service point. For example, electric service typically uses a substation / feeder / node facility hierarchy to define how electricity is supplied to a service point (the substation is the highest level in the hierarchy, the feeder comes next, and finally the node). On the other hand, gas service uses a city gate / main / feeder hierarchy.

If your organization maintains this type of information on service points, you will set up your facilities and their interrelationships. On this page you set up the number and type of facility levels used for every service and you define the valid values for each facility level. On the [Facility Level 1 & 2](#) and [Facility Level 2 & 3](#) pages, you define the values that may coexist in each level. After these set up tasks are complete, you're ready to enter facility levels on your service points.

Note:

A service point's facility levels are used to help pinpoint problems and dispatch service crews during outages.

The topics in this section describe how to set up service types and facility levels.

Service Type - Main

To define service types and the types of facility levels, select **Admin > General > Service Type > Add**.

Description of Page

Enter a unique **Service Type** and **Description** for each service type.

Use the **Facility Level Names** collection to define the **Facility Level** and **Description** for each level in the service type's hierarchy. The description is used as the label prefixing the respective facility level on the Service Point Maintenance page.

Move to the **Level 1** tab to maintain the valid values for the highest facility level.

Service Type - Level 1

Open **Admin > General > Service Type > Add** and navigate to the **Level 1** page to define the various facilities classified at the highest level.

Description of Page

You can optionally start the grid at a given **Facility Level 1**.

Enter a **Facility Level 1** code and a **Description** for each facility in the highest level.

Service Type - Level 2

Open **Admin > General > Service Type > Add** and navigate to the **Level 2** page to define the various facilities classified at the second level.

Description of Page

You can optionally start the grid at a given **Facility Level 2**.

Enter a **Facility Level 2** code and a **Description** for each facility at the second level.

Service Type - Level 3

Open **Admin > General > Service Type > Add** and navigate to the **Level 3** page to define the various facilities classified at the third level.

Description of Page

You can optionally start the grid at a given **Facility Level 3**.

Enter a **Facility Level 3** code and a **Description** for each facility at the third level.

Defining Service Tasks Options

This section describes concepts and procedures related to service tasks.

About Service Tasks

Service tasks are records that can be used to perform a variety of tasks. Examples include:

- Task-related records performed by users of other Oracle Utilities applications, such as Oracle Utilities Customer Self Service.
- Task-related records performed by Oracle Utilities Customer Care and Billing to manage specific processing, such as net energy metering true-ups, or prepaid billing to create bill segments for smart meter prepaid service agreements.

The main attribute used to define a service task is service task type. The service task type defines properties common to specific types of service tasks.

For more information, see [Searching and Viewing Service Tasks](#).

About Service Task Types

Service task types define properties common to specific types of service tasks. Service task types represent different types of tasks that can be performed by:

- Users of other Oracle Utilities applications, such as Oracle Utilities Customer Self Service. An example of a service task includes self service meter reads, in which users enter their own meter reads via the Customer Self Service application.
- Oracle Utilities Customer Care and Billing to manage specific processing. Examples include net energy metering true-ups, or prepaid billing to create bill segments for smart meter prepaid service agreement.

Service task types can be defined by the following attributes:

- **Service Task Type:** the name of the task type.
- **Service Task Type Business Object:** the business object that defines the behavior of the service task type.
- **Service Task Business Object:** the business object instantiated when service tasks of this type are created.
- **Service Task Class:** the category used to define service task types for reporting purposes (self-service, miscellaneous, etc).
- Other data based on the specific type of service task (such as minimum days in true-up period, billing frequency, or default payment method.)

For more information about defining service task types, see [Defining Service Task Types](#) on page 576.

For more information about the service task types delivered with the application, see [Base Package Service Task Types](#) on page 576.

Defining Service Task Types

To maintain existing service task event types, select **Admin > Customer > Service Task Type**, then use standard actions to edit, duplicate, or delete a service task type.

To define a new service task type, follow these steps:

1. Select **Admin > Customer > Service Task Type**.
2. Enter a name and a meaningful description for the service task type.
3. If needed, select the business object to use when creating service tasks of this type.
4. Select the service task class applicable to service tasks of this type, if applicable.
Some service tasks types used solely by Oracle Utilities Customer Care and Billing have a default class of **Miscellaneous**.
5. Enter a detailed description for the service task type.
6. Complete the remaining fields and sections, as needed.
7. If applicable, select a To Do type and corresponding To Do role to use when creating To Do entries related to service tasks of this type.
8. Click **Save**.

This service task type can now be used when service tasks are received from other Oracle Utilities applications, such as Oracle Utilities Customer Self Service, or service tasks created specifically by Oracle Utilities Customer Care and Billing.

For more information about service task types, see [About Service Task Types](#) on page 575.

For more information about the service task types delivered with the application, see [Base Package Service Task Types](#) on page 576.

Base Package Service Task Types

This section provides descriptions of the service task types provided with the base package.

| Service Task Type | Business Object | Detailed Description | Related Transaction Business Object |
|------------------------------------|-------------------------------|--|-------------------------------------|
| Appointment Notification Task Type | C1-NotifyAppointmentTaskType | This business object is used to capture the information to use in appointment notification processing. | Appointment Notification Task |
| Create Customer Contact Task Type | C1-CreateCustContactTaskType | This business object is used to capture the information to use in create customer contact task processing. | Customer Contact Request Task |
| Direct Debit Task Type | C1-DirectDebitMandateTaskType | This business object defines configuration information that is used for processing Single Euro Payments Area (SEPA) direct debit transactions. | Direct Debit Mandate Task |
| FA Completion Task Type | C1-FACompletionTaskType | This business object captures the attributes used in field activity completion task processing. | FA Completion Task |

| | | | |
|---|--------------------------------|---|--------------------------------------|
| Field Activity Remark Task Type | C1-FieldActivityRemarkTaskType | This business object is used to capture the information to use in create field activity remark task processing. | Field Activity Remark Task |
| Form Task Type | C1-FormTaskType | This business object captures attributes relevant for a particular form type to be used when a self-service customer creates a form. | Form Task |
| Missed Appointment Notification Task Type | C1-NotifyMissedApptTaskType | This business object is used to capture the information to use in missed appointment processing. | Missed Appointment Notification Task |
| Notification Task Type | C1-NotifyTaskType | This business object captures information about a notification that is made available for sign-up by self-service users. | Notification Preferences |
| Net Energy Metering Task Type | C1-NEMTrueUpTaskType | This business object is used to maintain the various configuration options that are used by the true up monitor (TUM) business object's algorithms. It defines the length of the true up period as well as the adjustments types used during the true up process. For true up reversals, the adjustment cancel reason to use is also captured here. | True Up Monitor Task |
| Outage Call Type | C1-OutageCallType | This business object defines the behavior of an outage call type used to support trouble calls captured in CCB and integrated to NMS. | Outage Call |
| Payment Arrangement Task Type | C1-PATaskType | This business object defines the expected behavior for when a self-service user requests a payment arrangement. | Payment Arrangement Task |
| PPB Payment Notification Task Type | C1-PPBPaymentNotifyTaskType | This business object captures information about the Prepaid Billing Payment Request notification that is made available for sign-up by self-service users. | Notification Preferences |

| | | | |
|----------------------------|---------------------------|--|--------------------|
| Prepay Biller Task Type | C1-PrepayBillerTaskType | This business object defines the behavior of a prepay biller task type used in smart meter prepay billing. | Prepay Biller Task |
| Product Offer Publish | C1-ProductOffer | This business object contains the product offer elements that are relevant when publishing product offers to Siebel Energy. It is used to read product offer information when building the initial and final snapshots for the sync request. | Not defined |
| Product Offer Task Type | C1-ProductOfferTaskType | This business object is used to define the behavior of a product offer. Product offers are configured in CCB and published to Siebel Energy. | Not defined |
| SA Creation Rule Publish | C1-SACreationRule | This business object contains the SA creation rule elements that are relevant when publishing product offers to Siebel Energy. It is used to read SA creation rule information when building the initial and final snapshots for the sync request. | Not defined |
| SA Creation Rule Task Type | C1-SACreationRuleTaskType | This business object defines the behavior of the SA creation rules for a product offer. Each SA creation rule indicates the type of service agreement to create for the product offer. | Not defined |
| Service Request Task Type | C1-ServiceRequestTaskType | This business object is used as a parent service task type business object for service request related task types such as appointment notification, missed appointment and customer contact creation requests. | Not defined |

| | | | |
|---------------------------------------|--------------------------------|--|----------------------------------|
| Siebel Customer Maintenance Task Type | C1-CustomerMaintenanceTaskType | This business object is used in the Siebel integration. When a customer maintenance request is received from Siebel, an inbound service determines the service task type to use for the event. | Siebel Customer Maintenance Task |
| Start/Stop Task Type | C1-StartStopTaskType | This business object defines the expected behavior for when a self-service user requests to start, stop or transfer service. | Start/Stop Request Task |

Defining Customer Questions

A customer question is used to capture specific information related to a request. For example:

- A customer can be asked questions about a service call being reported.
- A customer can be asked one or more questions during a start, stop or transfer service request.

The responses to customer questions are captured on the Response object that is linked to either a customer service request or a service task.

You can access the portal from **Admin > General > Customer Question**. You are brought to a query portal with options for searching for a specific question. Once a question is selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones appear as part of the portal's **Main** tab page:

- **Customer Question:** This zone provides information on question and answers. Refer to the zone's embedded help for more details.
- **Service Code List:** This zone displays a list of associated service codes. It is hidden if no service code is associated to the current question.

Defining Financial Transaction Options

Bills, payments and adjustments share one very important trait - they affect how much your customers owe. This section explains the financial design of the system and describes how to set up the tables that control the financial impact of these transactions.

Note:

The tables in this section are the first of many that must be set up before you can create bills and apply payments. In this section, we limit the discussion to those tables that control the financial impact of bills, payments and adjustments. In later sections, we describe the tables that control other billing-related functions like meter reading and rates. It is only after all of these tables are set up that you will be able to generate the various financial transactions.

The Financial Big Picture

This section provides an overview of the relationship between an account and the various financial transactions that influence how much a customer owes.

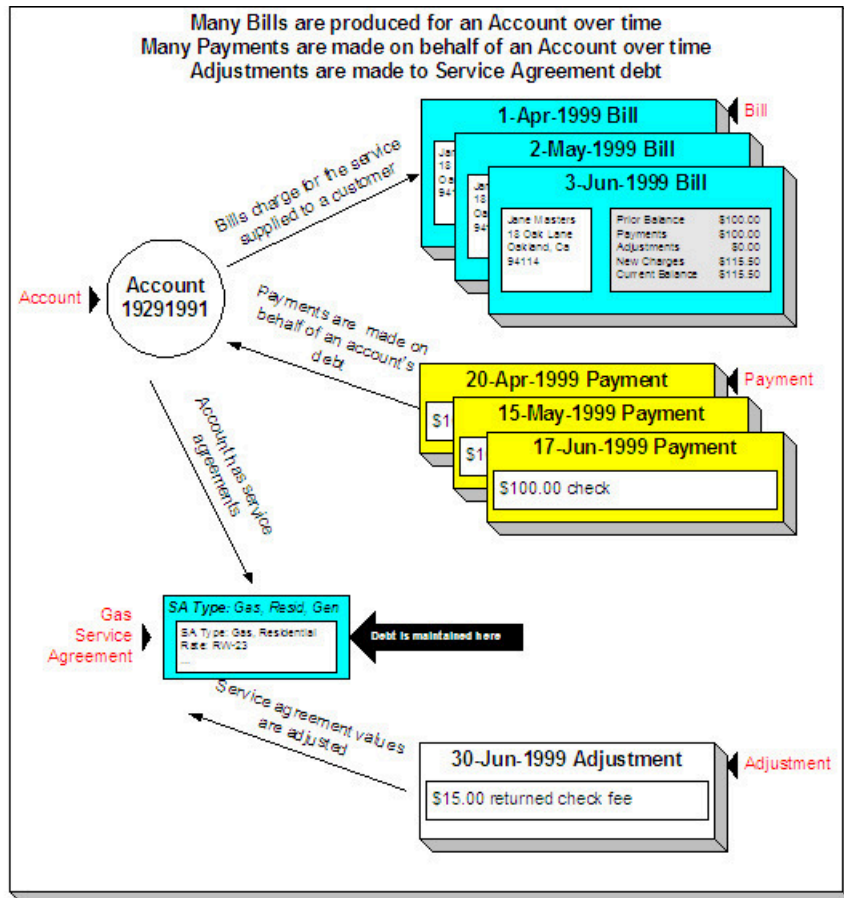

Warning:

If your organization practices cash accounting for payables (i.e., you only pay the taxing authority when you get paid), refer to [Payables Cash Accounting](#). If your organization practices open-item accounting (i.e., payments must be matched to bills), refer to [Open Item Accounting](#).

Bills, Payments & Adjustments

The following diagram illustrates the relationship between an account and its financial transactions:

The following concepts are illustrated above:

Bills are produced for accounts Over time, many bills may be produced for an account. For more information about a bill, see [Bill Details](#) .

Payments are made for accounts Over time, many payments may be applied to an account's debt. For more information about a payment, see [Payment Details](#) .

Service agreements have debt The system maintains debt on each individual service agreement. An account's debt is the sum of its service agreements' debt.

Service agreements are adjusted Over time, the debt that is stored on an account's service agreement(s) may be adjusted. For more information about an adjustment, see [Adjustment Details](#) .

Bill Details

The following diagram illustrates the relationship between an account and its bills:

The following concepts are illustrated above:

A bill is produced for an account Over time, many bills are produced for an account. Bills charge for the services supplied to a customer. The above illustration shows a single bill.

Bills contain bill segments A bill typically contains one bill segment for every active service agreement linked to its account. The only time this is not true is when service agreements for different frequencies exist. For example, an account with a monthly and a quarterly service agreement will only have 4 bills a year that contain both bill segments; the other months' bills will contain a single bill segment for the monthly service agreement.

Bill segments contain calculation details A bill segment contains information showing how the segment was calculated and how it should be printed on the customer's bill.

A bill segment has a financial transaction A bill segment has a related financial transaction. A financial transaction contains the financial effects of the bill segment on the service agreement's current and payoff balances and on the general ledger.

Canceling a bill cancels the financial tran. If the bill segment is eventually cancelled, another financial transaction will be linked to the bill segment to reverse its original financial transaction. The cancellation financial transaction appears on the next bill produced for the account as a bill correction.

Payment Details

The following diagram illustrates the relationship between an account and its payments:

The following concepts are illustrated above:

Payments are made for accounts Over time, many payments may be applied to an account's debt. The above illustration shows a single payment.

Payments contain payment segments A payment contains one payment segment for every service agreement to which the payment is distributed. For a customer who pays in full, the number of payment segments will coincide with the number of bill segments on the bill being paid.

A pay. segment has a financial transaction A payment segment has a related financial transaction. A financial transaction contains the financial effects of the segment on the service agreement's current and payoff balances and on the general ledger.

Canceling a payment cancels the fin. tran. If the payment is eventually cancelled, another financial transaction will be linked to the related payment segment(s) to reverse their financial effect. The cancellation financial transaction appears on the next bill produced for the account as a negative payment.

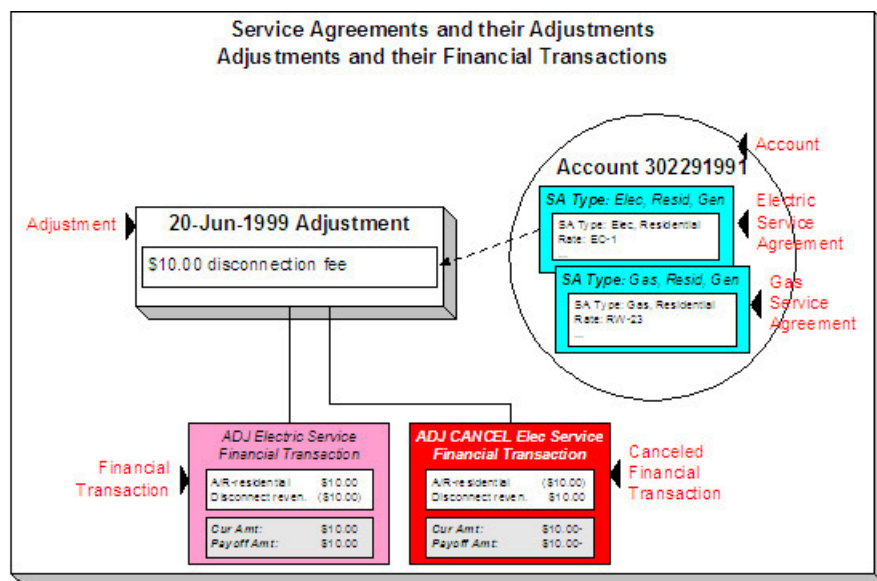

Fastpath:

A payment cannot be applied to an account's debt without an associated payment event. Refer to [The Big Picture of Payments](#) for more information.

Adjustment Details

The following diagram illustrates the relationship between an account and its adjustments:

The following concepts are illustrated above:

Service agreements have adjustments Over time, a service agreement may have many adjustments. The above illustration shows a single adjustment to one of the account's service agreements.

An adjustment has a financial transaction An adjustment has a related financial transaction. The financial transaction contains the financial effects of the adjustment on the service agreement's debt and on the general ledger.

Canceling an adjust. cancels the fin. tran. If the adjustment is eventually canceled, another financial transaction will be linked to the adjustment to reverse its financial effect. The cancellation financial transaction appears on the next bill produced for the account as an adjustment.

Current Amount versus Payoff Amount

A financial transaction contains two very important attributes: payoff amount and current amount. These attributes contain the grand total of how much the customer owes.

- Current amount contains how much the customer THINKS THEY OWE.
- Payoff amount contains how much the customer REALLY OWES.

You may be wondering when these two values can be different? Well, for most financial transactions, these values are the same. These values differ under the following situations:

- When a bill segment charges a customer for a charitable contribution, payoff amount will be zero because the customer doesn't really owe anything (they don't have to contribute if they don't want to). Current amount will be equal to the agreed charitable contribution amount (the customer thinks they owe the contribution).
- When a bill segment charges a customer for a deposit, payoff amount will be zero because the customer doesn't really owe anything (billed deposits are typically not viewed as being a receivable). Current amount will be equal to the amount billed (the customer thinks they owe the deposit amount).
- When a bill segment charges a customer who participates in a levelized payment program (e.g., budget billing or non-billed budgets) the two "amounts due" will contain different values. Payoff amount is equal to how much the customer really owes for the service they consumed; current amount is equal to how much they think they owe in accordance with their monthly budget.

A perhaps easier way to view these two attributes is to consider payoff amount as the "cash out amount", i.e., the amount the customer would owe the utility if they wanted to clear up all debt. The current amount contains the amount the customer thinks they owe. If you're still struggling with the difference, think about your monthly Visa bill: it contains a monthly minimum payment and the total amount owed. The minimum payment is the current amount; the total amount owed is the payoff amount.

The topics in this section provide more information about these two fields.

What Controls What Gets Booked To Current And Payoff Amount?

As described in [Bill Details](#) , every bill segment has a sibling financial transaction. The financial transaction defines the bill segment's affect on current and payoff amounts due. The system populates these two fields as per the Financial Transaction Algorithm defined on the bill segment's bill segment type.

Fastpath:

For more information, refer to [Billing - Current Balance versus Payoff Balance](#) and [Designing and Defining Bill Segment Types](#) .

As described in [Payment Details](#) , every payment segment has a sibling financial transaction. The financial transaction defines the payment segment's affect on current and payoff amounts due. The system populates these two fields as per the Financial Transaction Algorithm defined on the payment segment's payment segment type.

Fastpath:

For more information, refer to [Payment - Current Balance versus Payoff Balance](#) and [Setting Up Payment Segment Types](#) .

As described in [Adjustment Details](#) , every adjustment has a sibling financial transaction. The financial transaction defines the adjustment's affect on current and payoff amounts due. The system populates these two fields as per the Financial Transaction Algorithm defined on the adjustment's adjustment type.

Fastpath:

For more information, refer to [Adjustments - Current Balance versus Payoff Balance](#) and [Setting Up Adjustment Types](#) .

Arrears

The system keeps track of the age of each customer's debt to the day. For example, if a customer hasn't paid their last two bills, the customer's aged debt might look as follows:

- \$124.50: 22 days old
- \$213.41: 51 days old

Please be aware that it is the current balance (i.e., what the customer thinks they owe) that is aged. Also keep in mind that the moment an FT is frozen, it impacts a customer's current balance.

The system represents aged debt in a variety of ways of the various transactions in the system. On the [Current Customer Zone](#) and the [Financial Information Zone](#) arrears are shown in a colorful bar (where each color corresponds to different aged buckets):

Whereas on [Service Agreement - Main](#), aged debt is shown in a grid:

| Debt Class Arrears | |
|--------------------|----------------|
| Days Old | Arrears Amount |
| 4 | \$99.45 |
| 32 | \$76.36 |

The grid method is used on many pages throughout the system. The following rows *may* appear in the grid:

- A row labeled New Charge highlights all debt that hasn't started aging yet. For example, if you've created a late payment charge and it hasn't appeared on one of the customer's bills, it will be classified as a New charge until the next bill is completed for the customer (unless a user overrides the late payment charge's arrears date by drilling into the financial transaction).
- A row with a label containing n Future (where n is the number of days) appears if there is "future debt". Future debt is very rare and can only exist if a debit financial transaction has a future arrears date. Financial transactions can receive a future arrears date if a bill is completed with a future date or if a user overrides a financial transaction's arrears date with a future date).
- A row that contains a number (and nothing else) represents debt that has started aging. The number is the age of the respective debt. In the above example, the customer has 1 day old debt, and debt that is more than 150 days old. Notice that the 150 day old debt is prefixed with a +. This means that the related debt is more than 150 days old. This age limit is controlled by a field on [Installation Options - CC](#) called "Oldest Bucket Age". This field limits the number of days the system will age debt. For example, if you set this field to 150, the system will never age an FT more than 150 days (and all debt that's older than 150 days will be classified as 150 day old debt). Also note, the aged debt bar that appears on [Current Customer Zone](#) only ages debt a maximum of 60 days.
- A row with a label of Disputed appears if the account is an [open-item](#) customer and this customer has [disputed](#) financial transactions.

Fastpath:

Refer to [Financial Transactions And Aged Debt](#) for more information.

GL Accounting Information

Be aware that if payoff amount is non-zero, the financial transaction has general ledger detail lines.

There are unusual financial transactions whose payoff amount is zero, but still affect the general ledger:

- Bill segments for company usage do not impact payoff amount (because your organization doesn't really owe itself anything). However, the GL is affected.
- Payment segments for charitable contributions (created when your customers contribute extra money to a charity) do not impact payoff amount. Why? Because payoff amount is never debited when a charitable contribution is billed (the customer doesn't truly owe you for this receivable). It's only when the customer pays the contribution that the GL is impacted (debit cash, credit charitable contribution payable).
- If the SA has a special role of Loan, the financial transaction algorithms supplied with the base package transfer the current amount between the long-term receivables and the short-term receivables in the GL. This allows the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). Refer to [Payoff Balance and Current Balance for Loans](#) for more information.

The effect on your GL is controlled by the financial transaction algorithm defined on your bill segment and payment segment types.

Fastpath:

Refer to [The GL Interface](#) for how GL account information is interfaced to the general ledger.

A Complicated Example

The financial ramifications of a revolving charge account are predictable (if you're an accountant). The following table outlines the different financial events and their impact on the general ledger, arrearage history, and the amounts due (both current and payoff).

| Event | GL Accounting | Arrearage Rule | Effect On Payoff Amt | Effect On Current Amt | Payoff Balance | Current Balance |
|-------|---------------|----------------|----------------------|-----------------------|----------------|-----------------|
|-------|---------------|----------------|----------------------|-----------------------|----------------|-----------------|

| | | | | | | |
|-----------------------|----------------------------|------------------------------|-------|------|------|-----|
| Merchandise purchased | A/R 1000 Revenue <1000> | n/a (current amount is zero) | +1000 | 0 | 1000 | 0 |
| Monthly bill | A/R 10 Int. Rev <10> | \$120 aged accordingly | +10 | +120 | 1010 | 120 |
| Payment received | Cash 120 A/R <120> | \$120 relieved accordingly | -120 | -120 | 890 | 0 |

The following points describe the events in the above table:

- **Merchandise purchased.** When a customer purchases an air conditioner:
 - The system generates an adjustment to book the purchase.
 - The customer doesn't really think they owe the entire \$1,000 (because they've purchased it on credit), therefore no moneys are booked to current amount. However, if the customer wanted to cash out, they would owe your organization \$1,000, therefore the entire amount of the purchase is booked to payoff amount.
 - Because no money was booked to current amount, this event has no impact on the arrearage history.
- **Customer billed.** Monthly, the system calculates how much the client owes. In this example, interest is calculated to be \$10 and the minimum monthly payment is set at \$120.
 - The interest is posted to the GL, but principal isn't since it was booked when the merchandise was purchased.
 - The customer really thinks they owe the minimum payment amount, \$120. Therefore, current amount is affected. However, if the customer were to cash out, they would owe your organization \$1,000 + \$10 (the interest); therefore payoff amount is affected by only \$10.
 - Because current amount changed by \$120, arrearage history is affected accordingly.
- **Payment received.** With any luck, the client will pay the \$120 that was billed (note, they could obviously pay more).
 - The payment has a normal affect on the GL (debit cash, credit A/R).
 - The amount the customer thinks they owe decreases by \$120, therefore current amount is affected by the payment amount. And, if the customer was to cash out, they would owe the utility \$120 less, therefore payoff amount is affected by the payment amount.
 - Because current amount changed by \$120, arrearage history is affected accordingly.

Financial Transactions Created Between Bills

The following diagram illustrates how frozen financial transactions (FT's) accumulate between bills and are swept onto the next bill produced for the account (when the bill is completed). This example assumes

After the last bill is completed, the account's service will have no unbilled financial transactions

| | |
|---|--|
| SA Type: Elec, Resid, Gen No unbilled financial transactions | SA Type: Gas, Resid, Gen No unbilled financial transactions |
|---|--|

When an account is levied a late payment charge, FT's are created and linked to the account's service

| | |
|--|--|
| SA Type: Elec, Resid, Gen ADJ Electric Service Cur Amt: \$10.00 Payoff Amt: \$10.00 | SA Type: Gas, Resid, Gen ADJ Gas Service Cur Amt: \$5.00 Payoff Amt: \$5.00 |
|--|--|

When a payment is applied to the account's debt, two FT's are created and linked to the account's service

| | |
|--|--|
| SA Type: Elec, Resid, Gen ADJ Electric Service Cur Amt: \$10.00 Payoff Amt: \$10.00 | SA Type: Gas, Resid, Gen ADJ Gas Service Cur Amt: \$5.00 Payoff Amt: \$5.00 |
| PAY Electric Service Cur Amt: \$32.00- Payoff Amt: \$32.00- | PAY Gas Service Cur Amt: \$68.00- Payoff Amt: \$68.00- |

When a bill is generated for an account, two bill FT's are created and added to the account's service

| | |
|--|--|
| SA Type: Elec, Resid, Gen ADJ Electric Service Cur Amt: \$10.00 Payoff Amt: \$10.00 | SA Type: Gas, Resid, Gen ADJ Gas Service Cur Amt: \$5.00 Payoff Amt: \$5.00 |
| PAY Electric Service Cur Amt: \$32.00- Payoff Amt: \$32.00- | PAY Gas Service Cur Amt: \$68.00- Payoff Amt: \$68.00- |
| BILL Electric Service Cur Amt: \$42.00 Payoff Amt: \$42.00 | BILL Gas Service Cur Amt: \$73.50 Payoff Amt: \$73.50 |

When a bill is generated for account, it sweeps all unbilled FT's onto itself

| | |
|------------------|----------|
| Prior Balance | \$100.00 |
| Bill Corrections | \$0.00 |
| Payments | \$100.00 |
| Adjustments | \$15.00 |
| New Charges | \$115.50 |
| Current Balance | \$130.50 |
| ... | |

When any type of financial transaction is frozen, it impacts the related service agreement's **current and payoff balances**. If you do not want adjustments and bill segments to affect the customer's balance until they appear on the customer's next bill, refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) .

Notice the balances in the financial summary of the above bill:

- The **Prior Balance** is the ending balance from the customer's prior bill.
- The **Bill Corrections** portion is blank. It contains a value if you cancel / rebill a bill segment that appeared on an earlier bill.
- The **Payments** portion shows payment financial transactions (both new payments and cancellations) that have been created since the last bill.
- The **Adjustments** portion shows adjustment financial transactions (both new adjustments and cancellations) that have been created since the last bill.
- The **New Charges** portion shows bill financial transactions that were created when the bill was created.
- The **Current Balance** is the total amount owed.

Fastpath:

If you practice [Open Item Accounting](#), refer to [Open Item Versus Balance Forward Accounting](#) for more information about financial transactions and bills.

Financial Transactions And Aged Debt

The system keeps track of how old a service agreement's current balance is in order to determine if the customer is in arrears (and therefore credit and collections processing should start).

A financial transaction (FT) impacts the related service agreement's current and payoff balances the moment it is frozen. However, some types of frozen FTs have no impact on a customer's aged debt until the next bill is completed for the account associated with the service agreement.

As described in the previous section, a frozen financial transaction (FT) waits in limbo until the customer's next bill is produced. This limbo period could be several weeks if the customer is billed infrequently. When the customer's next bill is completed, all such frozen FT's are linked to the bill. It is important to stress the following in respect of these FT's:

- If the FT decreases the amount of debt, the customer's aged debt is affected immediately regardless of whether the FT appears on a bill.
- If the FT increases the amount of debt, the amount the customer owes from an aged debt perspective may or may not be affected by the FT. There is a switch on an FT called New Charge that controls the arrears behavior.
 - If this switch is on, the amount of debt will be reflected as a "new charge" when you look at the customer's aged debt. This amount will remain classified as a "new charge" until the FT is swept onto a bill. The moment the FT is swept onto the customer's bill, the debt starts aging. This logic exists because you probably don't want to start aging an FT until the customer has actually seen it.
 - If this switch is off, the date on which the FT starts aging must be defined in the Arrears Date field. The Arrears Date is used to compute how many days old the debt is.

Note:

Aged debt limitations. It's important to be aware that there's a field on [Installation Options - CC](#) called "Oldest Bucket Age" that limits the number of days old the system will age debt. For example, if you set this field to 360, the system will never age an FT more than 360 days (and all debt that's older than 360 days will be classified as 360 day old debt). Also note, the aged debt bar that appears on [Control Central - Account Information](#) only ages debt a maximum of 60 days.

Fastpath:

If you practice [Open Item Accounting](#), refer to [Open Item Versus Balance Forward Accounting](#) for information about how open-item FT's affect aged debt.

Preventing SA Balances And The GL From Being Impacted Until Bill Completion

It's important to understand that when any type of financial transaction is frozen, the related service agreement's balance is affected. For example:

- When a payment is frozen, the customer's balance is reduced.
- When an adjustment is frozen, the customer's balance is impacted.
- When a bill segment is frozen, the customer's balance is increased (typically).

For payments, there is no issue. However, for bill segments and certain types of adjustments, you may NOT want the customer's balance to be impacted until the next bill is completed. Consider the following scenarios:

- Late payment charges:
 - You can setup the system to create a late payment charge (i.e., an adjustment) say 5 days after an unpaid bill is due.
 - If the related adjustment is frozen, the customer's balance will be impacted. However, its impact will not affect [aged debt](#) until the next bill is completed. In other words, the amount of the frozen adjustment segment will appear as a "New Charge" until the bill is completed.
- Batch billing:

- If a customer has multiple service agreements, it's possible for one of the service agreements to have a bill segment that's in error and the other service agreement's bill segment to be error-free.
- If this happens and you have setup the bill cycle schedule to freeze bill segments if they're error-free, then you could have one bill segment frozen and another in error.
- The frozen bill segment will impact the customer's balance. However, its impact will not affect [aged debt](#) until the bill is completed (and a bill cannot be completed until all of its bill segments are error-free). In other words, the amount of the frozen bill segment will appear as a "New Charge" until the bill is completed.

Warning:

We'd like to stress that while a frozen financial transaction impacts a customer's balance the moment it is frozen, the amount of the financial transaction appears as a "New Charge" when viewing a customer's [aged-debt](#). This amount will remain classified as a "New Charge" until the next bill is completed (i.e., the customer's debt doesn't start aging until the next bill is sent to the customer).

While [aged-debt](#) isn't impacted by frozen FT's, the general ledger is. This is because a financial transaction is marked for [interface](#) to the general ledger when it is frozen. This can be problematic if you have a long period between FT freeze and bill completion (you could impact the general ledger but not impact the customer's balance). If this is unacceptable, you can setup the system to not allow certain types of FT's to be frozen until the next bill is completed. This means that neither the customer's balance nor the general ledger will be impacted until bill completion time. To do this:

- Choose the Freeze At Bill Completion option on [Installation Options - Billing](#).
- Examine each of your [adjustment types](#). Select Freeze At Bill Completion for those that should not impact the customer's balance or the general ledger until the next bill is completed. Select Freeze At Will for those that should impact the customer's balance and the GL when they are frozen. Typically, the only adjustment types for which you'd choose Freeze At Will option are those that cause a customer's balance to be reduced, those that are used to refund money to a customer, and those that are created at bill completion. Adjustment types for adjustments created during bill completion (e.g., by a bill completion algorithm) must have their adjustment freeze option set to Freeze At Will. Otherwise (i.e., if the option is Freeze At Bill Completion) they will not be frozen until a subsequent bill is completed.

Please be aware of the following in respect of the Freeze At Bill Completion options:

- If you turn on Freeze At Bill Completion on [Installation Options - Billing](#):
 - Users will not be allowed to freeze bill segments online. This means that the freeze button will be disabled on [Bill - Main](#) , [Bill - Bill Segments](#) and [Bill Segment - Main](#).
 - The Billing background process will not freeze bill segments until all segments on a bill are error free (and permission has been granted on the bill cycle schedule to complete bills).
 - Bill segments will exist in the freezable state until the bill is completed.
- If you turn on Freeze At Bill Completion on [Adjustment Type - Main](#):
 - Users will not be allowed to freeze adjustments of this type online. This means that the freeze button will be disabled on [Adjustment - Main](#) .
 - Background processes that create adjustments will not freeze this type of adjustment. Rather, the adjustments will be frozen when the next bill is completed.
 - Adjustments of this type will therefore exist in the freezable state until the next bill is completed.

Note:

Alerts highlight freezable FT's. Please be aware that messages appear in the [Account Information - Financial Information Zone](#) and in the [Sidebar - Financial Information Zone](#) to highlight the existence of freezable financial transactions.

Please be aware of the following in respect of the Freeze At Will options:

- If you turn on Freeze At Will on [Installation Options - Billing](#):
 - Users will be allowed to freeze bill segments online. This means that the freeze button will be enabled on [Bill - Main](#) , [Bill - Bill Segments](#) and [Bill Segment - Main](#).

- The Billing background process will freeze bill segments when the individual segment is error-free (and permission has been granted on the bill cycle schedule to freeze bill segments).
- Bill segments will exist in the frozen state regardless of whether the bill is completed.
- The frozen bill segment's FT will be interfaced to the GL when the interface next runs.
- All adjustment types must be also be set to Freeze At Will (otherwise they wouldn't get frozen).
- If you turn on Freeze At Will on [Adjustment Type - Main](#):
 - Users will be allowed to freeze adjustments of this type online. This means that the freeze button will be enabled on [Adjustment - Main](#).
 - Background processes that create adjustments will freeze this type of adjustment.
 - Adjustments of this type will exist in the frozen state prior to bill completion.
 - The frozen adjustment's FT will be interfaced to the GL when the interface next runs.

Forcing The Freeze Date To Be Used As The Accounting Date

Every financial transaction references an accounting date. The accounting date controls the accounting period to which the financial transaction is booked as described below:

- Every financial transaction references an accounting date and a service agreement
- Every service agreement references a service agreement type
- Every service agreement type references a GL division
- Every GL division references an [accounting calendar](#)
- The accounting calendar contains the cross-reference between the accounting date specified on the financial transaction and the related accounting period in your general ledger

The accounting date is populated on financial transactions when they are initially generated. The following points describe the source of the accounting date:

- The user who creates or cancels a bill segment online defines the accounting date as part of the generation/cancel dialog (note, the current date defaults).
- Bill segments that are produced by the [BILLING](#) background process have their accounting date defined on the [bill cycle schedule](#) that caused the bill to be created.
- The user who creates or cancels an adjustment online defines the accounting date as part of the generation / cancel dialog (note, the current date defaults).
- Payments are unusual in that their financial transaction is only created when they are frozen (rather than when the payment is first distributed amongst the account's service agreements). At payment freeze time, the accounting date is set to the current date.

For payments, there is no issue because the accounting date is only populated on the financial transaction when a payment is frozen. However, for bill segments and adjustments, your business practice may dictate that the freeze date should be used as the accounting date rather than the original accounting date. Alternatively, your business practice may dictate that the accounting date that's originally stamped on bill segments / adjustments should be used (unless this associated period is closed at freeze time). It's really a question of the interpretation of the local accounting rules. After you've decided on your approach, populate the **Accounting Date Freeze Option** on [Installation Options - Billing](#) with one of the following values:

- Choose Always change if the accounting date on your financial transactions should be populated with the freeze date (i.e., the current date when the financial transaction is frozen).
- Choose Change if period is closed if the accounting date defined when the financial transaction is generated should be used (unless the associated accounting period is closed).

Please be aware of the following in respect of your choice:

- If you choose Always change:
 - When a user freezes a bill segment online, they will be prompted to supply an accounting date. The current date will default, but the user can override this value.

- When a user freezes an adjustment online, they will be prompted to supply an accounting date. The current date will default, but the user can override this value.
- The **BILLING** background process will use the current business date as the accounting date on bill segments that it freezes.
- Also note, if you have chosen the Freeze At Bill Completion **Bill Segment Freeze Option** on the [installation record](#), bill segments and certain types of adjustments are frozen when a bill is completed. This means that the accounting date on the related financial transactions will be set to the completion date (because the completion date is the freeze date with this setting). Refer to [Preventing SA Balances And The GL From Being Impacted Until Completion](#) for more information.
- If you choose Change if period is closed:
 - When a user freezes a bill segment online, they will only be prompted to supply an accounting date if the related accounting period is closed (because the accounting period closes after the bill segment is generated but before it's frozen). The current date will default, but the user can override this date.
 - When a user freezes an adjustment online, they will only be prompted to supply an accounting date if the related accounting period is closed (because the accounting period closes after the adjustment is generated but before it's frozen). The current date will default, but the user can override this date.
 - The **BILLING** background process will use the accounting date defined on the related bill cycle schedule as the accounting date on the bill segments that it creates and freezes.

Note:

The above installation option only controls the final accounting date for GL recording purposes. Rate and bill factor value selection based on accounting date uses the date as initially determined.

How Late Payment Charges Get Calculated

Late payment charges are system-generated adjustments used to penalize a customer for late (or no) payments. This section describes how to set up the tables that control how and when late payment charges are generated. The following points describe how and when late payment charges are calculated.

- When a bill is completed, the system marks it with the date on which late payment charges will be calculated if the bill is not paid.
 - This date is calculated by adding grace days to the bill's due date. Grace days are defined on the account's [Customer Class / Division](#).
 - This date will be zero if the account's [Customer Class / Division](#) indicates the account is not eligible for late payment charge processing.
- The late payment charge background process (referred to by the batch ID of **LATEPYMT**) selects all bills on or after their late payment charge date.
 - For each such bill, the system determines if its account satisfies the late payment charge eligibility criteria defined on the account's [Customer Class / Division](#). The eligibility criteria are defined in an algorithm and can therefore be as flexible as required.
 - If an account is eligible for late payment charges, the system checks each of the account's service agreements to determine if it is eligible for late payment charges (as defined on the service agreement's [SA Type](#)).
 - If a service agreement is eligible for late payment charges, the system calls the SA type's late payment charge calculation algorithm. This algorithm should calculate the late payment charge amount, if applicable and return the calculated amount and an appropriate adjustment type to use. If this algorithm returns this information, an adjustment is generated to levy the late payment charge.

Fastpath:

Refer to [Setting Up Customer Classes](#) for more information about how to set up an account's due days and grace period. Refer to [SA Type - Main Information](#) for more information about enabling late payment charges calculations for your service agreements.

You can update the **Late Payment Charge Details** section on the Bill - Main Information page to indicate if and when late payment charges may be levied. For more information, see [Bill - Main Information](#).

Service Agreement Type Controls Everything

The previous section illustrated three important concepts:

The true financial impact of the three financial events - bills, payments, adjustments - is at the service agreement level, not at the account level. This means that bills and payments are meaningless on their own. It's the service agreements' bill segments, payment segments and adjustments that affect how much a customer owes.

- Every bill segment, payment segment, and adjustment has a related financial transaction. These financial transactions contain the double-sided journal entries that will be interfaced to your general ledger. They also contain the information defining how the customer's debt is affected by the financial event (i.e., current amount and payoff amount).
- A single bill can contain many bill segments, each of which may have a different frequency. For example, a bill could contain future charges, monthly retroactive charges based on service cycle, quarterly charges that must end on a quarter-end boundary.

You control the financial effects of the various financial events using a single field on the service agreement. This field is called the service agreement (SA) Type. In this section, we describe many of the tables that must be set up before you can create a SA type.

Note:

Foreshadowing. You will notice that we don't explain how to set up SA types in this section. This is because SA type controls numerous aspects of a service agreement's behavior in addition to its financial behavior. The non-financial aspects are discussed in later chapters. It's only after you have set up all of the control tables in this manual that you'll be able to finally define your SA types. Refer to [Setting Up SA Types](#) for more information.

Warning:

Take the time to define how you will record the various financial events in your general ledger before you attempt to set up these control tables. If you have simple accounting needs, this setup process will be straightforward. However, if you sell many services and use sophisticated accounting, this setup process will require careful analysis.

Understanding CIS Divisions

There are two types of Divisions referenced on a SA type: a CIS Division and a GL Division. This is a rather powerful structure, but it can be confusing.

- General Ledger divisions typically comprise individual entities (e.g., companies) in your general ledger. You must set up a GL division for each such entity. The GL division's sole purpose in the system is to define the accounting period associated with financial transactions linked to service agreements associated with the GL division (service agreements are associated with GL divisions via their SA type). The system cares about accounting periods in order to prevent a user from booking moneys to closed periods. It also uses accounting periods when it produces the flat file that contains the consolidated journal entry that is interfaced to your general ledger (refer to [The GL Interface](#) for more information).
- A CIS division is associated with a jurisdiction. The definition of a jurisdiction is a geographic-oriented entity with unique business rules. For example, if you conduct business in California and Nevada, and each state has different collection rules, you will need a separate jurisdiction for each state. You must set up a CIS division for each jurisdiction in which you conduct business.
- CIS division is also referenced on service agreement, premise and account.
 - The CIS division on SA is actually part of the SA's SA type. Because SA type controls many business rules, all business rules that are on the SA type can be thought of as being defined for a given jurisdiction and SA type combination. For example, you could define your valid rates for electric residential service in California which differ from the valid rates for electric residential service in Nevada. Refer to [Defining Service Agreement Types](#) for more information. In addition to controlling the business rules defined on the SA's SA type, the SA's CIS division also controls the type of collection criteria used to determine if and how to collect overdue debt. Refer to [Setting Up Collection Class Control](#) for more information.

- The CIS division on premise defines the jurisdiction in which the premise is located. This jurisdiction controls the types of service agreements that can be associated with the premise's service points (e.g., you can only link California-oriented service agreements to premises governed by the California jurisdiction). You can also set up your field activity types to execute special algorithms when a field activity is completed at a service point located in specific jurisdiction.
- The CIS division on account when combined with the account's customer class defines the jurisdiction that governs financial business rules (e.g., the bill's due date, when and how late payment charges are calculated, etc.). Refer to [Setting Up Customer Classes](#) for more information about these rules. The CIS division on account can also play a part in the addressee of To Do entries associated with the account. To assign To Do entries to a role based on the division, simply link the To Do type to the division. Refer to [To Do Entries Reference A Role](#) for more information.

CIS Division Overrides

Some configuration values in the system, such as those defined on the installation record, are global and applied to the entire system. CIS Division allows some of these values to be specified by CIS division, overriding the system-wide default configuration. The system processes check the CIS Division for the override before checking the default configuration. CIS Division allows for overrides to be specified for **customer class** (by person and business), and **credit rating** and **cash-only** beginning and threshold values.

The bill route type and quote route type are used to define the background process and extract algorithm for each route type. CIS Division allows overrides to be specified for the extract batch control and/or extract algorithms. These can be defined for any or all each bill route types and quote route types. While bill route type and quote route type allow many of each type to be configured, one of each type is defaulted from the installation record. This override allows CIS Division specific value for a common route type.

Users and CIS Division

When the installation option Control By CIS Division flag is set, it is necessary to associate the system users with CIS Division. This feature is applicable if your organization expects users to work on designated CIS Divisions only (as opposed to allowing users to serve customers across all CIS Divisions). Users can be associated with CIS Division(s) even if the above flag is not set. Some system functions take advantage of this such as defaulting CIS Division on control central searches. User - CIS Division is maintained in the user portal.

To navigate there, select **Admin > User > Search** and navigate to the **Miscellaneous** page.

How Does the System Use User CIS Division

Refer to [Installation Options – Main](#) for information on how this is used in conjunction with the Control By CIS Division and Premise/SP Search flags

The user's CIS Divisions are used in some circumstances to restrict case type and customer contact type by CIS Division.

The user's Primary CIS Division is used to default the CIS Division on the Control Central search that is provided with the system.

Restricting CIS Division

CIS Division appears through much of the system. The primary objects that reference a CIS Division are account, service agreement, and premise. It is also referenced on secondary objects such as orders and on pages that interact with the primary objects such as start/stop and payment arrangement.

A flag on CIS Division, Restrict to Account CIS Division, can be used to restrict service agreements and premise to the account's CIS Division. It is important to note that it is the account's CIS Division that matters. When this flag is set, many of the system pages default CIS Division and restrict the user for changing the value. The following rules are enforced in addition to the visible changes:

- Service agreement's CIS Division must match its account's CIS Division.
- Account CIS Division cannot be changed if the account has non-canceled service agreements.
- Account Protect CIS Division switch is turned on and is protected. This is done because the switch becomes irrelevant since all service agreements match the account's CIS Division and the account CIS Division would not change.

- When starting service, only premises that match the account CIS Division or do not have a CIS Division maybe chosen. This rule is applied when choosing a premise via start/stop or order.
- While most SA/SPs are created by the system when service is started, it is possible to manually maintain SA/SPs. When searching for a service point from Service Agreement - SA/SP, the search is limited to SPs whose premise matches the account CIS Division or does not have a CIS Division.
- As mentioned, this setting applies to the account CIS Division. When changing a premise's CIS Division, the system checks all accounts ever linked to the premise, to see if any of the accounts' CIS Division has set the Restrict to Account CIS Division option to **Restricted**.

Note: The Premise to Account association is checked through the relationship from Premise to Service Point to SA/SP to Service Agreement to Account.

- If the Account's CIS Division is set to restrict the CIS Division, then the Premise's CIS Division is restricted to remain the same as the Account's CIS Division. It can also be set to blank unless the premise type requires it.
- The characteristic premise on a service agreement is restricted to premises linked to the account if the service agreement requires an SP. For other service agreements the premise search is restricted to the account CIS Division.

Warning: Do not turn on this flag without reviewing your existing data to ensure that it adheres to the rules enforced when the flag is set. The above rules are enforced on not just current data, but historic data as well such as closed service agreements. It is intended to ensure a consistency over the life of the objects associated with the CIS Division. This flag is configurable for each CIS Division, but consider the implications of setting it on some, but not all CIS Divisions.

Using CIS Division for Operational Segmentation

CIS Division is found throughout many of the entities in the system and there are many configuration settings related to CIS Division. When these configuration settings are used in conjunction with each other, it is possible to operate distinct business entities or jurisdictions that are segmented by CIS division. The following summary describes the different settings and uses of CIS Division that you can configure if your organization operates in multiple jurisdictions and needs to segment data and business processes by CIS Division. Details about each of these can be found in the section of the document where the functionality is configured.

Associate CIS Divisions with Users

CIS Divisions can be associated with users and one can be denoted as the primary.

Control By CIS Division

Setting the Control By CIS Division flag on the installation record drives many system changes. On the account it makes CIS Division required. The flag drives functionality changes on other pages such as person, premise, and order.

Premise/SP Access

Setting the Premise/SP Search flag on the installation record restricts access to premise and SPs not link to an account. The access is restricted to the user's CIS Division(s).

CIS Division

CIS Division provides the configuration of a work calendar, default customer classes for persons and businesses, credit rating and cash only beginning and threshold values, and To Do role assignment for each CIS Division. Additionally, bill route type, quote route type, and auto pay route type configuration can be overridden.

Restrict CIS Division

The Restrict to Account CIS Division flag is a setting on CIS Division. It is used to ensure that service agreements and premises match the account CIS Division and is a main component of segmenting data by CIS Division.

Customer Class

Customer class is used to default collection class on accounts.

Customer Class Control

Customer Class Control defines many business rules directly or through algorithms. These rules are specified per CIS Division. As noted above, Customer Class can be defaulted from CIS Division so there is a lot of flexibility in

the configuration of these two entities. Some of the business rules are defaults such as access group and budget plan. Others such as payment distribution and billing days until due define the rule that apply to the account Customer Class/CIS Division combination.

SA Type

CIS Division is part of the SA Type key. SA Type defines the valid values for SAs of that type and also defines attributes such as debt class and write off debt class for of SAs of that type.

Collections

As noted above, Collection Class is defaulted on the account from customer class and SAs inherit their debt class from their SA Type. Collection Class Controls are defined for the unique combination of collection class and debt class. Collection class controls define the business rule and collection processes. Through configuration, collection rules can be defined for specific CIS Divisions.

Write Off

As noted above, collection class is defaulted on the account from customer class and SAs inherit their write off debt class from their SA Type. Write off controls are defined for the unique combination of collection class and write off debt class. Write off control define the business rule and write off processes. Through configuration, write off rules can be defined for specific CIS Divisions.

Premise Type

Premise Types can control if CIS Divisions are required, optional or not allowed for premise of that type. When starting service, if the premise has a premise type, only SA Types with the same CIS Division as the premise that are identified to start for SP Types for SPs at the premise will start. This allows more generic SP Types that start SA Types specific for the premise CIS Division.

Restricting Types by CIS Division

Adjustment type, budget plan, bill cycle, case type, and customer contact type allow a CIS Division to be specified if the type is used for a specific CIS Division. Types without a CIS Division are not restricted.

Background Processing By CIS Division

Batch billing and the collection, severance, and write off background processes can all be configured to select records by CIS Division. See [Choosing Which Records Are Selected](#) on page 1288 for more information

Setting Up CIS Divisions

This portal is used to display and maintain CIS Divisions.

Refer to [Understanding CIS Divisions](#) for more information.

You can access the portal from **Admin > General > CIS Division**.

The following zones may appear as part of the portal's **Main** page:

- **CIS Division List:** This zone lists all CIS division records. Broadcast a record to display the details of the selected record.
- **CIS Division:** This zone provides information about the selected CIS Division.

Setting Up Revenue Classes

Every service agreement references a service agreement (SA) type. Amongst other things, the SA type defines a service agreement's revenue class. The revenue class is used when the service agreement's rate books revenue to different GL distribution codes based on the service agreement's revenue class.

Fastpath:

See [Designing Calculation Groups and Rules](#) for more information about how revenue class is used to determine the GL revenue accounts referenced on a bill. See [Revenue Segmentation](#) for more information about how revenue class affects the number of SA types you will need.

To set up revenue classes, choose **Admin > Financial > Revenue Class**.

Description of Page

Enter an easily recognizable **Revenue Class ID** and **Description** for every revenue class.

Setting Up Distribution Codes

Distribution codes simplify the process of generating accounting entries by defining valid combinations of chart of account field values.

Fastpath:

Refer to [The Source Of GL Accounts On Financial Transactions](#) for more information about the accounting entries associated with bills, payments and adjustments.

To set up distribution codes, open **Admin > Financial > Distribution Code > Add**.

Description of Page

Enter a unique **Distribution Code** and **Description** for the distribution code.

If this distribution code is a holding account used for payables cash accounting, check the **Use For Non-Accrual Accounting** switch and select the accounting method from the **Accounting Method** list. Select the priority level for the distribution code from the **Accounting Priority** list and enter the actual payable **Accounting Code**. The system will transfer monies from the holding account to the distribution code when the cash event occurs. Transfers will occur based on priority and debt age. For more information, refer to [Payables Cash Accounting](#) and [Deferred Accrual Accounting](#).

Define the **GL Account Algorithm** used by the system when it interfaces financial transactions that reference this distribution code to your general ledger (refer to [GLDL - Create General Ledger Download](#) for more information about the download process). The logic embedded in this algorithm constructs the actual GL account number. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that constructs your general ledger account number.

The **Write Off Controls** control how the system writes off debt associated with the distribution code. Refer to [The Ramifications of Write Offs in the General Ledger](#) for an explanation of how these fields are used at write-off time.

- Define the **Division** and **SA Type** of the service agreement to which bad debt associated with this distribution code should be transferred at write-off time. Note: only SA Types with a special role of Write Off may be selected.
- When the system transfers debt to the write-off service agreement defined above, the distribution code defined on this **Division / SA Type** will be debited unless you turn on the **Override Switch**. When this switch is turned on, the system overrides the distribution code of the transfer to side of the adjustment with the distribution code associated with the debt being written off. You'd typically turn this switch on for liability distribution codes because you want to debit the original liability account when the debt is written off. Note: if this switch is on the system also overrides the characteristic type / value with the respective value associated with the debt that is being written off.

Use the **GL Account Details** scroll to define how the system constructs the GL account associated with the distribution code when it interfaces the financial transaction to your general ledger. For each distribution code, enter the following information:

- Enter the **Effective Date** of the following information.
- Define whether, on the **Effective Date**, the following information is Active or Inactive. The system will only use effective-dated information that is Active.
- Enter the **GL Account** that the general ledger uses to process financial transactions tagged with this distribution code.
- Enter the **Statistics** that should be passed to the general ledger during the GL interface for this **GL Account**. For example, if this **Distribution Code** is used to record electric, residential revenue, the **Statistics** would be kWh if you record the number of kWh in you general ledger along with the dollar value of the revenue.

- If you have configured your installation options to indicate that [fund accounting](#) is practiced, define the **Fund** associated with this distribution code. If your installation options indicate that fund accounting is not practiced, the field is not visible.
- Use the characteristics grid to define characteristic values for the **Distribution Code**. This grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the **Distribution Code GL Account Characteristics** table. To modify a characteristic, simply move to a field and change its value. The following fields display:
 - **Characteristic Type**. Indicate the type of characteristic.
 - **Characteristic Value**. Indicate the value of the characteristic.

Note:

You can only choose characteristic types defined as permissible on the distribution code record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Setting Up Billable Charge Templates

A user creates a billable charge whenever a customer should be levied an ad hoc charge. For example, you would create a billable charge to charge a contractor for the repair of a ruptured gas line.

Note:

Interfacing billable charges from an external system. In addition to being entered manually, billable charges can also be interfaced from an external system. You would interface billable charges if your organization provides "pass through" billing services for a service provider. Refer to [Uploading Billable Charges](#) for more information.

A billable charge must reference a service agreement. This service agreement behaves just like any other service agreement:

- **Bill segments are created for the service agreement.** Whenever billing is performed for an account with billable charge service agreements, the system creates a bill segment for each unbilled billable charge.
- **Payments are distributed to the service agreement.** Payments made by an account are distributed to its billable charge service agreements just like any other service agreement.
- **Overdue debt is monitored.** The credit and collections process monitors billable charge service agreements for overdue debt and responds accordingly when overdue debt is detected.

Note:

Rates can be applied to billable charges. Billable charges can be connected to a service agreement that also specifies a rate. The rate will be applied and lines added to the bill segment after the billable charge lines are added. For example, a rate can insert flat charges or be applied to service quantities associated with the billable charge.

Taxes on top of billable charges. Rates cannot be applied to billable charge lines. If you need to perform a calculation such as applying taxes on top of the existing lines, add a service quantity (SQ) that contains the taxable amount with an SQ identifier that describes it as a taxable amount. A calculation rule can apply the tax to this SQ.

Fastpath:

Refer to [How To Create A One-Time Invoice](#) for instructions describing how to create a bill for a billable charge outside of the normal bill creation process.

Billable charge templates exist to minimize the effort required to create a billable charge for a customer. A billable charge template contains the default bill lines, amounts and distribution codes used to levy a one-off charge.

The information on the template may be overridden by a user when the billable charge is created. For example, you can create a billable charge template to levy tree-trimming charges. This template would contain the bill lines, amounts and distribution codes associated with a tree trimming activities. Then, when you trim a tree for a customer,

a user can create a billable charge using the template and override the amount to reflect the actual amount (if it differs from the norm).

Note:

Templates aren't required. A billable charge can be created without a template for a truly unexpected charge.

After setting up the billable charge templates, you must indicate the SA types that can use each template. Obviously, only billable charge SA types (as defined on the SA type's special role) will reference billable charge templates.

Billable Charge Template - Main

Open **Admin > Billing > Billable Charge Template > Add** to define your billable charge templates.

Description of Page

Enter a unique **Billable Charge Template ID** and **Description** for the billable charge template.

Use **Description on Bill** to define the verbiage that should print on the customer's bill above the billable charge's line item details.

Use **Currency Code** to define the currency in which the billable charge's amounts are expressed.

Use the grid to define the line item details associated with the billable charge (note, the **Total Line Amount** field is automatically calculated. It is the sum of the **Charge Amount** on each of the Line Sequence items). The following fields are required for each entry in the grid.

Sequence Line sequence controls the order in which the line items appear on the bill segment.

Description on Bill Specify the verbiage to print on the bill for the line item.

Charge Amount Specify the default amount to charge for the line item.

Show on Bill Turn this switch on if the line item should appear on the customer's printed bill. It would be very unusual for this switch to be off.

Appears in Summary Turn this switch on when the amount associated with this line also appears in a summary line.

Memo Only, No GL Turn this switch on when the amount associated with this line does not affect the GL (or the total amount owed by the customer).

Distribution Code Specify the default distribution code associated with this line item.

If you use the drill down button on the left most column in the grid, you will be taken to the Line Characteristics tab with the selected line displayed.

Fastpath:

For more information about creating a billable charge, refer to [Maintaining Billable Charges](#). For more information about billing billable charges, refer to [How To Create A One-Time Invoice](#).

Billable Charge Template - Line Characteristics

Open **Admin > Billing > Billable Charge Template > Search** and navigate to the **Line Characteristics** page to define your billable charge templates line characteristics.

Description of Page

The **Line Sequence** scroll defines the billable charge template line to which you wish to assign characteristic values.

The characteristics grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the Billable Charge Template Line Characteristics table.

To modify billable charge template line characteristics, simply move to a field and change its value. To add characteristics, press + to insert a row and then fill in the information for each field. The following fields display:

Characteristic Type The type of characteristic.

Characteristic Value The value of the characteristic.

Billable Charge Template - SQ Details

Open **Admin > Billing > Billable Charge Template > Search** and navigate to the **SQ Details** page to define your billable charge templates service quantities.

Description of Page

To modify a template's service quantity, simply move to a field and change its value. To add a new service quantity to the billable charge template, press the + button to insert a row and fill in the information for each field. The following fields display:

Sequence Specify the sequence number of the SQ.

UOM Select the unit of measure of this SQ. One or more of UOM, TOU, or SQ identifier must be selected.

TOU Select the time of use period.

SQ Identifier Select the SQ identifier.

Service Quantity Specify the number of units of this service quantity.

Designing and Defining Bill Segment Types

Every service agreement references a service agreement (SA) type. Amongst other things, the SA type references a bill segment type. The bill segment type controls how bill segments and their related financial transactions are created.

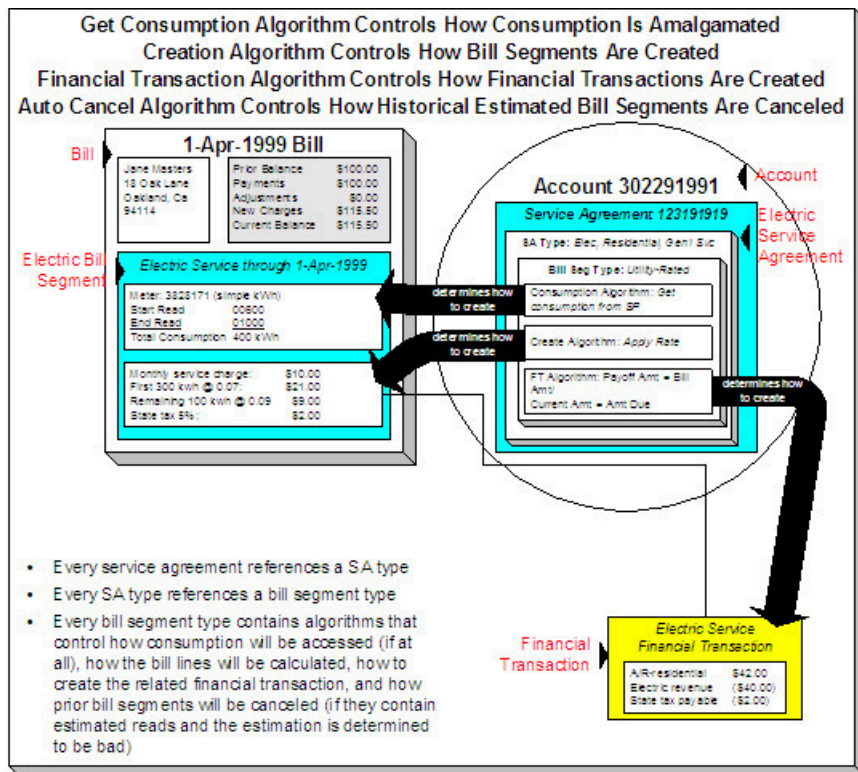

Warning:

We strongly recommend understanding the concepts described in [The Big Picture of Billing](#) before setting up your bill segment types.

The topics in this section describe how to design and set up bill segment types.

What Do Bill Segment Types Do?

Bill segment types control how bill segments and their related financial transactions are created. The following illustration will help you understand how the system uses bill segment types during the bill segment creation process:

Designing Your Bill Segment Types

Example Service Agreement Types

The following table contains a subset of the SA types listed under [Defining Service Agreement Types](#) and [Designing Your SA Types And Start Options For Sub SAs](#) and [Designing SA Types For Service Provider Financial Settlements](#). However, if you are reading this document from top to bottom, you probably don't know what your SA types are (they are only designed much later) and will have to forestall this task until that time.

We're going to cheat and assume you know what your SA types are and fill in the algorithms necessary to create bill segments for each SA type. After this table is complete, we will look for unique combinations of the 4 algorithms and create a bill segment type for each one.

Note:

Before you can fill in the columns for your own SA types, you should be comfortable with the descriptions of the algorithms described under [Setting Up Bill Segment Types](#).

| Div. | Calculation | FT | Consumption | Auto Cancel |
|----------|-------------|---|--------------------------|----------------------------------|
| SA Type | Algorithm | Algorithm | Algorithm | Algorithm |
| CA/G-RES | Apply Rate | Payoff = Bill Amount / Current = Amount Due | Get Consumption from SPs | Auto Cancel Bad Estimates |
| CA/G-COM | Apply Rate | Payoff = Bill Amount / Current = Amount Due | Get Consumption from SPs | NA - can't estimate consumption. |
| CA/G-IND | Apply Rate | Payoff = Bill Amount / Current = Amount Due | Get Consumption from SPs | NA - can't estimate consumption. |

| | | | | |
|-----------------|-------------------------------------|---|-------------------------------------|----------------------------------|
| CA/CABLE | Apply Rate | Payoff = Bill Amount / Current = Amount Due | Get Consumption from SPs | NA - can't estimate consumption. |
| CA/E-COY | Apply Rate | Payoff = 0 / Current = 0 | Get Consumption from SPs | NA - can't estimate consumption. |
| CA/E-RESU | Apply Rate To Usage Request | Payoff = Bill Amount / Current = Amount Due | Get Consumption Using Usage Request | NA - can't estimate consumption. |
| CA/E-COMU | Apply Rate To Usage Request | Payoff = Bill Amount / Current = Amount Due | Get Consumption Using Usage Request | NA - can't estimate consumption. |
| CA/WO-STD | N/A - non billable | N/A - non billable | N/A - non billable | N/A - non billable |
| CA/WO-LIA | N/A - non billable | N/A - non billable | N/A - non billable | N/A - non billable |
| CA/CHARITY | Recurring Charge | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed |
| CA/PA-REGU | Recurring Charge With Auto Stop | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed |
| CA/MERCH-I | Recurring Charge For Amount To Bill | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed |
| CA/DEP-I | Recurring Charge For Amount To Bill | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed |
| CA/ONETIME | Billable Charge | Payoff = Bill Amount / Current = Amount Due | N/A - no consumption is needed | N/A - no consumption is needed |
| CA/OVR UNDR | N/A - non billable | N/A - non billable | N/A - non billable | N/A - non billable |
| CA/E-SUB ENR | Apply Rate | Payoff = Bill Amount / Current = Amount Due | | |
| CA/E-SUB BC | Billable Charge | Payoff = Bill Amount / Current = Amount Due | N/A - no consumption is needed | N/A - no consumption is needed |
| CA/E-FIN SETTLE | N/A - non billable | N/A - non billable | N/A - non billable | N/A - non billable |

Algorithm Combinations

Now, we'll extract unique combinations of the four algorithms and create a bill segment type for each.

| Bill Segment Type | Calculation Algorithm | FT Algorithm | Consumption Algorithm | Auto Cancel Algorithm |
|-------------------|-------------------------------------|---|--|---|
| BD RATED | Apply Rate To Usage Request | Payoff = Bill Amount / Current = Amount Due | Get Consumption Using Usage Request | NA - can't estimate consumption. |
| BILLCHRG | Billable Charge | Payoff = Bill Amount / Current = Amount Due | N/A - no consumption is needed | N/A - no consumption is needed |
| COMPUSAG | Apply Rate To Usage Request | Payoff = 0 / Current = Bill Amount | Get Consumption Using Usage Request | N/A - no consumption is needed |
| RECUR | Recurring Charge | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed |
| RECUR AS | Recurring Charge With Auto Stop | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed |
| RECURATB | Recurring Charge For Amount To Bill | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed |
| SUB RATE | Apply Rate | Payoff = Bill Amount / Current = Amount Due | Get Consumption From Master Bill Segment | N/A - rated sub service agreements are cancelled when their master is canceled. |
| SUB BC | Billable Charge | Payoff = Bill Amount / Current = Amount Due | N/A - no consumption is needed | N/A - no consumption is needed |

Sample Service Agreement Types and Bill Segment Types

Just to make sure everything has been designed appropriately, we will return to our SA type samples and specify their respective bill segment types:

| Div. SA Type | Calculation Algorithm | FT Algorithm | Consumption Algorithm | Auto Cancel Algorithm | Bill Segment Type |
|--------------|-----------------------|---|--------------------------|---------------------------|-------------------|
| CA/G-RES | Apply Rate | Payoff = Bill Amount / Current = Amount Due | Get Consumption from SPs | Auto Cancel Bad Estimates | SP-RATED |
| CA/G-COM | Apply Rate | Payoff = Bill Amount / Current = Amount Due | Get Consumption from SPs | Auto Cancel Bad Estimates | NOESTRAT |

| | | | | | |
|--------------|-------------------------------------|---|--|---|----------|
| CA/E-RES | Apply Rate To Usage Request | Payoff = Bill Amount / Current = Amount Due | Get Consumption Using Usage Request | NA - can't estimate consumption. | BD RATED |
| CA/E-COM | Apply Rate To Usage Request | Payoff = Bill Amount / Current = Amount Due | Get Consumption Using Usage Request | NA - can't estimate consumption. | BD RATED |
| CA/G-IND | Apply Rate | Payoff = Bill Amount / Current = Amount Due | Get Consumption from SPs | Auto Cancel Bad Estimates | NOESTRAT |
| CA/CABLE | Apply Rate | Payoff = Bill Amount / Current = Amount Due | Get Consumption from SPs | Auto Cancel Bad Estimates | SP-RATED |
| CA/E-COY | Apply Rate | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed. | N/A - no consumption is needed. | COMPUSAG |
| CA/WO-STD | N/A - non billable | N/A - non billable | N/A - non billable | N/A - non billable | |
| CA/WO-LIA | N/A - non billable | N/A - non billable | N/A - non billable | N/A - non billable | |
| CA/CHARITY | Recurring Charge | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed | RECUR |
| CA/PA-REGU | Recurring Charge With Auto Stop | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed | RECUR-AS |
| CA/MERCH-I | Recurring Charge For Amount To Bill | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed | RECUR-AS |
| CA/DEP-I | Recurring Charge For Amount To Bill | Payoff = 0 / Current = Bill Amount | N/A - no consumption is needed | N/A - no consumption is needed | RECURATB |
| CA/ONETIME | Billable Charge | Payoff = Bill Amount / Current = Amount Due | N/A - no consumption is needed | N/A - no consumption is needed | BILLCHRG |
| CA/OVR UNDR | N/A - non billable | N/A - non billable | N/A - non billable | N/A - non billable | |
| CA/E-SUB ENR | Apply Rate | Payoff = Bill Amount / Current = Amount Due | Get Consumption From Master Bill Segment | N/A - rated sub service agreements are cancelled when their master is canceled. | SUB RATE |

| | | | | | |
|-----------------|--------------------|---|--------------------------------|--------------------------------|--------|
| CA/E-SUB BC | Billable Charge | Payoff = Bill Amount / Current = Amount Due | N/A - no consumption is needed | N/A - no consumption is needed | SUB BC |
| CA/E-FIN SETTLE | N/A - non billable | N/A - non billable | N/A - non billable | N/A - non billable | |

And now you're ready to set up your bill segment types.

Setting Up Bill Segment Types

To set up bill segment types, open **Admin > Billing > Bill Segment Type > Add**.

Description of Page

Enter an easily recognizable **Bill Segment Type** and **Description** for every type of bill segment.

For each bill segment type, define the **Create Algorithm**. The logic embedded in this algorithm creates the bill segment. Refer to [Designing Your Bill Segment Types](#) for examples.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that creates a bill segment in the appropriate manner.

Warning:

The **BS Create Algorithm** is a very important field as it controls how the system creates bill segments. There are some restrictions in respect of the values of certain fields on the SA type and the bill segment algorithm used on a SA type. Refer to [Require Total Amount Switch versus Bill Segment Creation Algorithm](#), [Allow Recurring Charge Switch versus Bill Segment Creation Algorithm](#), and [Rate Required Switch versus Bill Segment Creation Algorithm](#) for more information.

For each bill segment type, define the **Financial Algorithm**. The logic embedded in this algorithm constructs the financial transaction associated with the bill segment. Refer to [Designing Your Bill Segment Types](#) for examples.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that constructs the bill segment financial transaction in the appropriate manner.

Fastpath:

For more information about current and payoff amounts, refer to [Current Amount versus Payoff Amount](#).

If the bill segment requires consumption (e.g., meter reads) to be retrieved, define the **Get Consumption Algorithm**. The logic embedded in this algorithm retrieves the consumption that is billed on the bill segment. Refer to [Designing Your Bill Segment Types](#) for examples.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that retrieves consumption in the appropriate manner.

The **Auto Cancel Algorithm** is used by the system when it detects that a prior bill segment contains an estimated read that meets certain conditions when a non-estimated read is used on the current bill.

Examples include:

- The prior bill segment contains a bad estimated read (by "bad" we mean that the current bill has a non-estimated reading that is less than the estimated end read on the prior bill segment).

- The prior bill segment contains an estimated read (there may be situations where you want to cancel an estimated bill segment when a non-estimated read is also higher than the end read on the prior bill segment. For example, when tiered rates may cause a customer to be penalized by consumption being charged at a higher rate).

For detecting a bad estimated read on the prior bill segment, if you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that cancels bill segments that contain poorly estimated consumption.

For detecting an estimated read on the prior bill segment, if you haven't done so already, you must set up this algorithm in the system and configure a feature configuration option. To do this:

- Create a new algorithm for the Auto Cancel Algorithm.
- On this algorithm, reference an Algorithm Type that cancels bill segments that contain estimated consumption (refer to [Setting Up Algorithms](#)).
- Configure the **Always Call Auto Cancel** option type on the Financial Transactions Option feature configuration and set the option type value to 'Y'. For more information about Feature Configurations, see [Defining Feature Configurations](#).

Note that the Auto Cancel Algorithm is not used when Oracle Utilities Customer Care and Billing and Oracle Utilities Meter Data Management applications are integrated. This is because the reads are recorded in the Meter Data Management application which is responsible for validating reads used in billing. The following features replace the algorithm:

- Usage Transaction Correction Processor
 - This is created during IMD processing when an anomaly is detected in the reads used in usage calculation. It sets the stage for sending the corrected read notification
 - The Usage Transaction Correction Processor monitor job (D1-UTCRN) must be scheduled after all IMD processing batch jobs.
- Corrected Reads Notification
 - The application may be configured to automatically process all corrected read notifications by submitting the Corrected Reads Notification monitor job (C1-TCRNB). Refer to the configuration guideline below for automating this process.
 - If manual rebill is preferred, billing user may navigate to the off cycle generator portal to search for a customer's corrected read notification, review and rebill them one at a time starting from the oldest bill segment.
- Final Measurement Replacement — It is recommended that this VEE rule be configured for IMD processing. It is used to reject small changes in reads, which in turn prevents the creation and sending corrected reads notification and subsequent re-bill that would have resulted to small net differences in charges.

The **Bill Segment Information Algorithm** is used by the system to format the bill segment information that appears throughout the system. If the information you'd like displayed differs for bill segment types, you must set up this algorithm in the system. To do this:

Designing and Defining Deposit Classes

If you bill for deposits, you must set up one or more deposit classes. If your company does not bill for deposits, you can skip this section.

Fastpath:

We strongly recommend familiarizing yourself with the concepts described in [The Big Picture Of Deposits](#) before tackling the information in this section.

The topics in this section describe how to design and set up deposit classes.

What Do Deposit Classes Do?

A deposit class contains the business rules that govern:

- How and when deposit interest is calculated.
- How the recommended deposit amount is calculated.
- When a deposit will be automatically refunded to a customer.
- When the system will recommend a new or additional deposit.

When you link a deposit class to a SA type, you are indicating that the SA type's service agreements are governed by the deposit class' business rules.

In addition to linking a deposit class to the SA types used to bill for a deposit, you must also define a deposit class on SA types whose debt is covered by a deposit. Consider the following examples:

- Assume your company sells electricity, gas, and water; but deposits are only held only for electric service. In this situation, you'd need one deposit class - Electric - and you'd associate it with both the electric deposit SA type and the electric usage SA type(s) (the gas and water SA types would NOT reference a deposit class).
- If your company can apply a deposit to any type of debt, then you'd have just one deposit class - General Deposit. You'd link this deposit class to the deposit SA type, and to the other SA types whose debt is covered by the deposit.

Note:

Non-cash deposits. You can also use the system to manage non-cash deposits (e.g., letters of credit, surety bonds, 3rd party deposits). Non-cash deposits are held in respect of an account (and an account may have an unlimited number of non-cash deposits). Each non-cash deposit must reference a deposit class. Why? Because the system amalgamates cash and non-cash deposits when it determines if an account is holding an adequate deposit. Refer to [3rd Party Deposits](#) for more information.

Designing Your Deposit Classes

A deposit class contains the business rules that govern:

- How and when deposit interest is calculated.
- How the recommended deposit amount is calculated.
- When a deposit will be automatically refunded to a customer.
- When the system will recommend a new or additional deposit.

You will need multiple deposit classes if any of the above rules / conditions differ for different types of customers. For example, if residential customers use a different recommended deposit algorithm as compared to commercial customers, you'd need one deposit class for residential and another for commercial.

You will need additional deposit classes if your customers can have multiple deposits where each deposit is restricted to a specific type of debt. For example, if separate deposits are held for regulated and unregulated debt (and a customer could hold a combination of regulated and unregulated debt), you'd need one deposit class for regulated debt and another for unregulated debt.

We'll design deposit classes to satisfy the needs of a theoretical company to help you understand how to design your deposit classes. The following points describe the deposit requirements of our theoretical company:

- The recommended deposit amount is 2 times the average bill (averaged over the last 12 months). This is true regardless of the type of customer or debt.
- The system should automatically refund a deposit to a customer after:
 - The deposit has been held for at least 6 months; and
 - The account's credit rating is greater than the credit rating threshold defined on the installation record or the account's CIS Division (i.e., the credit rating is no longer considered bad)
- This is true regardless of the type of customer or debt.

- Interest is calculated every 6 months. The interest rate is defined using a bill factor (refer to [Setting Up Bill Factors](#) for more information). This is true regardless of the type of customer or debt.
- When it's time to refund a deposit, all outstanding debt will be paid off first. If any moneys remain, a check should be sent to the customer for the remainder. This is true regardless of the type of customer or debt.
- A customer could have both regulated and unregulated debt under a single account. When this happens, separate deposits will be held for each type of debt (where the regulated deposit can only be used to satisfy regulated debt and the unregulated deposit can only be used to satisfy unregulated debt).

You'd need the following deposit classes to satisfy the above requirement:

| Deposit Class | Recommended Amount Rule | Auto Refund Condition | Interest Rules | Deposit Refund Method |
|---------------|-------------------------|---|--------------------------------|--|
| Regulated | 2 x Average Bill | Held for 6 months and credit rating is good | Simple interest every 6 months | Apply to outstanding debt first, refund remainder with a check |
| Unregulated | 2 x Average Bill | Held for 6 months and credit rating is good | Simple interest every 6 months | Apply to outstanding debt first, refund remainder with a check |

You may wonder why two deposit classes are needed when the rules are the same for both? Well, besides defining the applicable business rules for a deposit service agreement, a deposit class is defined on the SA types whose debt is covered by the deposit class' deposit. So, if you have two different types of debt where each type of debt can have its own deposit, you'd need at two deposit classes. Each deposit class would be associated with the service agreements that are being secured by the deposit.

Refer to [Setting Up Deposit Classes](#) for a description of the various algorithms defined in respect of a deposit class.

Setting Up Deposit Classes

In the previous section, *Designing Your Deposit Classes*, we presented a case study that illustrated a mythical organization's deposit classes. In this section, we explain how to maintain your Deposit Classes.

Deposit Class - Main

To set up deposit classes, select **Admin > Credit & Collection > Deposit Class > Add**.

Description of Page

Enter an easily recognizable **Deposit Class** and **Description**.

Use **Refund Description on Bill** to define the information that appears on the bill segment produced when it's time to refund the customer's deposit.

The remaining information on this page is used by the various deposit-oriented processes.

Refer to [Deposit Class - Good Customer](#) for information about the **Good Customer Algorithm**.

Refer to [Deposit Class - Recommendation](#) for information about the **Recommendation Algorithm** and **Review Tolerance Percentage**.

Refer to [Deposit Class - Refund Method](#) for information about the **Refund Method Algorithm**.

Refer to [Deposit Class - Refund Criteria](#) for information about the **Refund Criteria Algorithm**.

Refer to [Deposit Class - Refund Interest](#) for information about the **Interest Refund Algorithm** and **Months Between Interest Refund**.

Refer to [Deposit Class - Review Method](#) for information about the **Review Method Algorithm**.

Deposit Class - Good Customer

On [Deposit Class - Main](#) you must define the **Good Customer Algorithm** used by the system when it determines if a customer is considered good (the system recommends new / additional deposits for bad customers). Refer to [Deposit Review](#) for a description of the background process that reviews customers for adequate deposits.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines if a customer is considered good.

Deposit Class - Recommendation

On [Deposit Class - Main](#) you must define the **Recommendation Algorithm** used by the system when it calculates a customer's recommended deposit amount.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that recommends deposits.

The system uses the **Review Tolerance Percentage** to prevent the recommendation of small deposits by the Deposit Review background process. For example, if this field contains 10(%), the system would only recommend an additional deposit if the recommended amount was more than 10% of the existing deposit.

Deposit Class - Refund Method

On [Deposit Class - Main](#) you must define the **Refund Method Algorithm** used by the system when it refunds a deposit to the customer.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that refunds a deposit to a customer.

Deposit Class - Refund Criteria

On [Deposit Class - Main](#) you must define the **Refund Criteria Algorithm** used by the system when it determines if it should automatically refund a deposit to a customer. Refer to [Deposit Review](#) for a description of the background process that reviews deposits for refunds.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines if a customer qualifies for a deposit refund.

Deposit Class - Refund Interest

On [Deposit Class - Main](#) you must define the **Interest Refund Algorithm** to define how the system calculates interest and how it refunds the interest to the customer.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that calculates interest on a deposit.

Interest will be automatically calculated every X months where X is defined in **Months Between Interest Refund**. Refer to [Deposit Interest](#) for a description of the background process that calculates interest on deposits. Also note that interest is calculated when a [deposit service agreement is stopped](#).

Deposit Class - Review Method

On [Deposit Class - Main](#) you must define the **Review Method Algorithm** used by the system to determine what action to take if the system recommends a deposit (or additional deposit) amount for an account. Refer to [Review Deposits](#) for a description of the background process that reviews deposits for refunds. The algorithm supplied with the base product highlights new deposits and deposit amounts on the [Deposit Review](#) page.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the review method the system uses if it recommends a deposit or additional deposit be applied to an account.

Setting Up Non-Cash Deposit Types

Non-cash deposit types are used to indicate the type of monetary instrument used for non-cash deposits. Refer to [Non-Cash Deposits](#) for more information.

To define your non-cash deposit types, select **Admin > Credit & Collection > Non-Cash Deposit Type**.

Description of Page

To modify a non-cash deposit type, move to a field and change its value.

To add a new non-cash deposit type, insert a row, then fill in the information for each field. The following fields display:

Non-Cash Deposit Type The unique identifier of the non-cash deposit type.

Description The description of the non-cash deposit type.

Review Before Expiration This switch indicates if the system will create a To Do entry when non-cash deposits of this type are close to expiration.

Third Party Deposit This switch indicates if the system requires a reference to a 3rd party's deposit service agreement for this type of non-cash deposit. Refer to [3rd Party Deposits](#) for more information.

Setting Up Payment Segment Types

Every service agreement references a service agreement (SA) type. Amongst other things, the SA type references a payment segment type. The payment segment type controls how payment segments and their related financial transactions are created. To set up payment segment types, open **Admin > Payment Segment Type**.

Description of Page

Enter an easily recognizable **Payment Segment Type** and **Description** for every type of payment segment.

Fastpath:

For more information about the source of the distribution codes on financial transactions, see [The Source Of GL Accounts On Financial Transactions](#) .

For each payment segment type, define the **Payment Segment Fin Algorithm**. The logic embedded in this algorithm constructs the actual financial transaction associated with the payment segment. Refer to [Examples of Common Payment Segment Types](#) for examples of how algorithms are used on common payment segment types.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).

- On this algorithm, reference an Algorithm Type that constructs the payment segment financial transaction in the appropriate manner.

Fastpath:

For more information about current and payoff amount, see [Current Amount versus Payoff Amount](#) .

Examples of Common Payment Segment Types

The following table shows several classic payment segment types used by many organizations:

| Payment Segment Type | Payment Segment Financial Transaction Algorithm |
|---|---|
| Normal payment (if you practice accrual accounting). Refer to Accrual versus Cash Accounting for more information. | Payoff = Pay Amount / Current = Pay Amount (no cash accounting) |
| Normal payment (if you practice cash accounting). Refer to Accrual versus Cash Accounting for more information. | Payoff = Pay Amount / Current = Pay Amount (plus Cash Accounting) |
| Charity payment | Payoff = 0 / Current = Pay Amount (the GL is affected) |
| Non-CIS Payments (When the FT is created, the distribution code and GL account to credit is retrieved from the pay). Refer to Non CIS Payments for more information | Payoff = Pay Amount / Current = Pay Amount (no cash accounting) |

Designing And Defining Adjustment Types

A service agreement's debt may be changed with an adjustment. Every adjustment must reference an adjustment type. The adjustment type contains a great deal of information that is defaulted onto the adjustment, including whether the adjustment amount is calculated. It also controls many business processes associated with the adjustment. The topics in this section describe how to design and set up adjustment types.

What Do Adjustment Types Do?

An adjustment type contains the business rules that govern how its adjustments are managed by the system. Please refer to [The Big Picture Of Adjustments](#) for a complete description of how adjustment types impact the lifecycle of adjustments.

Setting Up Adjustment Types

The topics in this section describe how to set up adjustment types.

Note:

When a new adjustment type is added. When you introduce a new adjustment type, you must update one or more adjustment profiles with the new adjustment type. Why? Because adjustment profiles define the adjustment types that may be levied on service agreements (adjustment profiles are defined on SA types). If you don't put the adjustment type on an adjustment profile, the adjustment type can't be used on any adjustment.

To set up adjustment types, open **Admin > Financial > Adjustment Type > Add.**

Description of Page

Enter a unique **Adjustment Type ID** and **Description** for the adjustment type.

If your implementation requires restricting the list of adjustments types that users are able to select by CIS Division, specify a **CIS Division** on the adjustment type.

The **Adjustment Amount Type** indicates whether the adjustment about is calculated or not. Select **Calculated Amount** when you want to use a rate to perform calculations to generate the adjustment amount otherwise select **Non-Calculated Amount**. Refer to [Setting Up Calculated Adjustment Types](#) for more information about calculated adjustments.

Enter the **Distribution Code** that references the GL account associated with the adjustment. For example, if this adjustment type is used to levy a charge for a bad check, the distribution code would reference the revenue account to which you associate such revenue. Note, the offsetting distribution code is kept on the SA type.

Note:

Distribution Code for Calculated Adjustments. Depending on the algorithm used for the *calculated adjustment*, the distribution code may come from the adjustment type or the calculation lines of the algorithm. If the adjustment's calculation algorithm gets the distribution code from the calculation lines, you do not need to specify a distribution code on the adjustment type.

Fastpath:

For more information about the source of the distribution codes on financial transactions, see [The Source Of GL Accounts On Financial Transactions](#).

Enter the **Currency Code** for adjustments of this type.

Turn on **Sync. Current Amount** if adjustments of this type exist to force a service agreement's current balance to equal its payoff balance. These types of adjustments are issued before a service agreement's funds are transferred to a write-off service agreement. If this switch is on, choose an **Adjustment Fin Algorithm** that does not impact payoff balance or the GL, but does affect the SA's current balance (refer to ADJT-CA for an example of such an algorithm).

Enter a **Default Amount** if an amount should be [defaulted](#) onto adjustments of this type.

Fastpath:

For more information about current and payoff amounts, refer to [Current Amount versus Payoff Amount](#).

If the AP Adjustment should be recorded in respect of the customer's 1099 amounts, indicate the **A/P 1099 Flag**. This would typically be used on the adjustment used to credit the deposit service agreement with accrued interest. The values of this field are Interest and Miscellaneous. This type of adjustment would also have an **A/P Request Type Code** selected, as 1099 reporting is handled in A/P.

Turn on **Print By Default** if information about adjustments of this type should print on the account's next bill.

Choose an **A/P Request Type Code** if this adjustment is interfaced to accounts payable (i.e., it's used to send a refund check to a customer). Refer to [A/P Check Request](#) for more information.

The **Adjustment Freeze Option** defines when adjustments can be frozen and therefore when a service agreement's balance and the general ledger are affected by an adjustment. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) to understand the significance of this option. Also note, if the **installation option's** Bill Segment Freeze Option is Freeze At Will, this field is defaulted to Freeze At Will and cannot be changed.

Warning:

Adjustment types for adjustments created during bill completion (e.g., by a bill completion algorithm) must have their adjustment freeze option set to Freeze At Will. Otherwise (i.e., if the option is Freeze At Bill Completion) they will not be frozen until a subsequent bill is completed.

If adjustments of this type require approval, define an **Approval Profile**. For more information, refer to [The Big Picture of Adjustment Approvals](#).

Enter the verbiage to appear on the printed bill in **Description on Bill**.

Use the characteristics collection to define a **Characteristic Type** and **Characteristic Value** common to all adjustments of this type. These can be used for reporting purposes or in your algorithms.

Adjustment Type - Adjustment Characteristics

To define characteristics that can be defined for adjustments of a given type, open **Admin > Financial > Adjustment Type > Search** and navigate to the **Adjustment Characteristics** page.

Description of Page

Use the **Adjustment Characteristics** collection to define characteristics that can be defined for adjustments of a given type. Turn on the **Required** switch if the **Characteristic Type** must be defined on adjustments of a given type. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on. Use **Sequence** to control the order in which characteristics are defaulted.

Adjustment Type - Algorithms

To define algorithms for adjustments, open **Admin > Financial > Adjustment Type > Search** and navigate to the **Algorithms** page.

Description of Page

The grid contains **Algorithms** that control important adjustment functions. If you haven't already done so, you must [set up the appropriate algorithms](#) in your system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|-------------------------|---------------------|--|
| Adjustment Cancellation | Optional | When an adjustment is canceled an algorithm of this type may be called to do additional work. Refer to The Lifecycle Of An Adjustment for more information about canceling an adjustment. |
| Adjustment Freeze | Optional | When an adjustment is frozen an algorithm of this type may be called to do additional work. Refer to The Lifecycle Of An Adjustment for more information about freezing an adjustment. |

| | | |
|---------------------------|----------|--|
| Adjustment Information | Optional | <p>We use the term "Adjustment information" to describe the basic information that appears throughout the system to describe an adjustment. The data that appears in "Adjustment information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the "Adjustment information" algorithm on installation options or the system default "Adjustment information" if no such algorithm is defined on installation options.</p> |
| Adjustment FT Creation | Required | <p>Algorithms of this type are used to construct the actual financial transaction associated with the adjustment. The financial transaction controls the adjustment's affect on the service agreement's payoff and current balances. It also constructs the information that is eventually interfaced to your general ledger. Refer to Examples of Common Adjustment Types for examples of how algorithms are used on common adjustment types.</p> |
| Default Adjustment Amount | Optional | <p>Algorithms of this type are used to default the adjustment amount. Refer to Default the Adjustment Amount for more information.</p> |
| Determine SA | Optional | <p>Algorithms of this type are used to find a service agreement for which the adjustment can be posted. This plug-in is used particularly during adjustment upload when a staging record does not identify the SA ID. Refer to Interfacing Adjustments From External Sources for more information.</p> |
| Resolve Suspense | Optional | <p>Algorithms of this type are used to automatically resolve adjustments that are in suspense. Refer to Suspense Adjustments for more information</p> |

| | | |
|---------------------|----------|---|
| Generate Adjustment | Optional | Algorithms of this type are used to calculate the adjustment amount if an adjustment type indicates that the adjustment amount is calculated. Refer to Setting Up Calculated Adjustment Types for more information. |
| Validate Adjustment | Optional | Algorithms of this type are used to validate information for the adjustment after it is generated. |

Setting Up Calculated Adjustment Types

You can use an algorithm to calculate an adjustment amount for example if you need to calculate tax on a base amount or calculate a non-sufficient funds charge based on the customer's credit rating. Because the base package algorithm calculates adjustment amounts by calling the rate application, calculated adjustments are sometimes referred to as ratable adjustments.

Note:

Ratable Adjustments Appear Deceptively Simple. But, they are not. Calculated adjustments that use the base package algorithm have all the power and flexibility (and complexity) of the rate application. Anything that you can do with a rate can be applied to a calculated adjustment. For examples that illustrate the flexibility of the rate application (and therefore calculated adjustments), refer to [Rate Examples](#).

Adjustment types that indicate they are calculated have a generate adjustment algorithm. The base package algorithm defines the rate schedule used to calculate the adjustment as well as any UOM, TOU or SQI parameters.

To set up calculated adjustment types using the base package generate adjustment algorithm type:

- Define the rate that performs the calculations, including the rate schedule, calculation groups, and calculation rules. Refer to [Rates](#) for information.

Note:

If you create your own Generate Adjustment algorithm type, you may not need to set up a rate that performs the calculations. It depends on the needs of your algorithm type.

- Create a Generate Adjustment algorithm (refer to [Setting Up Algorithms](#)) that references the base package algorithm type that generates calculated adjustments (see the table above).
- If you want the generation algorithm's calculation lines to provide the distribution codes when the adjustment is posted to the GL, create an Adjustment Financial Transaction algorithm (refer to [Setting Up Algorithms](#)) that references an algorithm type that creates the adjustment's financial transactions using the calculation lines. A parameter of the adjustment financial transaction algorithm determines whether the distribution codes are taken from the adjustment type (AT) or calculation lines (CL). The system comes supplied with several sample algorithm types that create adjustment financial transactions.
- Create an adjustment type where the **Adjustment Amount Type** is Calculated Amount, the Generate Adjustment event references the generation algorithm created above, and the Adj. Financial Transaction event references the adjustment financial transaction algorithm created above.

Examples of Common Adjustment Types

The following table shows several classic adjustment types used by many organizations:

| Adjustment Type | Typical Distribution Code | Default Amount | Financial Transaction Algorithm | Print On Bill | A/P Adjust-ment | 1099 |
|-----------------|-------------------------------|------------------------|--|---------------|-----------------|------|
| NSF | NSF revenue | Your NSF fee | Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type | Yes | No | No |
| LPC | Late payment charge revenue | N/A | Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type | Yes | No | No |
| CONNECT | Connection charge revenue | Your connection charge | Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type | Yes | No | No |
| CUSTREL | Customer relationship expense | N/A | Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type | Yes | No | No |
| ADDCHARG | Misc Revenue | N/A | Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type | Yes | No | No |

| | | | | | | |
|----------|---------------------------|-----|--|-----|-----|----|
| XFER | Balance transfer clearing | N/A | Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type | Yes | No | No |
| WO SYNC | N/A | N/A | Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type | No | No | No |
| REFUNDAP | A/P clearing | N/A | Payoff = Current = Adj. Amt Refer to ADJT-NM for an example of such an algorithm type | Yes | Yes | No |
| DPA FIX | N/A | N/A | Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type | Yes | No | No |
| CHARITFX | N/A | N/A | Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type | Yes | No | No |

| | | | | | | |
|----------|-----|-----|--|-----|----|----|
| BUDG ON | N/A | N/A | Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type | Yes | No | No |
| BUDG OFF | N/A | N/A | Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type | Yes | No | No |
| BUDG FIX | N/A | N/A | Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type | Yes | No | No |
| DEPOSREF | N/A | N/A | Payoff = 0 / Current = Adj. Amt Refer to ADJT-CA for an example of such an algorithm type | Yes | No | No |

| | | | | | | |
|---------|------------------|-----|---|-----|----|-----|
| DEPOSIT | Interest expense | N/A | <p>Payoff = Current = Adj. Amt. Refer to ADJT-NM for an example of such an algorithm type.</p> <p>Or</p> <p>Payoff Amt = Adj Amt / Current Amt = 0. Refer to ADJT-TA for an example of such an algorithm type.</p> <p>Use the first method if you want to have the interest reflected as a credit balance on the customer's bill. Use the second method if you roll the interest amount into the customer's existing deposit on hand.</p> | Yes | No | Yes |
| DEPFI | N/A | N/A | <p>Payoff = 0 / Current = Adj. Amt</p> <p>Refer to ADJT-CA for an example of such an algorithm type</p> | No | No | No |

Setting Up Adjustment Type Profiles

Adjustment type profiles categorize your adjustment types into logical groups. When you link a profile to a SA type, you limit the type of adjustments to be linked to the SA type's service agreements. The creation of adjustment profiles and their linkage to SA types prevents inappropriate adjustments from being linked to your service agreements. More than one adjustment type profile may be linked to a SA type.

For example, you can create an adjustment type profile called Miscellaneous Fees and link to it the miscellaneous fee adjustment types. Then, you would link this profile to those SA types that are allowed to levy such fees.

**Note:**

Bottom line. An adjustment can only be linked to a service agreement if its adjustment type is part of an adjustment type profile that is valid for the service agreement's SA type. If an adjustment type is not linked to a profile, it could never be levied.

To set up adjustment type profiles, open **Admin > Financial > Adjustment Type Profile > Add.**

Description of Page

Enter a unique **Adjustment Type Profile** and **Description** for the adjustment type profile.

Indicate the **Adjustment Types** that are part of the profile.

Examples Of Common Adjustment Profiles

The following table shows several classic adjustment profiles used by many organizations (we've displayed some attributes from the adjustment type in the following table to help make it more understandable):

| Adjustment Profile | Adjustment Type | Typical Distribution Code | Default Amount | Financial Transaction Algorithm |
|--------------------|-----------------|-------------------------------|------------------------|--|
| FEES | NSF | NSF revenue | Your NSF fee | Payoff Amt = Adj Amt / Current Amt = Adj Amt |
| | LPC | Late payment charge revenue | Your LPC | Payoff Amt = Adj Amt / Current Amt = Adj Amt |
| | CONNECT | Connection charge revenue | Your connection charge | Payoff Amt = Adj Amt / Current Amt = Adj Amt |
| MISCEXP | CUSTREL | Customer relationship expense | N/A | Payoff Amt = Adj Amt / Current Amt = Adj Amt |
| XFER | TRANSBAL | Balance transfer clearing | N/A | Payoff Amt = Adj Amt / Current Amt = Adj Amt |
| REFUND | REFUND | A/P clearing | N/A | Payoff Amt = Adj Amt / Current Amt = Adj Amt |
| DPA | ADJCURR | N/A | N/A | Payoff Amt = 0 / Current Amt = Adj Amt |
| | SYNCCURR | N/A | N/A | Payoff Amt = 0 / Current Amt = Adj Amt |
| CHARITY | CHAR FIX | N/A | N/A | Payoff Amt = 0 / Current Amt = Adj Amt |

| | | | | |
|---------|-----------|----------------------------------|---------------------------------|--|
| BUDGET | BUDG ON | N/A | N/A | Payoff Amt = 0 / Current Amt = Adj Amt |
| | BUDG OFF | N/A | N/A | Payoff Amt = 0 / Current Amt = Adj Amt |
| | BUDG FIX | N/A | N/A | Payoff Amt = 0 / Current Amt = Adj Amt |
| | FIX PAY | Customer relationship expense | N/A | Payoff Amt = Adj Amt / Current Amt = 0 |
| DEPOSIT | DEPOSBILL | N/A | Your standard deposit amount | Payoff Amt = 0 / Current Amt = Adj Amt |
| | DEPOSINT | Interest expense | N/A | Payoff Amt = Adj Amt / Current Amt = Adj Amt |
| | SYNCCURR | N/A | N/A | Payoff Amt = 0 / Current Amt = Adj Amt |
| | ADJCUR | N/A | N/A | Payoff Amt = 0 / Current Amt = Adj Amt |

The Big Picture Of Adjustment Approval

Some implementations require adjustments to be approved by one or more managers before they impact a customer's debt and the general ledger. For example, an adjustment used to rebate a credit balance may require managerial approval before the rebate is sent to the customer. The topics in this section describe how to set up the system to support the approval of adjustments.

Approval Is Controlled By Approval Profiles

An approval profile contains the rules that define if and how an adjustment is approved. If an adjustment type does not reference an approval profile, the related adjustments do not require third-party approval before they impact a customer's debt. If an adjustment type references an approval profile, the approval profile's approval hierarchy defines if the adjustment requires approval and who the authorized approvers are. For example, an approval profile can be configured with the following approval hierarchy:

- Adjustments < \$0 require approval by the "credit approvers role"
- Adjustments >= \$0 and <= \$10 do not require approval
- Adjustments > \$10 and <= \$100 require the approval of a user that belongs to the "level 1 approvers role"
- Adjustments > \$100 require two levels of approval: first a user that belongs to the "level 1 approvers role" must approve the adjustment; afterwards, the adjustment must be approved by a user that belongs to the "level 2 approvers role"

**Note:**

Transfer adjustments. The term "transfer adjustment" refers to two adjustments that are used to transfer moneys between two service agreements. The adjustment with the positive amount is considered to be the debit adjustment; the other adjustment is considered the credit adjustment. When a transfer adjustment requires approval, only one of the adjustments needs to be approved. You control whether the debit side or the credit side of a transfer adjustment is used to control the approval process when you set up the approval profile.

Approval Profiles Can Be Linked To Multiple Adjustment Types

Approval hierarchies are frequently the same for many adjustment types. The system allows an approval profile to be linked to multiple adjustment types to simplify the definition and maintenance of the rules over time.

Adjustments Created In Batch Are Not Approved

The system assumes that no approval is necessary for adjustments created by batch processes even those whose adjustment type references an approval profile.

Approval Inserts A Step Into An Adjustment's Lifecycle

[The Lifecycle Of An Adjustment](#) explains how an adjustment is transitioned from the Freezable state to the Frozen state when it should impact the general ledger and the customer's balance. If an adjustment's adjustment type references an approval profile, the user cannot freeze the adjustment directly. Rather, the user must submit the adjustment for approval when it's ready and only when the last applicable approver approves the adjustment will it become Frozen.

**Note:**

Freeze during bill completion. You can configure the system to only freeze certain types of adjustments when the next bill is completed for the adjustment's account. When the last approver approves such adjustments, they remain in the Freezable. When the next bill is completed for the account, these adjustment become Frozen. Such adjustments that have not been approved at the time of bill completion will remain in the Freezable state. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) for more information.

Approval Requests Manage And Audit The Approval Process

Users submit an adjustment for approval using a dedicated button on the [Adjustment](#) page. When an adjustment is submitted for approval, the system creates an "approval request". The approval request determines if the adjustment requires approval and, if so, the list of approvers. If the adjustment does not require approval, the approval request is updated to indicate such and the adjustment is Frozen immediately (if freezing is allowed prior to bill completion). If the adjustment requires approval, the approval request's state becomes Approval In Progress and the approver(s) are notified.

**Note:**

Approval submission logic is customizable. The previous paragraph describes how the base-package works when an adjustment is submitted for approval. This logic resides in an algorithm that's plugged in on the C1-AdjustmentApprovalProfile business object in the Determine Approval Requirements system event. Your implementation can change this logic by developing a new algorithm and plugging it into this business object. If your logic is meant to supersede the base-package algorithm, remember to inactivate the base-package algorithm by adding an appropriate inactivation option to this business object.

To Do Entries Are Created To Notify Approvers

When an approval request detects an adjustment requires approval, it notifies the first approver by creating a To Do entry. The To Do entry is created using the To Do type and To Do role defined on the approval profile. All users who belong to the approving To Do role can see the entry. When a user drills down on an adjustment approval To Do entry, the [Adjustment - Approval](#) portal is opened. This portal contains summary information about the adjustment and the approval history of the adjustment. This portal is also where the user approves or rejects the adjustment.

When the first user in the To Do role approves an adjustment, the To Do entry is Completed and the approval request's audit log is updated. If there are no higher levels of approval required, the adjustment is Frozen (if freezing is allowed prior to bill completion) and the approval request is moved to the Approved state. If there are higher levels of approval required, a new To Do entry is created to the next To Do role in the approval hierarchy.

Note:

To Do entries can create email. A To Do entry can be configured to create an email message for every user in the To Do role to inform the user(s) of new adjustments requiring their attention. Refer to [To Do Entries May Be Routed Out Of The System](#) for the details.

Monitoring and Escalating Approval Requests

The base-package is supplied with an algorithm that your implementation can use to monitor approval requests that have been waiting too long for approval. This algorithm can complete the current To Do entry and create a new one for a different role when the timeout threshold defined on the algorithm's parameters is exceeded. If you've configured the system to send email for approval, this algorithm can also send x reminder emails (where x is defined on the algorithm's parameters) before the approval request is escalated to the new To Do role. Refer to C1-APR-TMOUT for more information about this algorithm. If you plan to enable this functionality, plug-in your configured algorithm on the Approval In Progress state on the C1-AdjustmentApprovalRequest business object.

Rejecting Deletes The Adjustment

When an adjustment is being approved, anyone with access to the adjustment can reject it by using the [Adjustment - Approval](#) portal. Users other than the current approver are allowed to reject an adjustment to allow an "in process" an adjustment to be withdrawn.

When an adjustment is rejected, the following takes place:

- The user is prompted for a reject reason.
- The approval request's audit log is updated with the reject reason and the approval request is moved to the Rejected state.
- The adjustment is deleted.

Designing Your Approval Profiles

The following points describe a recommended design process:

- Create logical groups of adjustment types where each group has the same monetary hierarchy and approvers. An approval profile will be required for each of these groups.
- The number of To Do types (if any) that need to be created is dependent on how the adjustment approval To Do entries should be organized on To Do lists. For example, if all approval request To Do entries can appear in the same To Do list, you can use the base-package adjustment approval To Do type. However, if your organization prefers each approval profile's To Do entries to appear in a distinct To Do list, a separate To Do type will be needed for each list. Note that the base-package is supplied with a To Do type called C1-ADAPP that should be used as the basis for any new approval request To Do type.
- The number of To Do roles is dependent on who approves your adjustments. At a minimum, you will require a separate To Do role for each level in your approval profiles. Remember that every user in a To Do role will see its entries (and receive email if you've configured the system to do such).
- Refer to [Monitoring and Escalating Approval Requests](#) for how to configure the system to escalate approval requests that have been waiting too long.

- If your implementation requires email notification when an adjustment requires approval, the following setup is required:
 - Set up an outbound message type, external system, and message sender. Refer to [To Do Entries May Be Routed Out Of The System](#) for the details.
 - Every To Do type referenced on your approval profiles should be configured as follows:
- Define the F1-TDEER batch process as the To Do type's routing process
- Set up an algorithm that references the C1-ADJAREQEM algorithm type and plug it in the External Routing system event.

Implementing Other Approval Paradigms

The above sections describe how the base-package adjustment approval process works. Because adjustment approval has been implemented using the C1-AdjustmentApprovalProfile and the C1-AdjustmentApprovalRequest business objects, your implementation can add additional business rules and change the approval user interface as required. Alternatively, if your implementation has a radically different approval process, you can create a different business objects with their own business rules. To learn how to do this, please enroll in the Configuration Tools training class.

Setting Up Approval Profiles

Approval profiles contain the rules that control how adjustments are approved. To set up an approval profile, open **Admin > Financial > Approval Profile > Add**.

Fastpath:

Refer to [The Big Picture Of Adjustment Approval](#) for a detailed description of how approval profiles govern the adjustment approval process.

The topics in this section describe the base-package zones that appear on the Approval Profile portal.

Approval Profile List

The Approval Profile [List zone](#) lists every approval profile. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent approval profile.
- Click the Add link in the zone's title bar to add a new approval profile.

Approval Profile

The Approval Profile zone contains display-only information about an approval profile. This zone appears when an approval profile has been broadcast from the Approval Profile List zone or if this portal is opened via a drill down from another page. The following functions are available:

- Click the **Edit** button to start a business process that updates the approval profile.
- Click the **Delete** button to start a business process that deletes the approval profile.
- Click the **Duplicate** button to start a business process that duplicates the approval profile.

Please see the zone's help text for information about this zone's fields.

Approval Profile's Adjustment Types

The Approval Profile's Adjustment Types zone lists every [adjustment type](#) that is governed by this approval profile. This zone appears when there is at least one adjustment type governed by the approval profile displayed in the Approval Profile zone:

To add an adjustment type to this list:

- Navigate to the Adjustment Type page and display the desired adjustment type.
- Specify the governing approval profile and update the adjustment type.

To remove an adjustment type from this list:

- Navigate to the Adjustment Type page and display the desired adjustment type.
- Change or remove its approval profile and update the adjustment type.

Designing and Defining Budget Plans

If you allow your customers to pay a budget amount each month (as opposed to their actual bill amount), you must set up one or more budget plans. If your company does not offer budget billing options, you can skip this section.

The topics in this section describe how to design and set up budget plans.

The Financial Impact Of Budget Plans

The only difference between a customer who participates in budget billing and one who doesn't is that budget billing customer have bill segments where payoff amount differs from current amount. Why? Because the payoff amount is the actual amount of the bill. The current amount is the amount the customer is expected to pay (i.e., their budget amount).

Let's run through an example of a customer on a budget to illustrate a service agreement where these two balances are not the same. The values in the payoff balance and current balance columns reflect the amount due after the financial transaction has been applied:

| Date | Financial Transaction | Payoff Balance | Current Balance |
|-----------|---------------------------|----------------|-----------------|
| 1-Jan-19 | Bill: \$125, Budget \$150 | 125 | 150 |
| 15-Jan-19 | Payment: \$150 | -25 | 0 |
| 2-Feb-19 | Bill: \$175, Budget \$150 | 150 | 150 |
| 14-Feb-19 | Payment: \$150 | 0 | 0 |
| 3-Mar-19 | Bill: \$200, Budget \$150 | 200 | 150 |
| 15-Mar-19 | Payment: \$150 | 50 | 0 |

Fastpath:

For more information about current and payoff amounts, refer to [Current Amount versus Payoff Amount](#).

What Do Budget Plans Do?

A budget plan contains the business rules that govern:

- How the recommended budget amount is calculated.
- When and how a customer on an ongoing budget plan will have their budget amount periodically tried up.
- The conditions under which the system will highlight an existing budget amount as being anomalous with the customer's current use patterns.

You may have different budget plans for different customer segments. For example, customers with large bills may have their budget amount recalculated every month, whereas small customers may have their budget amount only recalculated annually. You define which budget plans govern a customer's bills via a **budget plan on the customers'**

accounts. An account's initial budget plan is defaulted from its customer class. You may override an account's budget plan at will.

Designing Your Budget Plans

Fastpath:

Refer to [Budget Billing](#) for background information about budget billing.

A budget plan contains the business rules that govern:

- How the recommended budget amount is calculated.
- When and how a customer on an ongoing budget plan will have their budget amount periodically true up.
- The conditions under which the system will highlight an existing budget amount as being anomalous with the customer's current use patterns.

You will need multiple budget plans if any of the above rules / conditions differ for different types of customers. For example, if residential customers use a different recommended budget algorithm as compared to commercial customers, you'd need one budget plan for residential and another for commercial.

We'll design budget plans to satisfy the needs of a theoretical company to help you understand how to design your budget plans. The following points describe the budget requirements of our theoretical company:

- The recommended budget amount is the last year's real bill amounts plus any existing debit/credit balance divided by 12. This is true regardless of the type of customer.
- The frequency of budget true up is monthly for commercial customers and annually for residential customers.
- The system should highlight when a residential customer's budget is more than 30% out of whack with what their budget amount would be if it was recalculated.
- The system should highlight when a commercial customer's budget is more than 20% out of whack with what their budget amount would be if it was recalculated.

You'd need the following budget plans to satisfy the above requirement:

| Budget plan | Recommended Amount Algorithm | True Up Algorithm | Monitor Algorithm |
|-------------|------------------------------|-------------------------|----------------------------------|
| Residential | Average Bill | True up every 12 months | Highlight when more than 30% out |
| Commercial | Average Bill | True up every month | Highlight when more than 20% out |

Refer to the Page Controls under [Setting Up Budget Plans](#) for a description of the various algorithms defined in respect of a budget plan.

Setting Up Budget Plans

In the previous section, Designing Your Budget Plans, we presented a case study that illustrated a mythical organization's budget plans. In this section, we explain how to maintain your Budget Plans.

Budget Plan - Main

To set up budget plans, select **Admin > Credit & Collection > Budget Plan > Add.**

Description of Page

Enter an easily recognizable **Budget Plan** and **Description.**

If your implementation requires restricting budget plans to accounts by CIS Division, specify a **CIS Division** on the budget plan.

The remaining information on this page is used by the various budget-oriented processes.

Refer to [Budget Plan - Calculation Algorithm](#) for information about the **Calculation Algorithm**.

Refer to [Budget Plan - Monitor Algorithm](#) for information about the **Monitor Algorithm**.

Refer to [Budget Plan - True Up Algorithm](#) for information about the **True Up Algorithm** and **Months for True Up**.

Budget Plan - Calculation Algorithm

On [Budget Plan - Main](#) you must define the **Calculation Algorithm** used by the system when it calculates a customer's recommended budget amount.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that calculates recommended budget amounts.

Budget Plan - Monitor Algorithm

On [Budget Plan - Main](#) you must define the **Monitor Algorithm** used by the [Budget Monitor](#) background process when it determines if a customer's budget plan is out-of-sync with their consumption patterns.

Note:

What happens? If the algorithm determines that a customer's budget plan is out-of-sync with its current recommended amount, an entry is added to the [Budget Review](#) page.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that highlights if a customer's current budget amount is out-of-sync with their consumption patterns.

Budget Plan - True Up Algorithm

On [Budget Plan - Main](#) you must define the **True Up Algorithm** used by the [Budget True Up](#) background process when it periodically true up a customer's budget.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that true up budget amounts.

The system will automatically true up a customer's budget amount every X months (X is defined in **Months for True Up**).

Tender Management

When a payment is received, a tender is created to record what was remitted (e.g., cash, check, credit card). The topics in this section describe control tables that must be set up in order to remit tenders.

Fastpath:

We strongly recommend [Tender Management and Workstation Cashiering](#) before setting up the control tables described in this section.

Setting Up Tender Types

Tender types are used to indicate the method in which the tender was made. A unique **Tender Type** must exist for every type of tender that can be remitted. For example, if you allow cash, checks, direct debits from a checking account, and direct debits from a credit card to be tendered, you'd need the following tender types:

| Tender Type | Description | Like Cash | Generate Auto Pay | Require External Source ID | Require Expiration Date | External Type |
|-------------|----------------------------|-----------|-------------------|----------------------------|-------------------------|------------------------|
| CASH | Cash | Yes | No | N/A | N/A | N/A |
| CHEC | Check | No | No | N/A | N/A | N/A |
| OVUN | Cash drawer - over/under | No | No | N/A | N/A | N/A |
| DDCH | Direct debit - checking | No | Yes | Yes | No | Checking withdrawal |
| CRED | Direct debit - credit card | No | Yes | No | Yes | Credit card withdrawal |

Go to **Admin > Financial > Tender Type** to define your tender types.

Description of Page

Enter a unique **Tender Type** and **Description** for the tender type.

Turn on the **Like Cash** switch if this tender type is cash or the equivalent of cash. This indicator controls if the system generates a warning if a cash-only account remits a tender other than cash. It is also used to generate a warning for online cashiers to turn in their tenders when the cash-like amount exceeds the maximum amount balance defined for the [tender source](#).

Turn on **Generate Auto Pay** if this type of tender causes an automatic payment request to be routed to a financial institution. For example, this switch will be on if this tender type is used for direct debits from a customer's checking account (because every tender of this type will have an automatic payment request created when the tender is created).

The following fields are only used for tender types associated with automatic payments:

External Type This field is used by the background process that creates the information that is interfaced to the automatic payment source. Specifically, it controls the record type associated with the different types of automatic payments that are routed to the automated clearinghouse (ACH).

Note:

The values for this field are customizable using the Lookup table. This field name is EXT_TYPE_FLG.

Require Ext. Src. ID This switch indicates if an Auto-Pay Source that references this type of tender must contain an External Source ID. The External Source ID is the unique identifier of the financial institution to which the automatic payment will be routed.

This switch is typically turned on for tender types associated with checking / saving direct debits. It is turned off for tender types associated with credit card debits (you don't need an external source for a credit card debit, you just need the credit card number).

Expiration Date Required Turn this switch on if an Auto-Pay Option that references an auto-pay source that references this type of tender must also contain an expiration date (e.g., automatic debit / credit cards).

Turn this switch off for tender types associated with checking / saving direct debits.

Tender Authorization Indicates that tenders of a particular type require authorization prior to being created.

Business Object If Tender Authorization has a value of Required, a Business Object must be specified for the tender type. The primary function of this Business Object is to manage the authorization of payment tenders.

Fastpath:

For more information on authorizing credit card payments, refer to the Tender Type - Credit Card with Authorization business object.

Turn on **Allow Cash Back** if the system should automatically calculate a cash back amount when a tender is remitted for this tender type and the amount tender exceeds the amount being paid.

Setting Up Tender Sources

A unique **Tender Source** must exist for every potential source of funds. For example,

- Every cashiering station will have a unique tender source.

Note:

If your organization accepts alternate currency payments online, then a tender source must exist for each currency code accepted at the cashiering station.

- Every lock box will have a unique tender source.
- Your remittance processor will have a unique tender source.
- If you allow customers to pay bills automatically (e.g., via EFT), you'll need a tender source for each institution to which you route automatic payment requests. For example, if you route automatic payment requests to the automated clearinghouse (ACH), you'll need a tender source for the ACH.

For example, if you have 3 lock boxes, 2 cash drawers at an area office A, 2 cash drawers at area office B, and a single remittance processor, you'd need the following tender sources:

| Tender Source | Type | External Source ID (Lockbox ID) | Default Starting Balance | Currency Code | Suspense Service Agreement |
|---------------|------------|------------------------------------|--------------------------|---------------|----------------------------|
| CASH-A01 | Cashiering | N/A | 150.00 | USD | N/A |
| CASH-A02 | Cashiering | N/A | 150.00 | USD | N/A |
| CASH-B01 | Cashiering | N/A | 150.00 | USD | N/A |
| CASH-B02 | Cashiering | N/A | 150.00 | USD | N/A |
| LB-INDUS | Lockbox | 112910-A | N/A | USD | 9291019281 |
| LB-COMM | Lockbox | 938219-C | N/A | USD | 4739837372 |
| LB-RESID | Lockbox | 372829-B | N/A | USD | 1912910192 |
| REMIT | Lockbox | N/A | N/A | USD | 1920038437 |
| ACH | Auto Pay | N/A | N/A | USD | N/A |

To set up a tender source, select **Admin > Financial > Tender Source > Add**.

Description of Page

Enter an easily recognizable **Tender Source** and **Description** for the tender source.

Define the **Tender Source Type**. Valid values are: Ad Hoc, Auto Pay, Online Cashiering and Lockbox. The system uses this information to prevent tender controls from different sources from being included under the same deposit control. In other words, you can't mix ad hoc, automatic payment, cashiering and lockbox tenders under the same deposit control.

Fastpath:

For more information, refer to [Maintaining Deposit Controls](#).

If the source is an external system (e.g., a lockbox or an automatic payment destination), use **External Source ID** to define the unique identifier of the source. The background process that interfaces tenders from this source uses this information to create the appropriate tender control when it interfaces payments from external sources.

If this source is a cash drawer, define the **Default Starting Balance**. This balance is defaulted onto new tender controls and may be overridden.

Note:

The tender type of the **Start Balance** is defined on the installation record.

If this source is a cash drawer, define the **Max Amount Balance**. When the amount of [cash-like](#) tenders in a cash drawer exceeds this balance, a warning is issued to remind the cashier to turn in some of the funds to a tender control.

Define the **Currency Code** of tenders linked to this source. All tenders in a source must be of the same currency.

If this tender source is associated with payments that are [interfaced from an external source](#) (e.g., a lockbox or a remittance processor), use Suspense **Service Agreement** to define the service agreement whose account will hold uploaded payments with an invalid account. Refer to [Payment Upload Error Segmentation](#) for more information about suspense service agreements. Also note, because the payment upload process simply books payments that reference invalid accounts to the account associated with this service agreement, this account should belong to a customer class with the appropriate payment distribution algorithms. This may entail creating a new customer class that will only be used on these "suspense accounts". This customer class would need the following algorithms:

- We'd recommend using a simple payment distribution algorithm like PYDIST-PPRTY (distribute payment based on SA type's payment priority and the age of the debt).
- We'd recommend using an overpayment distribution algorithm like OVRPY-PPRTY (distribute overpayment to highest priority SA type).

Define the **Bank** and **Bank Account** into which the tender source's moneys will be deposited. The bank account defines the distribution code used to build the GL details for the payment. Refer to The [Source of GL Accounts on Financial Transactions](#) for more information. Note that the bank code and bank account can later be overwritten when entering Tender Deposits on [Deposit Control](#).

Printer IP Address and **Printer Port** are for implementation use, if needed. The base samples for receipt printing do not use these settings, as they are designed for local printers. Refer to the Receipt Printing section of the Optional Products Installation Guide for more details.

If this tender source is associated with payments that are [interfaced from an external source](#), for example tender sources associated with Auto Pay and Lockbox **Tender Source Types**, the information is also used as follows:

- The [payment upload process](#) uses this information to populate the bank and bank account when it creates deposit control records for the tender controls it creates during the interface. Refer to [Managing Payments Interfaced From External Sources](#) for more information.
- The [automatic payment interface](#) uses this information to populate the bank and bank account when it creates deposit control records for the tender controls it creates during the interface.

Note:

If your organization accepts alternate currency payments online, then a tender source must exist for each currency code accepted at the cashiering station. When a user adds a tender control the system attempts to default a tender source based on the currency of the deposit control and the tender source(s) define on the user's record.

**Fastpath:**

Refer to [Alternate Currency Payments](#) for more information.

Automatic Payment Options

If your customers can pay their bills automatically (via direct debit or credit card debits), you'll need to set up the various control tables described in this section.

**Important:**

Besides the tables described in this section, additional values must also be added to control tables defined under [Tender Management](#). Specifically, refer to [Setting Up Tender Types](#) and [Setting Up Tender Sources](#).

**Fastpath:**

Refer to [Automatic Payments](#) for more information about how automatic payments are handled in the system.

Setting Up Auto Pay Route Types

This portal is used to display and maintain an Auto Pay Route Type.

Auto Pay Route Types are used to control when and how automatic payment requests are routed to a financial institution, and when the general ledger is impacted.

You can access the portal from **Admin > Financial > Auto Pay Route Type**.

The information captured on the auto pay route type depends on the business objects supported by your implementation. Refer to the embedded help for more information.

Setting Up Auto Pay Source Codes

A unique **Auto Pay Source** must exist for every bank / credit card company / bill payment service that your customer's use as the source of the funds when they sign up for automatic payment. For example,

- Every bank will have a unique auto pay source.
- Every credit card company will have a unique auto pay source.

To set up an auto pay source, select **Admin > Financial > Auto Pay Source Type > Add**.

Description of Page

Enter an easily recognizable **Auto Pay Source Code** and **Description** for the auto pay source.

The **Source Name** is the name of the financial institution.

When the system creates an automatic payment request, it also creates an associated payment tender. This tender (like all tenders) must have a tender type. This field defines the **Tender Type** associated with this auto pay source's tenders. The **Prenote Tender Type** is also specified on checking and savings tender types. It determines the transaction code to stamp on an auto pay extract records that are sent out for the purpose of debit prenotification. Refer to [Setting Up Tender Types](#) for more information.

The **External Source ID** is the unique identifier of the financial institution to which the automatic payment will be routed (e.g., the bank routing ID of the bank). This field is typically blank on automatic payments routed to credit card companies because the credit card company doesn't have an external source ID (whereas direct debits from banks must have a bank routing number). Whether this field is required is controlled by the **Tender Type**.

The **Auto Pay Route Type** controls when and how automatic payment requests get routed to a financial institution. It also controls when the general ledger is impacted by the automatic payments financial transaction. Refer to [Setting Up Auto Pay Route Types](#) for more information.

The **Work Calendar** defines the financial institution's workdays. This information is used to determine the date on which automatic payment requests will be sent to the financial institution. Refer to [Setting Up External Workday Calendars](#) for more information.

The **Validation Algorithm** defines how the system validates the customer's account ID at the financial institution. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that validates the customer's account ID at the financial institution.

Refer to [Account - Auto Pay](#) for more information.

SEPA Payments

The topics in this section provide background information about the Single Euro Payments Area (SEPA) payment functionality.

Note: This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization is participating in SEPA payment transactions such as direct debit collection.

What Is SEPA?

SEPA (Single Euro Payments Area) is a European Union (EU) integration initiative that is aimed at streamlining processes that are related to cross-border payments. SEPA consists of the EU member states plus a few additional countries. In SEPA, customers can make electronic Euro payments within and across these countries under the same rights and obligations. SEPA payment services are based on global ISO (International Organization for Standardization) standards.

SEPA Direct Debit

The SEPA Direct Debit (SDD) scheme allows a creditor to collect money from the debtor, with prior approval from the debtor. The direct participants are the following:

- Creditor
- Creditor's bank
- Debtor
- Debtor's bank

The debtor and creditor must each hold an account with a payment service provider located within SEPA. The accounts may be in Euro or in any other SEPA currency. However, the transfer of funds between the debtor's bank and the creditor's bank always takes place in the Euro currency. The indirect participants are the following:

- Clearing and Settlement Mechanisms (CSMs) such as an automated clearinghouse
- Intermediary Banks that offer intermediary services to debtor banks and/or creditor banks

SEPA Direct Debit Mandate

The mandate is the consent and authorization that the debtor gives to the creditor, to allow the creditor to initiate direct debit collections. The creditor is responsible for storing the original mandates, together with any amendments relating to the mandate or information regarding its cancellation or lapse. The contents of this section describe how mandates are issued and canceled.

Issuing a Mandate

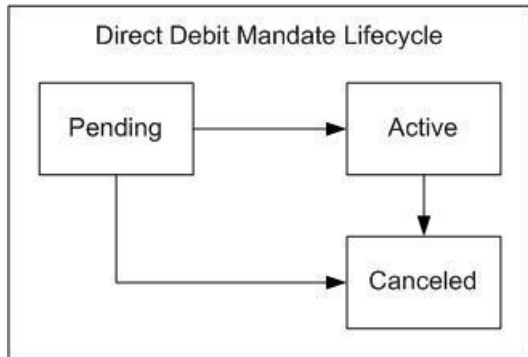

The creditor initiates the issuance of a mandate by sending the mandate form (either paper or electronic) to the debtor with the creditor information filled in. The creditor information includes the creditor's unique identifier as a SEPA creditor. An ISO standard specifies the structure of the creditor identification, which includes country code, a check digit, the creditor's business code and a country-specific identifier for the creditor. The creditor ensures that the mandate form contains the mandatory legal wording and the mandatory set of information, as specified in the standards. The debtor must ensure that the required information is supplied and that the mandate is signed, either in writing or electronically. The mandatory debtor information includes the debtor's international bank account number (IBAN) and bank identifier code (BIC). The creditor assigns a unique reference for the mandate and provides that reference to the debtor before the first initiation of a collection. The debtor can then use both the unique mandate reference and the creditor identification to verify the bank transactions.

Canceling a Mandate

A mandate can be canceled by either the debtor or the creditor, without the involvement of either bank.

The Lifecycle of a Direct Debit Mandate Task

The following diagram shows the possible lifecycle of the Direct Debit Mandate Task business object:

Pending State: The direct debit mandate starts out in a pending state.

Active State: The direct debit mandate is transitioned manually by a user to the active state. Once a mandate is created and activated in the system, the account's auto pay information must be updated to reflect information on the mandate. This process may be automated within the mandate's lifecycle and a sample algorithm exists in the demo database to achieve this. This algorithm is also included in the export bundle in the demo database.

Canceled State: The direct debit mandate is transitioned manually by a user to the canceled state.

Configuring the System for SEPA Direct Debits

The following sections describe the setup required if your organization intends to process SEPA direct debit transactions.

Define Auto-Pay Route Type

Configure an auto-pay route type for routing direct debit requests to a financial institution. This auto-pay route type must reference the SEPA Direct Debit Payment Extract (C1-SDDCE) batch process.

Refer to [Setting Up Auto-Pay Route Types](#) for more information.

Define Auto-Pay Source Type

Ensure that your auto-pay source codes reference the above auto-pay route type. You must also configure a validation algorithm on the auto-pay source type to ensure the International Bank Account Number (IBAN) defined on the Auto-pay Source of the Account has the correct format.

Refer to [Setting Up Auto Pay Source Codes](#) on page 630 for more information.

Define a Direct Debit Task Type

Your implementation must configure a **Direct Debit Task Type**. This service task type captures general information that the SEPA extract process needs to create the output file. The base product provides a business object for direct debit task type, **C1-DirectDebitMandateTaskType**.

Note that the direct debit task type is maintained on the Service Task Type portal.

Define SEPA Country Codes

The list of countries and territories that are part of the Single Euro Payment Area (SEPA) must be defined on extendable lookup **C1-SEPA Country Code Lookup**. These country codes are used by the system to validate the creditor identification entered on a direct debit task type.

Note that an export bundle exists in the demo database that includes a sample list of SEPA country codes. This list must be verified by your implementation for accuracy.

Define Mandate Cancel Reasons

A cancel reason is required when canceling a direct debit mandate. Ensure that these status reasons have been configured for the direct debit task business object, **C1-DirectDebitMandateTask**.

Define Navigation Options

The base product includes navigation options for easy access to query and maintain an account's direct debit mandate. To access these portals, add a new menu item to the account context menu (**CI_CONTEXTACCOUNT**). This menu item should include two menu lines:

- A context menu line for navigation to the direct debit mandate that references a navigation option of **c1DirectDebitMandate**. The system uses the account in context and attempts to find the most recent active mandate for the account. If a mandate exists, navigation is to the service task maintenance portal. If an active mandate does not exist, navigation is to the service task query portal.
- A context menu line for adding a new direct debit mandate that references a navigation option of **c1AddDirectDebitMandate**.

Setting Up Account Auto Pay

The SEPA direct debit extract process retrieves banking details from the account's auto pay record. Once a mandate is created and activated in the system, the account's auto pay information must be updated to reflect information on the mandate. This process may be automated within the mandate's lifecycle and a sample algorithm exists in the demo database to achieve this. This algorithm is also included in the export bundle in demo.

Web Debit Account Validation

Overview

This section describes Web Debit Account Validation and the steps to enable this functionality.

Note: This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization is required to validate bank accounts that are used for the first time in electronic payments initiated over an online channel such as web self-service. This functionality does not cover credit card payment types, which are verified through tender authorization.

Web Debit Account Validation allows your implementation to validate a first-use checking/savings account that is captured through any of the following self-service activity:

- Automatic Payment Setup
- Make One Time Payment
- Manage Payment Options (wallet)

The account validation method is your implementation's choice, based on what regulation prescribes as acceptable account validation options. For instance, the National Automated Clearinghouse Association (NACHA) - that governs the ACH network in the United States - prescribes any of the following options:

- **ACH prenotification.** With this option, a zero-amount checking/savings debit pre-note transaction is sent through the auto pay extract, to verify the bank account information. If a negative response is not received from the bank within a set number of days, the account is considered valid.
- **ACH micro-transaction verification.** With this option, two very small transactions – a debit to deposit the money and a credit to remove the money - are sent to the account. The account holder needs to confirm the amounts on the transactions. The account will only be considered verified if the account holder describes the amounts correctly.
- **Commercially available third party validation service vendors.** Some financial institutions and third parties have access to a large number of accounts and may offer a product that leverages this information. These services can be accessed for verifying that account information is correct and/or verifying the account holder's identity. The responses can be real-time, same-day or next-day.

Web Debit Account Validation is a Plug-in

An algorithm plugged in on Auto Pay Route Type or on CIS Division - Auto Pay Route Type Override Controls (if applicable) is responsible for web debit account validation. Payment methods captured for self-service automatic

payment setup and self-service one time payment specify the Auto Pay Source, which in turn, identifies the Auto Pay Route Type.

The base product provides a Web Debit Account Validation Algorithm for ACH prenotification. The algorithm creates an Auto Pay Clearing Staging record with the account number to verify and a zero amount. Refer to the Web Debit Account ACH Prenotification (C1WDAPRENTF) algorithm for details.

Web Debit Account Validation Applies to Self-Service Tasks that Manage Payment Options

The following self-service task business objects include an Account Validation status, where web debit account validation is performed:

- Automatic Payment Task - WX-AutoPayTask
- One Time Payment Task - WX-OneTimePayTask
- Self-Service Payment Option Task - C1-PaymentOptionsTask

The Account Validation status has an enter algorithm that performs the Web Debit Account Validation Algorithm configured in the Auto Pay Source's Auto Pay Route Type (or in the CIS Division's Override Auto Pay Controls, if applicable) when the service task type has Web Debit Account Validation enabled and the account number does not exist in any of the account's saved auto pay options and in any of the saved self-service payment options of persons on the account. The account auto pay option or self-service payment option is not saved until the bank account is deemed valid. The Account Validation Error status includes algorithms for retry processing and wait timeout processing. If the account is deemed invalid, the service task goes to the Rejected status. Refer to the business object for more details.

Note: When checking for the existence of a bank account number in person self-service payment options, the system relies on the hash value (in HASH_EXT_ACCT_ID). Implementations must ensure that encryption configuration for this table field includes both the encrypted and hash fields and that legacy data has both fields populated. Refer to [Encrypting Sensitive Data](#) on page 1307 and [Encrypting Legacy Data](#) on page 1309 for more details.

Validating Payment Methods Captured On Add One-Time Payment UI

The Add One-Time Payment user interface allows the capture of first-use checking/savings bank accounts. If a bank account has not been used on any prior recurring bill auto pays and prior self-service one time payments, the system will trigger web debit account validation by creating the One-Time Payment Task (C1-OneTimePaymentTask). Since the Add One-Time Payment UI can handle multiple tenders, a single One-Time Payment Task manages all auto pay tenders that require validation.

Note that the Payment Event is kept in an Incomplete state while web debit account validation is still in progress. Lifecycle processing on the service task will either complete or delete the Payment Event, depending on the result of account validation.

Refer to the C1-OneTimePaymentTask business object in the application, for more information on the service task lifecycle processing.

Specific Transaction Codes for Checking/Savings Debit Prenotification

The APAYACH and C1-APACH batch processes stamp specific transaction codes for checking debit prenotification (28) and savings debit prenotification (38) on the Entry Detail record. The transaction code is retrieved from the prenotification Tender Type's External Type.

Configuring the System for Web Debit Account Validation

The following are the steps to enable Web Debit Account Validation functionality:

- Determine the account validation option(s) that your implementation will use.
 - If opting for ACH prenotification, you can use the base-supplied Web Debit Account ACH Prenotification (C1WDAPRENTF) algorithm.

- If opting for ACH micro-transaction verification or third party validation, create a Web Debit Account Validation algorithm for your chosen method.
- Plug in the Web Debit Account Validation on your applicable Auto Pay Route Types and CIS Division - Auto Pay Route Type Override Controls (if applicable).
- On your Automatic Payment Setup and One Time Payment Service Task Types, set the Web Debit Account Validation flag to Yes. To use the wait timeout processing built into the Account Validation Error state, configure the Timeout Processing settings. Refer to the service task's embedded help for more details.
- On the Automatic Payment Setup and One Time Payment service task business objects:
 - If using the base-supplied Web Debit Account ACH Prenotification algorithm (or a CM algorithm that allows for a wait period after which the account is considered valid), monitor logic on the Account Validation status should check if the wait time has elapsed - and if so, transition the service task accordingly. Note that the Check Account Validation Status monitor algorithms provided in the base product simply transition the service tasks to the next state (i.e. Process Auto Pay, Process Payment or Process Request) when the wait time elapses. The base algorithms do not check for a negative response because the form of response is implementation-specific. If your implementation needs to check for a negative response, copy the base algorithms and add that processing. Refer to the Check Account Validation Status for One Time Payment (C1OTPACVAST) and Check Account Validation Status for Auto Pay Setup (C1APAYACVAST) algorithms for details.
 - To use the To Do creation algorithm plugged in on the Account Validation Error status, configure a new algorithm parameter instance to specify the Retry Frequency and Discard Cancel Terminate Reason (if applicable).
 - To use the retry processing on the Account Validation Error status, configure a new algorithm parameter instance to specify the Maximum Retry.
- Configure tender types for checking debit prenotification and savings debit prenotification. Use the applicable External Type value on each - i.e. Checking Debit Prenotification (28) or Savings Debit Prenotification (38), The auto pay extract process uses the Prenote Tender Type's External Type as the transaction code on the Entry Detail record in the extract file.
- Configure the checking and savings Auto Pay Sources with the applicable Prenote Tender Types.
- If your implementation enabled the Add One-Time Payment UI, configure the One-Time Payment Task feature option. Refer to [One Time Payment Options](#) for more details.

One-Time Payment Options

The Add One-Time Payment popup provides the ability to 'quick add' a payment event using existing auto pay methods, new checking/savings auto pay methods, cash and non-cash/non-auto pay methods (like check).

This user interface provides the same capabilities as the [Payment Event - Add Dialog](#), including processing for open-item and non-CIS payor accounts. In addition, it provides the following:

- Ability to specify auto pay tender details within the same popup. No need to navigate to the Payment Event page.
- Ability to select an existing auto pay method from either a currently enrolled Account Auto Pay option or a stored Person Self-Service Payment Option.
- Ability to specify new auto pay methods, with an option to save the payment method for future one-time payments
- Web debit account validation can be enforced for first-use checking and savings accounts. Refer to [Web Debit Account Validation](#) for more details.

Enabling the Add One-Time Payment User Interface

To enable the Add One-Time Payment popup, configure the following options in Financial Transaction Options feature configuration:

- **Enable Add One-Time Payment UI.** Set this to Y, to replace the Payment Event-Add pop-up with the Add One-Time Payment pop-up on all existing launch points of the old pop-up.
- **One-Time Payment UI Navigation.** Specify where the user should be navigated after successful one-time payment creation. This is optional. If not specified, the pop-up simply closes.

- **One-Time Payment Service Task Type.** If your implementation enabled [Web Debit Account Validation](#), add a One-Time Payment service task type using the base-provided C1-OneTimePaymentTaskType and C1-OneTimePaymentTask. Specify your One-Time Payment service task type on this feature option.
- **Override Script for Add One-Time Pmt UI.** If your implementation has additional requirements for the [Add One-Time Payment](#) UI, you can clone the base-owned BPA script (C1OTPayAddNv) and specify your CM script on this feature option. If configured, the system will launch this override script instead of the base-owned script.

Fastpath:

Refer to [Add One-Time Payment](#) for more information.

Third Party Payment Processing Options

If you allow customers to make one time payments and/or pay bills automatically through a third party payment processing system, you will need to set up a number of control tables to enable these functions in the system.

Important: Aside from the tables mentioned in these sections, control tables defined under [Automatic Payment Options](#) on page 630 must also be configured. Additional values must also be added to control tables defined under [Tender Management](#). Specifically, refer to [Setting Up Tender Types](#) and [Setting Up Tender Sources](#).

Fastpath: Refer to [Third Party Payment Processing](#) for the big picture of third party payment processing.

Define Service Task Types

The web services used to process one time payment notifications, automatic payment setup and account verification create a corresponding service task record to perform the needed actions.

The following service task types need to be configured and defined on the Third Party Payment Processing Integration master configuration:

- A **Third Party One Time Payment** service task type is used to create an immediate or scheduled third party one time payment. The base product supplies the following service task type and service task business objects: **C1-ThirdPartyOneTimePyTaskType** and **C1-ThirdPartyOneTimePyTask**. Refer to these business objects for details on schemas and processing logic.
- A **Third Party Account Verification** service task type is used to verify an account, which is typically done prior to capturing and processing a one time payment within the third party payment processing system. The base product supplies the following service task type and service task business objects: **C1-ThirdPartyAcctVerifTaskType** and **C1-ThirdPartyAcctVerifTask**. Refer to these business objects for details on schemas and processing logic.
- A **Third Party Auto Pay Setup** service task type is used to add or update an account's ongoing automatic payment option. The base product supplies the following service task type and service task business objects: **C1-ThirdPartyAutoPayTaskType** and **C1-ThirdPartyAutoPayTask**. Refer to these business objects for details on schemas and processing logic.

Refer to [Defining Service Task Types](#) on page 576 for details on setting up service task types

Define Auto Pay Sources and Auto Pay Route Types

Configure specific auto pay sources for the payment types that your third party payment processing system accepts for one time payment processing and ongoing automatic payment processing. Base-supplied Payment Type values are: Checking Withdrawal, Savings Withdrawal and Credit Card Withdrawal. Your implementation can add payment types. In the Third Party Payment Processing Integration master configuration, each accepted payment type is associated with a Tender Type that is used to create the payment tender associated with a third party one time payment. For checking and savings payment types, the tender type and routing number are used to identify the auto pay source.

Auto pay sources used for ongoing automatic payment processing (i.e. ACH) should be associated with an auto pay route type that specifies C1-TAPEX as the Extract Batch. This ensures that the correct extract batch code is stamped on bill-related auto pay staging records during auto pay activation.

Define Tender Cancel Reason

Configure a Tender Cancel Reason that will indicate that a payment tender was canceled from the third party payment processing system. This cancel reason is configured in the Third Party Payment Processing Integration master configuration and used when a scheduled or processed one time payment is canceled.

Third Party Processing DateTime

The services used in third party payment processing allow for the possibility that the third payment processing system is processing in a different time zone as the utility's. The Third Party Payment Processing Integration master configuration includes the third party's Processing Cutoff Time and Processing Cutoff Time Zone, as well as the local equivalent of the processing cutoff time, based on the Time Zone defined on the Installation record.

The payment datetime that is sent by the third party payment processing system with one time payment notifications and auto pay confirmations is stored as-is as a characteristic on the one time payment's tender. This is done for the purposes of tender controls processing and payments reconciliation (*i.e.*, with reports generated from the third party payment processing system).

As a standard, inbound and outbound communications external systems must use the standard xsd datetime format (yyyy-MM-dd'T'hh:mm:ss[+ or -]hh:mm). The payment datetimes sent with third party one time payment notifications and auto pay confirmations should follow this format.

The Third Party One Time Payment Task also stores the local equivalent of the payment datetime, based on the Time Zone defined on the Installation record. This local datetime is used anywhere third party one time payments (and their payment dates) are displayed in the system (*e.g.*, in the [Scheduled Payments Log](#) in Control Central - Account Information).

Third Party Payment Processing Master Configuration

The integration with a third party payment processing system requires the setup of master configuration data that controls the processing of one time payments and ongoing automatic payments.

To set up the third party payment processing master configuration, navigate using **Admin > General > Master Configuration**. You are brought to an all-in-one portal with options to add/edit the Third Party Payment Processing Integration master configuration record.

Refer to the master configuration's embedded help for more details on how each section in this record is configured.

Payment Advices

The topics in this section provide background information about payment advice functionality.

Note:

This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization issues payment advices to the customer instead of initiating electronic funds transfer directly to the customer's bank.

What Is A Payment Advice?

Payment advice is a money order that is established at the initiative of the utility. When a bill is completed, the utility sends the customer a document that indicates a payment amount and the customer's bank details. If the customer agrees to the information on the payment advice, they sign it and return it to the clearinghouse address that is indicated on the payment advice. The clearinghouse, in turn, sends the dated and signed payment advice to the customer's bank, which completes the payment.

Payment Advice vs. Direct Debit

The existing functionality that creates automatic payments is referred to as direct debit processing. Payment advice processing differs from direct debit processing in the way that automatic payments get initiated. With payment advice

processing, the usual automatic payment records - i.e. payment event, payment, tender and auto pay clearinghouse staging - are not created. Instead, a payment advice is printed and sent to the customer. The customer sends the approved payment advice directly to the clearinghouse.

Note:

The system does not provide sample processes for extracting and printing payment advice information. Your implementation team would have to create these.

Setting Up The System To Enable Payment Advices

You must set up a Financial Transaction Options [Feature Configuration](#) to define parameters that control payment advice functionality.

The following points describe the various **Option Types** that must be defined:

- **Payment Advice Functionality Supported.** This option controls whether the system allows for payment advice processing.
 - Enter Y if the system should allow for both direct debit and payment advice processing.
 - Enter N if the system should only allow for direct debit processing.
- **Default Auto Pay Method.** This option is used for defaulting the auto pay method on new account auto pay records.

Refer to [Account - Auto Pay](#) for more information on auto pay method.

Note:

The system assumes direct debit processing if the above feature options are not defined.

Credit Card Payments

If your organization accepts credit card payments, you can configure the system to authorize customers' credit card charges in real-time, and perform an authorization reversal (also in real-time) when the credit card payment is canceled. When the authorization web service is not available, you can permit users to enter authorization codes manually so that they can continue processing payments.

Configuring the System for Tender Authorization

The following sections describe the setup required if your organization intends to use the base CyberSource integration tender authorization functionality.

Define the Outbound Message Type

An outbound message type is required for the CyberSource authorization outbound message. This outbound message type must reference the base CyberSource - Credit Card Authorization business object.

An outbound message type is required for the CyberSource reversal outbound message. This outbound message type must reference the base CyberSource - Credit Card Reversal business object.

Define the Message Sender

A Message Sender is required to define how to send messages to CyberSource. Use the context of the Message Sender to define the web service interface.

Define the External System and Configure the Messages

Define an external system and configure the valid outbound message types and the method of communication for each (XAI, Batch or Real Time; Real Time is generally the appropriate choice for credit card authorization). You will also need to select the appropriate XSLs to format both the request and response to the outbound message types for CyberSource.

Define a User

Add a user to hold details required for CyberSource communication. Security information (e.g. Merchant Id, Merchant Reference Code, CyberSource User Name and Password) needed to interface with CyberSource is stored as user characteristics.

Set up the Tender Authorization Algorithm

A Tender Type (BO) - Tender Authorization algorithm must be configured. This algorithm performs a tender authorization or a tender authorization reversal through CyberSource.

Define a Business Object

A business object (BO) must be created for the TENDER TYPE maintenance object. This BO must reference the tender authorization algorithm created.

Define Tender Types

Update the appropriate tender type(s) to denote that authorization is required. The new business object must be specified on the tender type(s).

Tender Authorization - Feature Configuration

If your implementation has a need to prevent users from overriding the automatic tender authorization, then you must set up the Allow Manual Tender Authorization Override option type on the Financial Transaction Options [Feature Configuration](#). The Allow Manual Tender Authorization Override option must have a value of N in order to suppress the Authorization Override checkbox.

Fastpath:

For more information on credit card payment authorization refer to the Tender Type - Credit Card with Authorization business object.

Non CIS Payments

Payment Templates can be configured for common types of non CIS payment allocations. These templates are used to default the payment distribution and allow non CIS payments to be directly allocated to specific distribution codes.

Setting Up Payment Templates

Payment templates contain the rules that control how non CIS payments are created. You can use a payment template to default the payment distribution for common types of non CIS payments. To set up a payment template, open **Admin > Financial > Payment Template > Add**. The topics in this section describe the base-package zones that appear on the Payment Template portal.

Payment Template List

The Payment Template [List zone](#) lists every payment template. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent payment template.
- Click the Add link in the zone's title bar to add a new payment template.

Payment Template

The Payment Template zone contains display-only information about a payment template. This zone appears when a payment template has been broadcast from the Payment Template List zone or if this portal is opened via a drill down from another page. The following functions are available:

- Click the **Edit** button to start a business process that updates the payment template.
- Click the **Delete** button to start a business process that deletes the payment template.
- Click the **Duplicate** button to start a business process that duplicates the payment template.
- Click the **Activate** or **Deactivate** button to start a business process that updates the status of the payment template.

Please see the zone's help text for information about this zone's fields.

Alternate Currency Payments

The topics in this section provide background information about alternate currency payments.

Note:

This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization accepts payments tendered in a currency other than the customer's currency. If your organization does not accept alternate currency payments, you need only indicate such on the [Installation Record](#); no other setup is required.

What Is An Alternate Currency Payment?

The currency code on the customer's account defines the currency in which the account's financial transactions are expressed. If the customer remits a payment in a different currency, this is referred to as an alternate currency payment. The system enables conversion of the tendered amount to the account's currency and captures the alternate currency and amount, as well as the exchange rate used in the conversion on the payment tender. The payment tender is linked to a tender control that references the alternate currency.

Configuring the System for Alternate Currency Payments

Allowing Alternate Currency Payments

You must set the **Alternate Currency** flag on the [Installation Record](#) to Allowed if your organization accepts alternate currency payments. This option controls whether the **Currency Converter** button is displayed when a payment is processed on the payment portal.

Payment Event Business Object

A business object (BO) must be created for the PAY EVENT maintenance object. You must specify this BO as the option value for the CIS Payment Event Add BO option type on the Financial Transaction Options [Feature Configuration](#). This BO must have the Currency Conversion Script BO option defined. This BPA script is invoked when the user clicks on the **Currency Converter** button during CIS payment processing on the payment portal.

Note:

Currency conversion logic is customizable. The base product includes a script for currency conversion called C1-ConvCurr that's plugged in on the C1-CISPaymentEvent business object. This script converts an alternate currency amount to the account's currency using a bill factor value. The bill factor to use is

derived by concatenating the alternate currency code and the account's currency code. For example, if converting US Dollars (USD) to Barbados Dollars (BBD) the bill factor code to use would be USDBBD. Your implementation can change this logic by developing a new script and plugging it into the payment event business object.

Define the User's Tender Sources

Define the tender source(s) for the location (e.g., the specific cash drawer) in which a user's payment tenders are stored during the day. A tender source should be specified for each currency that payments are accepted in. The tender source(s) on the user record are used by the system when a user adds a new tender control. The system attempts to default a tender source on a new tender control based on the deposit control's currency and the tender source(s) defined on the user's record.

Payment Event Distribution

The base-package, by default, creates a single payment for a payment event. If your business requires potentially many payments to be created when payment events are added, you'll need to set up the various control tables described in this section.

Fastpath:

Refer to [Distributing A Payment Event](#) for more information about how payment event distribution is handled in the system.

Making Payments Using Distribution Rules

As part of this method, one or more distribution details are provided at payment time along with the usual payment and tender information. Each distribution detail record references a distribution rule and a corresponding value. The distribution rule encapsulates the business rules that govern the distribution of the payment amount into payments using the specified value.

The type of value being captured on the distribution detail and the logic that uses it to create payments are defined on the [distribution rule](#).

Rule Value

The primary use of the rule value is to identify the business entity whose balance is to be relieved by creating payment(s). In most cases where the payor account is the same as the payee account it may also be used to identify the tender account associated with the payment(s).

Determine Tender Account

The very first step in processing a distribution detail is to identify the tender account (i.e. the payor) associated with the payment. To do that the system calls the Determine Tender Account [algorithm](#) defined on the distribution rule providing it with the rule value and other tender information.

Creating Payment(s)

The business logic that distributes a payment amount into one or more payments(s) targeted towards the entity identified by a rule value is held in designated Create Payment [algorithms](#) defined on the distribution rule.

Rule Value Can Capture Additional Information

A rule value can also be used to capture additional information provided at payment time, like address information, comments, etc. Obviously payment distribution details with this type of rule value should have a zero payment amount, as they are not real payments. These distribution details end up being linked to a payment event, but unlike other distribution details they do not contribute any payments. You can think of these details as payment event characteristics.

You don't have to set up a Create Payment algorithm for distribution rules intended solely to capture additional payment information.

Setting Up The System To Use Distribution Rules

Setting Up Distribution Rules

Define a Distribution Rule for each payment event distribution method practiced by your business.

Distribution Rule - Main

To set up a distribution rule, navigate to **Admin > Financial > Distribution Rule > Add**.

Description of Page

Enter a unique **Distribution Rule** and **Description** for the distribution rule.

Provide a short and unique **Distribution Rule Label** to be used as rule's name throughout the system.

Characteristic Type defines the type of entity whose balance is relieved by the payment(s) this rule creates. For example, if this rule targets payments(s) towards a specific service agreement, you'd reference a characteristic that its value identifies a service agreement. We use the term "rule value" for the characteristic value.

Distribution Rule - Algorithms

Navigate to **Admin > Financial > Distribution Rule > Search** and navigate to the **Algorithms** page to set up the algorithms appropriate for your distribution rule.

Description of Page

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

| System Event | Optional / Required | Description |
|----------------|---------------------|--|
| Create Payment | Optional | This algorithm is executed to distribute a payment distribution detail payment amount into one or more payments. |

| | | |
|--------------------------|----------|---|
| Determine Tender Account | Optional | <p>This algorithm is executed to determine the tender account associated with the payment distribution detail.</p> <p>Only one such algorithm may be specified.</p> |
|--------------------------|----------|---|

Feature Configuration

You must set up a Financial Transaction Options [Feature Configuration](#) to define parameters that control various payment event distribution options.

The following points describe the various **Option Types** that must be defined:

- **Always Enable Distribution Rule.** This option controls whether the system should only use the distribution rule method to add payment events or rather allow both the default method and the distribution rule method to coexist.
 - Enter Y if the system should always use distribution rules. With this setting, navigation to the Payment Event page in add mode opens up the [Payment Event Quick Add](#) page (defaulting it to the single payment event dialog). This dialog is designed to create a payment event using distribution rules
 - Enter N if the system should allow both methods. With this setting, navigation to the Payment Event page in add mode opens up the standard [Payment Event - Add Dialog](#) that uses the default method to create a payment event. If you want to use the distribution rule method, navigate to the Payment Event Quick Add page from the menu.
- **Default Distribution Rule.** This option states your default distribution rule that appears throughout the system.

Cancel Reasons

As described in [The Financial Big Picture](#), the various types of financial transactions can be canceled if their financial impact needs to be reversed from the system. Whenever a financial transaction is canceled, a cancel reason must be specified. This section describes the control tables that contain the cancel reason codes.

Setting Up Bill (Segment) Cancellation Reasons

Open **Admin > Billing > Bill Cancel Reason** to define your bill segment cancellation reason codes.

Description of Page

Enter an easily recognizable **Bill Cancel Reason** and **Description** for the bill cancellation reason.

Only use **System Default** on those reason codes that are placed on bill segments that are automatically canceled by the system. Valid values are: Turn off auto-cancel, Bad estimated read auto-cancel, MDM Corrected Read, and Mass Cancel. The reason code identified as Turn off auto-cancel is placed on bill segments that are automatically canceled when the final bill segment ends before the prior bill (and therefore we have to cancel the prior bill). The reason code identified as Bad estimated read auto-cancel is placed on bill segments that are automatically canceled by the system when it detects that it used an estimated read whose consumption is greater than the next actual read (and therefore we have to cancel the estimated bill segment). The reason code identified as Mass Cancel is placed on bill segments that are canceled as a result of the execution of the Mass Cancellation background process. The reason code identified as MDM Corrected Read is placed on bill segments that are automatically canceled by the system when processing a corrected read notification. Corrected read notifications are received from MDM when reads that were used in bill determinant calculation requests (usage requests) are replaced or modified. This notification may result in the rebill of frozen bill segments. Refer to [Usage Requests](#) for more information.

Note:

Required values. You must have one reason code defined for each of the System Default values.

Setting Up Payment Cancellation Reasons

Open **Admin > Financial > Pay Cancel Reason** to define your payment cancellation reason codes.

Description of Page

Enter an easily recognizable **Cancel Reason** and **Description** for the payment cancellation reason.

Turn on the **NSF Charge** switch if the system should invoke the non-sufficient funds (NSF) algorithm when a tender is cancelled using this reason code. Refer to [NSF Cancellations](#) for more information.

The next several fields are used to change an account's credit rating or cash-only points if a tender is canceled using the respective reason code.

- Use **Affect Cash-Only Score By** to define how tenders canceled using this reason will affect the account's cash-only score. This should be a positive number. When a customer's cash-only points exceed the cash-only threshold amount defined on the installation record or the account's CIS Division, the account is flagged as cash only during payment processing and on Control Central.
- Use **Affect Credit Rating By** to define how tenders canceled using this reason will affect the account's credit rating. This should be a negative number. A customer's credit rating is equal to the start credit rating amount defined on the installation record or the account's CIS Division plus the sum of credit rating demerits that are currently in effect.
- Use **Months Affecting Credit Rating** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

Fastpath:

For more information, refer to [Account - Credit Rating](#).

Note:

The payor gets the credit rating / cash only hit. When you cancel a tender you must specify a cancellation reason. If the cancellation reason indicates a credit rating / cash only demerit should be generated, the system levies the credit rating transaction on the PAYOR's account.

The **System Default** is specified on those cancellation reasons that are placed on payment segments that are automatically cancelled by the system. Valid values are: Re-opened Bill. The Re-opened Bill value is used as follows:

- Payments are automatically created for accounts who pay their bills automatically when their bills are completed.
- If such a bill is reopened before the automatic payment is interfaced to the paying authority, the system automatically cancels the payment. The Re-opened Bill cancellation reason is placed on such payments.

Setting Up Adjustment Cancellation Reasons

Open **Admin > Financial > Adjustment Cancel Reason** to define your adjustment cancellation reason codes.

Description of Page

Enter an easily recognizable **Cancel Reason** and **Description** for each adjustment cancellation reason.

Miscellaneous Financial Controls

This section describes miscellaneous control tables.

A/P Check Request

Adjustments whose adjustment type is marked with an A/P check request code are interfaced to your A/P system. Your A/P system then cuts the checks.

**Fastpath:**

Refer to [Controls The Interface To A/P](#) for more information about the accounts payable interface.

You must set up at least one A/P check request code if you want A/P to cut checks.

To set up A/P check request types, open **Admin > Financial > A/P Request Type**.

Description of Page

Enter an easily recognizable **A/P Request Type** for the accounts payable request type.

Use **Due Days** to define when the check is cut. The cut date is equal to the adjustment date plus due days.

Select a **Payment Method**. Choose from these options:

System Check System check

Billable Charge Line Type**Note:**

Background information. Before using this page, you should be comfortable with the topics described under [Setting Up Billable Charge Templates](#) and [Uploading Billable Charges](#).

Billable charge line types will simplify the effort required to interface billable charges from an external system. Each line type contains values that will be defaulted onto the line details associated with the uploaded billable charges. Obviously, this defaulting is possible only if you specify a billable charge line type on the billable charge upload staging lines.

To set up billable charge line types, select **Admin > Billing > Billable Charge Line Type > Add**.

Description of Page

Enter an easily recognizable **Billable Charge Line External Type** and **Description**.

Use **Currency Code** to define the currency to be defaulted onto billable charge upload lines that reference this line type.

Use **Show on Bill** to define the value to be defaulted into the Show on Bill indicator on billable charge upload lines that reference this line type.

Use **App in Summary** to define the value to be defaulted into the App in Summary indicator on billable charge upload lines that reference this line type.

Use **Memo Only, No GL** to define the value to be defaulted into the Memo Only, No GL indicator on billable charge upload lines that reference this line type.

Use **Distribution Code** to define the values to be defaulted into the Distribution Code field on billable charge upload lines that reference this line type.

Payables Cash Accounting

In some areas, taxes and other 3rd party liabilities are not truly payable until the customer remits payment. We refer to this as "payables cash accounting". This practice should be contrasted with "payables accrual accounting" in which the liability is realized when the bill is created (as opposed to when it is paid).

**Note:**

Value Add Tax (VAT). VAT is a form of taxation common throughout the European Union. It is a common practice to only book the VAT payable when the customer remits payment. This means that most European implementations will use the functionality described in this section.

If your organization does not practice payable cash accounting, you may skip this section as accrual accounting is the system default. If you practice payables cash accounting, the contents of this section describe how to configure the system appropriately.

Accrual versus Cash Accounting Example

The following is an example of the financial events that transpire when a customer is billed and payment is received using accrual accounting.

| Event | GL Accounting | Tax Payable Balance |
|----------------------|------------------|---------------------|
| Bill segment created | A/R 110 | (10) |
| | Revenue <100> | |
| | Tax Payable <10> | |
| Payment received | Cash 110 | (10) |
| | A/R <110> | |

In the above example, you'll notice that the payable is booked when the bill is created. Let's contrast this with what takes place if the payable is subject to payables cash accounting.

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance |
|----------------------|------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) |
| | Revenue <100> | | |
| | Tax Holding <10> | | |
| Payment received | Cash 110 | (10) | 0 |
| | A/R <110> | | |
| | Tax Holding 10 | | |
| | Tax Payable <10> | | |

Notice that when the bill segment is produced, the liability is not booked, rather, the amount of the liability is placed in a "holding" GL account. When the customer pays, the moneys are transferred from the "holding" GL account to the true tax payable account.

Note:

Cash accounting is only applicable for liabilities. In the above example, you'll notice that only the tax payable account had cash accounting implications. This is because organizations that practice cash accounting only do it for liability accounts; they never do it for assets, revenue or expenses.

If the above seems simple, consider the following complications that must be considered:

- What happens if a partial payment is received?
- What happens if there are multiple taxes subject to cash accounting rules?
- What happens if the A/R is relieved via a deposit seizure (or transference of a credit balance from another SA)?
- What if, after payment, the original bill segment is cancel/rebilled resulting in a different amount of tax (keep in mind that the payable got booked when the payment was received)?
- What happens if the payment is cancelled?
- What if the payment isn't received and we have to write-off debt?

- What happens if the customer overpays?
- What happens if the customer is allowed to prepay their tax (this is a common practice in the United Kingdom) and then the tax rate changes at billing time?

The above points, and more, are discussed below.

Distribution Code Controls Cash Accounting For A GL Account

Note:

If you do not understand the significance of distribution codes, please refer to [Setting Up Distribution Codes](#).

Whether or not cash accounting is used for a specific GL account is defined on HOLDING GL account's distribution code (i.e., the holding GL account references the true payable account).

It is very important that unique payable and holding distribution codes be used for each type of tax subject to cash accounting rules. For example, if you have cash accounting requirements for both value-added tax (VAT) and a climate levy, you would need four distribution codes:

- VAT Payable.
- VAT Holding.
- Climate Levy Payable.
- Climate Levy Holding.

Without unique distribution codes for each payable and holding account, the system cannot keep track of how much of a given tax is being held, awaiting payment.

Bill Segments and Cash Accounting

The contents of this section describe how cash accounting is implemented when bill segments are created.

Bill Segment Financial Transactions Are Not Affected By Cash Accounting

There are NO changes to rate calculation associated with cash accounting. This is because the rate components that calculate tax reference the HOLDING payable distribution codes.

Note:

Prepaid taxes - future functionality. If your organization allows customers to prepay taxes in anticipation of a future tax increase (the customers receive the lower rate if they pay in advance), please speak to your account manager for information about when corresponding functionality will be available.

Payment Segments and Cash Accounting

The contents of this section describe how cash accounting is implemented when payment segments are created.

Payment Segment Financial Transaction Algorithms Transfer Holding Amounts to Payable GL Accounts

Logic exists in the pay segment's FT algorithm that transfers amounts from payable holding distribution codes to their respective payable real distribution codes.

Fastpath:

Refer to [Setting Up Payment Segment Types](#) for how to define the appropriate FT algorithm.

The following table shows what happens to the financial transaction associated with the payment segment for a cash accounting customer.

| | |
|---|------------------|
| Event | GL Accounting |
| Bill segment is created | A/R 110 |
| | Revenue <100> |
| | Tax Holding <10> |
| Payment segment relieves receivables | Cash 110 |
| | A/R <110> |
| Additional GL details created when the payment segment FT algorithm transfers the holding amount to a payable account | Tax Holding 10 |
| | Tax Payable <10> |
| Net effect of the above | Cash 110 |
| | A/R <110> |
| | Tax Holding 10 |
| | Tax Payable <10> |

How Does The System Know What Amounts To Transfer From Holding To Payables?

When a payment segment is created for an account that is subject to cash accounting processing, the system determines if there is a CREDIT balance for any holding distribution code in respect of the service agreement. If so, it generates additional GL details to transfer moneys from the holding distribution code to the payable distribution code in proportion to the amount of receivables relieved by the payment. Therefore, if 100% of receivables are relieved by the payment segment, 100% of the holding amounts will be transferred to payable distribution codes. Refer to [Partial Payments Result In Partial Payables](#) for an example of what happens when a partial payment is created.

Partial Payments Result In Partial Payables

The previous example showed the entire tax holding amount being transferred to the tax payable account. The entire holding amount was transferred because the service agreement was paid in full. If a partial payment is received, only part of the holding amount will be transferred to the payable amount (proportional to the amount of receivables reduced by the payment). An example will help make the point.

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance |
|--------------------------|--------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) |
| | Revenue <100> | | |
| | Tax Holding <10> | | |
| Partial payment received | Cash 27.50 | (2.50) | (7.50) |
| | A/R <27.50> | | |
| | Tax Holding 2.50 | | |
| | Tax Payable <2.50> | | |

The above example assumes the use of the base product payment segment FT creation algorithm PSEG-AC to transfer the holding amount to the tax payable account. If multiple holding accounts are used, you may want to

specify which holding amounts are relieved first. The base product includes an additional payment segment FT creation algorithm C1-FTGL-PSAC that handles booking holding amounts based on a priority.

Partial Payments Using Accounting Priority

To book holding amounts based on a priority, each holding distribution code must be assigned an **Accounting Priority**. When a partial payment is posted, only part of the holding amount will be transferred to the payable amount (proportional to the amount of receivables reduced by the payment). When the holding amount consists of various holding distribution codes with different accounting priorities, the amount to transfer is allocated as follows:

- Holding distribution codes associated with the oldest debt are settled first
- Within the same debt age, holding distribution codes with a higher accounting priority are booked first. If more than one distribution code shares the same priority, the settlement is distributed among them in proportion to the holding account balance

The above logic is handled by the payment segment FT creation algorithm C1-FTGL-PSAC. As an example of how these rules apply, let's assume an implementation practices cash accounting; i.e. revenue, taxes and other third party liabilities are not recognized until payment is received. Also assume the following distribution codes have been configured:

| Holding Distribution Code | Description | Cash Accounting Distribution Code | Accounting Priority |
|---------------------------|-------------------------------|-----------------------------------|---------------------|
| HLD-LPC | Late Payment Charge | R-MISC | 10 |
| HLD-RGEN | Revenue - Generation Charge | R-GEN | 20 |
| HLD-RDIS | Revenue - Distribution Charge | R-DIST | 30 |
| HLD-RTRN | Revenue - Transmission Charge | R-TRAN | 30 |
| HLD-THRD | 3 rd Party Charges | R-THRD | 40 |
| HLD-VAT | VAT | A/P-VAT | 90 |

Assume a customer has an outstanding third party charge with an arrears date of 2/Jan/2009:

| Event | GL Accounting | SA's Payoff Balance | Holding Balances | | | | | |
|---------------|---------------------------------------|---------------------|------------------|----------|----------|----------|----------|---------|
| | | | HLD-LPC | HLD-RGEN | HLD-RDIS | HLD-RTRN | HLD-THRD | HLD-VAT |
| Unpaid Amount | A/R 50 HLD-HRD <45> HLD-VAT <5> | 50 | 0 | 0 | 0 | 0 | (45) | (5) |

A bill is created for a customer and the result of the bill's financial transactions (an LPC adjustment in the amount of 10 and a bill segment in the amount of 127) include the following FT GL lines (both financial transactions have an arrears date of 15/Jan/2009):

| Event | GL Accounting | SA's Payoff Balance | Holding Balances | | | | | |
|----------------------|---|---------------------|------------------|----------|----------|----------|----------|---------|
| | | | HLD-LPC | HLD-RGEN | HLD-RDIS | HLD-RTRN | HLD-THRD | HLD-VAT |
| Bill segment created | A/R 127 HLD-RGEN <15> HLD-RDIS <20> HLD-RTRN <55> HLD-THRD <10> HLD-VAT <27> | 177 | 0 | (15) | (20) | (55) | (55) | (32) |
| Adjustment created | A/R 10 HLD-LPC <10> | 187 | (10) | (15) | (20) | (55) | (55) | (32) |

No payment is received prior to the next bill. The result of the next bill's financial transaction (a bill segment in the amount of 100) includes the following FT GL lines (this financial transaction has an arrears date of 16/Feb/2009):

| Event | GL Accounting | SA's Payoff Balance | Holding Balances | | | | | |
|----------------------|---|---------------------|------------------|----------|----------|----------|----------|---------|
| | | | HLD-LPC | HLD-RGEN | HLD-RDIS | HLD-RTRN | HLD-THRD | HLD-VAT |
| Bill segment created | A/R 100 HLD-RGEN <15> HLD-RDIS <20> HLD-RTRN <45> HLD-THRD <10> HLD-VAT <10> | 287 | (10) | (30) | (40) | (100) | (65) | (42) |

The following shows the result if a customer makes a payment on 20/Feb/2009. At payment time we'll build a table of holding amounts by accounting priority and debt age as follows:

| | | | | | | | | |
|------------------|-----------|---|---|---|---|---|---|---|
| Payment received | Cash 287 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| | A/R <287> | | | | | | | |
| | HLD-LPC | | | | | | | |
| | 10 | | | | | | | |
| | R-MISC | | | | | | | |
| | <10> | | | | | | | |
| | HLD-RGEN | | | | | | | |
| | 30 | | | | | | | |
| | R-GEN | | | | | | | |
| | <30> | | | | | | | |
| | HLD-RDIS | | | | | | | |
| | 40 | | | | | | | |
| | R-DIST | | | | | | | |
| | <40> | | | | | | | |
| | HLD-RTRN | | | | | | | |
| | 100 | | | | | | | |
| | R-TRAN | | | | | | | |
| | <100> | | | | | | | |
| | HLD-THRD | | | | | | | |
| | 65 | | | | | | | |
| | R-THRD | | | | | | | |
| | <65> | | | | | | | |
| | HLD-VAT | | | | | | | |
| | 42 | | | | | | | |
| | A/P-VAT | | | | | | | |
| | <42> | | | | | | | |

Example 2 - Customer Makes a Partial Payment

Assume the same financial history described above for a customer and a partial payment in the amount of 70 is made. This amount is not sufficient to satisfy the total holding amounts of 287, so the system will start settling held amounts starting with distribution codes with the oldest debt first from highest priority until the payment amount is exhausted.

A payment in the amount of 70 will be applied in the following sequence

| Distribution Code & Priority | HLD-LPC (10) | HLD-RGEN (20) | HLD-RDIS (30) | HLD-RTRN (30) | HLD-THRD (40) | HLD-VAT (NA) |
|------------------------------|--------------|---------------|---------------|---------------|---------------|--------------|
| Debt Age | | | | | | |
| 4 days old | | (15.00) | (20.00) | (45.00) | (10.00) | (10.00) |
| 36 days old | ③ (10.00) | ④ (15.00) | (20.00) | (55.00) | (10.00) | (27.00) |
| 49 days old | | | | | ① (45.00) | ② (5.00) |

The following describes how the holding amounts will be booked as a result of this partial payment:

- Settle oldest debt first (49 days old), i.e. 3rd Party Charges (HLD-THRD) and VAT (HLD-VAT). Note that even though these holding accounts have the lower accounting priorities, they are booked first because they have the oldest debt. An amount of 20 now remains on the partial payment.

- Next, we'll settle the 36 days old debt from the highest priority:
 - Late Payment Charge (HLD-LPC) in the amount of 10. An amount of 10 now remains on the partial payment
 - Revenue - Generation Charge (HLD-RGEN) gets the remaining payment amount of 10
- So, this partial payment in the amount of 70 will result in the following financial effect:

| Event | GL Accounting | SA Balance | Holding Balances | | | | | |
|------------------|----------------------------|------------|------------------|----------|----------|----------|----------|---------|
| | | | HLD-LPC | HLD-RGEN | HLD-RDIS | HLD-RTRN | HLD-THRD | HLD-VAT |
| Payment received | Cash 70 A/R <70> | 217 | 0 | (20) | (40) | (100) | (20) | (37) |
| | HLD-LPC 10 R-MISC <10> | | | | | | | |
| | HLD-RGEN 10 R-GEN <10> | | | | | | | |
| | HLD-THRD 45 R-THRD <45> | | | | | | | |
| | HLD-VAT 5 A/P-VAT <5> | | | | | | | |

[Top of the Page](#)

Example 3 - Customer Makes a Partial Payment

Assume the same financial history described above for a customer and a partial payment in the amount of 220 is made. This amount is not sufficient to satisfy the total holding amounts of 287, so the system will start settling held amounts starting with distribution codes with the oldest debt first from highest priority until the payment amount is exhausted.

A payment in the amount of 220 will be applied in the following sequence

| Distribution Code & Priority | HLD-LPC (10) | HLD-RGEN (20) | HLD-RDIS (30) | HLD-RTRN (30) | HLD-THRD (40) | HLD-VAT (NA) |
|------------------------------|--------------|---------------|---------------|---------------|---------------|--------------|
| Debt Age | | | | | | |
| 4 days old | | 9 (15.00) | 10 (20.00) | 10 (45.00) | (10.00) | (10.00) |
| 36 days old | 3 (10.00) | 4 (15.00) | 5 (20.00) | 6 (55.00) | 7 (10.00) | 8 (27.00) |
| 49 days old | | | | | 1 (45.00) | 2 (5.00) |

The following describes how the holding amounts will be booked as a result of this partial payment:

| | | | | | | | | |
|------------------|-----------------|----|---|---|---------|---------|------|------|
| Payment received | Cash 220 | 67 | 0 | 0 | (14.46) | (32.54) | (10) | (10) |
| | A/R | | | | | | | |
| | <220> | | | | | | | |
| | HLD-LPC | | | | | | | |
| | 10 | | | | | | | |
| | R-MISC | | | | | | | |
| | <10> | | | | | | | |
| | HLD- RGEN 30 | | | | | | | |
| | R-GEN | | | | | | | |
| | <30> | | | | | | | |
| | HLD- RDIS | | | | | | | |
| | 25.54 | | | | | | | |
| | R-DIST | | | | | | | |
| | <25.54> | | | | | | | |
| | HLD- RTRN | | | | | | | |
| | 67.46 | | | | | | | |
| | R-TRAN | | | | | | | |
| | <67.46> | | | | | | | |
| | HLD- THRD 55 | | | | | | | |
| | R-THRD | | | | | | | |
| | <55> | | | | | | | |
| | HLD- VAT32 | | | | | | | |
| | A/P-VAT | | | | | | | |
| | <32> | | | | | | | |

Adjustments That Behave Like Payments

There are several types of adjustments that behave just like payments (in respect of payables cash accounting). Consider the following events:

- Seizing a deposit (i.e., transferring a credit from a deposit service agreement to a regular service agreement)
- Overpayments transferred from one service agreement to another

The above events should cause the system to transfer holding amounts to true payable amounts (notice that the above examples are all transfer adjustments).

However, there are many other adjustments that should NOT behave like payments. You control how the adjustment works by selecting the appropriate FT algorithm when you [set up adjustment types](#) (refer to ADJT-AC and ADJT-TC for a description of the base package algorithms that cause the holding amounts to be manipulated in proportion to the amount of receivable being adjusted; and to C1-FTGL-ADAC and C1-FTGL-ADTC for the base package algorithms that take **Accounting Priority** into consideration). In other words, there are adjustment FT algorithms that cause the transference of holding payable amounts to real payable amounts when the A/R balance is decreased by the adjustment.

**Note:**

Cash refunds can behave like "anti-payments". In addition to the above examples of transfer adjustments behaving like payments, you should be aware that cash refunds may impact your holding and true payable balances. Refer to [Cash Refunds](#) for more information.

Overpayment Of Taxes Due To Cancel/Rebills

Let's assume a cancel / rebill occurs after a payment is received and the net effect of the cancel / rebill is that the customer has overpaid their taxes.

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance |
|----------------------|--------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) |
| | Revenue <100> | | |
| | Tax Holding <10> | | |
| Payment received | Cash 110 | (10) | 0 |
| | A/R <110> | | |
| | Tax Holding 10 | | |
| | Tax Payable <10> | | |
| Cancel | A/R <110> | (10) | 10 |
| | Revenue 100 | | |
| | Tax Holding 10 | | |
| Rebill | A/R 27.50 | (10) | 7.50 |
| | Revenue <25> | | |
| | Tax Holding <2.50> | | |

You'll notice that the amount payable to the taxing authority still indicates \$10 (the amount of tax that was paid by the customer). However, you'll notice that the tax holding balance is 7.50 (debit). This looks a bit odd, but it's correct. Remember that at this point, the customer has a credit balance of \$75 and this will be whittled down as successive bills are produced as shown below. Note: refer to [Cash Refunds](#) for an example of what happens if you refund the credit with a check rather than letting it whittle down.

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance |
|----------------------|------------------|---------------------|---------------------|
| | | (10) | 7.50 |
| Bill segment created | A/R 55 | (10) | 2.50 |
| | Revenue <50> | | |
| | Tax Holding <5> | | |
| Bill segment created | A/R 110 | (10) | (7.50) |
| | Revenue <100> | | |
| | Tax Holding <10> | | |

In the unlikely event of a payment being received while the tax holding has a debit balance, nothing will be done in respect of transferring funds from holding to payable (there is nothing to transfer).

Cash Refunds

If you refund moneys to a cash accounting customer, it's important to do the opposite of what was done when the payment was received (i.e., you need to transfer the payable back to the holding account). The following example should help clarify this situation (this example shows a refund due to a credit balance that occurred as a result of a cancel/rebill).

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance | SA's Payoff Balance |
|--|--------------------|---------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) | 110 |
| | Revenue <100> | | | |
| | Tax Holding <10> | | | |
| Payment received | Cash 110 | (10) | 0 | 0 |
| | A/R <110> | | | |
| | Tax Holding 10 | | | |
| | Tax Payable <10> | | | |
| Cancel | A/R <110> | (10) | 10 | (110) |
| | Revenue 100 | | | |
| | Tax Holding 10 | | | |
| Rebill | A/R 27.50 | (10) | 7.50 | (82.50) |
| | Revenue <25> | | | |
| | Tax Holding <2.50> | | | |
| Payment refunded (via an A/P adjustment) | Cash <82.50> | (2.50) | 0 | 0 |
| | A/R 82.50 | | | |
| | Tax Holding <7.50> | | | |
| | Tax Payable 7.50 | | | |

We understand this is tricky, but consider this - when a cash accounting customer makes a payment, the system transfers tax holding CREDIT balances to tax payable distribution codes in proportion to the amount of the receivable DEBIT amount that was reduced by the payment. Therefore, when cash is returned to the customer, the system should transfer tax holding DEBIT balances to tax payable distribution codes in proportion to the amount of the receivable CREDIT that was reduced by the refund.

Note:

The above takes place when an A/P adjustment is created if the related adjustment type references the appropriate FT algorithm (refer to ADJT-AC and C1-FTGL-ADAC for a description of the adjustment FT algorithms used for adjustments that behave like payments).

Overpayments

An overpayment, by definition, does not "match" to open items. However, the match type algorithms supplied with the base package will result in a balanced match event if an overpayment is made. The following points explain how this is achieved:

- The base package's match type algorithms will distribute the payment until the customer's current debt is satisfied.
- The amount of the overpayment will be kept on a separate SA (this only happens if you plug-in the appropriate Overpayment Distribution algorithm on your customer classes). Refer to [Overpayment Segmentation](#) for more information.
- When the payment is frozen, the payment segments that satisfy current debt will be matched against their respective open-items. The payment segment used to book the overpayment (on the overpayment SA) will not be matched.
- When future bills are completed, the credit balance on this "overpayment SA" will be transferred to the "real SAs" when future bills are completed (if you have plugged in the appropriate bill completion algorithm on the overpayment SA's SA type). If the overpayment satisfies all newly calculated charges, a match event is created that matches the new charges against the funds transferred from the overpayment SA. Refer to [When Are Match Events Created](#) for information about how the system creates match events at bill completion time when the new charges on the bill are satisfied by other credits (overpayments, deposit refunds, etc.).
- At some point in the future, the overpayment will be exhausted (i.e., all funds will be transferred to "real SAs"). At that point in time, the overpayment SA will close (assuming you set up the overpayment SA's SA type as a "one time"). At close time, the system creates a match event that matches the original overpayment payment segment with the adjustments that were used to transfer funds to the "real SAs". Refer to [When Are Match Events Created](#) for information about how the system creates match events when a SA closes.

Write Down Adjustment

Writing down debt is very different from [writing off debt](#). When you write down debt, you are removing the receivable with no expectation of it being paid. For example, most organizations write down small debit and credit balances as part of their write-off process (e.g., they don't send a very small amount to a collection agency).

Let's run through an example to illustrate this:

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance | SA's Payoff Balance |
|---------------------------------|-------------------------|---------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) | 110 |
| | Revenue <100> | | | |
| | Tax Holding <10> | | | |
| Payment received | Cash 109.50 | (9.95) | .05 | 0.50 |
| | A/R <109.50> | | | |
| | Tax Holding 9.95 | | | |
| | Tax Payable <9.95> | | | |
| Write down cash accounting debt | Tax Holding 0.05 | (9.95) | 0 | 0 |
| | Write Down Expense 0.45 | | | |
| | A/R <0.50> | | | |

In order to achieve the above, you must set up an adjustment type that references a special financial transaction algorithm (refer to non-accrual accounting write down algorithms ADJT-AD and **C1-FTGL-AD** for more information). This algorithm will reduce or increase the receivable balance accordingly AND cause any holding

amounts to be set to zero. This adjustment type should be referenced on your write-down algorithm that is referenced on your write-off controls.

Write-Offs

At write-off time we may refund credit balances. The refunding of credit balances is handled by A/P adjustments and these have cash accounting processing as described under [Cash Refunds](#).

If we have to write-off debt, holding balances are relieved in proportion to the amount of debt that is written off (as usual). It's important to understand that for this to work, you must set up the system as follows:

- The tax holding distribution codes must have their override distribution switch turned on.
- The distribution code on the SA type associated with the service agreement to which the written-off payables are transferred must be the REAL payable distribution codes. This is important so that if the customer pays after the payables are reversed, we will be able to debit cash and credit the REAL payable distribution code.

Let's run through an example to illustrate this.

| Event | Normal SA GL Accounting | Write Off Revenue SA GL Accounting | Reverse Liabilities SA GL Accounting |
|-----------------------------------|--|-------------------------------------|--|
| Bill segment created | A/R 110 Revenue <100> Tax Holding <10> | | |
| Write Off Time | | | |
| Reverse the held payables | Xfer 10 A/R <10> | | Tax Holding 10 Xfer <10> Note, the tax holding only gets debited if you have turned on the override at write-off switch on its distribution code |
| Write off revenue | Xfer 100 A/R <100> | Write Off Expense 100 Xfer <100> | |
| If the customer subsequently pays | | Cash 100 Write Off Exp <100> | Cash 10 Tax Payable <10> Note, the tax payable only gets credited if the SA type's distribution code has been defined as such |

Deferred Accrual Accounting

Some implementations use a hybrid accounting method that combines cash and accrual accounting. In this case revenue, taxes, etc. are recognized on the earlier of the bill due date or the date payment is received. In this scenario, the cash accounting method is used up until the bill's due date, at which time the accrual method is enforced (let's call this "deferred accrual accounting"). A simpler flavor of deferred accrual accounting is when the revenue and liability recognition is done solely at bill due date regardless of when the payment is made.

Deferred accrual accounting affects distribution codes identified as **Use For Non-Accrual Accounting** with an associated **Accounting Method** of either Payable on Earlier of Payment or Due Date or Payable on Due Date. The system accomplishes the holding amount settlement on the bill due date using a customer class post bill completion algorithm C1-CR-BLRVWS that creates a bill review record to be processed on the bill's due date. The bill review batch process then analyzes these bill review records on the bill due date. If a bill review record is due for processing, the algorithm checks the outstanding balance of the holding accounts on each SA linked to the bill and creates a settlement adjustment for each SA.

Deferred Accrual Accounting Examples

The examples below illustrate the financial transactions that transpire under these different scenarios.

Example 1 - Payable On Due Date, Customer Pays In Full

The following is an example of the financial events that transpire when a customer is billed and full payment is received prior to the bill due date. The accounting method in this case is Payable On Due Date.

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance |
|-------------------------------------|------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) |
| | Revenue <100> | | |
| | Tax Holding <10> | | |
| Payment received | Cash 110 | 0 | (10) |
| | A/R <110> | | |
| Adjustment created on bill due date | Tax Holding 10 | (10) | 0 |
| | Tax Payable <10> | | |

Example 2 - Payable On Due Date, Customer Does Not Pay

In the following example a customer is billed and no payment is received prior to the bill due date. The bill review batch process is responsible for creating the settlement adjustment for any outstanding holding amounts on the bill's due date. The accounting method in this case is Payable On Due Date.

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance |
|-------------------------------------|------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) |
| | Revenue <100> | | |
| | Tax Holding <10> | | |
| Adjustment created on bill due date | Tax Holding 10 | (10) | 0 |
| | Tax Payable <10> | | |

Example 3 - Payable On Due Date, Customer Makes A Partial Payment

In the following example a customer is billed and a partial payment is received prior to the bill due date. The bill review batch process is responsible for creating the settlement adjustment for any outstanding holding amounts on the bill's due date. The accounting method in this case is Payable On Due Date.

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance |
|-------------------------------------|------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) |
| | Revenue <100> | | |
| | Tax Holding <10> | | |
| Payment received | Cash 27.50 | 0 | (10) |
| | A/R <27.50> | | |
| Adjustment created on bill due date | Tax Holding 10 | (10) | 0 |
| | Tax Payable <10> | | |

Example 4 - Payable On Earlier Of Payment Or Due Date, Customer Pays In Full

In the following example a customer is billed and full payment is received prior to the bill due date. The accounting method in this case is Payable On Earlier Of Payment Or Due Date.

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance |
|----------------------|------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) |
| | Revenue <100> | | |
| | Tax Holding <10> | | |
| Payment received | Cash 110 | (10) | 0 |
| | A/R <110> | | |
| | Tax Holding 10 | | |
| | Tax Payable <10> | | |

Example 5 - Payable On Earlier Of Payment Or Due Date, Customer Does Not Pay

In the following example a customer is billed and no payment is received prior to the bill due date. The bill review batch process is responsible for creating the settlement adjustment for any outstanding holding amounts on the bill's due date. The accounting method in this case is Payable On Earlier Of Payment Or Due Date. Note that if a payment is subsequently received after the settlement adjustment has been created, it's financial transaction(s) will not have any impact on the holding or liability accounts as these have already been booked.

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance |
|-------------------------------------|------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) |
| | Revenue <100> | | |
| | Tax Holding <10> | | |
| Adjustment created on bill due date | Tax Holding 10 | (10) | 0 |
| | Tax Payable <10> | | |

Example 6 - Payable On Earlier Of Payment Or Due Date, Customer Partially Pays

In the following example a customer is billed and a partial payment is received prior to the bill due date. The bill review batch process is responsible for creating the settlement adjustment for any outstanding holding amounts on the bill's due date. The accounting method in this case is Payable On Earlier Of Payment Or Due Date. Note that if a payment is subsequently received after the settlement adjustment has been created, it's financial transaction(s) will not have any impact on the holding or liability accounts as these have already been booked.

| Event | GL Accounting | Tax Payable Balance | Tax Holding Balance |
|-------------------------------------|--------------------|---------------------|---------------------|
| Bill segment created | A/R 110 | 0 | (10) |
| | Revenue <100> | | |
| | Tax Holding <10> | | |
| Payment received | Cash 27.50 | (2.50) | (7.50) |
| | A/R <27.50> | | |
| | Tax Holding 2.50 | | |
| | Tax Payable <2.50> | | |
| Adjustment created on bill due date | Tax Holding 7.50 | (10) | 0 |
| | Tax Payable <7.50> | | |

Payment Cancellations and Deferred Accrual Accounting

If a payment was responsible for transferring moneys from the holding distribution code to the payable distribution code, it stands to reason that if the payment is cancelled, it results in the reversal of this transfer from the holding distribution code to payable distribution code. If deferred accrual accounting is used and the payment is cancelled after the bill due date, the holding amounts that were transferred should remain booked.

Assume, for example, that the payment below was cancelled after the bill due date:

| Event | GL Accounting |
|------------------|------------------|
| Payment received | Cash 110 |
| | A/R <110> |
| | Tax Holding 10 |
| | Tax Payable <10> |

At cancellation, the above entry will be reversed, reinstating the balance in the holding account:

| Event | GL Accounting |
|---------------------------------------|------------------|
| Payment cancelled after bill due date | Cash <110> |
| | A/R 110 |
| | Tax Holding <10> |
| | Tax Payable 10 |

However, since the bill's due date has passed, the holding account needs to be booked. For open item accounts, the system comes with a customer class FT freeze algorithm (C1-PR-CA-RVS) that creates a bill review schedule for the affected bill, if one does not already exist. When the bill review batch process next runs, it checks the outstanding balance of the holding accounts on each SA linked to the bill and creates a settlement adjustment for each SA.

| | |
|--------------------|------------------|
| Event | GL Accounting |
| Adjustment created | Tax Holding 10 |
| | Tax Payable <10> |

Note that this solution is only applicable to open item accounting where the bill matched to the payment can be determined. If balance forward accounting is practiced, the bill or bills that the payment applied to cannot be determined. In this case, the next bill review record created for the account as part of billing will cause the balances of the holding accounts to be analyzed and the settlement will catch up at that point.

Open Item Accounting

The topics in this section provide background information about open-item accounting.

Note:

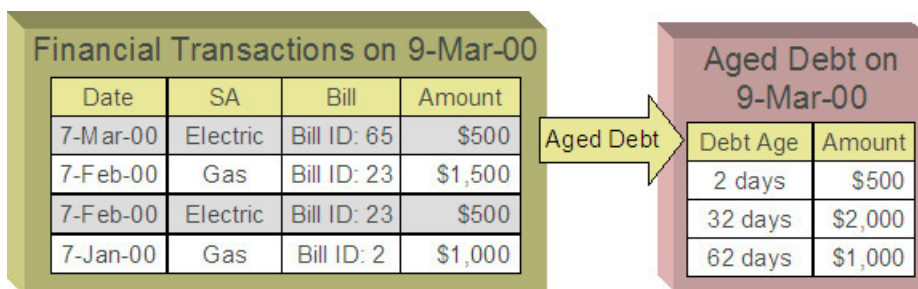

This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization practices open-item accounting. If your organization practices balance-forward accounting, you need only indicate such on your [customer classes](#); no other setup is required. Refer to [Open Item Versus Balance Forward Accounting](#) for more information about these two accounting practices.

Open-Item Versus Balance-Forward Accounting

If you practice open-item accounting, you match payments against bills. The term "open-item accounting" is used to describe this accounting practice because:

- Payments are matched against "open items" (i.e., unpaid bills and adjustments)
- Only unmatched bills and adjustments (i.e., open items) affect aged debt.

Contrast open-item accounting with "balance-forward" accounting - in a balance-forward world, payments are not matched to bills. Rather, payments implicitly relieve a customer's oldest debt. For example, consider the following unpaid financial transactions that exist for an account and the resultant aged debt.

In a balance-forward world, if a \$1,000 payment was made on 9-Mar-00, the customer's aged debt would look as follows:

| Aged Debt on 9-Mar-00 | |
|--------------------------|---------|
| Debt Age | Amount |
| 2 days | \$500 |
| 32 days | \$2,000 |

Notice how the \$1,000 payment relieves the 62 day old debt - it does this because, in a balance-forward world, payments payoff oldest debt first.

However, let's assume the customer wants the payment to settle their electric debt (e.g., because they disagree with the gas bills). If you could match the \$1,000 payment to the two electric bills (i.e., open-item accounting exists), the customer's aged debt would look as follows:

| Aged Debt on 9-Mar-00 | |
|--------------------------|---------|
| Debt Age | Amount |
| 32 days | \$1,500 |
| 62 days | \$1,000 |

In sum,

- In an open-item world, payments are matched to bills and only unpaid bills and adjustments (i.e., open items) affect aged debt.
- In a balance-forward world, payments are not matched to bills and therefore a customer's aged debt is computed by aging debits (bills and adjustments) and then relieving the oldest debits using credits (payments and adjustments).

Note:

Financial Transactions and Bills. In an open-item world, only bill segments and adjustments are presented on a bill. When a bill is completed, only those bill segments and adjustments to be presented are swept onto a bill. Payment and payment cancellation FTs, bill segment FTs canceled before bill completion together with their corresponding bill segment cancellation FTs, and adjustment FTs marked as do not show on bill are not swept onto a bill. An adjustment's adjustment type and its algorithms determine if its FT will show on a bill by default.

Accounting Method Defined On Your Customer Classes

You define the type of accounting method that is practiced ([balance-forward versus open-item](#)) on your [customer classes](#). For example, residential customers can practice balance-forward accounting whereas industrial / commercial customers can practice open-item accounting.

Match Events

Match events are used to match open-items (i.e., debit and credit financial transactions) together. The topics in this section provide an overview of match events.

Match Events Match Debit FTs To Credit FTs

For open-item customers, the system matches credit financial transactions (FT's) to debit FT's under a [match event](#). The following is an example of a match event associated with two \$500 payments that satisfy the debt associated with one bill (on February 2000).

Match Event

Account: 10291011

Status: Balanced

Credit FT's: \$1,000

| Date | SA | FT Info | Amount |
|----------|----------|---------|--------|
| 7-Mar-00 | Electric | None | \$500 |
| 1-Mar-00 | Electric | None | \$500 |

Debit FT's: \$1,000

| Date | SA | FT Info | Amount |
|-----------|----------|-------------|---------|
| 15-Feb-00 | Electric | Bill ID: 22 | \$1,000 |

Notice the following:

- The match event matches 2 credit FT's against a single debit FT. A match event may contain an unlimited number of FT's.
- The match event contains FT's associated with a single account. While the FT's under a match event may belong to multiple service agreements, all FT's under a match event must belong to the same account.
- The match event only contains bill segments that belong to a single bill. If you mix multiple bills under a single match event, then an individual bill balance cannot be properly determined when partial payments exist.
- The status of the match event is balanced. This is because the sum of the debits equals the sum of the credits. If debits do not equal credits, the status of the match event would be open and the various FT's would still affect the customer's aged debt. Refer to [Match Event Lifecycle](#) for more information.

Warning:

It is strongly encouraged that you refrain from mixing multiple bills on a single match event. If you stick by the rule of "just one bill per match event" you will then be able to determine the outstanding balance of a partially paid bill (see the [bill page](#), bill summary section). However, if you mix more than one bill under a match event, a particular bill's balance may become indeterminate. Algorithm types have been provided which help to enforce this rule of "one bill per match event", please refer to Match By Bill, Pay Oldest Bill First for an example of a matching algorithm that enforces this notion.

When Are Match Events Created?

The following points describe when match events are created for open-item accounts:

Note:

Match events are only created for open-item accounts (i.e., those accounts with a customer class that indicates open-item accounting is practiced). Match events may not be created for balance-forward accounts.

- The system can create one or many match events when a payment is added. This match event matches the payment's credit FT's with the debit and credit FT's from bill segments and adjustments. The FT's that are linked to the match event are controlled by the payment's **match type** and **match value** (payments made by open-item customers must reference a match type and match value). Refer to [Payments And Match Events](#) for more information.
- The system may create a match event when any type of financial transaction is cancelled. This match event groups together the original FT with its cancellation FT. Refer to [How Are Match Events Cancelled?](#) for more information.

- The system creates a match event when a bill is completed for customers that pay automatically (i.e., direct debit customers). The match event groups together the bill's new charges against the automatic payment's payment segments.
- The system creates a match event when a bill is completed where the new charges are offset by other financial transactions. For example,
 - Consider a bill that contains a deposit refund. If the sum of the deposit refund equals or exceeds the amount of the bill, the bill's FT's can be matched against the debit refunds FT's. Refer to [Refunding Deposits](#) for more information about deposit refunds.
 - Consider a bill whose new charges are offset by a previous overpayment. Refer to [Over Payments](#) for more information about overpayments.

Fastpath:

Refer to [Bill Lifecycle](#) for more information about what happens during bill completion.

- The system creates a match event when a service agreement closes and the service agreement has unmatched FT's. For example,
 - Consider a deposit service agreement that closes when the deposit is refunded to the customer. The system will create a match event with the deposit SA's FT's (the original credit and the debits used to refund the deposit) when the deposit SA closes (i.e., when its credit balance falls to zero). Refer to [Refunding Deposits](#) for more information about deposit refunds.
 - Consider a service agreement for utility debt that is written off. This service agreement closes when the system creates transfer adjustments to transfer the utility debt to a write-off service agreement (or writes down the debt). The system creates a match event to match the original debt to the transfer adjustments used to write-off the debt. Refer to [How Is Debt Financially Written Off](#) for more information about write-off processing.
- A user can create a match event manually at any time. Manual match events would be created under a variety of situations. For example:
 - If a customer disputes a charge. Refer to [Disputing Items](#) for more information about disputes.
 - To handle unusual situations when the system is unable to automatically match FT's together.

Match Event Lifecycle

The following diagram shows the possible lifecycle of a match event:

Match events are initially created in the open state. Financial transactions (FT's) linked to open match events affect arrears, but not in an open-item fashion. Rather, FT's linked to open match events affect arrears in a balance-forward fashion. Refer to [Open Item Versus Balance Forward Accounting](#) for more information about these two accounting methods.

A user may delete an open match event. When an open match event is deleted, its FT's may be linked to other match events.

The system automatically changes an open event's status to balanced when the sum of the debit financial transactions (FT's) equals the sum of the credit FT's for each SA on the match event. It's worth stressing that a match event may contain FT's from many SAs and each SA's FT's must sum to zero before the match event can become balanced.

A user may re open a balanced event (by adding / removing FT's so that the match event becomes unbalanced).

A user may cancel a balanced or open match event. Refer to [How Are Match Events Cancelled?](#) for more information about cancellation.

Payments And Match Events

As described under [When Are Match Events Created?](#), the system creates a match event when a payment is added for an open-item account. The system uses the payment's **match type** and **match value** to determine the FT's (e.g., bill segments and adjustments) that will be matched with the payment's FT's (i.e., the payment segments).

Another way to think of this is as follows:

- When most payments are distributed, the system calls the payment distribution algorithm that is plugged-in on the account's customer class.
- However, a payment that is made in respect of a specific bill requires a different distribution algorithm because the payment should only be distributed amongst the debt associated with the specific bill being paid. This is accomplished by referencing a match type / match value on the payment. The match type references the appropriate payment distribution algorithm. This algorithm is used rather than the customer class distribution algorithm.

For example, if a payment were made in respect of bill ID 192910192101, this payment would reference a match type of bill ID and a match value of 192910192101. At payment distribution time, the system calls the override payment distribution algorithm associated with this match type. The base package bill ID distribution algorithm does several things:

- It distributes the payment amongst service agreements associated with the bill.
- It creates a match event and links the bill's bill segment and adjustment FT's to it.
- Refer to the Bill ID Match Type Algorithm for more information about this algorithm.

Note:

The match type's distribution logic is not "hard coded". Because the match type's payment distribution logic is embedded in a plug-in algorithm, you can introduce new algorithms as per your company's requirements.

It's worth noting that payment *distribution* and *freezing* are two separate steps that typically happen in quick succession. The system's standard match event algorithms create the match event during payment distribution. This match event exists in the open state (because the payment segment's FT's have not yet been linked to the match event and therefore debit FT's do not equal credit FT's). The open match event references the debit FT's (the bill segments and adjustments) for which it pays. It is only at payment freeze time that the credit FT's (the payment segments) are linked to the match event thus allowing the match event to be become balanced.

If, at freeze time, the payment's credit FT's do not equal the debit FT's on the match event, the match event is left in the open state. An alert will appear on Control Central to highlight the existence of open match events (if the appropriate alert algorithm is plugged in the installation record). In addition, you can also set up a To Do entry to highlight the existence of open match events.

Payments Are Matched To Debit Credit FTs

While the above discussion dealt with the typical situation where the payment's credit FT's are matched against a bill's debit FT's, we want to note that a payment's FT's may be matched against debit and credit FT's. Consider the following example:

Match Event

Account: 10291011

Status: Balanced

Bill 1929: \$2,900

| Date | SA | FT Info | Cur Amount |
|----------|----------|------------|------------|
| 7-Mar-00 | Electric | Bill seg | \$1,500 |
| 6-Mar-00 | Gas | Bill seg | \$1,500 |
| 1-Mar-00 | Gas | Adj-Credit | \$-100 |

Pay: \$2,900

Match Type: Bill ID 1929

| Date | SA | FT Info | Cur Amount |
|-----------|----------|---------|------------|
| 15-Mar-00 | Electric | Pay seg | \$-1,500 |
| 15-Mar-00 | Gas | Pay seg | \$-1,400 |

Notice that:

- The \$2,900 payment is distributed amongst two service agreements (electricity and gas).
- The FT's to which the payment segments are matched are both debit and credit FT's. Notice that the debit FT's (the bill segments) and the credit FT (the adjustment) sum to \$2,900.

Credits may result in a situation where the total amount on a bill for an SA is negative. This would be the case if in the above example the credit adjustment were for \$-1600 resulting in the total amount for the Gas SA on this bill to be \$-100 (credit). Assume a full payment of \$1400 is made towards this bill. The Bill ID Match Type Algorithm first allocates negative payment amounts to any SA credit amount on the bill being paid. It then carries over the credit amount to pay off other bill amounts. In this example, a "negative" payment segment is created to match the \$-100 credit of the Gas SA. Using the carried over credit a \$1500 payment segment is created to match the \$1500 debit of the Electric SA.

How Are Match Events Cancelled?

A user can cancel an open or balanced match event at any time. When a match event is cancelled, the event's FT's again effect arrears (and they can be associated with new match events). In other words, when a match event is cancelled, its FT's are released from the match event and become open-items.

In addition to manual cancellation, the system may automatically cancel a match event when the last of its payment FT's, if any, is cancelled (if you plug-in the appropriate FT freeze plug-in on your open-item customer classes).

For example, consider a match event that was created when a payment was made. If the payment is subsequently cancelled, the match event is also cancelled (thus releasing the match event's FT's) if no other payment FT's are linked to the match event. Please be aware that FT cancellation also causes a new match event to be created. This match event matches the original FT (the payment segment) and its cancellation FT. This means that the only "open items" that will exist after a payment is cancelled are the debit FT's that were originally paid.

Note:

Reopening bills associated with automatic payment customers. While many payments are cancelled due to non-sufficient funds, please be aware that if you reopen a bill for which an automatic payment was created, the system will cancel the associated payment. If this payment is associated with a match event (because the account is an open-item account), the match event will be cancelled and a new match event will be created to match the original automatic payment with its cancellation details. This is necessary because a new payment

will be created with the bill is subsequently completed and this payment's FT's will be matched to the bill's FT's.

Canceling a payment can result in many match events being created. If a cancelled payment has multiple payment segments, a separate match event will be created for each payment segment.

While payment cancellation is the most common type of FT cancellation, be aware that bill segment or adjustment cancellation may also cause a new match event to be created. We don't necessarily want to always link the cancellation FT and its original FT to the same match event. For example, when the cancellation FT is swept on to the next bill it affects the next bill and not the original FT's bill. For cancellations that will not be swept on to the next bill (payment cancellation, cancellation of an adjustment that is not shown on bill, credit notes, and bill segment cancellation before the bill is completed) the system creates a new match event that matches the original FT and its cancellation FT. This way, neither FT affects aged debt. If the original FT was linked to an existing match event and no other FTs are left on this match event it is automatically canceled.

Current Amount Is Matched, Not Payoff

The system matches the current amount of financial transactions, not the payoff amount.

Fastpath:

Please refer to [Current Amount versus Payoff Amount](#) for more information about current and payoff amounts.

Disputing Items

Open-item customers may dispute FT's that they are not comfortable paying. For example, a customer who receives a bill with an anomalous charge may decide to dispute it.

When an open-item customer disputes a charge, a user creates a match event and links the disputed FT(s) to it. This match event will be in the open state (because it does not contain FT's that sum to zero). In addition, the match event's "disputed switch" is turned on.

Note:

Alerts. An alert is displayed on control central to highlight the existence of disputed match events (if the appropriate alert algorithm is plugged in). In addition, you can also set up a To Do entry to highlight the existence of disputed match events.

While the dispute is being researched, the disputed amount will not affect aged debt, but it still forms part of the customer's balance. For example, consider the following unpaid financial transactions that exist for an account:

| Financial Transactions on 9-Mar-00 | | | | Aged Debt | Aged Debt on 9-Mar-00 | |
|------------------------------------|----------|-------------|---------|-----------|-----------------------|--------|
| Date | SA | Bill | Amount | | Debt Age | Amount |
| 7-Mar-00 | Electric | Bill ID: 65 | \$500 | | | |
| 7-Feb-00 | Gas | Bill ID: 23 | \$1,500 | | | |
| 7-Feb-00 | Electric | Bill ID: 23 | \$500 | | | |
| 7-Jan-00 | Gas | Bill ID: 2 | \$1,000 | | | |
| | | | | 2 days | \$500 | |
| | | | | 32 days | \$2,000 | |
| | | | | 62 days | \$1,000 | |

If the customer disputes the two electric bill segments, the customer's aged debt will look as follows:

Notice how a new category of debt appears - Disputed. Also notice how the 2 day old debt disappears and the 32 day old debt is reduced by the disputed amount.

The system shows disputed debt on Control Central. In addition, in all places where aged debt appears in the system, disputed debt is shown as a separate debt category.

If the dispute goes in your company's favor, the disputed match event should be cancelled (thus allowing the FT's to again impact aged debt). For example, if we assume 3 days have passed and the dispute match event is cancelled, the customer's aged debt will look as follows:

If the dispute goes in the customer's favor:

- You may decide to issue a credit note to cancel the offending bill or bill segment(s). As described above, the system in this case will automatically create new match events that match the original FTs with their cancellation FTs and cancel the disputed match event when the last item is unlinked from it.
- You may decide to cancel the offending bill segment(s) / adjustment(s). As described above, these cancellations are going to be swept on to the next bill. The system therefore will not automatically cancel the disputed match event. Notice that the cancellation effect of the disputed items is carried over on to the next bill. This means that the previously disputed items still need to be paid.

Note:

Cancel / rebill. If you cancel / rebill an offending bill segment, both the cancel and the rebill will become open-items that will be matched when the next bill is paid.

- You may decide to issue an adjustment to counter the effect of the disputed FT's. In this situation, you would simply link the adjustment FT to the disputed FT's (thus allowing the match event to become balanced). It is important to use in this case an adjustment that does not show on bill.

Pay Plans

You create a [pay plan](#) when a customer agrees to make one or more scheduled payments to satisfy past (or future) debt. These payments cannot be matched to open items because it is unlikely that debit FT's exist that equal the amount of each scheduled payment. However, you must specify a match type on all payments made by open-item customers. Therefore, a conundrum exists - the system requires a match type on payments made by open item accounts, but payments made for pay plans cannot be matched to existing FT's. This conundrum is solved by the fact that match types do not have to specify an override payment distribution algorithm. The customer class's standard distribution algorithm is used for payments that reference such a match type.

You may wonder how these payments will eventually get matched to open items? If ALL payments associated with a pay plan occur before the next bill is paid (or if the pay plan exists to satisfy future debt), these payments will be swept onto the match event that is created when the customer pays their next bill. However, if the pay plan exists to payoff historical debt and this debt has not been entirely paid by the time of the next bill, an unmatched event will exist when the customer pays their subsequent bills (if the payment amount doesn't match the amount of new charges on the bill). Why? Because, the customer is not paying the entire amount of the bill and therefore the system will not be able to match the payment to open items. If this occurs, we recommend canceling the match events that are created when the customer pays their subsequent bills. When the customer finally pays off all outstanding debt, the system will create a single match event that will contain all payments and bill segments.

Over Payments

If a customer overpays a bill (i.e., we receive more cash than receivables), we strongly recommend you set up the system to NOT keep the excess credit on the customer's regular service agreements. Rather, we recommend you segregate the receivable onto an "excess credit" service agreement. If you do this, the system will transfer any excess credits to the regular service agreements at bill completion time. When this transfer occurs, the same accounting described under [Payments Segment Financial Transaction Algorithms Transfer Holding Amounts To Payable GL Accounts](#) occurs as shown in the following example. Note: this example assumes an excess credit of \$110 was transferred to a normal service agreement and the normal service agreement had \$10 of held payables.

Fastpath:

Refer to [Overpayment Segmentation](#) for how to set up the system to segregate overpayments on a separate service agreement.

Note:

Why not keep excess credits on a customer's regular service agreement? Because the system can't differentiate between a credit that exists as a result of an overpayment and a credit that exists because of cancel/rebills, it would be impossible for the system to know if payables should be realized as a result of the reduced credit balance. However, if you keep overpayments on an excess credit service agreement, the system knows to treat any transference of these credits as "payments" and therefore it can transfer holding balances to true payables.

| Event | Normal SA GL Accounting | Excess Credit SA GL Accounting |
|---|---|--------------------------------|
| Bill segment created | A/R 110 Revenue <100> Tax Holding <10> | |
| Payment of \$300 is received | Cash 110 A/R <110> Tax Holding 10 Tax Payable <10> | Cash 190 Overpay <190> |
| Bill segment created | A/R 110 Revenue <100> Tax Holding <10> | |
| Transfer excess credit amount to normal service agreement (when bill is completed). | Xfer 110 A/R <110> | Overpay 110 Xfer <110> |

| | | |
|--|---|---------------------------|
| Because the transfer adjustment is the equivalent of a cash relief outstanding tax holding is relieved in proportion to the amount of receivables that are reduced by the transfer | Tax Holding 10 Tax Payable <10> | |
| Net effect of the transfer | Xfer 110 A/R <110> Tax Holding 10 Tax Payable <10> | Overpay 110 Xfer <110> |

**Note:**

Prepaid taxes - future functionality. If your organization allows customers to prepay taxes in anticipation of a future tax increase (the customers receive the lower rate if they pay in advance), we do not consider this prepayment to be an overpayment. Rather, it is a payment of future taxes that will be remitted to the taxing authorities at payment time (due to cash accounting). Please speak to your account manager for when corresponding functionality will be available.

Setting Up The System To Enable Open Item Accounting

The following section provides an overview of how to enable open-item accounting.

Match Type Setup

The number of match types that you will need is dependent on the number of ways you want payments to be matched to open items. At a minimum, you will probably need the following match types:

- **Bill ID.** This match type should reference an override payment distribution algorithm that distributes the payment based on the bill ID specified on the payment (in match value). Refer to [Payments And Match Events](#) for more information.
- **SA ID.** This match type should reference an override payment distribution algorithm that distributes the payment based on the SA ID specified on the payment (in match value). Refer to [Payments And Match Events](#) for more information.
- **Pay Plan.** This match type should NOT reference an override payment distribution algorithm (if this algorithm is blank, the customer class's payment distribution algorithm is used). Refer to [Pay Plans](#) for more information.

Match Event Cancellation Reason Setup

The number of match event cancellation reasons that you will need is dependent on the number of ways your organization can justify the cancellation of a match event. At a minimum, you will probably need the following match event cancellation reasons:

- **FT Cancellation.** This cancel reason should be referenced on the Customer Class FT Freeze algorithm that is responsible for canceling match events when one of its financial transactions is cancelled.
- **Incorrect Allocation.** This cancel reason should be specified by users when they cancel match events that were created by the system erroneously.

Customer Class Setup

The following points describe [customer class](#) oriented set up functions:

- Turn on the open-item accounting switch.
- Set up the following algorithms for each CIS division:
 - Specify a **payment freeze** algorithm that causes a payment's FT's to be linked to the match event that was created when the payment was distributed. Refer to [Payments And Match Events](#) for more information.
 - Specify a **FT freeze** algorithm that causes match events to be cancelled (and a new match event to be created) when a FT is cancelled. Refer to [How Are Match Events Cancelled](#) for more information about cancellation.
 - We strongly recommend specifying an **overpayment** algorithm that causes overpayments to be segregated onto an "excess credit / overpayment" SA. Refer to [Overpayments](#) for more information.

Overpayment SA Type Setup

Specify a **bill completion** algorithm that causes the credit amount on overpayment SAs to be transferred to newly create debt (created when the bill is created). This algorithm transfers an overpayment SA's balance to regular SAs and creates a match event if the overpayment covers the entire bill. Refer to [Overpayments](#) for more information.

Installation Record Setup

Specify an **automatic payment** algorithm that causes a match event to be created when automatic payments are created for open-item accounts. The base package algorithm will do this for you if you specify the appropriate parameter on the algorithm. Refer to APAY-CREATE for more information about this algorithm.

If you want a Control Central alert to highlight when the current account has any open match events, plug in the appropriate **control central alert** algorithm on your installation record. Refer to C1-OPN-MEVT for more information about this algorithm.

If you want to enable manual pay segment distribution for open item accounts, along with other functions, you will need to plug in an installation algorithm for bill balance calculation. Refer to C1-OI-BI-AMT for more information about this algorithm.

To Do Entry Setup

Two To Do types are supplied with the base package:

- **TD-MODTL**. This To Do type highlights the presence of open, disputed match events.
- **TD-MONTL**. This To Do type highlights the presence of open, non-disputed match events.

Each of the above To Do types should be configured with the roles that work on entries of each type.

In addition, the account management group and/or divisions from which the default roles are extracted should be updated to define the role that should be defaulted for each of the above To Do types.

Fastpath:

Refer to [The Big Picture Of To Do Lists](#) for more information about To Do lists.

Setting Up Match Types

Most payments are distributed amongst service agreements using the payment distribution algorithm specified on the payment's account's customer class. This algorithm decides how to distribute a payment amongst an account's existing debt if the customer doesn't specify how the payment should be distributed.

A customer can specify how a payment is distributed by specifying a match type and match value on their payments. Consider the following examples:

- Customers that are subject to open-item accounting (this is defined on the account's customer class) tell the system exactly which debt is covered by their payments. For example, an open-item customer might make a payment in respect of bill ID 123919101919.

- Even non open-item customers can direct payments to specific SAs. For example, the system allows a balance-forward customer's payment to be directed to a specific service agreement (however, they cannot direct payments to specific bills as only open-item customers can do this).

Match types are used to define the specific type of debt that is covered by a payment. The match type contains the algorithm that effectively overrides the standard payment distribution algorithm defined on the account's customer class.

Note:

Background information. Please refer to [Payments And Match Events](#) and [Match Type Setup](#) for more information about how match types are used.

To set up match types, select **Admin > Financial > Match Type**.

Description of Page

Enter an easily recognizable **Match Type** and **Description**.

Define the **Pay Dist Override Algorithm** used to distribute payments that reference this match type. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that overrides the normal payment distribution algorithm.

Setting Up Match Event Cancellation Reasons

When a match event is canceled, a cancel reason must be supplied.

Note:

Background information. Refer to [How Are Match Events Cancelled?](#) and [Setting Up Match Event Cancellation](#) for more information about cancellation.

To set up match event cancellation reasons, select **Admin > Financial > Match Event Cancel Reason**.

Description of Page

Enter an easily recognizable **Match Event Cancel Reason** and **Description**.

Fund Accounting

The topics in this section provide background information about fund accounting.

Note:

This section is only relevant for some organizations. The system configuration requirements described in this section are only relevant if your organization practices fund accounting (this type of accounting is typically performed by municipal utilities). If your organization does not practice fund accounting, you need only indicate such on the [Installation Record](#); no other setup is required.

Fund Accounting Overview

Municipal utilities, and not-for-profit organizations in general, often use a form of accounting different from that used by for-profit corporations. Municipal utilities typically practice fund accounting, whereas corporations practice corporate accounting.

Regulations or other restrictions may require a municipal utility to account for the finances of each of its departments as a separate entity. If a municipal utility provides both water and wastewater service, a municipal utility may need to track the receivables, revenue, and liabilities for water service separately from those of wastewater. In contrast, a corporation is free to co-mingle the moneys of the two services.

To track the services separately, the municipal utility sets up a fund for each department. A fund is an accounting entity with its own self-balancing set of accounts. Each fund has its own "sub general ledger" with its own chart of accounts, and within each fund, its debits equal its credits at all times. This allows the utility to report on the financial state of each fund independently.

In addition to having a fund for each department, there is also a general fund, which is used to handle inter-fund transfers as well as shared accounts.

Fund Accounting Example

Consider a municipal utility which provides water and wastewater service. The utility has two departments: water and wastewater. Each department must track their finances separately therefore a fund is setup for each department:

- Water (fund 01).
- Wastewater (fund 02).

In addition, with fund accounting, there is always a general fund (fund 99).

Assume the following bill is generated.

The bill would produce the following GL entries:

For each fund, the GL details of the bill will include a debit to the accounts receivable (A/R) account and credits to the revenue and taxes payable accounts. In organizational terms, each department is owed a portion of the overall bill by the customer, part of which is sales by the department and part of which is owed to the taxing authorities by the department. Each fund is balanced.

Note that the accounting could be identical under corporate accounting if each service is its own division with its own chart of accounts.

The following diagram illustrates the initial GL accounting that would occur when the payment arrives:

The utility's general cash account is debited, and the departmental funds' A/R accounts are credited. In other words, the cash is held by the utility as a whole but the receivables are reduced for the individual departments.

If the accounting were left in this state, the fund accounting principal - that each fund represents an independent entity with a self-balancing chart of accounts - would be violated. This violation is caused due to the fact that cash is recorded on the general fund, not the departmental funds, causing the general fund to have an excess debit and the departmental funds to have an excess credit.

From an organizational viewpoint, to make each department whole, the departments need to note what portion of the cash they own, and correspondingly, the utility needs to note what portion of the cash is owed to each department. The following diagram illustrates this point.

To maintain a balance of debits and credits within each fund, the departmental funds have an "equity in pooled cash" (EPC) account and the general fund has a liability account for each departmental fund. In addition to debiting the general fund's cash account and crediting the departmental funds' A/R accounts, the departmental funds' EPC accounts are debited and the general funds liability accounts are credited.

And so, with the additional GL entries, all funds have matching debits and credits.

An Example Of A Bill Segment That References Multiple Funds

Consider a municipal utility that primarily supplies water service but is also responsible for maintaining the city's fire hydrants. The costs for fire hydrant maintenance are borne by the water customers and make up just a small portion of the overall bill. These costs are simply added to the water bill as a line item. The utility has two departments:

- Water service (fund 01)
- Hydrant maintenance (fund 39).

In addition, there is a general fund (fund 99).

Assume the following bill is generated for water and hydrant services.

The following diagram illustrates the initial GL entries for the bill:

In accounting for the bill, the water fund's A/R is debited, the water and hydrant funds' revenue accounts are credited, and the water's taxes payable account is credited.

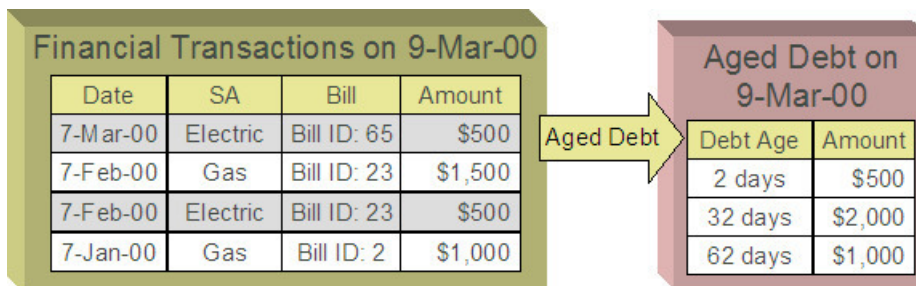

If left at this, the funds would be out of balance; the water fund would have an overall excess debit and the hydrant fund would have an equal excess credit. In organizational terms, the hydrant fund has recorded sales but that amount is recorded as being owed to the water department.

To balance each department, the water department accepts the responsibility for collecting the hydrant charges from the customer but immediately remunerates the charges to the hydrant fund.

This transfer is done using the general fund. The water fund's EPC account is credited and the liability to water is debited with the amount of the hydrant revenue. Also, the hydrant fund's EPC account is debited and the general fund's liability to hydrant account is credited by the hydrant revenue. In effect, the water department owes the hydrant charges to the general fund, and the general fund owes the hydrant charges to the hydrant fund.

The following diagram illustrates the initial GL accounting that would occur when the payment arrives:

When the payment arrives, the cash is debited to the general fund's cash account, and the water fund's A/R is relieved. Again, the funds would be unbalanced if left in this condition; the water fund would have an excess of credits and the general fund would have an excess of debits.

To maintain each fund's balance of debits and credits, the general fund's liability to the water fund is credited by the amount of the department's share of the cash, and the water fund's EPC is debited. Note that the payment has no effect on hydrant fund's EPC and the general fund's liability to the hydrant fund. The hydrant department "received" its money from the water department when the bill was created.

And so, all funds have matching debits and credits.

Accounting Method Is Defined On The Installation Options

You must turn on a switch on the [Installation Record](#) to enable fund accounting.

Fund Controls Fund-Balancing Entries

There are two levels of debit and credit balancing in fund accounting. There is the balancing required by double entry accounting: the total debits in the entire GL must equal the total credits. This is required regardless of whether fund or corporate accounting is used. The distribution codes for these entries come from varying sources, depending on the type of financial event.

Fastpath:

Refer to [The Source Of GL Accounts On Financial Transactions](#) for information on the sources of the distribution codes.

The second level of balancing is specific to fund accounting. Within each fund—not just across the GL—the total debits must equal the total credits. The original distribution code from the financial event has a fund specified. For example, a bill would cause a debit to a fund's A/R distribution code, and included in that A/R distribution code is the fund. It is the definition of the fund that specifies whether fund-balancing entries are required and provides the distribution codes for these entries.

For a departmental fund, the fund-balancing debit and credit would be specified. When a debit is applied to a departmental fund's GL account, an additional account (typically the general fund's liability to the departmental fund) is debited and an account (typically the departmental fund's EPC) is credited. When a credit is applied to a departmental fund's account, an additional account (typically the general fund's liability to the departmental fund) is credited and an account (typically the department's EPC) is debited.

For the general fund, no fund-balancing debits and credits are specified.

Building Fund-Balancing GL Details

Building the GL details for a financial event is a two-step process.

- First, the system generates the regular GL details for a financial transaction (FT). This is done regardless of whether corporate or fund accounting is used.
- Second, if fund accounting is activated (by turning on a switch on the [Installation Record](#)), the system analyzes the distribution code on each GL detail associated with the FT. If a **fund** is specified on a distribution code, the system

checks the definition of the fund. If fund-balancing entries are specified on the fund, two additional GL entries are added to the FT:

- An offsetting entry to the Equity in Pooled Cash account is created for the departmental fund (e.g., if the FT is debiting a given fund, an offsetting credit is created in the funds EPC account).
- Another entry to the departments Liability account is created for the general fund.

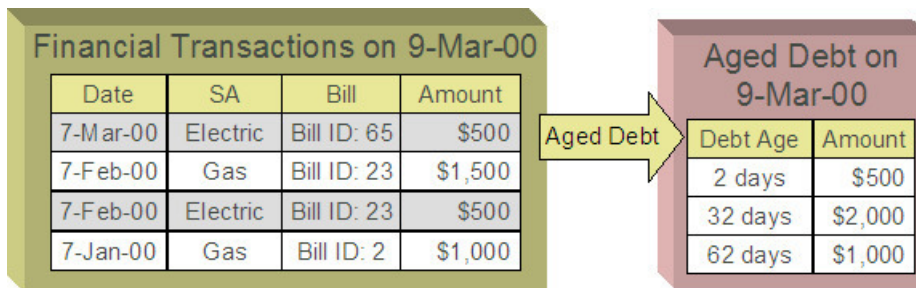

The result is a consolidated set of GL entries for the FT, incorporating the regular entries as well as the fund-balancing entries.

The topics in this section illustrate the generation of the GL details for the earlier examples.

FTs Whose GL Details All Reference The Same Fund Do Not Impact the General Fund or EPC Accounts

In [Fund Accounting Example](#), where the bill's bill segments reference a single fund, the system creates a fund-balancing GL entry for each GL entry applied to a departmental fund:

- A debit to a departmental GL account triggers a debit to the general fund's liability-to-departmental-fund account and a credit to the departmental fund's equity-in-pending-cash account.
- A credit to a departmental GL account triggers a credit to the general fund's liability-to-departmental-fund account and a debit to the departmental fund's equity-in-cash account.

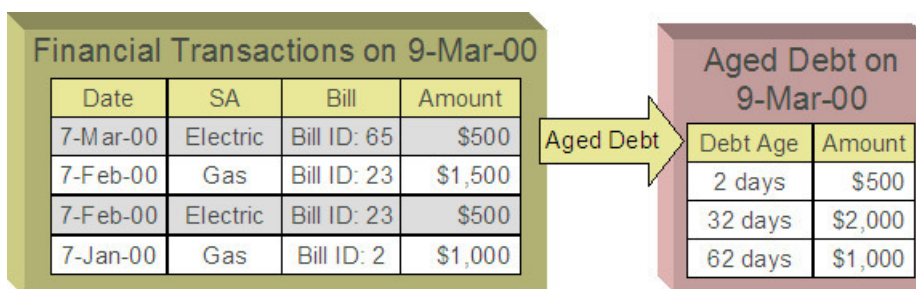

The net effect on the individual equity-in-cash and general fund's liability accounts is zero because the debits and credits net to zero for each GL account. In other words, the yellow boxes net to zero and therefore fund accounting does not impact the bill segment's financial transactions. Refer to [Fund Accounting Example](#) for the resulting consolidated GL entries.

An FT Whose GL Details Reference Multiple Funds

In [An Example Of A Bill Segment That References Multiple Funds](#), where the bill's bill segments reference multiple funds (water and hydrant), the system also creates fund-balancing GL entries for the financial transaction:

- A debit to a departmental GL account triggers a debit to the general fund's liability-to-departmental-fund account and a credit to the departmental fund's equity-in-pending-cash account.
- A credit to a departmental GL account triggers a credit to the general fund's liability-to-departmental-fund account and a debit to the departmental fund's equity-in-cash account.

The net effect of the bill on the GL is that the water fund's EPC has a credit of \$0.80, the hydrant fund's EPC has a debit of \$0.80, the general fund's liability to the water fund has a debit of \$0.80, and the general fund's liability to the

hydrant fund has a credit of \$0.80. Note that, overall, the general fund's overall liability to the departmental funds nets to zero. Refer to [An Example Of A Bill Segment That References Multiple Funds](#) for the resulting consolidated GL entries.

Setting Up The System To Enable Fund Accounting

The following section provides an overview of how to enable fund accounting.

Turn On Fund Accounting

On the [Installation Record](#), indicate that fund accounting is Practiced.

Defining Funds

A fund must be setup for each specific fund in your organization. Don't forget to also set up a fund for the general fund. Navigate using **Admin > Financial > Fund**.

Description of Page

Enter a **Fund** and a **Description** to identify the fund.

If this fund is used to balance other funds or to hold cash, indicate a **Fund Type** of General, otherwise indicate that it is Specific.

If the fund type is Specific, specify the **Equity Distribution Code** and **Liability Distribution Code**. These codes are used to balance financial transactions that span funds. The equity distribution code should belong to the same **Fund** as the one you are defining. The liability distribution code should belong to the general fund.

Distribution Codes Must Include Fund ID

All of your distribution codes must include their respective fund ID.

Fastpath:

For more information, refer to [Setting Up Distribution Codes](#).

Update Your Funds With Their Respective Equity and Liability Distribution Codes

After distribution codes have been setup, you must update your funds to indicate the equity and liability accounts used to balance inter-fund financial transactions.

Bill Taxation Threshold

Some implementations only apply taxes if the accumulated tax amount at the bill level exceeds some specified threshold amount.

Taxation Threshold Examples

The following examples show how taxation thresholds affect a customer's bill. In the examples a tax rate of 5% and a threshold amount of \$21.30 is used.

Example 1 - Account With Taxes Under Threshold

This example shows the bill for an account where the accumulated tax amount is less than the threshold amount. Since the accumulated tax amount of \$10.50 is less than the threshold amount, taxes are not applicable and the account's bill should be adjusted to exclude the tax amount of \$10.50.

| Bill Line | Amount |
|----------------------|--------|
| Standing Charge | 10.00 |
| 2,000 units @ \$0.10 | 200.00 |
| Tax @ 5% on \$210.00 | 10.50 |
| Total | 220.50 |
| Adjusted Total | 210.00 |

Example 2 - Account With Taxes Above Threshold

This example shows the bill for an account where the accumulated tax amount is greater than the threshold amount. Since the accumulated tax amount of \$27.92 is greater than the threshold amount, taxes are applicable and the account should be billed for the total amount.

| Bill Line | Amount |
|----------------------|--------|
| Standing Charge | 10.00 |
| 4,000 units @ \$0.10 | 400.00 |
| Additional Charge | 148.45 |
| Tax @ 5% on \$558.45 | 27.92 |
| Total | 586.37 |

Example 3 - Account With Rounding Discrepancy

This example shows the resulting bill segment calc lines for an account with 3 service agreements. Here the accumulated tax amount at the bill level is \$21.29 with taxes calculated and rounded for each SA's bill segment. However, if the same taxes were calculated for each SA's bill segment and then accumulated and rounded at the bill level, the accumulated tax amount would be \$21.30 implying that taxes are applicable and the account should be billed for the tax amount of \$21.30 accounting for the discrepancy of \$0.01.

| Bill Segment | Bill Line | Amount | Pre-rounding Amount |
|-----------------------|------------------------|--------|---------------------|
| Bill segment for SA 1 | 964.70 units @ \$0.10 | 96.47 | 96.47000 |
| | Tax @ 5% on \$96.70 | 4.82 | 4.82350 |
| | Bill Segment Total | 101.29 | |
| Bill segment for SA 2 | 2222.90 units @ \$0.10 | 222.29 | 222.29000 |
| | Tax @ 5% on \$222.29 | 11.11 | 11.11450 |

| | | | |
|-----------------------|------------------------|--------|-----------|
| | Bill Segment Total | 233.40 | |
| Bill segment for SA 3 | 1072.40 units @ \$0.10 | 107.24 | 107.24000 |
| | Tax @ 5% on \$107.24 | 5.36 | 5.36200 |
| | Tax Discrepancy | 0.01 | |
| | Bill Segment Total | 112.61 | |

**Note:**

Pre-rounding amount. Rate application captures two calculated amounts on the resulting bill segment calc lines. The first is the calculated amount rounded to two decimal places, and the second is a raw calculated amount with a five decimal precision. The base package algorithm that calculates taxation thresholds uses both amounts to account for any rounding discrepancy; however, only the raw calculated amount is used to compare against the taxation threshold.

Billing and Taxation Thresholds

The following sections describe how taxation threshold rules are implemented when a bill is produced.

Calculation of Taxation Thresholds

When taxation thresholds are applied at the account's bill level, it means that the system must calculate taxes for each of the account's service agreements, then sum these tax amounts and apply any applicable rounding rules. This accumulated tax amount is compared to a threshold amount and if the accumulated tax amount is less than the threshold amount, then taxes should not be applied to the customer's bill. To ensure the accumulated tax amount is accurate, all service agreements for an account whose tax amounts should be taken into consideration when comparing to the specified threshold should be billed together and the threshold comparison should take place after the bill segments have been generated. In addition, all bill segments whose tax amounts should be taken into consideration when comparing to the specified threshold must be for the same bill period.

**Note:**

Bill segments from different periods may not appear on the same bill. If a bill segment is canceled, all bill segments associated with that bill must be canceled and re-billed together. You cannot re-bill the bill segment on a bill for a different period.

An algorithm type is supplied with the base package that checks for taxation thresholds at bill completion time. The base bill completion algorithm type accumulates identified tax calc line amounts (accomplished using a bill segment calc line characteristic), and compares this to a specified threshold amount to determine if taxes apply for the account. If taxes do not apply, it sets a bill characteristic indicating this and regenerates the bill segment. Refer to the C1-CPBC-TAXT algorithm type for more information on how this type of algorithm operates.

**Note:**

Calculated adjustments are included in the evaluation against taxation thresholds. Adjustments that use a rate to calculate the adjustment amount may be included in the taxation threshold evaluation if their rate's components are set up to do so. The base algorithm C1-CPBC-TAXT looks at adjustments that are about to be swept onto the bill and, if applicable, includes them in the calculation.

The calculation rule(s) that calculate taxes make use of calculation rule eligibility criteria to ensure that taxes are only computed if the bill does not have the characteristic indicating that taxes are not applicable. Note that during the initial generation of each bill segment, the characteristic will not exist and taxes will be applied. This means that if you look at a bill before it is complete, taxes may not be accurately reflected.

Tax Amount Discrepancies

Since tax calculation rules are calculated and rounded at the bill segment level, it's possible that rounding discrepancies may occur if rounding of these tax amounts occurs at the bill level instead as illustrated in the example above. To account for this, the system uses both the two decimal precision and the five decimal precision calculated amounts that rate application captures on bill segment calc lines; however, only the raw calculated amount is used to compare against the taxation threshold. If there is a discrepancy in the tax amount (as shown in example 3 above), the system captures this amount as an entry in one of the bill segment's SQ collections prior to regenerating the bill segments. This is depicted in example 3 above where the tax discrepancy SQ resulted in an additional bill segment calc line on one of the bill segments for the rounding amount of 0.01. Note that a calculation rule is configured to bill for this discrepancy amount SQL.

Note:

Pre-rounding amount. Rate application captures two calculated amounts on the resulting bill segment calc lines. The first is the calculated amount rounded to two decimal places, and the second is a raw calculated amount with a five decimal precision. The base package algorithm that calculates taxation thresholds uses both amounts to account for any rounding discrepancy; however, only the raw calculated amount is used to compare against the taxation threshold.

Setting Up The System For Bill Taxation Thresholds

This section provides an overview of how to configure the system to calculate taxes at the account's bill level.

Installation Option

Select Freeze at Bill Completion as the bill segment freeze option. The system compares tax amounts calculated to a specified threshold amount and based on this determines if taxes should apply at bill completion time. If taxes should not be applied for the account, the system has to regenerate the bill segments as necessary.

Adjustment Types

Select Freeze at Bill Completion as the adjustment freeze option. The system compares tax amounts calculated to a specified threshold amount and based on this determines if taxes should apply at bill completion time. If taxes should not be applied for the account, the system has to regenerate the adjustments as necessary.

Bill Factors

Tax Threshold. Set up a separate bill factor for each distinct tax threshold amount.

Characteristic Type

Set up a characteristic type and value to identify the tax calculation rules and bill segment calculation lines that the system will use to compare to the specified threshold amount. Specify this characteristic type and value as parameters to the algorithms that apply the taxation threshold. This characteristic type and value must also be specified on each of your tax calculation rules that should be included in the threshold comparison.

Set up a characteristic type and value to use for the bill characteristic that indicates when bill level taxes apply. Specify this characteristic type and value as parameters to the algorithms that apply the taxation threshold.

Service Quantity Identifiers

Optional service quantity identifiers may be configured to capture the following:

- **Tax Amount.** The system compares the accumulated bill's tax amount to the specified threshold amount to determine if taxes are applicable. If taxes should not be applied for the account, the system regenerates the bill segments as necessary. If you wish to capture the tax amount computed for informational purposes, then a tax amount SQI should be set up and specified as a parameter on the algorithms that apply the taxation threshold.
- **Tax Discrepancy Amount.** Since tax calculation rules are calculated and rounded at the bill segment level, it's possible that rounding discrepancies may occur if rounding of these tax amounts should take place at the bill level. If you wish to account for these rounding discrepancies, then a tax discrepancy amount SQI should be set up and specified as a parameter on the algorithms that apply the taxation threshold. Your rates should also be configured to cater for this rounding discrepancy. The system adds an entry for the discrepancy amount to one of the bill segment's SQ collections prior to regenerating the bill segments.

Algorithms

Apply Taxation Threshold. Define an algorithm for each distinct tax threshold amount. Plug the algorithm(s) in on the appropriate customer class for the Pre Bill Completion system event. Refer to the C1-CPBC-TAXT algorithm type for more information about the base package algorithm.

Adjustment Generation - Apply Rate. Define an algorithm for each rate to be used by calculated adjustment types that are to be included in the tax threshold evaluation. Plug the algorithm(s) in on the appropriate adjustment type for the Generate Adjustment system event. Refer to the ADJG-RT algorithm type for more information about the base package algorithm.

Calculation Rules For Bill Taxation Thresholds

Your calculation rules that bill for taxes require the following:

- A characteristic that identifies them as calculation rules to include in taxation threshold comparisons
- Calculation rule eligibility criteria to ensure that taxes are not calculated if the taxation threshold algorithm dictates this

Only one eligibility group on the calculation rule is required. It would look as follows:

| Group No. | Group Description | If Group is True | If Group is False |
|-----------|--|------------------------|-----------------------|
| 1 | Tax applies if total accumulated tax amount at the account's bill level exceeds the threshold amount | Apply calculation rule | Skip calculation rule |

The following criteria will be required for this group:

| Seq | Field to Compare | Comparison Method | If True | If False | If Insufficient Data |
|-----|--|-------------------|----------------|----------------------|----------------------|
| 10 | Bill characteristic: Characteristic type = Tax Not Applicable indicator | = YES | Group is false | Check next condition | Group is true |

| | | | | | |
|----|---|-------|----------------|---------------|---------------|
| 20 | Characteristic Collection: Characteristic type = Tax Not Applicable | = YES | Group is false | Group is true | Group is true |
|----|---|-------|----------------|---------------|---------------|

Note:

The second criterion included above is used to evaluate the applicability of the tax on calculated adjustments. Since these adjustments are not yet linked to the bill, the first criterion cannot be used to evaluate the applicability of the tax threshold. The pre-bill completion algorithm C1-CPBC-TAXT instead adds the characteristic to the characteristic collection for use by the rate application when evaluating the adjustment's rate's eligibility rules. Refer to the ADJG-RT algorithm type for more information about the base package algorithm.

Fastpath:

For more information, refer to [Designing Calculation Groups and Rules](#).

An additional calculation rule is required to bill for the tax rounding discrepancy as follows

- Calculation Rule type = Service Quantity
- UOM/TOU/SQI = the identifier of the service quantity containing the tax discrepancy amount
- Value Type = Unit Rate
- Value Source = Value
- Value = 1

Other Financial Transaction Topics

Various topics about financial transactions are discussed in this section.

The Source Of GL Accounts On Financial Transactions

The following table lists the major financial events, their standard accounting, and the source of distribution codes used to derive the GL accounts sent to your general ledger.

| Financial event | GL Accounting | Source Of Distribution Code |
|--|--|-----------------------------|
| Create a normal utility bill segment. Bill Segment FT Algorithm is Payoff Amt = Bill Amt / Current Amt = Amt Due | Debit: A/R | SA Type |
| | Credit: Revenue / Taxes Payable | Calculation Rule |
| Create a bill for company usage. Bill Segment FT Algorithm is Payoff Amt = 0 / Current Amt = 0 | Debit: Company Usage Expense | SA Type |
| | Credit: Revenue / Taxes Payable | Calculation Rule |
| Create a bill for charity. Bill Segment FT Algorithm is Payoff Amt=0 / Current Amt = Bill Amt | N/A - charity bills have no effect in the GL | N/A |

| | | |
|--|-------------------------|--|
| | N/A | N/A |
| Create a payment segment for a normal utility service agreement | Debit: Cash | Bank Account on the Tender Source of the Tender Control for the Payment Segment's Tender. |
| | Credit: A/R | SA Type |
| Create a payment segment for a charitable contribution service agreement | Debit: Cash | Bank Account on the Tender Source of the Tender Control for the Payment Segment's Tender. |
| | Credit: Charity Payable | SA Type |
| Create a payment segment for auto-pay at bill completion time | Debit: Cash | Bank Account on the Tender Source on the Auto-pay Route Type of the Auto-pay Source. |
| | Credit: A/R | SA Type |
| Canceling a payment | Debit: A/R | SA Type |
| | Credit: Cash | Bank Account specified by the user on the cancel tender page. Note that this defaults to the original tender's bank account. |
| Create an adjustment to levy a charge | Debit: A/R | SA Type |
| | Credit: Revenue | Adjustment Type |

The bottom line is as follows:

- If a bill segment has a financial effect, the distribution code to debit comes from the distribution code on the SA Type, the distribution code to credit comes from the calculation rule(s) used to calculate the bill segment.
- Payment segments always have a financial effect; the distribution code to debit comes from the bank account on the tender source of the tender control of the tender, the distribution code to credit comes from the SA type.
- If an adjustment has a financial effect, the distribution code to debit and credit comes from the SA type and adjustment type. If the adjustment is positive (i.e., the customer owes your organization more money), the distribution code to debit comes from the SA type; the distribution code to credit comes from the adjustment type. Vice versa if the adjustment is negative.

Defining Customer Options

The definition of a customer is someone (or something) with financial obligations with your company. These obligations ensue because the customer has agreed to purchase goods or services at an agreed price.

You may be surprised to learn that there is no "customer" record in the system. Rather, the system subdivides customer information into the following records:

- **Person.** The person record holds demographic information about your customers and every other individual or business with which your company has contact. For example, in addition to customers, person records also exist for landlords, contractors, accountants at corporate customers, guarantors of customers, energy distributors, collection agencies, etc.

- **Account.** Accounts are the entities for which bills are produced and therefore you must create at least one account for every person who has financial obligations with your company. The account record contains information that controls when the bills are created and how the bills are formatted.
- **Service Agreement.** Think of a service agreement as a contract between your company and the customer. The service agreement contains the terms and conditions controlling how the bill details are created. Every account will have at least one service agreement (otherwise, nothing will appear on the account's bills).

Before you can define persons, accounts, and service agreements, you must set up the control tables defined in this section.

**Fastpath:**

For more information about how persons, accounts and premises are used by your customer service reps, refer to [Understanding The "V"](#).

**Note:**

The tables in this section are only some of many tables that must be set up before you can bill your customers for the service(s) they consume. In this section, we limit the discussion to those tables that control basic demographic and financial information. In later sections, we describe the tables that control other billing-related functions like bill creation algorithms, meter reading and rates. It is only after all of these tables are set up that you will be able to generate bills and record payments.

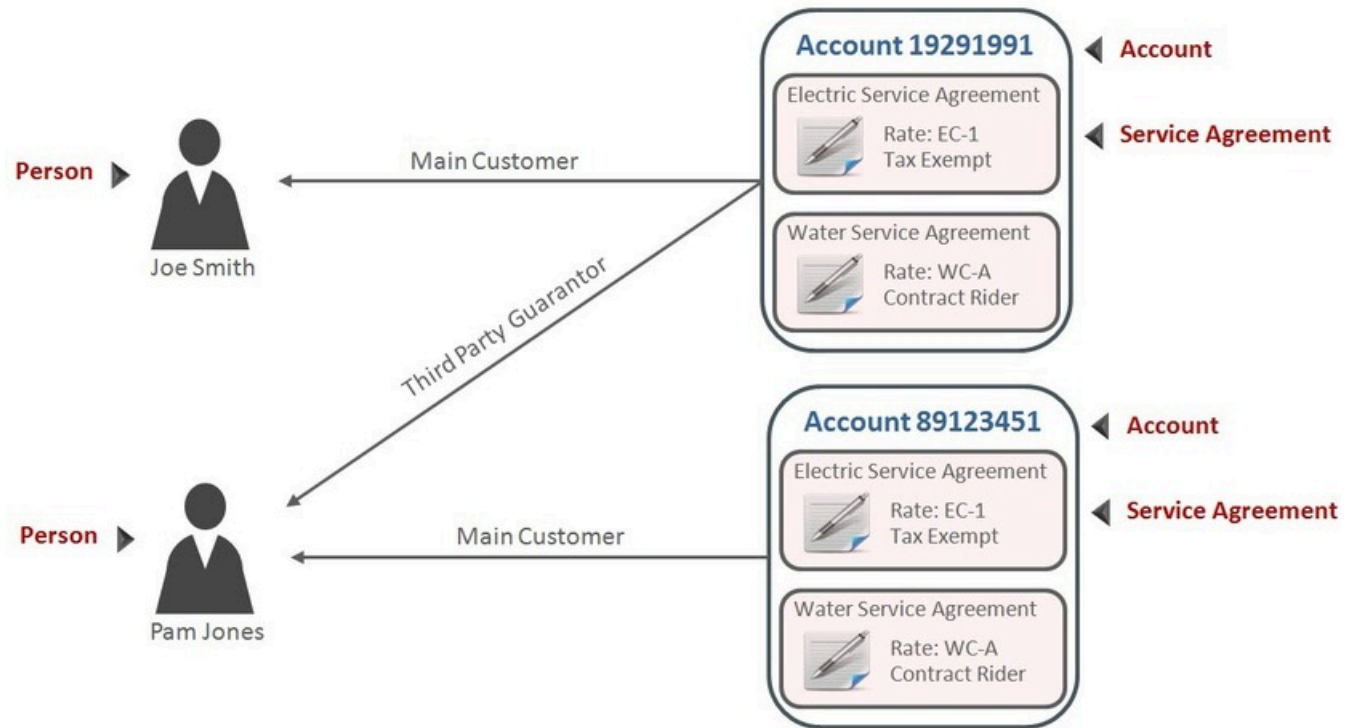

Customer Overview

This section describes how the person, account, and service agreement records are used to record your customers' demographic and billing options.

A Simple Example Of Two Customers

The following picture illustrates two customers: Joe Smith and Pam Jones. Joe is the "main customer" on the first account. Pam is the "main customer" on the second account. Pam is also the "third party guarantor" on Joe's account.

A Simple Example Of Two Customers

Persons

Person records hold demographic information about the individuals and businesses with whom your organization communicates. Demographic information includes phone number(s), names and aliases, identification numbers, life support equipment needs, employment information, etc.

In the above example, 2 person records would be needed; one for Pam Jones and another for Joe Smith.

A new person is added when you first have contact with a person; the person does not have to be a customer before it is added. So, for example, if your company is starting a new marketing campaign, you can add information about potential customers the moment they are identified.

Note:

Businesses are persons too. In addition to humans, you use person records to maintain basic information about the businesses with which your organization has contact.

Fastpath:

For a description of the control tables that must be set up before you can define a person, refer to [Setting Up Person Options](#) .

Accounts

An account is analogous to an account at a bank:

- A person or business with no financial dealings with a bank will have no account (but the bank may choose to keep demographic information about the person as part of their marketing efforts). The exact analogy exists in this system.
- Individuals with financial dealings with a bank will have one or more accounts. The number of accounts is up to the customer. The exact analogy exists in this system.

A simple way to determine the number of accounts a customer will have is to ask "how many bills do they want each period?" because a customer receives one bill for each account. For example:

- A residential customer who also owns a small business may choose to receive two bills each month; one for the residence, the other for the business. This way, the charges for their business would be segregated from their personal charges. This customer would have two accounts.
- A conglomerate that owns several factories may want their transportation gas charges to appear on a single bill rather than have a separate bill for each factory. This customer would have a single account.

Account ID Is Non-Intelligent

The unique number of an account is referred to as the "account ID". You are probably very comfortable with this concept. You may, however, have difficulty dealing with the fact that the account id in this system has no intelligence built into it (e.g., many systems include the bill cycle and geographic location in the account id). In this system, the account ID is a random, system-assigned value.

Because the account ID contains no meaning, it can remain with a customer for life, regardless of where they live, when they are billed, the type of service they receive, etc. This is important because it means that all of the financial history linked to the account remains with the customer for life.

Note:

The non-intelligence of the account ID is also important from the perspective of the parallel processing that takes place when the system creates bills. Because the collection of accounts to be billed in any given bill cycle will be randomly distributed through the number spectrum, the system can distribute account number ranges to parallel threads and each thread will process roughly the same number of accounts.

Account / Person Cross-Reference

A person may be linked to zero or more accounts. A person won't be linked to an account when they have no financial relationship with your organization. A person will be linked to multiple accounts when they have financial relationships with more than one account.

An account must reference at least one person (i.e., the main customer), but may reference an unlimited number of individuals. Multiple persons are linked to an account when several parties have some type of financial relationship with the account (e.g., third party guarantors, account contact, bill copy recipients, etc.).

When Is An Account Created?

A person can exist without an account until such time as the person formally requests the commencement of service. The moment the customer requests service, an account must be created (and the person must be linked to the account).

When Is An Account Expired?

Accounts never expire. Once a customer has an account, the account remains in the system forever. Linked to the account are service agreements that define the price and conditions of a service supplied to the customer. When an account has active service agreements, the system produces bills for it. If the account doesn't have active service agreements, the system will not produce a bill for it. You can think of an account without active service agreements as being "dormant", waiting for the day when the customer again starts service. If the customer never restarts, the account (along with its financial history) remains dormant forever.

Service Agreements

A service agreement is a contract (either formal or implied) between your organization and a customer. Every service agreement contains the price and conditions of a service supplied to a customer.

A service agreement is linked to an account. There is no limit to the number of service agreements that may be linked to an account.

When Is A Service Agreement Created?

A service agreement is created when the customer requests service (not when service commences). Typically, service agreements are created in the pending state and field activities are generated to connect service. When the field activities are complete, the service agreement becomes active and the billing process starts generating bill segments for the service agreement.

Fastpath:

For more information about starting service, refer to [The Big Picture Of Starting Service](#). For more information about bill segments, refer to [Bill Details](#).

Financial Transactions Are Linked To Service Agreements

Fastpath:

For more information about how financial transactions are linked to service agreements, refer to [The Financial Big Picture](#).

When Is A Service Agreement Expired?

A service agreement is expired when the customer requests service be stopped. At that time, the service agreement is transitioned to the pending stop state and field activities are generated to stop service (these activities might involve simply reading the meter or they could involve disconnecting or removing the meter). When the field activities are complete, the system transitions the service agreement to the stopped state and the billing process generates a final bill for the service agreement. When the customer pays the final bill, the system transitions the service agreement to the closed state.

Fastpath:

For more information about stopping service, refer to [The Big Picture Of Stopping Service](#).

Setting Up Person Options

This section describes tables that must be set up before you can define persons.

Person Identifiers

This section describes the setup and use of person identifiers.

Setting Up Person Identifier Types

When you set up a person, you may define the various types of identification associated with the person, e.g., their driver's license number, their tax identity, etc. Every piece of identification associated with a person has an identification type.

**Note:**

How are person identifiers used? The reason why identifiers are defined on a person is so that users can look for a customer using one of their person identifiers (see [Control Central - Search Facilities](#) for more information). In addition, person identifiers help prevent duplicate persons from being added to the database. The base product provides an algorithm type C1-PERSONVAL that can issue a warning or error to a user before they add a new person or update an existing person when another person exists with the same identifier. This is a BO validation algorithm on the person MO's identifying BO.

Person identifier types are optional. An [installation option](#) controls whether at least one identifier type is required on every person.

You can access the portal from **Admin > Customer > Person Identifier Type**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Understanding Person Identifiers

Person Identifiers have many uses in the system. Their main use is to help uniquely identify persons and businesses. Another use is to store other non-uniquely identifying attributes about a person that are better suited to identifiers than they are to person contacts or characteristic. An example is a customer provided password or PIN that is verified before account details are provided.

The installation record defines if and when at least one person identifier is required on persons and businesses. Identifiers can be required when the record is created (always), when linked to an account, when linked to an account as financially responsible, or when linked to an account as the main customer. The system enforces these rules when a person is added or maintained or when persons linked to accounts are maintained. The installation record also defines the default identifier types for person and business records.

When a person identifier is required, the person identifier collection requires that one and only one record is marked as the primary identifier. Identifier types indicate if they can serve as the primary ID and also if they are validated for duplicates. Typically only ID types that should have unique values are configured to validate or duplicates.

Identifier types can be setup to indicate a format such as prefix, delimiter, and value. For example, an identifier for passport can indicate that the country code is the prefix followed by a dash then the passport number. A validation algorithm is provided to ensure all entered data conforms to this format.

Most organizations prefer that the primary identifier is uniquely identifying or a high-quality ID. However, it is not always possible to obtain such an identifier from all customers. The following are two common ways this is handled:

- An identifier type, such as a PIN, is configured and allowed to be the primary identifier, even if it considered a lesser quality or non-uniquely identifying identifier. These types should not be configured to validate for duplicates as their values are not uniquely identifying.
- The desired identifier is used, but a value such as all zeros or all nines is entered, indicating that the customer did not provide the value. In this scenario, the system cannot distinguish between an entry with a quality value and an entry with all zeros since the same ID type is used.

Note: Note: the customer service request-based start service process has configuration that allows your organization to differentiate between identifier types that can be primary and those that represent a high-quality ID. Refer to [Verifying Identity, Checking Credit and Requiring Deposits](#) for more information on how the start service process uses person identifiers.

Setting Up Person Relationship Types

It is possible to associate persons to other person. For example,

- You might want to define the subsidiaries of a parent corporation
- You might want to define spouses as separate persons and then link each person to another person

When you link a person to another person, you must define in what way the person is related to the other person by using a person relationship type code. These codes are defined using **Admin > Person Relationship Type**.

Description of Page

Enter the following for each relationship type:

- Enter an easily recognizable **Relationship Type** code.
- Use **Description (Person1=>Person2)** to describe how the first person is related to the second person.
- Use **Description (Person2=>Person1)** to describe how the second person is related to the first person.

Note:

Person1 versus Person 2. When you link persons together, you do it in respect of one of the persons (which we call Person 1). For example, if you want to link the subsidiaries to a parent company, you do this in respect of the parent company (i.e., you define the parent company's subsidiaries using the [Person - Persons](#) transaction).

Setting Up Contact Routings

Base values for Contact Routing are supplied. You can add your specific contact routings using the **Contact Routing** extendable lookup. You can add more contact routings, but the ones supplied with the system cannot be edited or deleted.

Note: Person contacts that reference the CSS routing type cannot be added by a user, and are not permitted to be edited or deleted. As well, records with this contact routing are only visible in the Person - Main page and are not displayed in the Account Portal or other places in the system.

Refer to [Defining Extendable Lookups](#) and for more information on lookups.

If your implementation is using notification preferences, you may need to set up delivery types before setting up contact routings. Refer to [Setting Up Delivery Types](#) on page 713 for more information.

Setting Up Person Contact Status

Person contacts can have a status; for example, the status of an email contact could be pending, verified, or bounced. The product is delivered with statuses that are used in conjunction with opt-in functionality. When new person contacts are added, the initial status can be defaulted from the person contact type. See [The Person Contact Status Can Be Controlled By A Process](#), *System Person Contact Statuses* and *Opt-in Process* sections for more information.

Your implementation may choose to introduce other logic to update the status. See [The Person Contact Status Can Be Controlled By A Process](#) for more information. You can add your specific person contact statuses by updating the value for the CND_VERIF_STATUS_FLG lookup field.

When new person contacts are added, the initial status can be defaulted from the person contact type. Refer to the Person Contact zone's help text for more information.

Setting Up Person Contact Type Algorithms

Format Validation

Person contact information can be subject to format validation such as ensuring a phone number is entered in a particular format.

The base product provides the algorithms C1-VALEMFMT (Validate Email Format), C1-VALPHFMT (Validate Phone Format), and C1-VALANYFMT (Any Format Valid), which your implementation may use (and if so, no further configuration is needed). If your implementation's business rules require additional format validation algorithms, you may introduce your own.

Note: These algorithms confirm that a specific format exists and do not reformat or apply formatting to the corresponding field; for example, the *C1-VALEMFMT* (Validate Email Format) algorithm confirms that the email address contains required features (such as an @ symbol and domain). It will not, however, insert these features.

If your implementation's business rules require additional format validation algorithms, you may introduce your own.

Setting Up Person Contact Types

Person contact types define the format for entering person contacts and information about the person contact.

To set up contact types, select **Admin > Customer > Person Contact Type > Add**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Choosing to Use Person Contact or Person Phone

Person contact is an updated and more configurable alternative to person phone and email. In this release, a feature is introduced that some system processes use to determine if person contact or person phone and email is being used. Person phone and email are referred to as legacy behavior. Legacy behavior is enabled when the Legacy Person Phone and Email **Option Type** on the Customer Information Options is set to Y. When set to N or not set legacy behavior is not enabled.

If your implementation uses functionality that has not been updated to use the feature, such as campaigns and order, you may wish to enable legacy behavior and continue to use person phone and email. It is important to note that Person Contacts are required for notifications.

The following system processes have been updated to alter functionality based on whether legacy behavior is enabled or not.

| System Process | Behavior When Feature is Not Set | Behavior When Feature is Set |
|---------------------|---|--|
| Person | The Person Phone Grid and the Person Email field are not shown | The Person Phone Grid and the Person Email field are shown. Person Contact is always shown. |
| Person | The functionality to maintain person contacts from person phone is not triggered even when a person contact type is associated with a phone type. | The functionality to maintain person contacts from person phone is enabled. |
| Account/ Person | When an email or fax bill or quote route type is chosen, then information displayed is related to person contacts. | When an email or fax bill or quote route type is chosen, then information displayed is related to person phone or email. |
| Start/Stop | The Person Contact collection is shown and can be edited. | The Person Phone collection and Person Email are shown and can be edited. |
| Case | The Preferred Contact Methods associated with legacy person phone and email are not shown. | The Preferred Contact Methods associated with legacy person phone and email are available. Person Contact is always available. |
| Customer Contact | The Preferred Contact Methods associated with legacy person phone and email are not shown. | The Preferred Contact Methods associated with legacy person phone and email are available. Person Contact is always available. |

Person Contact Status Can Be Controlled By A Process

Overview

Person contact types can be configured to allow a status. For some person contact types, your implementation may want to control the status through a process instead of allowing the status to be set manually. An example of this is using person contact status to capture opting in for receiving text messages, which is required in some jurisdictions. Opt-in is seeking permission from a customer to use a person contact for a purpose such as sending a customer text messages.

Opt-in works in conjunction with the functionality to enable opt-in for a delivery type. Each can function independently, but together they offer a complete solution. Since they can function apart from each other, each is described independently. See [Enabling Opt-in for a Delivery Type](#) for more detail on this logic.

To control a person contact status with a process, the person contact type must first be configured to allow status. The person contact type must then be set up in the opt-in section of the **Notification Preferences master configuration**. By defining a Status Script, the person contact status can only be changed by the logic contained in or initiated from the script. The product is delivered with a script that creates an opt-in service task. This is designed specifically to support opting in to receiving notifications via text messages (SMS).

Opt-In Process

To use the delivered functionality, configure a new service task type for opt-in. This task type should reference the Notification Preference Opt-In Task Type Business Object (C1-NotifPrefOptInTaskType). The product is delivered with a service task business object. The service task is responsible for initiating an opt-in request, updating the person contact status, and logging the user response. An inbound web service receives responses and transitions the service task. These components are designed to integrate with Notification Center. When a customer is sent an opt-in request, they are asked to confirm. The content of the message explains the commands to the user. Examples are CONFIRM or STOP. Notification Center is configured to interpret the specific commands and map them to those expected by the inbound service, which transitions the service task appropriately.

Aside from the initial opt-in request, users can stop or unsubscribe from notifications at any time. The delivered solution supports two modes for this functionality: unsubscribing from all notifications for a particular person contact or unsubscribing from a specific notification type for a particular person contact. This is controlled through configuration, and relies on the external system such as Notification Center to determine the notification type.

The **Notification Preferences master configuration** help text contains detailed information about the configuration required to control person contact status and setting up opt-in processes.

It is important to note that while the delivered process to control person contact status was designed to work in conjunction with the opt-in process, your implementation can design a custom process that can create a service task or do something completely different. Also, it can be independent of opt-in and notifications. For example, the process can be used to verify that an email address is valid by sending the customer a verification request.

There is another concept, which is enabling opt-in for a delivery type. This is closely related to the functionality described here, but has different implications in the system. See [Enabling Opt-in for a Delivery Type](#) for more information.

There is a limitation worth noting. A person contact type may be set up to allow multiple delivery types, however the delivered solution only allows a single delivery type to be associated with the process used to automate person contact status. Without this limitation, different processes would be responsible for updating a single person contact status and those updates could be conflicting.

The System Person Contact Statuses

The opt-in solution delivered with the product utilizes the three delivered status values. They are: **Pending**, **Approved**, and **Rejected**. Your implementation can add your own person contact statuses, but they will not work with the solution delivered with the product. See [Setting Up Person Contact Status](#).

How the System Automates Person Contact Status

There are many ways that the process that controls person contact status can be invoked. For all of these, the person contact type must be set up in the **Notification Preferences master configuration** to have its status controlled by a process and, unless noted otherwise, the person contact is not already *Approved*.

- The primary way to initiate the process to control person contact status is when a person contact is used to add a contact preference and the contact preference's delivery type matches the delivery type associated with the person contact type as defined in the Notification Preferences master configuration. This method relies on enabling opt-in for a delivery type. This is how the two processes work with each other. See [Enabling Opt-in for a Delivery Type](#) for more information. An example of this scenario is that a person contact exists and is of a type that can

receive text messages, such as “Mobile Phone”. Until the person contact is used on a contact preference to receive a notification, there is no reason to initiate an opt-in process.

- This process can be automatically initiated by configuring a person contact to default to an initial status of **Pending**. When a person contact is added, the process is initiated. An example of this scenario is an email person contact initiating a process to verify the email address as soon as it is added to the system.
- When the value of an approved person contact is changed, the process is reinitiated. For example, even though the approval is attached to a specific person contact in the system, which has a unique ID, externally the approval was for a particular phone number or email address. When the person contact value (i.e. the phone number or email address) is changed, the prior approval is no longer valid. The person contact status is changed to **Pending**.

A user can manually initiate the process. A button is provided on the Person Contact row on Person - Main. The button can be used to reinitiate the process when the customer does not have the request and needs it resent. It can also be used to manually initiate the process upfront - before the person contact is used on a contact preference.

Maintaining Person Contact via Person Phone

Person phone is referenced extensively throughout the system. All system processes have been updated to determine if phone data and email data is being maintained on person contacts or being maintained on person phone and email. See [Choosing to Use Person Contact or Person Phone](#) for more information.

To keep person contacts records in sync with a person phone, you should consider which phone types should be stored as contacts, configure the person contact type corresponding to each phone type, and update the person contact type to reference the corresponding phone type. Many phone types may be associated with a single person contact type, but a single phone type may only be associated with one person contact type.

The base product provides a batch process C1-INPUS (Create Person Contact from Person Phone/Email) that creates a person contact for all person phone records whose phone type is associated with a person contact type. The batch process can also create person contact records for the email address on the person. You would run this process to create person contact records if you already have phone or email data for persons, and you wanted to start leveraging person contact as the repository for phone and email information. See the batch process description for more information.

Note:

There is a primary switch on person contact records; one person contact for each unique contact routing must be set as the primary contact. When the batch process creates person contacts from person phone data, the first person contact added for each unique contact routing is set as primary. This can be controlled to some extent by your implementation by associating phone types with person contact types sequentially and running the batch process multiple times. For example, you may prefer that a home phone be the primary over a cell phone if both exist. To ensure this happens, associate the home phone with a person contact type and run the batch process. Then associate the cell phone with a person contact type and run the batch process again. This will force all home phone records to be processed first. It is recommended that regardless of how many times the batch processes run, they are run back to back. This should be thought of as a conversion of data and should be treated as such.

When a phone type is associated with a person contact type the following occurs:

- When a phone record is added, a corresponding person contact is added if one does not already exist.
- When a phone record is updated, corresponding updates are made to the person contact.
- When a phone record is deleted, the system tries to delete the corresponding person contact. All business rules for person contacts are enforced. If the person contact is associated with a contact preference, the person contact cannot be deleted, and in turn the phone record cannot be deleted.
- Person contacts associated with phone types cannot be deleted directly. The delete function is disabled.
- Contact information on person contacts associated with phone types cannot be updated directly. The contact information and extension are disabled.
- Person contacts whose person contact type is associated with a phone type cannot be added from the account contact information zone in the account portal. These need to be added through person phone.

There is no direct association between a person phone record and person contact (i.e. there are no foreign keys on either record pointing to the other). The system uses the association between phone type and person contact type and the specific phone number in order to find the associated person contact.

Your implementation may decide to use person contacts to store phone data and not associate them with phone types. Functionality related to the system use of person phone will not be available such as updating a phone number through an order.

If your implementation associates phone types with person contact types and wishes to remove this association, it is best to remove all phone types from all person contact types.

Warning: Making changes to the association of phone type to person contact type can have serious implications for your data. Changing the person contact type associated to a phone type will likely result in difficulty maintaining both person phone and person contact data.

Setting Up Statement Construct Options

This section describes tables that must be set up before a statement construct can be set up for a person to begin receiving financial statements.

Fastpath:

For more information, refer to [The Big Picture of Complex Statements](#).

Setting Up Statement Route Types

Statement route types define the method used to route statements to persons. To define a statement route type, open **Admin > Billing > Statement Route Type**.

Description of Page

Enter a unique **Statement Route Type**, **Description** and **Statement Routing Method** for every statement route type.

Note:

The values for Statement Routing Method are customizable using the Lookup table. This field name is STM_RTG_METH_FLG.

The next two fields control how statements that are routed using this route type are printed (both in batch and online). Refer to [Technical Implementation Of Batch Statement Production](#) for more information about producing statements in batch. Refer to [Technical Implementation Of Online Statement Production](#) for more information about online statement production.

- Use **Batch Control** to define the process that creates the flat file that is passed to your statement printing software. If you use an **Extract Algorithm** to construct the downloaded information, you can use the STMDWLD process.
- Use **Extract Algorithm** to define the plug-in component that constructs the "flat file records" that contain the information to be merged onto statements routed using this route type. This algorithm is called when a user requests an online image of a statement on [Statement - Main](#) and it may also be called by the batch statement extraction process defined above.

Setting Up Account Options

This section describes tables that must be set up before an account can receive a bill.

Setting Up Account Management Groups

Users are informed that something requires their attention by entries that appear in To Do lists. For example, consider what happens when billing can't find a reading (and it's not allowed to estimate):

- The billing process creates a bill segment that is in error - meter read cannot be found.
- This error bill segment, in turn, triggers the creation of a To Do entry.
- The To Do entry is addressed to a role. A role is one or more users who can "action" the To Do entry.
- When a user views their To Do entries, they see all entries addressed to all roles of which they are part.

You can optionally use account management groups (AMG) to define the respective role to be assigned to To Do entries that are associated with an account and a given To Do type. For example, you can create an AMG called Credit Risks and assign this to accounts with suspect credit. Then, whenever an account-oriented To Do entry is created for such an account, it will be assigned a role based on the Credit Risks AMG. Refer to [Assigning A To Do Role](#) for more information..

Note:

Account management groups are optional. You need only set up account management groups (and link them to accounts) if you wish to address specific To Do entries associated with specific accounts to specific roles.

Account management groups are defined using **Admin > Customer > Account Management Group > Add.**

Description of Page

Enter an easily recognizable **Account Management Group** code and **Description** for each account management group. Use the grid to define the **To Do Role** to be assigned to entries of a given **To Do Type** that are associated with accounts that reference the **Account Management Group**.

Note:

Only To Do entries that are account-oriented take advantage of the roles defined for an account management group (because only accounts reference an account management group).

Setting Up Account Relationship Codes

When you link a person to an account, you must define in what way the person is related to the account by using an account relationship code. These codes are defined using **Admin > General > Account Relationship Type.**

Description of Page

Enter an easily recognizable **Relationship Type** and **Description** for each relationship type.

Setting Up Alert Types

Account based alerts that appear in control central have an **Alert Type**. To define valid alert types, navigate to **Admin > Customer > Alert Type.**

Description of Page

Enter an easily recognizable **Alert Type Code** and **Description** for each alert type. Specify the **Alert Days** to indicate the amount of time that alerts of this type will be effective by default. Specify a value of zero to indicate that alerts of this type will be effective indefinitely by default.

Setting Up Bill Messages

There are various informational and warning messages that may appear on an account's bills. Each message is identified with a bill message code. To define a bill message, open **Admin > Billing > Bill Message > Add.**

Description of Page

Enter a unique **Bill Message** and **Description** for every bill message.

The following attributes control how and where the bill message appears on the customer's bill:

Priority controls the order in which the message appears when multiple messages appear on a bill.

**Note:**

The values for this field are customizable using the Lookup table. This field name is MSG_PRIORITY_FLG.

Insert Code controls whether a document should be inserted into the bill envelope when the bill message appears on a bill.

Message on Bill is the actual verbiage that appears on the customer's bill. If the message text is not static (e.g., field values need to be substituted into the body of the message), you can use the % *n* notation within the **Message on Bill** to cause field values to be substituted into a message. Refer to [Substituting Field Values Into A Bill Message](#) for more information.

Setting Up Bill Route Types

Bill route types define the method used to route bills to accounts. To define a bill route type, open **Admin > Billing > Bill Route Type**.

Description of Page

Enter a unique **Bill Route Type** and **Description** for every bill route type.

Bill Routing Method controls the type of information that may be defined when the respective **Bill Route Type** is selected on [Account - Person Information](#). The following options are available:

- **Postal:** Use this method if the routing is via the postal service.
- **Fax:** Use this method if the routing is via fax.
- **Email:** Use this method if the routing is via email.

**Note:**

The values for **Bill Routing Method** are customizable using the [Lookup](#) table. This field name is BILL_RTG_METH_FLG.

The next two fields control how bills that are routed using this method are [printed](#) (both in batch and online).

- Use **Batch Control** to define the background process that performs the actual download of the billing information. Refer to [Technical Implementation of Printing Bills In Batch](#) for more information about these processes.
- Use **Extract Algorithm** to define the algorithm that constructs the records that contain the information that appears on a printed bill. Refer to [Printing Bills](#) for more information.

Setting Up Bill Cycles

**Fastpath:**

Refer to [Defining Bill and Service Cycles](#) on page 880 for a description of how to set up bill cycles.

Setting Up Customer Classes

When you set up an account, you must assign it a customer class. The topics in this section describe the customer class control table.

Customer Class - Main

To set up customer classes, navigate to **Admin > Customer > Customer Class > Add** and use the **Main page** to define your Customer Class.

Description of Page

Enter a unique **Customer Class** code and **Description** for every customer class.

Use **Collection Class** to define the collection class that defaults onto new accounts that belong to this customer class. An account's collection class may be subsequently modified if the account has special collection problems or needs.

Fastpath:

For more information about the significance of collection class, refer to [Designing Your Collection Classes](#).

Turn on **Business Activity Required** if service agreements linked to accounts with this customer class require a Business Activity description to be entered.

Turn on **Open Item Accounting** if accounts belonging to this customer class are subject to open-item account. Refer to [Open Item Accounting](#) for a complete explanation of the significance of this switch.

Turn on **Non CIS Payment** if accounts belonging to this customer class are used for payments made to reduce non-CIS debt. For example, assume your company accepts payments for a county assessor and you don't want to set up a separate account for each person who pays their assessment bill. You should set up the following information to accept such payments:

- Create a new customer class called "Non CIS Customer".
- Create a SA type for each type of non-CIS payment that customers can make. Make sure to enter a distribution code on each SA type that references the appropriate revenue (or payable) account. Don't forget to indicate that each SA type is not billed.

Note:

Payment Templates can be used for common types of non-CIS payment allocations. These templates are used to default the payment distribution and allow non-CIS payments to be directly allocated to specific distribution codes.

Fastpath:

For more information about using Payment Templates to process non-CIS payments, refer to [Non-CIS Payments](#).

- Create an account to which you'll book such payments. Have this account reference the new customer class. We recommend creating a separate account for each SA type that you created in the previous step.
- Create and activate a service agreement for the new account(s).

When someone pays for non-CIS debt, the operator will add a payment for the above account. On the payment, the operator should record reference information in order to know exactly why the payment was made. Refer to [Payment Event - Main](#) for more information.

You must define a variety of business rules for every division in which a customer class has customers. For example, if you operate in both California and Nevada AND you have CIS divisions for each state AND you have residential customers in each state, you must define **Customer Class Controls** for each CIS division. You do this on the [Customer Class - Controls](#) page. The grid that follows simply shows the CIS divisions for which business rules have been set up.

Customer Class - Bill Messages

When a customer class has bill messages, the system will sweep these messages onto bills created for accounts belonging to the customer class. Use this page to define a customer class's bill messages. Navigate to **Admin > Customer > Customer Class > Search** and then navigate to the **Bill Messages** page to maintain this information.

Description of Page

Use the bill messages collection to define **Bill Message** codes that should appear on bills that created for accounts that belong to a given customer class. For each message, also specify the **Start Date** and **End Date** when such a message should appear on the bill (leave **End Date** blank if the message should appear indefinitely).

Where Used

The system snaps customer class bill messages on a bill during bill completion. For more information about bill messages, refer to [The Source Of Bill Messages](#).

Customer Class - Controls

You must define a variety of business rules for every division in which a customer class has customers. For example, if you operate in both California and Nevada AND you have CIS divisions for each state AND you have residential customers in each state, you must define **Customer Class Controls** for each CIS division in respect of the residential customer class. Open **Admin > Customer > Customer Class > Search** and then navigate to the **Controls** page to maintain this information.

Description of Page

The **Customer Class Controls** scroll contains business rules governing accounts that belong to a **CIS Division** and **Customer Class**. The following fields should be defined for each **CIS Division**:

- Use **Days Till Bill Due** to define the number of days after the bill date that the customer's bill is due. If the due date is a weekend or company holiday, the system will move the due date forward to the next workday (using the workday calendar defined on the account's CIS division).
- Specify the **Budget Plan** that defaults onto new accounts belonging to this customer class. Please note that an account's budget plan may be subsequently modified if the account has special budget processing needs. Refer to [Setting Up Budget Plans](#) for more information.
- Use **Min Credit Review Freq (Days)** to define the maximum number of days that can elapse between the reviews of an account's debt by the [account debt monitor](#). Note, a value of zero (0) means that accounts in this customer class will be reviewed every day.
- Use **Credit Review Grace Days** to define the number of days after the bill due date that an account should be reviewed by the [account debt monitor](#).
- Turn on the **Late Payment Charge** if customers in the class / division combination are eligible for late payment charges.
- Use **LPC Grace Days** to define the number of days after a bill's due date that a late payment charge will be generated (if the various LPC algorithms allow such - refer to [How Late Payment Charges Get Calculated](#) for the details). If the grace date falls on a weekend or holiday, the system moves the grace date to the next available workday (using the workday calendar defined on the account's CIS division).
- Specify an **Access Group** to default an access group onto an account based on the account's CIS Division and customer class. This will override the access group defaulted from the user's default access group. Note: the access group defined here will not apply if a Customer Class Control - Determine Access Group algorithm is defined and successfully returns an access group.

The grid that follows contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

Warning:

These algorithms are typically significant system processes. The absence of an algorithm may prevent the system from operating correctly.

You can define algorithms for the following **System Events**:

| System Event | Optional / Required | Description |
|--------------|---------------------|-------------|
|--------------|---------------------|-------------|

Auto Pay Amount Over Limit

Optional

This algorithm is called to handle the situation when a system-initiated [automatic payment](#) is created that exceeds the customer's [maximum withdrawal limit](#). Specifically, this algorithm is called when:

- The account has a maximum withdrawal limit on their [automatic payment options](#)
- The system attempts to create an automatic payment that exceeds this amount
- The automatic payment algorithm that's plugged into the [installation record](#) has logic that invokes this algorithm when the above conditions are true

If you do not plug-in this type of algorithm and the above situation is detected, the automatic payment will be created and no error will be issued.

Refer to [How To Implement Maximum Withdrawal Limits](#) for more information.

Bill Completion

Optional

When a bill for an account is completed, bill completion algorithms are called to do additional work.

Refer to the description of the Complete button under [Bill Lifecycle](#) for a description of when this algorithm is called during the completion process.

Bill Eligibility

Optional

Algorithms for this plug-in spot are called when generating a bill in batch billing. It provides the ability to determine if an account is ineligible for billing and should therefore be skipped from further processing.

If an eligibility algorithm is not used, a bill is created for any account in the open bill cycle and is later deleted by the billing process if it detects that there is no information linked to the bill.

| | | |
|----------------------------|----------|--|
| Bill Segment Freeze/Cancel | Optional | <p>When a bill segment for an account in this customer class / division is frozen or canceled, an algorithm of this type may be called to do additional work.</p> <p>Refer to Bill Segment Lifecycle for more information about freezing and canceling bill segments.</p> |
| Cancel Bill | Optional | <p>This algorithm provides the ability to include additional cancel logic when canceling online.</p> <p>Algorithms of this type can be called in two modes: D (Determine Bill Page Buttons) and X (Cancel Bill). Mode 'D' governs whether an action button to cancel the bill will appear on the Bill page and mode 'X' performs the actual cancellation logic.</p> |
| Determine Access Group | Optional | <p>When an account is added or an account's CIS Division or customer class is changed, this plug-in spot can be used to determine the appropriate access group. This plug-in spot allows more complex logic to be defined, such as checking the access group on the main person's others account's.</p> <p>If a determine access group is not used, the access group can be defaulted from the customer class control or the user.</p> |
| FT Freeze | Optional | <p>When an FT is frozen, this algorithm is called to do additional work.</p> <p>For example, if you practice Open Item Accounting, you will need such an algorithm to handle the cancellation of match events when a financial transaction is canceled that appears on a match event. Refer to How Are Match Events Cancelled? for more information about cancellation.</p> |

LPC Eligibility

Required if the customer class / division is eligible for late payment charges

This algorithm is called by the late payment process to determine eligibility for late payments.

Just because an account's customer class allows late payment charges to be calculated doesn't mean the account's delinquent service agreements will be levied late payment charges. In addition, a delinquent service agreement's SA type must reference a late payment charge algorithm. Refer to [SA Type - Main](#) for more information about SA type late payment charge issues. Refer to [How Late Payment Charges Get Calculated](#) for more information about late payment charges in general.

**Note:**

Only One Algorithm. Only one late payment charge eligibility algorithm may be defined for a customer class / CIS division combination.

Levy NSF Charge

Optional

This algorithm is called when a payment is canceled with a cancellation reason that indicates an NSF.

Refer to [NSF Cancellations](#) for more information about what happens when a payment is canceled due to non-sufficient funds.

**Note:**

Only One Algorithm. Only one algorithm to levy an NSF charge may be defined for a customer class / CIS division combination.

Order Completion

Optional

When an [order](#) is completed for a customer linked to this customer class, this algorithm is called to do additional work (e.g., create a customer contact). You need only specify this type of algorithm if you require additional work to be performed when an order is completed for customers who belong to this customer class.

| | | |
|--------------------------|----------|---|
| Overpayment Distribution | Required | <p>When a customer pays more than they owe, this algorithm is called to determine what to do with the excess funds. Refer to Overpayment Segmentation for a description on how to configure the system to handle your overpayment requirements.</p> <p> Note: Only One Algorithm. Only one overpayment distribution algorithm may be defined for a customer class / CIS division combination.</p> |
| Override Due Date | Optional | <p>An account's bill due date will be equal to the bill date plus its customer class' Days Till Due. If you need to override this method for accounts in a specific customer class, specify the appropriate algorithm here.</p> <p> Note: Only One Algorithm. Only one due date override algorithm may be defined for a customer class / CIS division combination.</p> |
| Payment Cancellation | Optional | <p>Algorithms of this type are called when a payment is canceled.</p> |
| Payment Distribution | Required | <p>This algorithm is called to distribute a payment amongst an account's service agreements. Refer to Payment Distribution for more information about how payment distribution works.</p> <p> Note: Only One Algorithm. Only one payment distribution algorithm may be defined for a customer class / CIS division combination.</p> |

Payment Freeze

Optional

When a payment is frozen, this algorithm is called to do additional work. If you practice [Open Item Accounting](#), you will need such an algorithm to link the payment's financial transactions to the match event that was originally created when the payment was distributed. Refer to [Payments and Match Events](#) for more information.

Post Bill Completion

Optional

When a customer class has algorithms of this type, they are called after the completion of a bill for an account linked to this customer class.

Refer to the description of the Complete button under [Bill Lifecycle](#) for a description of when this algorithm is called during the completion process.

Pre Bill Completion

Optional

When a customer class has algorithms of this type, they are called immediately before completion starts for an account linked to this customer class. These algorithms have the potential of:

- Deleting a bill. You might want a pre completion algorithm to delete a bill if a condition is detected that should inhibit the sending of a bill to a customer (e.g., the bill just contains information about recent payments).
- Aborting the completion process and creating a bill exception. If the algorithm indicates this should be done, the bill is left in the pending state and a bill exception is created describing why completion was aborted. You might want a pre completion algorithm to do this if, for example, integrity checks detect there is something wrong with the account or its service agreements. If the integrity check fails, the bill can be left in the pending state and a bill exception created describing why.

Refer to the description of the Complete button under [Bill Lifecycle](#) for a description of when this algorithm is called during the completion process.

Quote Completion

Optional

When a *quote* is completed for a customer linked to this customer class, this algorithm is called to do additional work (e.g., create a customer contact). You need only specify this type of algorithm if you require additional work to be performed when a quote is completed for customers who belong to this customer class.

Write Off Method

Required if you allow users to write-off debt real time using the [write off transaction](#)

When a user presses the create button on the [write off transaction](#), this algorithm is executed to write-off the selected debt. Refer to [The Ramifications of Write Offs in the General Ledger](#) for more information.

Setting Up Collection Classes

Fastpath:

Refer to [Setting Up Collection Classes](#) for a description of how to set up collection classes.

Setting Up Customer Information Options

When you add a new person, the system is set up by default to add an account for the person and go to the Start Service page when you save the new person information. You can change this functionality by configuring the following option types on the Customer Information Options feature configuration:

- **Add Account and Start Service Default:** Indicates whether the Add Account and Start Service option is selected on the person page, by default. If this option is not configured, the Add Account and Start Service option is selected by default.
- **Post Add Person BPA Script:** Indicates a BPA script to invoke when a user successfully adds or changes a person on the person page.

When you use control central to search for accounts, the system limits your search results based on your access rights. You can change this functionality by configuring the following option type.

- **Search All Accounts:** Indicates whether a Control Central search should allow a user to search all accounts without validating the user's access rights. If the user tries to select an account without having the required access, they will not be able to navigate to the Account Information tab on Control Central for the selected account.

For more information about Feature Configurations, see [Defining Feature Configurations](#).

Setting Up Customer Contact Options

This section describes tables that must be set up before you can define customer contacts.

Fastpath:

Refer to [The Big Picture Of Customer Contacts](#) for more information about customer contacts.

Setting Up Customer Contact Classes

Every customer contact record has a contact type that classifies the record for reporting purposes. And every contact type, in turn, references a customer contact "class". The class categorizes customer contacts into larger groupings for reporting purposes.

Open **Admin > Customer > Customer Contact Class** to define your customer contact classes.

Description of Page

Enter a unique **Contact Class** and **Description** for each customer contact class.

After you have created your customer contact classes, you'll be ready to setup your [customer contact types](#).

Setting Up Customer Contact Types

Every customer contact record has a contact type that controls the behavior of the customer contact.

Fastpath:

Refer to [The Big Picture Of Customer Contacts](#) for more information about customer contacts.

Open **Admin > Customer > Customer Contact Type > Add** to define your customer contact types.

Description of Page

Every customer contact type is identified by a unique combination of **Contact Class** and **Contact Type**.

Enter a brief **Description** of the customer contact type.

Only specify a **Contact Shorthand** if customer contacts of this type can be added in the [Customer Contact Zone](#). The value you specify in this field is what the user selects to add a customer contact in this zone.

If your implementation requires restricting customer contact types by CIS Division, specify a **CIS Division** on the customer contact type.

Person Usage controls the applicability of a person on customer contacts of this type. Select **Required** if a person must be defined on this type of customer contact. Select **Optional** if a person can optionally be defined on this type of customer contact. Select **Not Allowed** if a person is not allowed on this type of customer contact.

Account Usage controls the applicability of an account on customer contacts of this type. Select **Required** if an account must be defined on this type of customer contact. Select **Optional** if an account can optionally be defined on this type of customer contact. Select **Not Allowed** if an account is not allowed on this type of customer contact.

Premise Usage controls the applicability of a premise on customer contacts of this type. Select **Required** if a premise must be defined on this type of customer contact. Select **Optional** if a premise can optionally be defined on this type of customer contact. Select **Not Allowed** if a premise is not allowed on this type of customer contact.

Note:

Person usage and premise usage cannot both be set to not allowed, as the customer contact must at least one of them. Account usage is dependent on person usage.

Entity Relationship controls the validation of relationships on customer contacts of this type. *All* ensures that the account belongs to the person and that the account and premise are related. *Person and Account Only* disables the account and premise validation. *Premise and Account Only* disables the person and account validation. *None* disables all validation and allows any values. This setting only impacts the validation of values entered and works in conjunction with the three usage fields described above.

Use **Contact Action** if something should be triggered when customer contacts of this type are added or if the contact has a special use. When set to *Send Letter*, you must also specify a **Letter Template**. Refer to [Printing Letters](#) for more information about how letters are produced. Set to *Record Notification* if this contact type is used on template-based notification types as a record of the communication.

The **Business Object** defined here controls how customer contacts of this type are show on the customer contact portal. The system is delivered with three customer contact business objects. The value is defaulted based on the contact action.

Note: Unlike many objects, the customer contact business object is not stored directly on the customer contact. The system obtains it from the type and uses it to control how the customer contact is displayed, such as which fields are shown. It does not impact the behavior of the customer contact.

Set the **Custom Archive Eligibility Criteria** flag to *Applicable* if customer contacts of this type require additional custom eligibility criteria checks when being evaluated for archiving.

Note: The base product provides an ILM Eligibility algorithm for Customer Contact (C1-CCILMELIG) that marks a customer contact as eligible for archiving based on the customer contact's age and the state of the related person's information. This algorithm will not mark the customer contact as eligible for archive if the customer contact type's Custom Archive Eligibility Criteria flag is *Applicable*. Your implementation is responsible for providing the additional criteria checks for customer contact types that require custom eligibility criteria.

Use the **Customer Contact Type Characteristics** collection to define characteristics that can be defined for contacts of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on customer contacts of a given type. Turn on the **Default** switch to default the **Characteristic Type** when customer contacts of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Setting Up Notification Preference Options

The topics in this section provide background information about notification preferences.

Notification Preferences Overview

The Notification Preferences functionality is comprised of two main components: sending messages out of the system and maintaining customers' communication preferences for receiving these messages.

Notifications are created by an algorithm plugged into the Create Notification plug-in spot on the Notification Type (BO). The base product provides the C1-CRE-NTF algorithm, which creates the notification via an outbound message.

The following sections describe specific notification preference concepts and how to configure the system to use notification preferences.

Setting Up Notification Event Types

This portal is used to display and maintain a Notification Event Type.

Notification Event Types are system events used to send communications or notifications to customers.

You can access the portal from **Admin > Customer > Notification Event Type**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Template-Based vs. Message-Based Notification Types

The application supports two different notification formats: template-based and message-based. For message-based notifications, the outbound message contains the message that is delivered. It contains the fixed and variable information and comes from the message catalog. For template-based, the outbound message contains the data necessary for an external system to create the notification. In this model, the external system owns the message format and fixed content and uses the data from the system for the variable information. The notification type's business object has an option that indicates the format. This business object option is used by the programs that initiate notifications from the application. The programs that initiate a notification and need to know the notification type's format and must have the responsibility to populate the correct elements before calling the create notification plug-in spot. These programs know how to prepare notification information based on the format before calling the notification type's BO create notification plug-in spot. That plug-in spot's API has elements that support both notification formats.

Push vs. Subscription Notification Types

Notification types are defined as either push – which means that a customer need not sign up to receive notifications of this type, or subscription – which means that a customer must sign up to receive this type of notification. As you can tell, they have different uses and different behaviors.

Push notification types allow users to specify communication preferences for a general type of notification, which are referred to as parent push notification types. These preferences include contact preferences and opt-out preferences, which are applied to individual notifications belonging to the parent type. For example, "Products and Offers" may be the parent type, and the individual notification types may include several different types of product and offers notifications that contain different messages and are targeted at different customers. Refer to [Parent vs. Individual Push Notification Types](#) on page 710 for more information.

In the absence of any contact preference or opt-out preference, push-based notifications can determine a default contact and send the notification using it. The logic to determine a default contact is defined via an algorithm plugged into the Determine Default Contact plug-in spot on the Notification Type (BO). The base product provides the C1-NTF-DFPRF (Determine Default Contact for Notification Type) algorithm, which looks to retrieve a default contact from the account's main person.

Subscription notification types define a particular notification and its message. Customers must have an active contact preference to receive these notifications. Subscription-based notification types can use an underlying service task. Refer to [Some Notification Types Use Service Task](#) on page 711 for more information. A subscription-based notification type can also be set up to allow routing of bills or quotes to multiple destinations.

Note: For template-based notifications, there are distinct business objects for subscription, parent push and individual push notification types. For message-based notifications, there is a single business objects and the behavior of the notification type must be defined when configuring the notification type.

Parent vs. Individual Push Notification Types

Push notification types are configured as either a parent or individual notification type. An individual notification type references a parent notification type; a parent cannot reference another parent. Customers define communication preferences for parent push notification types. Notifications are sent out for individual push notification types. The preferences defined for parent push notification types are applied to the associated individual push notification types.

This means that customers do not have to supply their preferences for every individual notification that your implementation may send. Storing customer preferences for a parent notification type permits those preferences to be inherited for individual notification types added later in time under the same parent. The parent push notification types can be thought of as categories of notifications for which your customers define contact preferences and opt-out preferences.

When system processes or your custom processes attempt to send out a push notification, it should be for an individual notification type. The system will retrieve the parent notification type from the individual notification type when checking for communication preferences.

One function available to push-based notifications as described in [Push vs. Subscription Notification Types](#) on page 709 is the ability to determine a default contact in the absence of a contact preference or opt-out preference. If your implementation wants to take advantage of this function, but would like the customer to supply preferences for receiving an individual notification, a parent push notification type can be set up with only one individual push notification type.

Delivery Type

Delivery Type is the channel used to send a notification. Examples are email, text message (SMS), fax, and outbound IVR. Delivery type is used throughout notification preferences. If your implementation is not using notification preferences, you would not utilize delivery type.

- Notification types list the supported delivery types. For example, a bill ready notification type may support email and SMS while a notification type to encourage customers to enroll in a budget plan may only support email. The message subject and body are configured for each notification type's supported delivery type.
- Person contact types list the allowable delivery types. For example, a cell phone person contact type may allow SMS while a home phone person contact type may not allow any delivery types. An email person contact type would allow an email delivery type unless the person contact type exists to capture a customer's email address and not to be used in conjunction with notification preferences. Note: the delivery types that can be specified on a person contact type are restricted to those defined on the person contact types contact routing. Refer to [Setting Up Contact Routings](#) on page 692 for more information.
- A contact preference for a customer consists of the combination of notification type, delivery type, and person contact.

Enabling Opt-In for a Delivery Type

Overview

Opt-in can be enabled for a delivery type and is configured using the **Notification Preferences master configuration**; for example, opt-in can be enabled for SMS, but not email.

To help clarify some terminology, as explained in [Person Contact Status Can Be Controlled by a Process](#), the product is delivered with a process that initiates a service task to request opt-in or permission to use a person contact. This solution requires that opt-in is enabled for the delivery type associated with the person contact type. In this regard, the two concepts are intertwined, but enabling opt-in for a delivery type can function independently.

Enabling opt-in is centered on the person contact status, while the process that controls the status can vary; therefore, it is possible to use enable opt-in for a delivery type while manually controlling the person contact status. Enabling opt-in for a delivery type has two key impacts system behavior.

- When a contact preference is added and the delivery type is enabled for opt-in, there is logic that checks if the person contact associated with the contact preference is in the *Approved* status. If it is not, and the person contact type is associated with a process to control the status, that process is initiated. If the person contact type is not associated with a process to control its status, a To Do Entry is created. The To Do Type is configured on the

Notification Preferences master configuration. The system is delivered with To Do Type Opt-In Errors (C1-OPTIN) for this purpose.

- Notifications will not be delivered to person contacts that are not **Approved**. When a system process initiates an outbound notification based on an active preference, if the person contact associated with the contact preference is not **Approved**, a flag is set in the notification indicating that it should not be delivered. It is up to the receiving system, such as Notification Center, not to deliver the notification based on this flag. This is designed so that a record of the notification being generated is still captured. Also, C1-NTF-DFPRF (Determine Default Contact for Notification Type) will not choose a person contact that is not approved.

The **Notification Preferences master configuration** help text contains detailed information about the configuration required to enable opt-in for a delivery type.

Some Notification Types Use Service Task

Prior to the introduction of notification preferences functionality, the system supported notifications set up through self-service. These notifications used service tasks to store customer preferences and in some cases trigger notifications. The destination information for the notification existed outside of the system. Notification preferences, and more particularly communication preferences, define the user’s preferences on how to be notified for each notification type and where the notification is to be sent. This reduces, but does not eliminate, the need to use a service task to store a customer’s preference. These service tasks will not contain the self-service information when created internally by the system

There are four existing notification types that rely on service tasks to trigger a notification. Additionally, one of the prepaid notifications uses a service task type business object with specific fields for that notification type. Refer to [Designing Notification Types](#) on page 711 for information regarding the configuration requirements for certain notification types.

Notification Preferences supports configuring notification types with or without a service task and only subscription-based notification types can be configured with an underlying service task.

Designing Notification Types

Some notification types require a specific configuration in order for the system to create notifications for that type.

Service Task Based Notification Types

There are system processes that rely on a hard-coded notification type lookup, referred to as notification type (legacy) on the notification type configuration. The system identifies the user-defined notification type from the lookup value.

The following identifies the configuration requirements for the notification types that are supported by existing processes in the system that rely on service tasks.

| Notification Type (User Defined) | Push/Subscription | Controlled By | Notification Type (Legacy) | Service Task Type |
|----------------------------------|-------------------|---------------|----------------------------|--|
| Prepaid billing new charge | Subscription | Service Task | C1PC | Self-Service Task Type with BO C1-NotifyTaskType |
| Prepaid billing payment request | Subscription | Service Task | C1PP | Self-Service Task Type with BO C1-PPBPaymentNotifyTaskType |
| Payment Received | Subscription | Service Task | WSPR | Self-Service Task Type with BO C1-NotifyTaskType |
| Bill Ready | Subscription | Service Task | WXBR | Self-Service Task Type with BO C1-NotifyTaskType |

| | | | | |
|--------------|--------------|--------------|------|--|
| Bill Due | Subscription | Service Task | WXBD | Self-Service Task Type with BO C1-NotifyTaskType |
| Late Payment | Subscription | Service Task | WSLP | Self-Service Task with BO C1-NotifyTaskType |

Non-Service Task Based Notification Types

The following identifies the configuration requirements for the notification types that are supported by existing processes in the system that rely on the user-defined notification type to be configured.

Note:

Marketing and forms notification types can be set up one of two ways: as subscription-based or as push-based. For it to be push-based, it would be an individual push, meaning that it references a parent push notification type specified by the implementer.

| Notification Type (User Defined) | Push/Subscription | Controlled By | Notes |
|-----------------------------------|---------------------------------|---------------|--|
| Marketing Preference (Lead Event) | Subscription or Individual Push | N/A | Notification type configured on lead event type of BO C1-LeadEvtTypeNotificationPref |
| Forms Update | Subscription or Individual Push | N/A | Notification type configured on form task type of C1-FormTaskTypeForNotification |
| Forms Closed | Subscription or Individual Push | N/A | Notification type configured on form task type of C1-FormTaskTypeForNotification |

Bill and Quote Routing

Notification types can also be used to define contact preferences for bill and quote routing for email and fax. This can enable a bill or quote to create a routing for each active contact preference. For example for a single person on an account that receives a copy of the bill, the bill can be sent to more than one email address.

Some specific configuration is needed to support this.

The notification types are to be set up as follows and must use the message-based notification type business object.

| Notification Type (User Defined) | Push/Subscription | Controlled By | Bill/Quote Route Type | Algorithm |
|----------------------------------|-------------------|---------------|------------------------------|--|
| Bill Route | Subscription | Bill Route | Specify the Bill Route Type | Use the Suppression Algorithm for Bill/Quote Route |
| Quote Route | Subscription | Quote Route | Specify the Quote Route Type | Use the Suppression Algorithm for Bill/Quote Route |

Configure only the delivery type that corresponds with the bill or quote route's routing method. For example, if the bill route type's routing method is email, configure the email delivery type on the notification type.

Configure only person contact types whose contact routing corresponds with the bill or quote route's routing method. For example, if the bill route type's routing method is email, configure only person contact types with a contact routing of email. Ensure that the person contact type allows only the delivery type specified on the notification type.

This very specific configuration is needed because the system will override the existing logic that creates bill and quote routings when a notification type exists as described above and there are active contact preferences for that notification type with the specified delivery type and the person contact's person contact type.

Collection Events

The system is delivered with a collection event algorithm type that supports template-based notifications. To send collection based notifications, define individual push notification types for each collection notification. These notification types should reference a parent notification type such as "Collection Notices". Configure algorithm(s) using the delivered algorithm type, specifying the individual push notification type(s) in the algorithm parameter. Create collection event types using these algorithms and incorporate them into your collection process templates.

Setting Up Notification Type Algorithms

Suppression Criteria

Notification types can be suppressed from appearing in a list for a particular customer. This is done by plugging in a suppression criteria algorithm on the notification type.

The base product provides the C1-ALWY-SUP (Always Suppressed) algorithm, which suppresses the notification type for all customers. This does not impact active contact preferences for the notification type, nor does it prevent processes from creating notifications of this type. This should be used with business process changes to stop sending notifications of this type. This can also be used temporarily after a notification type has been configured, but before it should be used.

The base product provides the C1-CKSP-PPB (Check Prepaid Biller Suppression) algorithm, which suppresses the notification type if the customer does not have an active prepaid biller task. This should be used on prepaid related notification types so that only customers on prepaid billing receive these notifications.

If your implementation's business rules require additional notification type suppression rules, you may introduce your own algorithm.

Override Do Not Disturb

Do not disturb information can be captured on person contacts. Person contacts are associated with a notification type to define a contact preference. When notifications are sent out, do not disturb information is included in the message to the receiving system. Some notification types might be important enough to not honor the customer's do not disturb information. For example, a notification might be sent to a subset of customers to warn of a gas leak and evacuation and needs to be sent regardless of the customers do not disturb wishes. This is done by plugging in an override do not disturb algorithm on the notification type. Note: this does not actually override the customer's information, but sends an indicator in the message to the receiving system that the do not disturb information should be overridden or ignored.

The base product provides the C1-OVR-DND (Override Do Not Disturb) algorithm, which returns a value of true that is passed to the receiving system in the notification.

If your implementation has more specific business rules related to overriding a customer's do not disturb preference, you may introduce your own algorithm.

Setting Up Delivery Types

Base values for Delivery Type are supplied. You can add your specific delivery types by updating the value for the C1_SS_DELIVERY_TYPE lookup field.

Setting Up Notification Types

Each notification type defines the controls and behavior for defining communication preferences and sending out notifications of that type.

There are two main categories of notification types: subscription and push. These behave differently. Refer to [Push vs. Subscription Notification Types](#) on page 709 for more information.

Push notification types are configured as either parent or individual push notification types. A parent push notification type is used to define communication preferences and an individual push notification type is used to send notifications. Refer to [Parent vs. Individual Push Notification Types](#) on page 710 for more information.

The base product supplies one Notification Type business object for message-based notification types and distinct business objects for template-based notification types. Refer to [Template-Based vs. Message-Based Notification Types](#) for more information. For more details, refer to the specifications for these business objects.

Some notification types require specific configuration. Refer to [Designing Notification Types](#) on page 711 for more information.

To set up notification types, select **Admin > Customer > Notification Type +**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Setting Up the Outbound Message Type

An outbound message type is required for the notification outbound message. This outbound message type must reference the base C1-NotifPrefOutboundMessage (Notification Preference Outbound Message) business object.

Setting Up the Message Sender

A Message Sender is required to define how to send notifications. Use the context of the Message Sender to define the web service interface.

Setting Up the External System and Configure the Messages

Define an external system and configure the valid outbound message types and the method of communication for each (XAI, Batch, or Real Time); Real Time is generally the appropriate choice notifications).

Setting Up Notification Preferences Master Configuration

General configuration details for the notification preferences functionality is captured in the [Notification Preferences master configuration](#).

For more information about specific fields in the master configuration, refer to the embedded help.

Other Edge Application Notification

Other applications such as *Oracle Utilities Network Management System* or *Oracle Utilities Meter Data Management* may initiate notifications; for example, the network management product can create notifications for outages or restoration information. The customer's preferences to receive these notifications will reside in Oracle Utilities Customer Care and Billing, since this is where their contact information exists. The other applications need to be notified when an active contact preference is created for one of their notifications. The [Notification Preferences master configuration](#) provides the section to indicate if a Notification Type is owned by another edge application. When a contact preference is created or inactivated for one of these notification types, an outbound message is sent to notify the other edge product. When the system event in another edge application occurs that initiates a notification, that application calls and inbound web service that creates the notification.

The [Notification Preferences master configuration](#) help text contains detailed information about other edge applications.

Setting Up Service Agreement Options

This section describes tables that must be set up before you can define service agreements.

Setting Up Standard Industry Codes (SIC)

A service agreement for non-residential service should reference a standard industry code (SIC). This code is used to categorize service agreements for reporting purposes. To define a SIC, open **Admin > Customer > SIC Code**.

Description of Page

Enter a unique **SIC** and **Description** for the SIC.

Setting Up Tax Exempt Types

Your rates will probably have provisions for the calculation of taxes of one type or another. Frequently you will have customers who are completely or partially exempt from these taxes. The service agreements for these customers will need to have tax exemption information in order for them to be billed properly. Tax Exempt Type is used to define the precise nature of the applicable exemption. To define the Tax Exempt Types you will use, open **Admin > Customer > Tax Exempt Type**.

Description of Page

Enter a unique **Tax Exempt Type** and **Description** for each type of tax exemption.

Setting Up Contract Quantity Types

You may have customers whose contracts (service agreements) have contractual consumption limits. The service agreements for these customers must have information regarding this quantity in order to be billed properly. Contract Quantity Type is used to precisely define the nature of the quantity. To define the Contract Quantity Types, open **Admin > Rates > Contract Quantity Type**.

Description of Page

Enter a unique **Contract Quantity Type** and **Description** for each type of contract quantity.

SA Type Controls Everything

Every service agreement references a SA type. The SA type controls all aspects of a service agreement's behavior including how service is started, how bills are created, how its financial transactions are booked in the general ledger, and much more. We don't explain how to set up SA types in this section because it's only after you have set up all of the control tables in this manual that you'll be able to finally define your SA types.

Fastpath:

For more information about SA types, refer to [Defining Service Agreement Types](#) .

Financial Controls

Fastpath:

There are also a number of control tables that must be set up to control the bills, payments, and adjustments that are linked to a service agreement. For more information about these tables, please refer to [Defining Financial Transaction Options](#) .

Setting Up Order Options

This section describes tables that must be set up before orders can be used to start service.

Fastpath:

For more information, refer to [The Big Picture of Campaigns, Packages and Orders](#).

Setting Up Column References

A column reference must be created for each miscellaneous field that's captured on an order that doesn't reside in a characteristic. Refer to [Determine The Properties Of Every Miscellaneous Field](#) for more information.

Open **Admin > Sales & Marketing > Column Reference > Add** to define your column references.

Description of Page

Enter an easily recognizable **Column Reference** code and **Description** for each column reference.

Specify the **FK Reference** to use if this column reference uses field values from another table. Use **Long Description** to describe the data that fields using this column reference capture.

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated. You can define algorithms for the following system events: Post when order completed, Retrieve current value, Validate field value, Service task order processing, and Pre-process field value. Refer to [Extract Column References](#) for a description of these events.
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

Warning:

These algorithms are typically significant processes. The absence of an algorithm may prevent the system from operating correctly.

Setting Up Order Cancellation Reasons

An order cancellation reason must be supplied when an order is cancelled. Open **Admin > Sales & Marketing > Order Cancel Reason** to define your reason codes.

Description of Page

Enter an easily recognizable **Order Cancel Reason** and **Description** for each order cancellation reason.

Where Used

Cancellation reasons are used when an [order is canceled](#).

Setting Up Order Hold Reasons

An order hold reason must be supplied when an order is held. Open **Admin > Sales & Marketing > Order Hold Reason** to define your reason codes.

Description of Page

Enter an easily recognizable **Order Hold Reason** and **Description** for each order hold reason.

Where Used

Hold reasons are used when an [order is held](#).

Setting Up Order Feature Configurations

Defining a [feature configuration](#) with a feature type of Order Configuration can increase performance of the Order page when campaigns have a large number of packages or criteria. Open **Admin > Feature Configuration > Add** to define a configuration for the feature type Order Configuration.

Note:

Only one. The system expects only one order configuration feature configuration to be defined.

Description of Page

The following points describe the various **Option Types** that may be defined:

- Eligibility Tree - Suppress Error Packages node. Select this option type and define a value if you would like the [Order Eligibility Tree](#) to suppress the node that contains packages with errors in their eligibility criteria. This is an optional setting. If the option type is not defined, the error packages node is displayed, if applicable.
- Eligibility Tree - Suppress Ineligible Packages node. Select this option type and define a value if you would like the [Order Eligibility Tree](#) to suppress the node that contains packages that are not applicable to the customer based on the eligibility criteria. This is an optional setting. If the option type is not defined, the ineligible packages node is displayed, if applicable.
- Eligibility Tree - Suppress Other Campaigns node. Select this option type and define a value if you would like the [Order Eligibility Tree](#) to suppress the node that contains other eligible campaigns. This is an optional setting. If the option type is not defined, the other campaigns node is displayed, if applicable.

Setting Up Program Management Options

This section describes how to set up the system for program management.

For more information about program management, see [The Big Picture of Program Management](#)

Designing Initiative Eligibility Criteria

The following describes guidelines for designing initiative eligibility criteria. These guidelines apply when using the base-supplied business objects and any additional business objects that the implementation defines.

There are two general types of initiative eligibility criteria business objects provided in base: specific and freeform. Your implementation decides whether to use only one of these types or a mixture of both.

Note: Initiative criteria has three categories: eligibility criteria, related object criteria, and participation criteria. (The participation criteria type is currently not used.) During criteria maintenance and lead generation, the system identifies the category to use through a business object option called Initiative Criteria Type. Eligibility criteria business objects are defined with an Initiative Criteria Type of either C1EC (Eligibility Criteria) or C1BT (Both Eligibility Criteria and Participation Criteria).

Specific Criteria Business Objects

Most of the base-supplied business objects are designed to perform comparisons to a specific field. The algorithm type for retrieving/determining the value to compare with is already preset in the business object, such that the Algorithm values that the user sees on the user interface are restricted to the instances of that algorithm type.

Refer to the following base business objects for more details:

- Communication Channel Criteria
- Conservation Program Criteria
- Contract Option Criteria
- Rate Schedule Criteria
- SP Type Criteria
- Service Type Criteria
- Is Account Current Criteria
- Account is on Autopay Criteria
- Account is on Budget Criteria
- Number of Days Since Last Lead Criteria
- Account Customer Class Criteria
- Average Service Quantity Criteria
- Premise Cities Criteria

To add similar business objects:

- Identify the specific value for comparison. This could be a reference to an object or entity in the system, or a character string; such as, true/false.
- Develop the algorithm program to retrieve or determine the comparison value.

- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Configure your business object schema so that the Algorithm field retrieves all algorithm instances of the algorithm type you created.
- Define algorithm instances of your algorithm type.

Freeform Criteria Business Object

The Freeform Criteria business object, on the other hand, is designed to perform comparisons for different types of values. The comparison value is determined by a Derive Value Algorithm Type that is defined as an option on this business object. A number of these Derive Value Algorithm Types are supplied with this business object and your implementation can add to these, as necessary.

Note: The supplied Derive Value Algorithm Types perform similar comparisons as those in the base-supplied specific criteria business objects (listed above). The Freeform Criteria business object should only be used if the available specific criteria business objects are not sufficient to perform the needed field value comparisons.

To add Derive Value Algorithm Types:

- Identify the specific value for comparison. It could be a reference to an object or entity in the system, a character string (such as, true/false), or a scalar value (such as, number of days or number of kwh).
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Define an algorithm instance for your algorithm type.
- Update the Freeform Criteria business object to add a Derive Value Algorithm Type business object option referencing your algorithm.

Repeat the above steps for each specific field to compare.

Designing Related Object Criteria

The following describes guidelines for designing related object criteria. These guidelines apply when using the base-supplied business objects and additional business objects that the implementation defines.

An initiative defines the related object(s) to associate with leads via the Object Nomination algorithm on the initiative business object. The lead generation process executes this object nomination algorithm after executing initiative eligibility criteria. The base supplied parent Initiative business object (C1–Initiative) is configured with an object nomination algorithm that retrieves the premises that are associated with the account’s active and pending start service agreement’s service points. This algorithm applies the related object criteria, which is configured on the initiative, to each premise. If the premise is determined to be eligible, it is returned as a related object for the lead. To override the base object nomination algorithm, add another instance of the Object Nomination System Event and specify your own algorithm.

The base product supplies related object criteria business objects that look for one or more premise to associate with a lead.

There are two general types of related object criteria business objects provided in base - specific and freeform. Your implementation decides whether to use only one of these types or a mixture of both.

Note: Initiative criteria has three categories: eligibility criteria, related object criteria, and participation criteria. (The participation criteria type is currently not used.) During criteria maintenance and lead generation, the system identifies the category to use through a business object option called Initiative Criteria Type. Related object criteria business objects are defined with an Initiative Criteria Type of C1EO (Related Object Criteria).

Specific Criteria Business Objects

The base product supplies two business objects that perform comparisons to a specific premise-related field. The algorithm type for retrieving or determining the comparison value is preset in the business object, such that the Algorithm values that the user sees on the user interface are restricted to the instances of that algorithm type.

Refer to the following base business objects for more details:

- Premise SP Type Criteria
- Geographic Value Criteria

To add similar business objects:

- Identify the specific comparison value. It could be a reference to an object or entity in the system (such as, SP Type), or any other attribute that can be used to find the related object.
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Configure your business object schema so that the Algorithm field retrieves all algorithm instances of the algorithm type you created.
- Define algorithm instances of your algorithm type.

Freeform Premise Criteria Business Object

The Freeform Premise Criteria business object, on the other hand, is designed to perform comparisons to different types of values. The comparison value is determined by a Derive Value Algorithm Type that is defined as an option on this business object. Derive Value Algorithm Types are supplied with this business object and your implementation can add to these, as necessary.

Note: The supplied Derive Value Algorithm Types perform similar comparisons as those in the base-supplied specific criteria business objects (listed above). The Freeform Premise Criteria business object should only be used if the available specific criteria business objects are not sufficient to perform the needed field value comparisons.

To add Derive Value Algorithm Types:

- Identify the specific comparison value.
- Develop the algorithm program to retrieve or determine the comparison value.
- Configure your algorithm type using the Initiative Criteria - Derive Field Value algorithm entity and reference the program you created.
- Define an algorithm instance for your algorithm type.
- Update the Freeform Premise Criteria business object to add a Derive Value Algorithm Type business object option referencing your algorithm.

Repeat the above steps for each specific field to compare.

Setting Up Lead Event Types

Each initiative can define a structured marketing effort for the events that take place during the life of a lead. For example, one event could be that a letter or an email is sent to the customer.

Each event references a lead event type. An initiative defines a lead event type profile that specifies one or more lead event types and the sequence in which those event types should occur. Refer to [The Big Picture of Initiatives](#) for more information.

Some types of lead events may also involve sending outbound messages to an external system (*e.g.*, to notify a third party representative about a customer who has signed up). The lead event type business object can specify the outbound message type(s) to use.

Event types that involve additional workflow activities can define one or more steps; for instance, when work is outsourced to a third party representative (after customer sign-up), the third party lead event includes a list of steps to complete. Each event step has information (such as, completion date) that can be used to track progress.

The base product supplies a number of Lead Event Type business objects. For more details, refer to the specifications for these business objects.

To set up lead event types, select **Admin > Sales & Marketing > Lead Event Type**.

The Lead Event Type portal contains the following zones:

Lead Event Type List

The Lead Event Type List zone lists all lead event types. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent lead event type.
- The standard actions of **Edit**, **Delete** and **Duplicate** are available for each lead event type.

Click the **Add** link in the zone's title bar to add a new lead event type.

Lead Event Type

The Lead Event Type zone contains display-only information about the Lead Event Type. This zone appears when a Lead Event Type has been broadcast from the Lead Event Type List zone or if this portal is opened via drill down from another page.

Please see the zone's help text for information about this zone's fields.

Overriding Initiative Sign Up Options

The behavior of the Sign Up action on Lead maintenance is controlled by two business object options on the initiative:

- Sign Up UI Map
- Sign Up Service Script

When invoking a lead's Sign Up action, the system retrieves these options and displays or executes them accordingly.

The base-owned parent initiative business object, C1-Initiative, is supplied with the Sign Up Service Script option referencing the C1-IntvSignU script. To override this, add another *Sign Up Service Script* option with a higher sequence number.

The Sign Up UI map, on the other hand, is not plugged in on the base BO, because this could vary across implementations. The Sign Up UI map C1-SignUpResponseCh provided in base simply prompts for a Response Channel. Implementations can use this map or their own specific map.

Note: The system does not issue an error if the Sign Up UI map is not specified. It proceeds with executing the Sign Up Service Script and, if there are no problems, displays a sign up confirmation. The base-supplied C1-IntvSignU script includes logic to recheck the account's eligibility for the initiative and update the *Has Signed Up* indicator on the lead.

Program Management Master Configuration

The master configuration business object for Program Management defines general configuration details for the program management functionality.

Navigate using **Admin > General > Master Configuration**. In the Master Configuration list, scroll to Program Management Configuration and click the add icon if there is no record yet or the edit icon to modify an existing record.

For more information about specific fields in the master configuration, refer to the embedded help.

Setting Up Letter Templates

You can set up a customer contact type to generate a form letter whenever a customer contact of this type is added. In fact, this is the only way to generate a letter in the system.

**Fastpath:**

Refer to [Printing Letters](#) for more information about how letters are produced.

Every customer contact that causes a letter to be sent must reference a unique letter template. To define a letter template, open **Admin > Customer > Letter Template**.

**Note:**

Document composition application users. If you use the document composition software to produce letters, there will be a template in the software associated with each letter. The name of the template must be the same as the code associated with the letter template set up in the system.

Refer to the embedded help for details on the letter template fields.

Setting Up Customer Service Request Types

This portal is used to display and maintain a Customer Service Request Type.

A Customer Service Request Type controls how a specific customer service request is processed.

Refer to [Understanding Customer Service Requests](#) for more information.

To maintain customer service request types, open **Admin > Customer > Customer Service Request Type**.

You are brought to a query portal with options for searching for a specific customer service request type. Once a question is selected, you are brought to the maintenance portal's Main tab, to view and maintain the selected record.

The Duplicate action includes options for copying questions, service eligibility criteria and/or response-related updates with the customer service request type.

Refer to the zone's embedded help for more information.

The Questions tab is used to configure one or more questions to ask during the flow of a start/stop/transfer service request. Refer to [Setting Up Customer Service Request Questions](#) on page 731.

The Service Eligibility tab is used to configure one or more service eligibility criteria that are applied using question responses and existing information for the customer or premise request. Refer to [Setting Up Service Eligibility Criteria](#) on page 731.

The Related Updates tab is used to configure how question responses should be stored when the service request is processed and/or completed. Refer to [Setting Up Response-Related Updates](#) on page 731.

Setting Up Consumer Contract Request Types

A consumer contract request type is a Customer Service Request Type that controls how a contract change request is processed.

Refer to [Understanding Customer Service Requests](#) for more information on customer service requests.

For contract change requests, the Consumer Contract Request Type also defines the service location business object that is applicable to a market and action (i.e. Add to Contract, Remove from Contract, Meter Change, etc.)

Setting Up Start, Stop and Transfer Request Types

The following sections describe how the request types and process flow types provided in the base product can be extended for your specific business rules.

Verifying Identity, Checking Credit and Requiring Deposits When Starting Service

The Start Service Request Type (request type) provides controls to help verify customers' identity and/or check their credit. The start service process provided with the system can begin with or without a person being passed into the process. The process orchestrates the following:

- When there is no person passed into the process, the assumption is that this is a new customer, but the first step is to ensure they are not already in your system. This is done by performing a person search using, name, phone, e-mail or person identifiers. The search options are configured on the start service type. When a record is not found, the last search criteria are retained to minimize asking the customer for the same information again. If an existing

person is found, the record can be selected and the process continues as if the process began with an existing customer. For this purpose, existing customers are simply those in your system before beginning the start service process. They may be long-standing customers with current service, or a person record added moments before beginning the start service process. For this reason, the start service process follows the same steps after choosing to add a new customer or selecting an existing one.

- Ensuring customers are who they say they are is often an important step in starting service, especially for new customers. This is often done by asking the customer for a unique identifier such as a government issued ID like a driver's license, or Social Security number. This information is often verified with a third-party and is sometimes combined with a credit check.

The start service process allows you to configure what identifier types your organization accepts when both new and existing customers are starting service. This may be a subset of all of the person identifier types defined in your system. Refer to [Understanding Person Identifiers](#) for more information. Note: This help topic pertains to the primary identifier; the start service process supports additional, non-primary identifier types separately.

When setting up the start service type and configuring the primary identifier types, you need to indicate their usage. The usage for most uniquely identifying identifiers is probably **New & Existing**. These are identifier types that you accept and can uniquely identify a person or business and are probably the primary ID type on the person record. If there is an identifier that was once accepted and is still considered valid for existing customers, but is not used for new customers, these can be set to **Existing Only**. Lastly, some identifier types such as a PIN or password are used when an identifier is required, but the customer is not willing or is unable to provide a high-quality unique ID. These identifier types should be set to **New & Non-Identifying**. This allow agents to input an ID when one is required, but the process knows that the record is not a unique identifier.

For existing customer, the start service process sets an indicator when an existing identifier is found from the list of identifiers valid for existing customers. Note: the identifier need not be the primary, although it is likely that it is. For new and existing customers, a different indicator is set when a new uniquely identifying identifier is provided during the start service process. ID types that are configured as non-identifying are not considered when setting the indicator. It is not possible for both indicators to be set since the user is not prompted to enter a new ID when a valid existing one is found. These indicators are passed into plug-in spots called during the start service process.

- Your business rules, might include asking customers for their date of birth. This could be used when deciding whether or not to perform a credit check or ID verification or if it does not factor into the decision, it could be passed to the third party as part of the credit check or ID verification process. If date of birth is not part of the credit or ID process, it may be requested only if the customer is eligible for service and may be used when determining if a deposit is required. Since this could be considered sensitive data, it is possible that is used during the start service process, but not saved on the person record.

To support a wide range of business rules, the start service process provides options for capturing and saving date of birth. When the use of date of birth is enabled, there are options to determine when the date of birth field is shown. It can be show always. It can be show only if a credit check or ID verification is going to be performed. This means the presence of the date of birth cannot factor into the decision to perform a credit or ID check. Lastly it can be shown only if service can start. There is also an option to save the date of birth as a person characteristic. For existing persons, if the date of birth already exists, it is shown, but cannot be updated during the start service process. Note: the date of birth functionality is only available for persons and not businesses.

- After the data entry is complete, the start service process calls the algorithm(s) plugged into the ID/Credit Check Should be Performed plug-in spot, passing the two ID indicators and the date of birth if enabled, to determine if an identity or credit check should be performed. This can be used to ensure the customer has provided the necessary information to pass to an external service to check credit or verify ID. This can also check the indicator that person has an existing ID and no further checking is needed. This is a multi plug-in spot so you can configure as many business rules as necessary. Each algorithm can indicate if the next algorithm should be called. The system is delivered with a sample algorithm that chooses to run a credit check based on the availability of a unique ID and a sample algorithm that bases the decision on the account history. Refer to the algorithm types for this plug-in spot for more details.
- If a credit check should be performed, the user is prompted to perform the credit check or ID verification. The algorithm plugged into the ID/Credit Check plug-in spot is then called. The user is shown if the credit check

passed or failed, but the process relies on subsequent plug-in spots to determine use the results of the credit check or ID verification.

- After checking the credit or verifying ID, the next step is ensuring the criteria has been met for starting service and, if so, identifying if the person or business has existing accounts that eligible for service. This is done by calling the algorithm(s) plugged into the Start Service Eligibility plug-in spot. These algorithms receive ID indicators, date of birth if enabled, and the output from the ID/credit check plug-in spot, which can be used to determine if service can start. Algorithms in this plug-in spot are also responsible for returning the eligible accounts if there are any. For example, accounts previously used for bankruptcy or those dormant too long might not be eligible for new service based on your business rules. This is a multi plug-in spot so you can configure as many business rules as necessary. Each algorithm can indicate if the next algorithm should be called. When there are existing accounts that are eligible for service, a control on the start service request type indicates if new accounts are also allowed. You would set the control if a new account can be created even when there are existing eligible accounts. Algorithms in this plug-in spot also support returning a list of ineligible accounts that are shown on the start service process to show information about all of the customer's accounts. If your business rules do not support using existing accounts for new service, your algorithms would not return any eligible accounts. The system is delivered with a sample algorithm that determines start eligibility and account eligibility. Refer to the algorithm type for this plug-in spot for more details.

Note:

If the CIS Division is configured to ensure the same CIS Division is used on related accounts, premises and service agreements (**Restrict to Account CIS Division** is set to *Restricted*), an account is eligible if its CIS Division is the same as the current CIS Division. Otherwise, the account is ineligible. The current CIS Division is determined based on the following hierarchy:

- Premise
 - Customer Service Request Type
- Your business rules may require a deposit before a customer starts service. If so, the deposit functionality should be enabled for the start service process and optionally for the transfer service process. There is a control on the customer service request type that allows you to define if a deposit is always required or if the determination is situational, in which case algorithms in the Determine Deposit Required plug-in spot are called. The following explains the plug-in spot.

Since deposits can be based on more than one factor, this is a multi plug-in spot. When the plug-in spot is called, the deposit required indicator is not set and a generic message is set that a deposit is not required. The system then relies on the algorithms plugged into the plug-in spot to indicate that a deposit is required, or update the message with a specific reason that a deposit is not required.

When called from within the Start Service process flow, the ID indicators, date of birth if enabled, and the results of the ID verification or credit check are passed into this plug-in spot and can be used in determining if a deposit is required. Note: the transfer service process uses the same plug-in spot, but is not passed any date of birth, ID or credit information since transfer only applies to accounts with current service and the transfer process does not contain the identifier and credit check logic.

There are four sample algorithms provided to determine if a deposit is required. The following illustrates how these algorithms can be used to support both new and existing customers. When a specific condition requiring a deposit or exempting a customer from a deposit is met, the reason is output from the algorithm and displayed to the user in order to communicate with the customer. As mentioned, the system's default assumption is not required and a default message would be shown to the user if none of the algorithms output a more specific message explaining why the deposit is or is not required. Refer to the algorithm type descriptions for more detail information about each.

- C1DEPEXBAGE illustrates how an algorithm is used to waive a deposit when a condition is met, which in this case is the customer's age. This sample indicates that other algorithms in the plug-in spot should not be performed when the condition is met. If your business rules waive deposits when a condition is met and no further checking is required, you'd plug-in the algorithm(s) that check for this first. These algorithms should tell the system not to perform the additional algorithms in this plug-in spot.
- C1REQDEPAID uses the results from the ID or credit check to determine if a deposit is required. This algorithm has logic for both new and existing customers. It uses inputs including an indicator if an ID or credit

check was run and, if run, the results of the ID or credit check. Based on the results, this algorithm can require a deposit. This algorithm tells the system not to perform the subsequent algorithms in this plug-in spot when a deposit is required.

- CIREQDEPBACR is intended for existing customers and uses the account's internal credit rating to determine if a deposit is required. It's possible that you'd not verify ID nor run an external credit check for existing customers, so the preceding algorithm would not have required a deposit, leaving downstream algorithms such as this one to make the determination. If the customer's internal credit rate is too low, a deposit is required, and this algorithm tells the system not to perform the subsequent algorithms in this plug-in spot.
- CIDEPEXMPBAH is the last sample and is based on account history. If the customer has recent or current service, the algorithm indicates that a deposit is not required and updates the message explaining that a deposit is not required. If there is no recent account history, the algorithm indicates that a deposit is required. In this example, this is the last algorithm, but it could be performed before other algorithms. To accommodate calling it in any sequence, this algorithm tells the system not to perform the subsequent algorithms only when a deposit is required.

Note: If your business follows the model where a deposit is required unless there is a reason to waive it, then your algorithms will behave in the inverse from the delivered samples. Your first algorithm plugged into the plug-in spot must set the deposit required indicator and update the default message. Subsequent algorithms or subsequent steps in the first algorithm can then clear the deposit required indicator when conditions to waive the deposit are met.

The delivered algorithms for these four plug-in spots work with each. You can design the algorithms in these four plug-in spots to work together or independently to implement your business's rule for adding new customers or ensuring existing persons or businesses meet the requirements for verifying ID or credit, starting service, choosing an account, and checking if a deposit is required.

Introducing Your Business Rules For Starting Or Transferring Service

The Start Service and Transfer Service requests are designed to allow you to define pre-requisites before customers start service. Each request has an "Waiting for Additional Actions" status where you can plug-in your business rules that define the actions required to start service. The requests have monitor algorithms to transition into and out of the waiting status.

For example, if you require a deposit to be paid before starting service, you can plug-in your business rule that ensure that the deposit is paid before our process starts the customer's service.

Understanding UI Override Controls

Process flow type panels are made up of a data area or UI map fragment. The delivered start, stop, and transfer process flow type panels are built using data areas. Instead of a single data area, these panels are built using nested or included data areas. This is done to facilitate custom extension of the data area at the lowest. This is useful when your business rules include adding something at the end of one of the delivered sections. However, there are times when your business rules are more complex than just adding on to a delivered section. Some of the UI sections that are delivered can be overridden with a custom replacement UI section. This logic is enabled through UI Override Controls on the request types.

The start, stop, and transfer processes each contain a summary header that is shown at the top of each step in the process that can be overridden. By overwriting this, you can create a custom header that is displayed throughout the process flow.

When starting service, especially for a new customer, business rules can differ between different organizations or within different operating units of the same organization. For example, a utility with customers in different states may have different requirements around verifying identity or checking credit. The sections responsible for new customer and existing customer identification can be replaced with a custom experience using the UI override controls.

When the request type indicates that the UI section is overridden, the extension data area replaces the UI component of the delivered data area that it extends. It does not override or replace the data area's schema

Displaying More Details for the Move-to Premise

When starting or transferring service, additional scrutiny may be given to the move-to premise. Some of the pertinent information might related to knowing if the premise has had frequent move-ins and move-outs and what the outstanding balance is on the previous account(s). Perhaps the meter information or usage history is important.

The system is delivered with a feature that is not enabled by default. On the start and transfer customer service request type business objects, you can specify a BPA script in the **Move-To Premise Details BPA Script** BO Option type. This script should invoke a map that contains the additional premise information that is relevant to your business. The Move-To Premise steps on the start and transfer service processes display an icon next to the selected premise when this option is configured. The system is delivered with a sample BPA script (**C1SSDisPrDe**) that can be used as a guide for any custom script you wish to introduce.

Capturing Custom Elements in the Start, Stop, and Transfer Processes

Your business rule may require capturing information beyond what is delivered in the start, stop, and transfer processes. Additional elements can be added to specific places in the processes and the values then made available to the requests and therefore the request's lifecycle algorithms.

To create custom extensions in the processes, create a new data area to hold the custom elements that extends the Panel Extension Data Area where you want to make the extension. The data areas need to use UI Hints or map fragments.

To pass the custom elements values from the process to the request, make the identical extension to the corresponding Request Extension Data Area. The system handles copying the values using "move by name".

| Process | Panel | Panel Extension Data Area | Request Extension Data Area |
|-----------------|----------------------------|-------------------------------|-----------------------------|
| Start | Move-To Premise | C1-StartMoveToPremPanelExtend | C1-StartMoveToPremCSRExtend |
| | Customer Identification | C1-StartCustIDPanelExtend | C1-StartCustIDCSRExtend |
| | Services to Start | C1-StartSvcToStartPanelExtend | C1-StartSvcToStartCSRExtend |
| | Person and Account Details | C1-StartAcctDetailPanelExtend | C1-StartAcctDetailCSRExtend |
| Stop | Services to Stop | C1-StopSvcToStopPanelExtend | C1-StopSvcToStopCSRExtend |
| | Person and Account Details | C1-StopAcctDetailPanelExtend | C1-StopAcctDetailCSRExtend |
| Transfer | Move-To-Premise | C1-TransferMoveToPremPanelExt | C1-TransferMoveToPremCSRExt |
| | Services to Start | C1-TransferSvcToStartPanelExt | C1-TransferSvcToStartCSRExt |
| | Services to Stop | C1-TransferSvcToStopPanelExt | C1-TransferSvcToStopCSRExt |
| | Person and Account Details | C1-TransferAcctDetPanelExtend | C1-TransferAcctDetCSRExtend |

Adding Custom Text to the Start, Stop, and Transfer Processes

When using the start, stop, or transfer processes, agents or CSRs users may need specific instructions or may need to provide specific information to customers, such as how their information such identifiers or email are used. This functionality is referred to as "Agent Contact Scripting" and the system is delivered with specific places in the

processes where custom text can be added. These places are called “Script Points” and are maintained as extendable lookup values.

When setting up start, stop, and transfer customer service request, you can configure the text that appears for the provided script points. Refer to the embedded help on the Agent Contact Scripting sections for more information on how to configure this feature.

If your implementation has added custom elements through data area extensions, those extensions can reference custom script points. To implement this, you need to ensure your map fragment’s class attribute is set to “contact-script-point” and the scriptPoint attribute is set to the CM script point extendable lookup value. Here is the sample syntax: `<div class="contact-script-point" scriptPoint="CM-NewScriptPoint"/>`.

Using the Start Service Process with Multiple Jurisdictions

If your organization operates in multiple jurisdictions, it is likely that you have used CIS division to segment your accounts by jurisdiction, require premises to have a CIS division by requiring it on the premise types, have distinct customer service request (CSR) types for each CIS division, and use action method to map the CSR Types to CIS Division. The functionality delivered with the system relies on this configuration.

The start service process has specific functionality to support multiple jurisdictions. This functionality is enabled when the installation option to Control by CIS Division is set. Before beginning the start service process flow, the user is presented with a premise search to obtain the CIS division from the premise. This is then used to call the action method to determine the correct customer service request type and/or process flow type, assuming that the action method has been configured with specific types based on CIS division. The "Move-to-Premise", typically the first step in the start service process, is then presented to the user with the previously selected premise loaded. Further searching from this panel is not allowed. If the chosen premise is not correct, the user needs to exit the current flow and re-initiate the start service process.

Refer to [The Start Service Process and Request](#) for specific features of the start service process based on the system configuration used to support multiple jurisdictions.

Questions and Response Processing

A customer service request type defines the questions to ask the customer during the flow of self-service start / stop / transfer service requests. Questions are presented, based on the applicability to the customer and / or the premises / SPs / SA(s) being started or stopped.

The responses to questions can be inputs to service eligibility criteria processing, to determine: start options (for new/ additional services), additional SAs to start (e.g. non-SP-based SAs) and changes to whether or not selected services (for start / stop) are eligible to be started / stopped.

Questions can also be configured to update person / account / premise / SP / SA attributes and characteristics with the captured responses when the start / stop / transfer service request is processed or completed.

The following sections describe question configuration and response processing.

Understanding Customer Service Request Questions

One or more questions can be asked during the flow of a self-service New Service / Add Service / Stop Service / Transfer Service request. The questions can vary across customer service request types. For instance, the questions asked during New Service or Add Service request differ from the questions asked during a Stop Service request. Transfer Service requests can ask questions for both stopping service and starting service.

The base product provides a Customer Service Request Type Question business object (**C1-CSRTQuestion**) for configuring questions. Refer to the business object in the application for more information

The following sections describe the functionality that this business object supports.

Question Structure and Valid Answers

A Customer Service Request Type Question references a Customer Question that defines the structure of the question - i.e., question text, answer style (i.e., data type), and valid answers (if applicable).

Refer to [Defining Customer Questions](#) on page 579 for more details.

Question Applicability

The questions to ask during the flow of a customer service request can be determined using any of the following applicability criteria:

- The customer starting/stopping service is a Person or Business
- Account's Customer Class
- Start / Stop Premise's Premise Type
- SP Type(s) on the Premise(s) being started / stopped

Applicability criteria is optional. General questions can be configured to be always applicable.

Questions are marked as either Required or Optional. When marked as Optional on the CS Request Type Questions, it can be overridden as Required for certain SP Type(s) or Premise Type(s) or any other custom applicability criteria.

Your implementation can extend applicability criteria by:

- Adding elements to the CS Request Type Question - Main (**C1-CSRTQuestionMain**) data area, and / or
- Adding lookup values for Question Related Object Type (QSTN_REL_OBJ_TYPE_FLG)

Note that if you choose to extend the Question Related Object Types, you will also need to customize the **Read Questions** algorithm plugged in on the Customer Service Request Type BOs, to handle your additional applicability criteria.

Answer-Based Question Relationships (Conditional Questions)

A question can have one or more valid answers. Each valid answer, in turn, can determine the next question to ask.

A Customer Service Request Type Question can reference a related question for each Valid Answer. The related question must be one that is already configured on the Customer Service Request Type. Therefore, questions configuration should be a two-step process:

- Add all questions to the Customer Service Request Type.
- For each question, set up the related question(s) based on its valid answer(s).

The system has validation in place to ensure that question relationships do not result in recursion.

Question Placement Groups

A customer service request type can logically group questions based on where they are shown on the user interface. For instance, with a Transfer Service Request, the questions for stopping service are shown separately from the questions for starting service. For cases like this, the Question Placement Group should be used, to ensure that the correct set of questions are retrieved and shown on the user interface.

A Customer Service Request Type Question can be designated with a Question Placement Group, which is an extendable lookup (**C1-QuestionPlacementGrpLookup**) field. Base-owned lookup values are provided for Self-Service Start Service and Self-Service Stop Service. Each lookup value defines the customer service request type business objects that can use the Question Placement Group. Your implementation can define additional lookup values, if the groupings need to be more specific / granular.

Retrieving Applicable Questions

The **Read Questions** plug-in on the Customer Service Request Type BO is responsible for retrieving the questions that are applicable to a customer service request type. Given the inputs (Customer Service Request Type, Person ID, Account ID and Premise ID), the questions are read based on applicability criteria: Person / Business, Customer Class, Question Placement Group, Premise Type, SP Type(s) and/or any implementation-specific question applicability criteria (configured in Question Related Objects).

The **Read CS Request Type Questions By Applicability (C1RDCSRTQSTN)** base algorithm will apply Person / Business, Customer Class, Premise Type and SP Type criteria. Any additional implementation-specific question applicability should be handled via custom algorithm.

The Read Questions plug-in spot is invoked using a common service script, **Read CS Request Type Questions By Applicability (C1RDCSRTQSTN)**. The [Service Questions](#) on page 1322 operation of the **Start Stop Transfer Tasks** inbound web service calls this script to read the applicable questions to show on the self-service user interface.

Customizing the Questions Tree

The Questions Tree (**C1-CSRTQuestionTree**) is built on the Tree object in Framework. Refer to [Trees](#) on page 100 for more information.

C1-CSRTQuestionTree is configured to display up to 25 levels of related / conditional questions. Implementations can extend this by adding tree nodes to this base-owned tree.

The tree nodes are configured with Populate Node algorithms that use messages to display the information:

- **Tree Node - CS Request Type Question Root (C1CSRTQROOT)** - populates the information on the top-level nodes. It uses the messages (11131,12409) and (11131,12410) to display the question's sort sequence, question text and status (if Inactive).
- **Tree Node - CS Request Type Question - Related Questions (C1CSRTQRELO)** - populates the information on the child nodes that display related/conditional questions. It uses the messages (11131,12411) and (11131,12412) to display: valid answer, question's sort sequence, question text and status (if Inactive).

The text of these messages can be overridden to change the order in which the information is shown - e.g. to move the sequence number at the end.

If the base-supplied node information is not suitable to the implementation, the Populate Node algorithm can be overridden by plugging in a custom Override Information algorithm on the base tree node.

Lastly, the base product provides a Populate Node algorithm that checks if there are more related question levels than can be displayed, based on the configured number of tree nodes - i.e., either the 25 levels provided in base or the implementation-specific number of levels. To use this algorithm, configure an extra tree node level at the end and specify the Populate Node algorithm, **Tree Node - Check If More Related Questions Exist (C1CSRTQCHKRQ)**.

Understanding Service Eligibility

A service eligibility criterion has four components:

- The value to compare. This can be either a response to a question, or a value that is algorithm-derived.
- The comparison method, which consists of an operator and a comparison value.
- The instruction or action to take, based on the comparison result, which can be any of: True, False or Insufficient Data. For each result, the instruction can be any of: Eligible, Not Eligible for SA Type(s), Not Eligible for Start Option(s) and Check Next Condition.
- SA Type(s) to start (or stop) and any applicable Start Options when the comparison results in an Eligible instruction.

The base product provides a CS Request Type Svc Eligibility Criteria business object (**C1-CSRTSvcEligCriteria**) for configuring service criteria. Refer to the business object configuration in the application for more information.

The following describe the functionality that this business object supports.

Criteria Basis and Comparison Method

The **Criteria Basis** on CS Request Type Service Eligibility Criteria determines the value to compare:

- **Question Response** uses the response to a question that is configured on the CS Request Type.
- **Derive Value Algorithm** retrieves a field or characteristic value from an existing object, such as Person, Account or Premise. The base product provides algorithms to retrieve: an attribute from Account, an attribute from Premise and a characteristic value from Person / Account / Premise / SP / SA. Refer to the algorithm types for the **CS Request Type Svc Criteria - Derive Value** algorithm entity, for details.

The **Criteria Comparison** defines the operator to use and the value to compare with either a question response or an algorithm-derived value. The base product supports the operators: =, <>, >, >=, <, <=, Between and In. The comparison value is a free-form string, which should contain comma-separated values when the operator is Between or In.

Configuring Eligible SA Types and Start Options

At least one Eligible SA Type must be configured on a service eligibility criterion. If configuring multiple SA Types, designate one of them as the default. Configure any applicable Start Option(s) and designate one as the default.

Note: If there is a need to set a default SA Type and Start Option without relying on a question response, configure a Derive Value algorithm that simply returns 'true' and plug in the algorithm in the service eligibility criteria that defines the default SA Type and Start Option.

Applying Service Eligibility Criteria

The **Apply Svc Criteria** plug-in on the Customer Service Request Type BO is responsible for processing service eligibility criteria, given the following inputs: the selected SPs and SAs to start / stop, the list of question responses and the service task ID.

The **Apply Service Eligibility Criteria (C1CSRTAPSEC)** base algorithm reads the service eligibility criteria and performs the criteria comparisons for each.

The **Apply Svc Criteria** plug-in spot is invoked from the common service script for response processing, **Process Question Responses (C1ProQstnRsp)**, which in turn, is called by the [Process Services To Start](#) on page 1322 and [Process Services To Stop](#) on page 1324 operations of the **Start Stop Transfer Tasks** inbound web service.

Enabling Service Eligibility Criteria

To enable service eligibility criteria:

- Identify the CS Request Type Questions for which the responses will be used as the values to compare on service eligibility criteria.
- Determine the 'Derive Value' processing that your implementation needs:
 - To use the base-provided **CS Request Type Svc Criteria - Derive Value** algorithms:
 - Configure algorithm instances for the **Retrieve Account Attribute (C1SCRETACCT)** algorithm type.
 - Configure algorithm instances for the **Retrieve Premise Attribute (C1SCRETPREM)** algorithm type.
 - Configure algorithm instances for the **Retrieve Effective-Dated Characteristic Value (C1SCRETEFFCH)** algorithm type.
 - Identify and develop any additional **CS Request Type Svc Criteria - Derive Value** algorithms.
- Configure the Service Eligibility Criteria for your implementation's self-service New Service, Add Service, Stop Service and Transfer Service customer service request types. For each criterion, specify:
 - The criteria comparison details - criteria basis, question or algorithm (depending on the criteria basis), operator and comparison value.
 - The actions to take for comparison results True, False and Insufficient Data.
 - The eligible SA Types and any applicable start options.

Refer to [Setting Up Service Eligibility Criteria](#) on page 731 for more details.

Understanding Response-Related Updates

The questions configured on the customer service request type can be set up to perform related updates when the start / stop / transfer service request is processed and / or completed.

A response-related update can store the response value in a specific attribute or characteristic on objects such as Person, Account, Premise, SP and SA. In some cases, the the response value can be used to derive the actual value to store on a particular field, e.g. when the field is a foreign key to an admin table.

The base product provides a CS Request Type Related Update business object (**C1-CSRTRelUpd**) for configuring response-related updates. Refer to the business object configuration in the application for more information.

The following describes the functionality that this business object supports.

Related Update Entity Defines The Object To Update

A response-related update specifies a Related Update Entity, which identifies the maintenance object - i.e. Account, Person, Premise, SP or SA - and the part of the object to update - i.e., table field, characteristic or a custom element in the CLOB (XML) field.

Related Update Entity is an extendable lookup (**C1-CSRTRelUpdEntity**) that has base-supplied values for updates to the following:

- Fields on the Person, Account, Premise or SP tables
- Characteristics on Person, Account, Premise, SP or SA
- Custom elements in the Person or SP CLOB fields

Your implementations can add other objects to update by adding values to this lookup.

Response-Related Updates Are Staged For CS Request Processing

Response-related updates are staged into the CS Request Person / Account / Premise or directly on the CS Request, so that all object updates are done at the same time - i.e. when the CS Request transitions to a specific status.

For instance, with a Start Service Request, the Person(s) and Account are updated when the CS Request transitions to the Service Processing state. An algorithm on that state transitions the CS Request Person and CS Request Account staging records, that will in turn, update the Person(s) and Account. The CS Request SA records are also created and transitioned at that point. Thus, the updates to SA characteristics are also applied at that time. The CS Request Premise(s) are transitioned when the CS Request transitions to the Completed state. The same applies to SP-related updates that are staged directly on the CS Request, as there is no staging object for SP.

Each response-related update specifies a Processing Algorithm that is responsible for staging the update on the applicable CS Request staging object. The base product provides processing algorithms for the Related Update Entities that are supported in base. Refer to the algorithms types for the **CS Request Type Related Update - Process** algorithm entity, for more details. If your implementation opts to extend the values of the Related Update Entity lookup, you must develop the corresponding algorithms.

Staging Related Updates

The **Stage Related Updates** plug-in on the CS Request Type (BO) is responsible for invoking a customer service request type's response-related updates. It reads the Response-Related Update configuration and invokes the associated **CS Request Type Related Update - Process** algorithm for each response-related update.

The **Stage Related Updates** plug-in spot is invoked using a common service script, **Process Related Updates (C1ProcRelUpd)**.

When a self-service start / stop / transfer request is finalized, an enter algorithm on the service task's Service Processing state calls the Process Related Updates service script before transitioning the CS Request (that in turn, transitions CS Request Person, CS Request Account and CS Request SAs). Refer to the Self-Service Start/Stop/Transfer Task (C1-SSStartStopXferServiceTask) business object, for details on this lifecycle processing.

Premise and SP updates are applied when the start/stop request completes and when a transfer request pre-completes. Refer to the Start Service Request (C1-StartServiceRequest), Stop Service Request (C1-StopServiceRequest) and Transfer Service Request (C1-TransferServiceRequest) business objects, for details on this lifecycle processing.

Note: For more information on start/stop/transfer finalization, refer to the [Start Service Finalization](#) on page 1323, [Stop Service Finalization](#) on page 1324 and [Transfer Service Finalization](#) on page 1324 operations.

Enabling Response-Related Updates

To enable response-related updates for configured CS Request Type Questions:

- Determine the Related Update Entities that your implementation needs to support:
 - To use the base-provided Related Update Entities, configure the **CS Request Type Related Update - Process** algorithm instances for the specific fields and / or characteristics that should be updated from the responses.

- Configure any additional **Related Update Entity** lookup values and develop the corresponding **CS Request Type Related Update - Process** algorithms for them.
- Identify the CS request type questions that will trigger response-related updates. Configure a Response-Related Update for each of these questions, specifying the applicable Related Update Entity and Processing Algorithm.

Refer to [Setting Up Response-Related Updates](#) on page 731 for more details.

Setting Up Customer Service Request Questions

A customer service request type can define one or more questions to ask during the flow of customer service requests, such as self-service New Service, Add Service, Stop Service and Transfer Service.

Refer to [Understanding Customer Service Request Questions](#) for more information.

To configure questions, open **Admin > Customer > Customer Service Request Type** and navigate to the **Questions** tab page.

The Questions List zone displays all questions that are configured for the customer service request type. Search filters are provided, to allow specific search using any of the following criteria: Person/Business, Customer Class, Premise Type (applicability), SP Type (applicability), Sort Sequence (range) and Status.

The Question zone displays when a record is broadcast from the Questions List. Refer to the zone's embedded help for more details.

The Questions Tree zone shows the hierarchical structure of the questions, including conditional questions. Each node navigates to the Customer Question configuration.

Note: The Questions Tree is built on the Tree object in Framework. Refer to [Trees](#) on page 100 and [Customizing the Questions Tree](#) on page 728 for more information.

Setting Up Service Eligibility Criteria

A customer service request type can define one or more service eligibility criteria to apply, using the responses to questions and/or information that is already stored in the system (e.g. person / account / premise attributes and characteristics).

Service eligibility criteria processing can determine one or more of the following:

- Applicable start option(s) for SP-based service agreements that are selected for starting service.
- Additional service agreements that are eligible to start. For example, non-SP-based service agreements, such as charitable contributions, equipment rentals, loans, etc.
- A change in whether or not a selected SP-based service agreement can be started/stopped.

Refer to [Understanding Service Eligibility](#) on page 728 for more information.

To configure service eligibility criteria, open **Admin > Customer > Customer Service Request Type** and navigate to the **Service Eligibility** tab page.

The Service Eligibility Criteria List zone displays all service eligibility criteria that are configured for the customer service request type. Search filters are provided, to allow specific search using any of the following criteria: Sort Sequence range, Question text and Status.

The Service Eligibility Criteria zone displays when a record is broadcast from the Service Eligibility Criteria List. Refer to the zone's embedded help for more details.

Setting Up Response-Related Updates

Question responses can trigger updates to Person, Account, Premise, SP and / or SA attributes and characteristics, when the request is processed or completed. A Response-Related Update defines: the object to update, the object's attribute / field to update and the algorithm that will process the update. The base product provides algorithms that store question responses in: characteristics, table fields (on the object's primary table), or a custom element in the object data area (CLOB) field on Person or SP.

Refer to [Understanding Response-Related Updates](#) on page 729 for more information.

To configure Related Updates, open **Admin > Customer > Customer Service Request Type** and navigate to the **Response-Related Updates** tab page.

The Response-Related Updates List zone shows all questions that are currently configured for the customer service request type. Each can be configured with a related update that stores the response to the question in an attribute / characteristic on Person, Account, Premise, SP or SA. Click **Add Related Update** or **Edit Related Update** to configure the related update.

The Response-Related Update zone displays when a record is broadcast from the Response-Related Updates List. Refer to the zone's embedded help for more details.

Defining Customer 360 Options

The following section provides an overview of how to enable Customer 360.

Fastpath:

Refer to [Customer 360](#) for more information on this functionality.

Setting Up The System To Enable Customer 360

To set up the system for Customer 360, do the following:

- Define Display Icon Override Configuration settings.
- Define Billing and Usage Configuration settings.

Display Icon Override Configuration

This section describes the process for configuring display icons that are used within the various zones for Customer 360. For example, icons that appear alongside nodes within the Premise Context tree, as well as icons that appear within records of the Customer Activity and Financial History zones.

By default, display icon references are configured at the Maintenance Object or Business Object level using the **Default Icon Reference** Option Type. For certain Maintenance Objects, these icons can be overridden based on their type fields. For example, a Customer Contact can have an override icon based on its Contact Class or Contact Type, a Service Agreement can have a override icon based on the SA Types Service Type, etc.

Display icon overrides are configured by adding or changing a Master Configuration. You can access the portal through **Admin > General > Master Configuration**.

From the Master Configuration list, add or edit the **Display Icon Override Configuration** record. Use the Add button to configure for the first time. If a record has already been added, click the Edit button instead. Use the embedded help to guide you through the options.

Billing and Usage Display Configuration

There are several options available to tailor your Customer 360 Billing & Usage data display via Master Configuration - Billing and Usage Display Configuration. The units of measure, the specific service quantities to display per rate, the default time period, as well as the summarization of the data within the bar chart can all be adjusted per your organization's needs.

Billing and Usage display settings are configured by adding or changing a Master Configuration. You can access the portal through **Admin > General > Master Configuration**.

From the Master Configuration list, add or edit the **Billing and Usage Display Configuration** record. Use the Add button to configure for the first time. If a record has already been added, click the Edit button instead. Use the embedded help to guide you through the options.

Defining Field Order Options

A field order is a group of field activities that take place at a premise's service point(s). These activities can range from the simple (e.g., read a meter) to the complex (e.g., install both the power line and a new meter). Before you can issue field orders, you must establish the control data defined in this section.

**Note:**

Appointments. Refer to [The Big Picture of Appointments](#) for information about how appointments can be scheduled for field activities.

**Warning:**

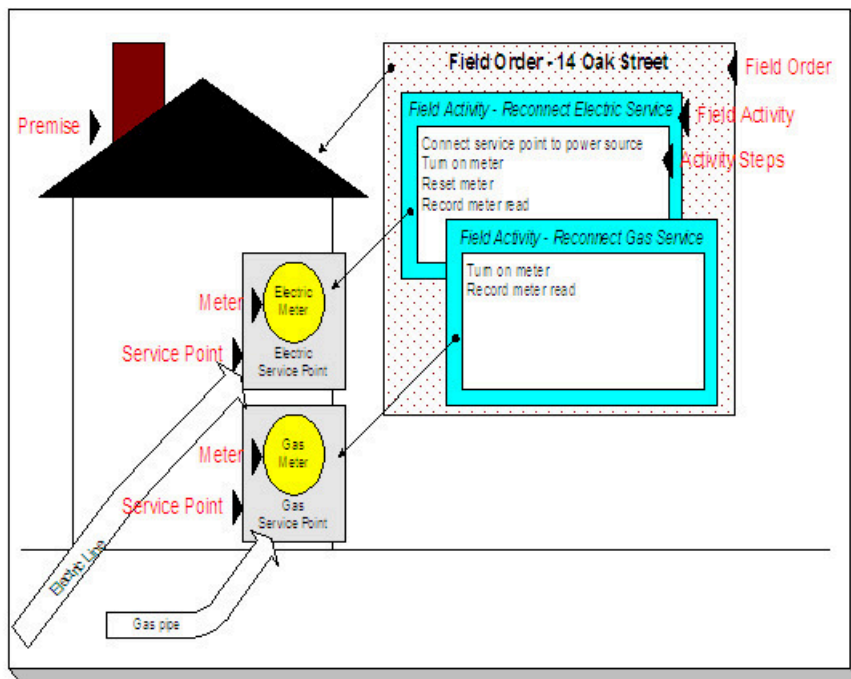

Setting up the tables that control your field activities will be as complicated as the fieldwork your organization performs. If your company doesn't do fieldwork, then you won't have to set up any of these tables. If your company has a single service and the fieldwork you perform is straightforward, this setup process will be straightforward. If your company performs sophisticated fieldwork (e.g., utilizing multiple crews and multiple dispatch locations), this setup process will require careful analysis.

**Fastpath:**

For more information about field orders and how they use the information described in this chapter, refer to [The Big Picture Of Field Orders](#).

An Example Of A Field Order

The following picture illustrates a field order that controls the work to be performed at a premise with 2 service points.

The following field order-related concepts are illustrated above:

Field Order A field order is a group of field activities performed by one person (or crew) at a premise. Refer to [How Are Field Orders Created And Dispatched](#) for information about how field orders are created.

Field Activity A field activity is a task that takes place at a service point. Examples of field activities include reconnect service, exchange meter, disconnect service, cut for nonpayment, investigate trouble order.

The system automatically creates field activities when specific events happen. Refer to [Designing Your Field Activity Profiles](#) for a discussion of how the system does this.

When a field activity is first added, its state is pending. If the activity is not done (for whatever reason), the activity is canceled. After the activity is done, the results of the activity are recorded in the system and its state becomes complete.

Activity Step A field activity has one or more steps. For example, the field activity to exchange a meter would have the following activity steps: Remove existing meter, Test meter, Install new meter.

The number and types of steps involved with a field activity are controlled by the activity's activity type. Refer to [Setting Up Field Activity Types](#) for more information.

Premise See [An Illustration Of A Premise](#) for a description.

Service Point See [An Illustration Of A Premise](#) for a description.

Meter See [An Illustration Of A Premise](#) for a description.

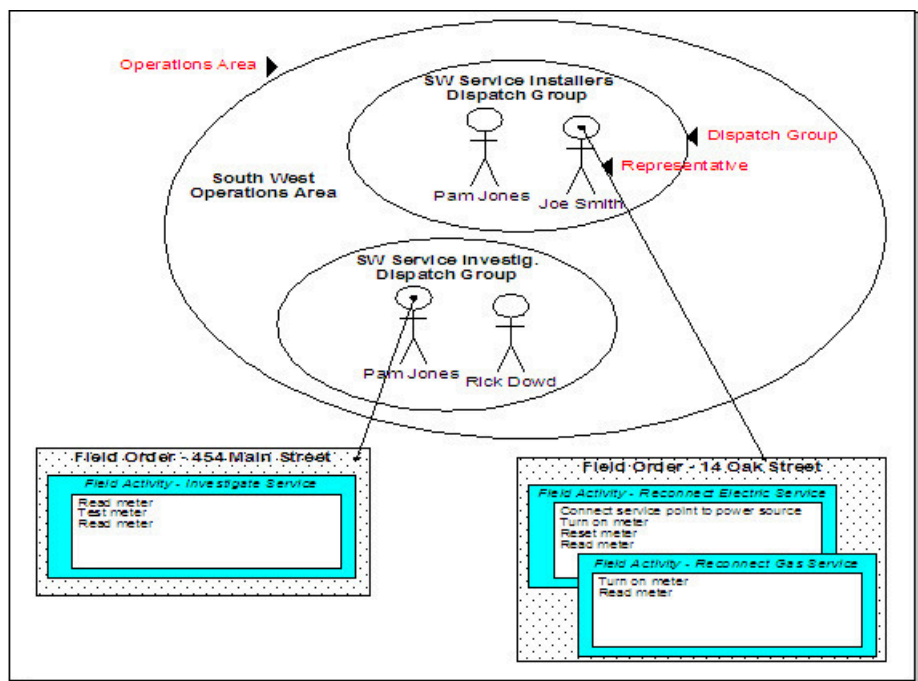

Note:

More than just meters. While the above diagram illustrates field order concepts in respect of meters, the field orders system has been designed to handle meters, lamps, and any other type of device located at a service point (e.g., a cable box).

An Example Of The Entities Involved In Field Order Dispatch

The following picture illustrates two field orders that are dispatched from the same operations area where each field order is assigned to a different representative.

The following dispatch-related concepts are illustrated above:

Representative A representative is the individual (or crew) that performs a field order's activities. A representative may work in any number of dispatch groups. Refer to [Setting Up Representatives](#) for more information.

Operations Area An operation area is a physical or logical location from which field orders are dispatched. Every service point references the operation area(s) responsible for its service. Refer to [Setting Up Operations Areas](#) for more information.

Dispatch Group A dispatch group is a logical group of representatives located at an operations area. For example, in the South West Operations Area you may have the dispatch groups of SW Service Installers, SW Service Investigators, SW Meter Exchangers, etc. Within each dispatch group are representatives with interchangeable skills (i.e., you can assign a field activity to any representative within a dispatch group). Refer to [Setting Up Dispatch Groups](#) for more information.

The system automatically assigns a field activity a dispatch group when it's first created. It does this based on: 1) the type of field activity, 2) the service point's SP type, and 3) the operation area on the service point that's linked to the field activity type's field service classification. Refer to [Designing Who Does Your Field Activities](#) for more information.

Setting Up Representatives

A representative is the individual (or equipment) that performs a field order's activities. At dispatch time, a representative may be assigned to a field order. To define your organization's representatives, open **Admin > Field Work > Representative**.

Description of Page

Enter an easily recognizable **Representative** and **Description** for each representative.

Setting Up Operations Areas

When you set up a service point, you must define the operation areas that manage its fieldwork.

Note:

How a service point gets its operation area(s). A service point's operation areas default based on its service type and its premise's postal code. See [Setting Up Premise & Service Point Postal Defaults](#) for more information.

To define your organization's operation areas, open **Admin > Operations Area**.

Note:

A service point may have multiple operation areas. For example, a service point may have one operations area for installs and removals, a separate operation area for trouble orders, and yet a third operation area for meter exchanges. Refer to [Setting Up Field Service Classifications](#) for more information about how different types of fieldwork can be classified.

Description of Page

Enter an easily recognizable **Operations Area** and **Description** for each operation area.

Setting Up Dispatch Groups

A dispatch group is a logical group of representatives located at an operations area. When a field activity is created, the system assigns it to a dispatch group based on the type of activity, the type of service point, and the operations area that manages the service point. The topics in this section describe the pages used to maintain a dispatch group.

Dispatch Group - Main

To define your organization's dispatch groups, open **Admin > Field Work > Dispatch Group > Add**.

Description of Page

Enter an easily recognizable **Dispatch Group ID** and **Description** for each dispatch group.

Turn on **Allow Dispatch** if orders allocated to this dispatch group are "dispatchable".

Note:

Trouble orders without a premise. The only example we can think of where Allow Dispatch is off would be for the dispatch group associated with trouble orders without a premise. These trouble orders are associated with a "dummy" service point, and the dummy service point's operations area should reference the unknown

dispatch group. Someone would need to periodically look at the unknown dispatch group and associate its field activities with the appropriate service point and dispatch group.

If this dispatch group is "dispatchable" and work for this dispatch group is interfaced to an external system, indicate the appropriate external system [feature configuration](#) or outage management feature configuration for the dispatch group.

Note:

Separate module. Functionality related to integrating with an [external system](#) or an outage system is associated with separate function modules. The feature configuration field is not available if these modules are [turned off](#).

Batch Control along with the Field Order Extract algorithm defined on the **Algorithms** tab control how field orders that reference this dispatch group are printed (both in batch and online). Refer to [Technical Implementation Of Batch Field Order Production](#) for more information about producing field orders in batch. Refer to [Technical Implementation Of Online Field Order Production](#) for more information about online field order production.

- Use **Batch Control** to define the process that creates the flat file that is passed to your field order printing software. If you use an **Extract Algorithm** to construct the downloaded information, you can use either the [FODL](#) or the [DSGPFODL](#).
- Use the Field Order Extract algorithm defined on the **Algorithms** tab to define the plug-in component that constructs the "flat file records" that contain the information to be merged onto field orders that reference this dispatch group. This algorithm is called when a user requests an online image of a field order on [Field Order - Main](#) and it may also be called by the batch field order extraction process defined above. Please be aware that the system comes with a sample algorithm type - FOEX-OX - that should be used as a sample if you have to write a new plug-in [algorithm](#).

Use **Alternative Dispatch Group** to define the dispatch group that can do everything that this dispatch group can do. This field is used when the system attempts to find a common dispatch group for all field activities associated with a premise (when such field activities don't have the same dispatch group) during the appointment scheduling process. Refer to [Using Alternate Dispatch Groups To Find The Lowest Common Denominator](#) for more information.

Use **Allow FA Type Change When Dispatched** to indicate if FA Type changes are allowed once a field activity is dispatched.

The **Representative** collection shows the representatives who may be assigned to field orders performed by a dispatch group.

Dispatch Group - Field Activity Type Review

Open **Admin > Field Work > Dispatch Group > Search** and navigate to the **FA Type Review** page to review the field activities that can be performed by the dispatch group. For each field activity in the tree, you can view the SP types associated with the activity.

Note:

Four dimensions. For every **field activity type**, you define the **dispatch group** that performs the activity at every **SP type** located in every **operations area**. This information is maintained on the Field Activity Type page. This is a rather complex relationship because it involves the four dimensions highlighted in bold. Due to this complexity, we have provided review trees on the SP Type, Dispatch Group, and Field Activity Type pages to help you understand what you've set up.

Description of Page

This page is dedicated to a tree that shows the field activity types performed by the dispatch group. And for each field activity and operations area, you can view the applicable SP types.

Dispatch Group - Algorithm

Open **Admin > Field Work > Dispatch Group > Search** and navigate to the **Algorithm** page to define the algorithms that should be executed for field activities / field orders associated with a given dispatch group.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

Warning:

These algorithms are typically significant processes. The absence of an algorithm may prevent the system from operating correctly.

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|------------------------|---|--|
| Available Appointments | Required if you use base appointment scheduling functions (and not external system integration) | <p>The algorithm plugged into this spot is responsible for determining which appointment periods may be linked to a field activity.</p> <p>Refer to Appointment Maintenance for a description of the transaction that's used to setup an appointment.</p> <p>Refer to The Big Picture Of Appointments for general information about appointments.</p> |
| FA Integration | Required if dispatch group interfaces with an external system. | <p>The algorithm plugged into this spot is responsible for creating appropriate notification download staging records used to interface field activity information to an external system.</p> <p>This algorithm is not allowed if the dispatch group does not interface with an external system.</p> <p>Refer to Algorithms Control FA Integration for more information.</p> |
| Field Order Extract | Required if dispatch group is "dispatchable" (refer to the description of Allow Dispatch on the Main page for more information) | Refer to the description of Batch Control on the Main for a description of this system event. |

| | | |
|-----------------------|---|---|
| Validate Appointments | Optional if you use base appointment scheduling functions | <p>The algorithm plugged into this spot is responsible for determining if a field activity can be linked to an appointment period. If you don't plug-in a Validate Appointments algorithm, the system will allow any appointment period that's displayed on the Appointment Maintenance transaction to be linked to a field activity.</p> <p>Refer to Appointment Maintenance for a description of the transaction that's used to setup an appointment.</p> <p>Refer to The Big Picture Of Appointments for general information about appointments.</p> |
|-----------------------|---|---|

Defining Disconnect Locations

When a service point is disconnected from the supply source, a disconnect location must be specified. This location defines where service was severed. It also controls the type of field activity generated to reconnect service.

Note:

A service point's disconnect location is updated as part of the service disconnection process. This location is used to determine the appropriate crew to send out when it's time to reconnect service.

To define disconnect location codes, open **Disconnect Location** page.

Description of Page

Enter a **Disconnect Location** and **Description** for every disconnect location.

Designing Your Field Activity Profiles and Types

A field activity is a task that takes place at a service point. Every field activity references a field activity type. The field activity type defines the steps involved in the execution of the activity.

Most field activities are created:

- When a customer service representative starts or stops service at a premise, the system automatically creates field activities to perform the necessary fieldwork based on the type and state of the service point.
- When service is cut due to lack of payment.

If you set the system up correctly, your CSR's won't have to create these field activities. Rather, the system creates field activities based on the information you set up in your field activity type profiles. You typically have a different field activity profile for every major category of service point. We recommend that you familiarize yourself with the following documentation before you set up your field activity type profiles:

- Refer to [Starting Service & Field Activities](#) for a description of how field activities are created to start service.
- Refer to [Stopping Service & Field Activities](#) for a description of how field activities are created to stop service.
- Field activities used to cut service due to non-payment are created by two modules:
 - If you use severance process to stop a service agreement due to nonpayment, refer to [Field Events And Their Activities](#) for a description of how these field activities are created.
 - If you use cut processes to stop a service agreement due to nonpayment, refer to [Field Activities To Cut and Reconnect Service](#) for a description of how these field activities are created.

The topics in this section describe how to design your field activity profiles and field activity types.

How Does A Field Activity Type Profile Get Used?

A field activity type profile contains:

- A list of field activity types that can be performed at service points.
- Matrices defining the specific activity type(s) to generate in order to start service, stop service, or disconnect due to non-payment.

You may wonder how field activity type profiles get related to your service points. It's a little indirect, but the indirection provides a great deal of flexibility:

- Every service point references an SP type.
- Every SP type references the specific field activity type profile used by the start/stop and credit and collections process to generate field activities.

An example will help illustrate how this works:

- When you start service at a specific service point, the system extracts the service point's SP type.
- Then, the system determines the field activity type profile that is to be used on this SP type.
- Then, the system determines the state of the service point (e.g., connected, no meter).
- And finally, it generates the appropriate field activity.

Designing Field Activity Type Profiles

The number of field activity type profiles is dependent on a variety of factors:

- If your field crews (i.e., dispatch groups) are highly specialized, you'll need more profiles than when your crews can perform a variety of activities. For example, if you have electric installers who just install electric service and gas installers who just install gas service, you'll need a different profile for electricity versus gas.
- If the field activities you perform differ based on the type of service point, you'll need more profiles than if you have standard activities. For example, if you turn off residential service differently than you turn off commercial service, you'll need a profile for each type of customer.
- If you have meters and item-based service, you'll need a separate profile to distinguish the field activities for these two types of service.
- If more than one of the above points applies to your organization, you'll need a separate profile for the superset.

The easiest way to design your profiles is to pick an SP type and design its profile by filling in matrices similar to those defined below (choose either meter or item-based as per the SP type). After you've designed the profile, determine how many other SP types on which it can be used. Then design the next SP type's profile and determine where it can be reused. Repeat this process until all your SP types have a profile.

Fastpath:

In order to design your field activity type matrices, you must have a good understanding of field activity types and how they control the actions performed by your field crews. Refer to [Setting Up Field Activity Types](#) for more information.

Typical Metered Service Matrix

In this section, we provide a sample of how the activity type matrix would look for metered service. The topics show two matrices; one for start/stop field activities, the other for credit & collections activities. In reality, there is a separate matrix for every column in the matrices.

Starting and Stopping Metered Service Matrix

The following matrix is representative of how a metered SP type's field activity type profile would look. The following points describe the rows, columns and cells in the matrix:

- The customer events represent the three start and stop events that may take place at the service point.
 - Start service is the event that takes place when a service point is to be started and the system has no knowledge of a related stop event.
 - Stop service is the event that takes place when a service point is to be stopped and the system has no knowledge of a related start event.
 - Start/stop service is the event that takes place when a service point is to be stopped for one customer and started for another at the same time.
- The SP conditions represent the state of service at a service point. The following conditions are represented:
 - A device (the meter) is either installed or not installed.
 - The installed device is either turned on or off.
 - The source of service (the line or pipe) is either connected to the service point or disconnected.
 - If the source is disconnected, define a field activity for each potential disconnect location.
- Each cell in the matrix represents a field activity to be created by the system for the combination of customer event and service point condition.

| SP Condition | Customer Event: Start Service | Customer Event: Stop Service | Customer Event: Start/Stop Service |
|--|---|--|--|
| No Device / SP Disconnected at meter | Install meter and connect line | N/A - no field work is necessary because the meter should have been read when it was removed | N/A |
| No Device / SP Disconnected at pole | Install meter and connect line | N/A - no field work is necessary because the meter should have been read when it was removed | N/A |
| No Device / SP Connected | Install meter | N/A - no field work is necessary because the meter should have been read when it was removed | N/A |
| Device Installed / Device Off / SP Disconnected at meter | Connect line and turn on meter | N/A - no field work is necessary because the meter should have been read when the service was severed | N/A |
| Device Installed / Device Off / SP Disconnected at pole | Connect line and turn on meter | N/A - no field work is necessary because the meter should have been read when the service was severed | N/A |
| Device Installed / Device Off / SP Connected | Turn on meter | N/A - no field work is necessary because the meter should have been read when the meter was turned off | N/A |

| | | | |
|---|-----------------------------|---|------------|
| Device Installed / Device On / SP Connected | Read meter | Turn off meter | Read meter |
| Device Installed / Device On / SP Disconnected at meter | Connect line and read meter | N/A - no field work is necessary because the meter should have been read when the line was disconnected | N/A |
| Device Installed / Device On / SP Disconnected at pole | Connect line and read meter | N/A - no field work is necessary because the meter should have been read when the line was disconnected | N/A |

Cutting Metered Service Due To Nonpayment

The following matrix is representative of how a metered SP type's field activity type profile might look. The following points describe the rows, columns and cells in the matrix:

- The customer events represent the three C&C-oriented field activities that may take place at the service point.
 - Disconnect warning is the event that warns the customer of imminent severance if payment is not received.
 - Cut for non-payment is the event that causes service to be severed due to non-payment.
 - Reconnect is the event that takes place when a service point is reconnected because payment was received after service was cut.
- The SP conditions represent the state of service at a service point. The following conditions are represented:
 - A device (the meter) is either installed or not installed.
 - The installed device is either turned on or off.
 - The source of service (the line or pipe) is either connected to the service point or disconnected.
 - If the source is disconnected, define a field activity for each potential disconnect location.
- Each cell in the matrix represents a field activity to be created by the system for the combination of customer event and service point condition.

| SP Condition | Customer Event: | Customer Event: | Customer Event: |
|---|-----------------------------|------------------------|--------------------------------|
| | Disconnect Warning | Cut For Non-Payment | Reconnect |
| Device Installed / Device On / SP Connected | Leave disconnection warning | Cut metered serviced | N/A |
| Device Installed / Device Off / SP Connected | N/A - service is off | N/A - service is off | Turn on meter |
| Device Installed / Device On / SP Disconnected at pole | N/A - service is off | N/A - service is off | Connect line |
| Device Installed / Device Off / SP Disconnected at pole | N/A - service is off | N/A - service is off | Connect line and turn on meter |
| No Device / SP Connected | N/A - service is off | N/A - service is off | Install meter |

| | | | |
|--|----------------------|----------------------|-----------------------------------|
| No Device / SP Disconnected at pole | N/A - service is off | N/A - service is off | Install meter and connect line |
|--|----------------------|----------------------|-----------------------------------|

Meter Testing Activities

While the field activity types associated with meter testing should not appear in the above matrixes, these field activity types must be defined in the metered service points' field activity type profiles (under Valid Activity Types). Refer to [Examples of Device Testing Activity Types and their Steps](#) for example of these field activity types.

Typical Badged Item Service Matrix

In this section, we provide a sample of how the activity type matrix would look for BADGED item-based service (e.g., badged lamps). The topics show two matrices; one for start/stop field activities, the other for credit & collections activities. In reality, there is a separate matrix for every column in the matrices.

Fastpath:

Refer to [Service Points \(SPs\)](#) for more information about the difference between badged and non-badged items.

Starting and Stopping Badged Item Service Matrix

The following matrix is representative of how a lamp SP type's field activity type profile would look. The following points describe the rows, columns and cells in the matrix:

- The customer events represent the three start and stop events that may take place at the service point.
 - Start service is the event that takes place when a service point is to be started and the system has no knowledge of a related stop event.
 - Stop service is the event that takes place when a service point is to be stopped and the system has no knowledge of a related start event.
 - Start/stop service is the event that takes place when a service point is to be stopped for one customer and started for another at the same time.
- The SP conditions represent the state of service at a service point. The following conditions are represented:
 - A device (the item) is either installed or not installed.
 - The installed device is either turned on or off.
 - The source of service (the line or pipe) is either connected to the service point or disconnected.
 - If the source is disconnected, define a field activity for each potential disconnect location.
- Each cell in the matrix represents a field activity to be created by the system for the combination of customer event and service point condition.

| SP Condition | Customer Event: Start Service | Customer Event: Stop Service | Customer Event: Start/Stop Service |
|--|----------------------------------|---|---------------------------------------|
| No Device / SP Disconnected at pole | Install lamp and connect line | N/A - no field work is necessary because there is no lamp | N/A |
| No Device / SP Connected | Install lamp | N/A - no field work is necessary because there is no lamp | N/A |

| | | | |
|---|------------------------------|--|-------------------------|
| Device Installed / Device Off / SP Disconnected at pole | Connect line and install eye | N/A - no field work is necessary because the lamp is off | N/A |
| Device Installed / Device Off / SP Connected | Install eye | N/A - no field work is necessary because the lamp is off | N/A |
| Device Installed / Device On / SP Disconnected at pole | Connect line | N/A - no field work is necessary because the lamp is off | N/A |
| Device Installed / Device On / SP Connected | No field work necessary | Turn off lamp | No field work necessary |

Cutting Badged Item Service Due To Nonpayment

The following matrix is representative of how an item-based SP type's field activity type profile would look. The following points describe the rows, columns and cells in the matrix:

- The customer events represent the three C&C-oriented field activities that may take place at the service point.
 - Disconnect warning is the event that warns the customer of imminent severance if payment is not received.
 - Cut for non-payment is the event that causes service to be severed due to non-payment.
 - Reconnect is the event that takes place when a service point is reconnected because payment was received after service was cut.
- The SP conditions represent the state of service at a service point. The following conditions are represented:
 - A device (the item) is either installed or not installed.
 - The installed device is either turned on or off.
 - The source of service (the line or pipe) is either connected to the service point or disconnected.
 - If the source is disconnected, define a field activity for each potential disconnect location.
- Each cell in the matrix represents a field activity to be created by the system for the combination of customer event and service point condition.

| SP Condition | Customer Event: Disconnect Warning | Customer Event: Cut For Non-Payment | Customer Event: Reconnect |
|---|--|---|-------------------------------------|
| Device Installed / Device On / SP Connected | Leave disconnect warning | Cut lamp service | N/A |
| Device Installed / Device Off / SP Connected | N/A - service is off | N/A - service is off | Turn on item |
| Device Installed / Device On / SP Disconnected at pole | N/A - service is off | N/A - service is off | Connect line |
| Device Installed / Device Off / SP Disconnected at pole | N/A - service is off | N/A - service is off | Connect line and turn on item |
| No Device / SP Connected | N/A - service is off | N/A - service is off | Install item |

| | | | |
|--|----------------------|----------------------|----------------------------------|
| No Device / SP Disconnected at pole | N/A - service is off | N/A - service is off | Install item and connect line |
|--|----------------------|----------------------|----------------------------------|

Item Testing Activities

While the field activity types associated with item testing should not appear in the above matrixes, these field activity types must be defined in the item-based service points' field activity type profiles (under Valid Activity Types).

Typical Unbadged Item Service Matrix

In this section, we provide a sample of how the activity type matrix would look for UNBADGED item-based service (e.g., parking lots, sewage service). The topics show two matrices; one for start/stop field activities, the other for credit & collections activities. In reality, there is a separate matrix for every column in the matrices.

Starting and Stopping Unbadged Item Service Matrix

The following matrix is representative of how a field activity type profile would look for a parking lot's SP type. The following points describe the rows, columns and cells in the matrix:

- The customer events represent the three start and stop events that may take place at the service point.
 - Start service is the event that takes place when a service point is to be started and the system has no knowledge of a related stop event.
 - Stop service is the event that takes place when a service point is to be stopped and the system has no knowledge of a related start event.
 - Start/stop service is the event that takes place when a service point is to be stopped for one customer and started for another at the same time.
- The SP conditions represent the state of service at a service point. The following conditions are represented:
 - The source of service (the line or pipe) is either connected to the service point or disconnected.
 - If the source is disconnected, define a field activity for each potential disconnect location.
 - Notice that the SP Conditions always indicate "No Device". This is because a device (i.e., a meter or badged item) cannot be installed at this type of service point.
- Each cell in the matrix represents a field activity to be created by the system for the combination of customer event and service point condition.

| SP Condition | Customer Event: Start Service | Customer Event: Stop Service | Customer Event: Start/Stop Service |
|--|--|---|---|
| No Device / SP Disconnected at pole | Connect service in parking lot | N/A - no field work is necessary because there is no lamp | N/A |
| No Device / SP Connected | No field activity necessary | Disconnect service in parking lot | No field activity necessary |

Cutting Unbadged Item Service Due To Nonpayment

The following matrix is representative of how an item-based SP type's field activity type profile would look. The following points describe the rows, columns and cells in the matrix:

- The customer events represent the three C&C-oriented field activities that may take place at the service point.

- Disconnect warning is the event that warns the customer of imminent severance if payment is not received.
- Cut for non-payment is the event that causes service to be severed due to non-payment.
- Reconnect is the event that takes place when a service point is reconnected because payment was received after service was cut.
- The SP conditions represent the state of service at a service point. The following conditions are represented:
 - Notice that the SP Conditions always indicate "No Device". This is because a device (i.e., a meter or badged item) cannot be installed at this type of service point.
 - The source of service (the line or pipe) is either connected to the service point or disconnected.
 - If the source is disconnected, define a field activity for each potential disconnect location.
- Each cell in the matrix represents a field activity to be created by the system for the combination of customer event and service point condition.

| SP Condition | Customer Event: | Customer Event: | Customer Event: |
|-------------------------------------|--------------------------------|-------------------------|-------------------------------|
| | Disconnect Warning | Cut For Non-Payment | Reconnect |
| No Device / SP Connected | Parking lot disconnect warning | Cut parking lot service | Reconnect parking lot service |
| No Device / SP Disconnected at pole | N/A - service is off | N/A - service is off | Reconnect parking lot service |

Designing Field Activity Types

The number of activity types you need is related to the different field activities your company performs at your service points. For example, if your company installs and maintains meters, you will set up field activity types for every conceivable meter-related task you assign to your field staff. If your company installs and maintains lamps, you will set up field activity types for every conceivable lamp-related task you assign to your field staff.

The topics in this section describe how to design your field activity types.

Designing Field Activity Types From Your Field Activity Type Profiles

After designing your field activity type profiles, the resulting matrices will reference every field activity type needed to:

- Start service
- Stop service
- Leave disconnect warnings
- Cut service due to non-payment
- Reconnect service after cut

The topics in this section illustrate every field activity type that would be needed to satisfy the needs of the field activity type profiles illustrated above.

Examples of Meter-Oriented Activity Types and their Steps

The following table shows several classic meter-oriented activity types and their respective steps:

| Activity Type | Step | Step Type Action |
|------------------------------|----------------------------|-----------------------|
| Connect SP and install meter | Connect SP to power source | Connect Service Point |

| | | |
|-------------------------------|-------------------------------------|--------------------------|
| | Install meter | Install Meter |
| | Attempt to notify owner - optional | Contact Customer |
| Connect SP | Connect SP to power source | Connect Service Point |
| Disconnect SP | Disconnect SP from power source | Disconnect Service Point |
| Install meter | Install meter | Install Meter |
| Remove meter | Remove meter | Remove Meter |
| Read meter | Read meter | Read Meter |
| Turn on meter | Turn meter on | Turn On Meter |
| Turn off meter | Turn meter off | Turn Off Meter |
| Reconnect meter after payment | Turn meter on - optional | Turn On Meter |
| | Install meter - optional | Install Meter |
| Disconnect warning | Place disconnect warning | Contact Customer |
| Cut meter for non payment | Turn meter off - optional | Turn Off Meter |
| | Remove meter - optional | Remove Meter |
| Remove and disconnect meter | Verify premise is vacant - optional | Contact Customer |
| | Remove meter | Remove Meter |
| | Disconnect SP from power source | Disconnect Service Point |

Examples of Badged Lamp-Oriented Activity Types and their Steps

The following table shows several classic lamp-oriented activity types and their respective steps:

| Activity Type | Step | Step Type Action |
|---------------------------------|------------------------------------|--------------------------|
| Connect SP and install lamp | Connect SP to power source | Connect Service Point |
| | Install lamp | Install Item |
| | Attempt to notify owner - optional | Contact Customer |
| Connect SP | Connect SP to power source | Connect Service Point |
| Disconnect SP | Disconnect SP from power source | Disconnect Service Point |
| Install lamp | Install lamp | Install Item |
| Remove lamp and leave connected | Remove lamp | Remove Item |

| | | |
|----------------------------|-------------------------------------|--------------------------|
| Install eye | Install eye | Turn On Item |
| Remove eye | Remove eye | Turn Off Item |
| Remove and disconnect lamp | Verify premise is vacant - optional | Contact Customer |
| | Remove lamp | Remove Item |
| | Disconnect SP from power source | Disconnect Service Point |
| Disconnect warning | Place disconnect warning | Contact Customer |
| Reconnect lamp | Install eye - optional | Turn On Item |
| | Install lamp - optional | Install Item |
| Cut lamp for non payment | Remove eye - optional | Turn Off Item |
| | Remove lamp - optional | Remove Item |

Examples of Unbadged Service Point Activity Types and their Steps

The following table shows several classic lamp-oriented activity types and their respective steps:

| Activity Type | Step | Step Type Action |
|---------------------------|--------------------------|------------------------|
| Connect lamps in lot | Connect lamps | Reconfigure Multi-Item |
| Disconnect lamps in lot | Disconnect lamps | Reconfigure Multi-Item |
| Reconnect after pay | Reconnect lamps | Reconfigure Multi-Item |
| Disconnect warning | Place disconnect warning | Contact Customer |
| Cut lamps for non payment | Disconnect lamps | Reconfigure Multi-Item |

Designing Other Field Activity Types

Besides those activity types that are needed to start/stop - cut service, you'll also need some field activity types for ad hoc service investigations and trouble orders.

The topics in this section illustrate these additional field activity types.

Examples of Meter-Oriented Service Investigation Activity Types and their Steps

The following table shows several classic meter-oriented activity types and their respective steps:

| Activity Type | Step | Step Type Action |
|----------------|--------------------------------|------------------|
| Meter exchange | Remove meter | Remove Meter |
| | Define meter's retirement date | Change Meter |

| | | |
|-----------------------------------|-----------------------------------|------------------------------|
| | Install meter | Install Meter |
| Investigate meter accuracy | Read meter | Read Meter |
| | Verify constant - optional | Change Meter's Configuration |
| | Read meter - optional | Read Meter |
| Meter service investigation order | Read meter - optional | Read Meter |
| | Check service point - optional | Change Service Point |
| | Remove meter - optional | Remove Meter |
| | Check meter attributes - optional | Change Meter |
| | Check constant - optional | Change Meter's Configuration |
| | Install meter - optional | Install Meter |
| | Contact customer - optional | Contact Customer |

Examples of Lamp-Oriented Service Investigation Activity Types and their Steps

The following table shows several classic lamp-oriented activity types and their respective steps:

| Activity Type | Step | Step Type Action |
|----------------------------------|----------------------------------|----------------------|
| Retire lamp and install another | Remove lamp | Remove Item |
| | Define lamp's retirement date | Change Item |
| | Install lamp | Install Item |
| Lamp service investigation order | Check service point - optional | Change Service Point |
| | Remove lamp - optional | Remove Item |
| | Check lamp attributes - optional | Change Item |
| | Install lamp - optional | Install Item |
| | Contact customer - optional | Contact Customer |

Examples of Trouble Order Activity Types and their Steps

The following table shows trouble order-oriented activity types and their respective steps:

| Activity Type | Step | Step Type Action |
|------------------|------------------|------------------|
| Contact customer | Contact customer | Contact Customer |

Examples of Device Testing Activity Types and their Steps

The following table shows device test-oriented activity types and their respective steps:

| Activity Type | Step | Step Type Action |
|--------------------------------|-------------------------------|------------------|
| Bench test meter | Remove existing meter | Remove Meter |
| | Install new meter | Install Meter |
| | Test meter | Test Device |
| Field test meter | Remove existing meter | Remove Meter |
| | Test meter | Test Device |
| | Install new or existing meter | Install Meter |
| Bench test current transformer | Remove existing CT | Remove Item |
| | Install new CT | Install Item |
| | Test CT | Test Device |

Field Activity Completion Considerations

The [Field Activity Step Upload Staging](#) table provided by the system supports the completion of the following "standard" step types:

- Connect Service Point
- Disconnect Service Point
- Install Meter
- Turn On Meter
- Turn Off Meter
- Read Meter
- Remove Meter
- Install Item
- Turn On Item
- Turn Off Item
- Remove Item

These step types are supported because the amount of information required to complete the step type is limited and is always the same for every step of that type. For example, to install a meter, the system must know the badge number and the effective date/time and a reading must exist for that date/time. Every Install Meter step requires the same information.

However, there are other step types whose completion information depends on what specifically occurred in the field. For example, if the meter configuration changed, there are several possible fields whose value may have changed such as dial format, read out type, full scale, etc. Because of the large number of possible fields that would need to be available to support completion of these "generic" step types, the field activity step upload staging table does not support capturing this information. The step types included in this category are the following:

- Change Item
- Change Meter

- Change Meter's Configuration
- Change Service Point
- Contact Customer
- Reconfigure Multi-Item
- Test Device

To complete field activities with one of the above step types, the recommendation is to use XAI to upload field activity completion information rather than using the [field order completion upload background processes](#) . Using XAI, you can design a service to update the appropriate data in the system for the above step types and complete the field activity and all its steps.

Note:

Remove Meter. The system only allows meter reads marked as **Use on Bill** to be specified as removal reads. If your implementation wants to relax this validation and use reads that are not usable on bill as removal reads during FA completion, set the Removal MR Always Usable on Bill **Option Type** on the Meter Management Options [Feature Configuration](#) to Y.

Fastpath:

Refer to [Field Activity Completion](#) for a sample service provided with the system to support completion for all step types.

Designing Field Service Classifications

When you set up a service point, you must define the operation area(s) that manage its fieldwork. If you have service points whose operation area differs based on the type of field activity, you will need multiple field service classifications (otherwise you'll just need 1 - call it All). For example, a service point may have one operation area for turn on / off field activities, a different operation area for trouble orders, and yet a third operation area for meter exchanges. We refer to each major category of service for which operation area differs as a Field Service Classification. In this example, you would need to define 3 field service classifications - On/Offs, Trouble Order, and Meter Exchanges.

Note:

Bottom line: if all types of activities at a given service point are dispatched from the same field office (i.e., operation area), you will only need one field service classification. If the field office of dispatch differs based on the type of field activity, you will need a field service classification for each category of field activity.

After you define your field service classifications, you need to associate them with your field activities (each field activity references a field service classification). You also need to define the field offices (i.e., operation areas) that perform work for each classification. For example,

- If trouble orders are dispatched from a central location, the Trouble Order service classification would have a single operation area linked to it.
- If turn ons / offs are dispatched from 4 separate operations area, you have the four operation areas linked to the On / Off field service classification.
- Etc.

If you're struggling with this concept, consider why the system needs to know about field service classifications:

- When a field activity is created, the system must associate it with an operation area. Why? Because operation area is one of the elements that controls the dispatch group to be associated with a field activity.
- The system finds the operation area by: a) extracting the field service classification from the field activity's activity type, and b) extracting the operation area for this classification defined on the service point.
- And finally, once the operation area is known, the system can allocate the dispatch group to the field activity. The other components that dictate the dispatch group are field activity type and service point type.
- Each service classification, in turn, would have its operations area defined.

Note:

How a service point gets its field service classifications and operation areas. A service point's field service classifications / operation areas will default based on its service type and its premise's postal code. See [Setting Up Premise & Service Point Postal Defaults](#) for more information.

Designing Who Does Your Field Activities

At this point, you have designed the following:

- Field activity types. These define what you do to your service points.
- SP types. These define the various services that exist at your premises.
- Operations areas. These define the locations from which you dispatch field activities.
- Dispatch groups. These define crews who do your field activities.

Now you have to pull it all together and define which dispatch group performs each field activity at every SP type in every area office. This is a four dimensional matrix that is easier to represent in two dimensions. We'll fill in this matrix for one of our many activity types. You'll need to do this for EVERY activity type:

| Activity Type | SP Type | Operations Area | Dispatch Group |
|------------------------------|------------------------|-----------------|---------------------------|
| Connect SP and install meter | GAS - RESIDENTIAL | North Area | North - Gas&Water Crew |
| | | South Area | South - Gas&Water Crew |
| | GAS - COMMERCIAL | North Area | North - Gas&Water Crew |
| | | South Area | South - Gas&Water Crew |
| | WATER - RESIDENTIAL | North Area | North - Gas&Water Crew |
| | | South Area | South - Gas&Water Crew |
| | WATER - COMMERCIAL | North Area | North - Gas&Water Crew |
| | | South Area | South - Gas&Water Crew |
| | ELECTRIC - RESIDENTIAL | North Area | North - Electric Res Crew |
| | | South Area | South - Electric Res Crew |
| | ELECTRIC - COMMERCIAL | North Area | North - Electric HV Crew |
| | | South Area | South - Electric HV Crew |

We made the following assumptions when filling in the above table:

- You have two operations areas: North Area and South Area.
 - The North Area handles all service requests in the northern part of your service territory.
 - The South Area handles all service requests in the southern part of your service territory.
- You have the following dispatch groups in the South Area.
 - North - Gas&Water Crew. This crew performs all field activities associated with ALL gas and water service points in the northern area regardless of SP type (i.e., residential and commercial installs are handled by the same group).

- South - Gas&Water Crew. This crew performs all field activities associated with ALL gas and water service points in the southern area regardless of SP type (i.e., residential and commercial installs are handled by the same group).
- North - Electric Res Crew. This crew performs all field activities associated with electric residential service points in the northern area.
- South - Electric Res Crew. This crew performs all field activities associated with electric residential service points in the southern area.
- North - Electric HV Crew. This crew performs all field activities associated with electric commercial service points in the northern area (the HV stands for high voltage).
- South - Electric HV Crew. This crew performs all field activities associated with electric commercial service points in the southern area (the HV stands for high voltage).

You must fill in the above matrix for EVERY activity type. We'll give you one more example to show how to set up this information if you have centralized dispatching of some types of field activities. Our example assumes that all cuts for non-payment are handled by a single crew located at the North office.

| Activity Type | SP Type | Operations Area | Dispatch Group |
|---------------------------------------|------------------------|-----------------|----------------|
| Cut metered service due to nonpayment | GAS - RESIDENTIAL | North Area | All - C&C crew |
| | | South Area | All - C&C crew |
| | GAS - COMMERCIAL | North Area | All - C&C crew |
| | | South Area | All - C&C crew |
| | WATER - RESIDENTIAL | North Area | All - C&C crew |
| | | South Area | All - C&C crew |
| | WATER - COMMERCIAL | North Area | All - C&C crew |
| | | South Area | All - C&C crew |
| | ELECTRIC - RESIDENTIAL | North Area | All - C&C crew |
| | | South Area | All - C&C crew |
| | ELECTRIC - COMMERCIAL | North Area | All - C&C crew |
| | | South Area | All - C&C crew |

We understand if you have the above situation, there is some redundancy. But this is the price of the flexible design.

At this point, you're ready to set up your field activity types and field activity type profiles. We recommend first setting up your field activity types. Then set up your field activity type profiles designed earlier.

Note:

Don't forget. A field activity type profile contains a list of ALL field activity types that can be performed at service points that use the profile. This list must include all of the field activity types needed to: start and stop service, cut and reconnect service, investigate service, and record trouble orders for the service. Refer to [Designing Your Field Activity Profiles & Types](#) for more information.

Setting Up Field Service Classification

To define your organization's service classifications and the locations at which each classification of service can be performed, open **Admin > Field Work > Field Service Class > Add**.

Fastpath:

For more information about field service classifications, refer to [Designing Field Service Classifications](#).

Description of Page

Enter an easily recognizable **Field Service Class** and **Description** for each service classification.

The **Operation Area** collection shows the operation areas in which field activities associated with a service classification are dispatched.

Setting Up Field Activity Types

The topics in this section describe how to set up field activity types.

Note:

When a new activity type is added. When you introduce a new field activity type, you must define the field activity type profiles on which the activity can be performed. Refer to [Setting Up Field Activity Type Profiles](#) for more information. If the field activity type is "dispatchable", you must set up the rules used by the system to default the dispatch group onto field activities of this type. You do this on [Field Service Control](#).

Fastpath:

For more information about field activity types, refer to [Designing Your Field Activity Profiles & Types](#).

Field Activity Type - Main

You begin to define a field activity type by opening **Admin > Field Work > Field Activity Type > Add**.

Description of Page

Enter an easily recognizable **Activity Type** and **Description** for each field activity type.

Use **Field Activity Priority** to define the priority associated with field activity requests of a given type.

Note:

The values for this field are customizable using the Lookup table. This field name is FA_PRIORITY_FLG.

If this FA type is for activities that will be synced to service orders from an external system, specify the external system in **Fieldwork Orchestration**.

Use **Field Service Class** to define the field activity's category of service. Refer to [Designing Field Service Classifications](#) for information about the significance of this field.

Turn on **Eligible for Dispatch** if this type of field activity is dispatched to a field crew. This switch will be on for all field activities except the one used to indicate the system should use the next scheduled meter read as the initial or final read on a service agreement. If this switch is on you must set up the rules used by the system to default the dispatch group onto field activities of this type. You do this on [Field Service Classification](#).

If your FA type is eligible for dispatch and the [Appointments](#) module is not **turned off** indicate if **Appointment Booking** for field activities of this type is Required for Dispatch, Optional or Not Applicable. If eligible for dispatch is checked, this value is defaulted to optional; otherwise it is defaulted to not applicable.

Turn on **Display as Alert** if Control Central should display an alert if its premise has a completed field activity of this type. If this switch is on,

- Use **Nbr Days Alert Active** to define the number of days the alert should appear on Control Central. The field activity's scheduled date is used as the start date for the alert period.
- Enter the **Alert Information** to appear on Control Central.

Note:

Recommendation. We recommend only using this feature on unusual field activity types (e.g., disconnect warnings, cut for non-payments) so that a CSR is not presented with an alert for every field activity type.

Enter the **Business Object** for this FA Type if the FA type will need access to the BO plug-in spots. If the FA type has a business object specified, the system applies the business object's rules when the FA is added, changed, or deleted. This includes the business object's validation algorithms (only executed after the "core validation" specified on the maintenance object is done), post-processing algorithms, and audit algorithms. The maintenance object for the FA should specify an algorithm that finds its business object using its FA Type. Refer to the base package Determine Standard Business Object algorithm for an example of this type of algorithm.

Use the **Field Activity Step** collection to define the discreet actions involved in the execution of the activity. Keep in mind that an activity type's steps are used to:

- Provide guidance to the field staff in respect of the expected steps involved in the execution of the activity.
- Simplify navigation to the page groups used to record what actually took place in the field.

The **Step Sequence** is system-assigned and may not be modified.

Enter the step's **Description**. This information is printed on the field order.

Indicate whether the step is **Optional**. This indicator is used when the user attempts to complete the field activity (after the fieldwork is complete). If an activity contains required steps, the system will not allow the activity to be completed unless every required step has an indication of what happened. For example, if an activity contains a step indicating the meter must be read, the activity cannot be completed until the meter read is referenced on the activity.

Use **FA Step Type Action** to define the activity associated with the step. The action determines the foreign key that must be referenced on the step in order to complete it. For example, the Read Meter action requires a meter read id to be linked to the step in order to complete the activity. The permissible values are defined in the following table.

| Step Type Action | What it's used for |
|------------------------------|---|
| Change Item | Used when the activity changes attributes on an item (e.g., the date retired). |
| Change Meter | Used when the activity changes attributes on a meter (e.g., the date retired) |
| Change Meter's Configuration | Used when the activity changes attributes on a meter's registers (e.g., the constant) |
| Change Service Point | Used when the activity changes attributes on service point (e.g., the location) |
| Connect Service Point | Used when the activity connects a service point to its source (e.g., connecting an electric service point to the source of electricity) |
| Contact Customer | Used when the activity involves contact with a customer |
| Disconnect Service Point | Used when the activity disconnects a service point from its source (e.g., disconnecting an electric service point from the source of electricity) |

| | |
|------------------------|---|
| Install Item | Used when the activity installs a badged item at a service point |
| Install Meter | Used when the activity installs a meter at a service point |
| Read Meter | Used when the activity reads a meter |
| Reconfigure Multi-Item | Used when the activity changes the number / type of unbadged items at a service point |
| Remove Item | Used when the activity removes a badged item from a service point |
| Remove Meter | Used when the activity removes a meter from a service point |
| Test Device | Used when the activity tests a meter or item. |
| Turn Off Item | Used when the activity turns off a badged item at a service point |
| Turn Off Meter | Used when the activity turns off a meter at a service point |
| Turn On Item | Used when the activity turns on a badged item at a service point |
| Turn On Meter | Used when the activity turns on a meter at a service point |

Use the **Characteristic** collection to define **Characteristic Types** and their respective **Characteristic Values** to describe characteristics that are common to all field activities of this type.

Note:

You can only choose characteristic types defined as permissible on the field activity type record.

Field Activity Type - FA Characteristics

To define characteristics that can be defined for field activities of a given type, open **Admin > Field Activity Type > Search** and then navigate to the **FA Characteristics** page.

Description of Page

Use the **Characteristics** collection to define characteristics that can be defined for field activities of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on field activities of a given type. Turn on the **Default** switch to default the **Characteristic Type** when field activities of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Note:

Field activities created by the system. When setting the Required switch, remember that most field activities are created by the system. Only turn on the required switch for these types of activities if a default characteristic value can also be indicated

Field Activity Type - FA Completion Control

Open **Admin > Field Work > Field Activity Type > Search** and then navigate to the **FA Completion Control** page to define special functions that should be executed when a field activity is completed.

Description of Page

Note:

These algorithms are optional. The use of completion algorithms on a field activity type is optional. You would only use them if you have special functions that should be executed when a given field activity type is completed. Read the information below for examples.

The **Field Activity Completion Controls** tab is used when an algorithm should be executed when a field activity is completed. For example, if a charge should be levied when a certain type of activity is completed, you would indicate the "levy adjustment" algorithm should be executed. The type of algorithm may differ based on the CIS division in which the service point's premise is located. The following fields must be defined:

CIS Division Defines the division associated for which the algorithm will be executed. The system will only execute the algorithm when a field activity is performed at a service point whose premise is governed by the division.

FA Completion Algorithm Defines the algorithm that will be executed when a field activity is performed at a service point whose premise is governed by the associated division.

Field Activity Type - SP Type Review

The **Field Activity Type - SP Type Review** page is not applicable when Service Order Management is being used.

Setting Up Field Service Control

Open **Admin > Field Work > Field Service Control > Add** to define the dispatch group that is responsible to perform a field activity in each operation area for each SP type.

Description of Page

Note:

Eligible for dispatch. You would only define this information for field activity types that are eligible for dispatch because these are the only ones that need dispatch groups.

If a field activity type is **Eligible for Dispatch**, you must define the **Default Dispatch Group** that will be assigned to field activities. You do this in respect of the **Field Activity Type**, the field activity's service point's **SP Type**, and the service point's **Operation Area**. In addition you must define the following for every combination of **Activity Type**, **SP Type** and **Operation Area** you define the following:

Priority The priority controls the order in which the system calls the algorithms that determine the **Dispatch Group** to be assigned to field activities associated with a given **Activity Type**, **SP Type** and **Operation Area**. Higher priorities are used before lower priorities.

Dispatch Algorithm Select the algorithm that determines the dispatch group to be assigned to the field activity.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that assigns a dispatch group.

Important:

You must have at least one entry in this collection otherwise the system will not assign a dispatch group to a field activity. This entry should have the lowest priority code and should reference a **Dispatch Algorithm** that references the OFSDGRP DFLT algorithm type.

Where Used

This information is used to default the appropriate dispatch group on new field activities.

Setting Up Field Activity Type Profiles

The topics in this section describe the pages used to define a field activity type profile.

Note:

When a new profile is added. When you introduce a new field activity type profile, you must define the SP types that use it. Refer to [SP Type - Main](#) for more information.

Fastpath:

For more information about field activity type profiles, refer to [Designing Your Field Activity Profiles & Types](#).

Field Activity Type Profile - Main

Open **Admin > Field Work > Field Activity Type Profile > Search** to maintain a field activity type profile.

Description of Page

Enter a unique **Field Activity Type Profile** and **Description** for the activity type profile.

The **FA Type Profile Templates** indicate the templates that exist for this field activity type profile. Use the drill down button to go directly to the desired template. Alternatively, you can go to the **Template** tab and scroll until you find the correct template.

Field Activity Type Profile - Template

Open **Admin > Field Work > Field Activity Type Profile > Search** and then navigate to the **Template** page to define the field activity(s) used for various situations in the system.

Description of Page

The information in the **Field Activity Profile Template** collection defines the field activity(s) created for each situation identified by the **Customer Event**. The possible customer events are Cut for Non-payment, Disconnect Warning, Reconnect for Payment, Reread, Stop Service, Start Service, and Start/Stop. Other customer events can be defined on the [Look Up](#) page (search for the CUST_EVT_FLG field name). Refer to the following sections for more detail about customer events included with the base product.

The fields defined for each event are common. You define the field activity(s) to be generated given the condition of the service point and the location at which service was disconnected (when applicable). The following fields display:

SP Field Condition Define the condition of the service point associated with the field activity. Valid values correspond to those described under [Typical Metered Service Matrix](#), [Typical Badged Item Service Matrix](#) and [Typical Unbadged Item Service Matrix](#) .

Sequence You will typically have a single field activity for any specific combination of SP Field Condition and Disconnect Location. Therefore you'll just have a single sequence (say 10) for each combination. If you need to generate multiple field activities based on a given combination, use a unique sequence number for each activity.

No Activity Turn on this switch if no field activity should be generated for the condition. This is typically off for non-metered (e.g., lamp) starts when the service is already started.

Disconnect Location The type of field activity can differ based on where the service point was disconnected from the source of service. For example, if it the SP is disconnected at the pole, you would have a different field activity than if it is disconnected at the meter.

Activity Type Define the type of activity to be generated. You should take care to use activity types defined as valid for the SP type (on the last page).

Where Used

Refer to the following sections for information about where each template is used.

Field Activities Initiated To Start Service

Use the customer event Start to define the field activity(s) used to start service at a service point whose SP type references this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

The start service process uses this information to determine the type of field activities to create to start service at a service point.

Warning:

Warning. Field activities will only be created for starts if you have defined the appropriate field work creation algorithm on the service agreement's SA type. Refer to [SA Type - Algorithms](#) for more information.

Field Activities Initiated To Stop Service

Use the customer event Stop to define the field activity(s) used to stop service at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

The stop service process uses this information to determine the type of field activities to create to stop service at a service point.

Warning:

Warning. Field activities will only be created for stops if you have defined the appropriate field work creation algorithm on the service agreement's SA type. Refer to [SA Type - Algorithms](#) for more information.

Field Activities Initiated For Back-to-Back Service

Use the customer event Start/Stop to define the field activity(s) used to stop service for one customer and start service for another at a service point whose SP type uses this profile.

Note:

Terminology. We use the term **back-to-back** to describe the situation when a single field activity supports both the stop and start service requests. The system sets up a back-to-back situation by default when it is aware of both the start and stop customers at a premise.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

The start/stop service process uses this information to determine the type of field activities to create to start service at a service point.

Field Activities Initiated To Cut Service Due To Non-Payment

Use the customer event Cut for Non-Payment to define the field activity(s) used to cut service at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

Severance and cut events use this information to determine the type of field activities to create to cut service at a service point.

Field Activities Initiated To Place A Disconnect Warning At A Service Point

Use the customer event Disconnect Warning to define the field activity(s) used to place a disconnect warning at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

Severance and cut events use this information to determine the type of field activities to create to leave a disconnect warning at a service point.

Field Activities Initiated To Reconnect Service At A Service Point

Use the customer event Reconnect for Payment to define the field activity(s) used to reconnect service (after being cut) at a service point whose SP type uses this profile.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

Severance and cut events use this information to determine the type of field activities to create to reconnect service at a service point.

Field Activities Initiated To Reread A Meter At A Service Point

Use the customer event Reread to define the field activity(s) used to reread a meter located at a service point whose SP type uses this profile.

The field activity type, M-REREAD, is used by the [meter read](#) page to create a field activity when a user requests a meter to be reread.

Description of Page

See [Field Activity Type Profile - Template](#) for a description of the fields.

Where Used

The [meter read](#) page uses this information to determine the type of field activity to create to reread a meter.

Defining A Profile's Valid Field Activity Types

Open **Admin > Field Work > Field Activity Type Profile > Search** and choose the **Type** page to define the superset of field activity types that may be performed on service points whose SP type uses this profile.

Description of Page

The **Field Activity Type** collection shows the field activities that may be performed at service points whose SP type references the field activity type profile.

Where Used

This information is used to control the types of field activities that may be performed at a service point.

Setting Up Fieldwork Cancellation Reasons

When you cancel a field activity, you must supply a cancellation reason. To define fieldwork cancellation reasons, open **Admin > Field Work > Fieldwork Cancel Reason**.

Description of Page

Enter a **Cancel Reason** and **Description** for every field activity/field order cancellation reason.

Only use **System Default** on those reason codes that are placed on field activities that are automatically canceled by the system. The following table lists the valid values and the condition where this cancel reason is used.

| System Default | System Condition |
|--------------------------------|---|
| Cut Process canceled | Placed on field activities that are canceled when a Cut Process is canceled. |
| Device Test Selection canceled | Placed on field activities that are canceled when a Device Test Selection is canceled. |
| Near MR FA Completion canceled | Placed on field activities that use a scheduled meter read to start/stop service when they are canceled. Refer to How To Start Service Using A Scheduled Meter Read for more information about these special field activities and how they may be canceled. |
| SA Start/Stop canceled | Placed on field activities that are canceled when a pending start/stop is canceled. |
| Severance Process canceled | Placed on field activities that are canceled when a severance process is canceled . |

Note:

Required values. You must have one reason code defined for each of the System Default values that corresponds to an event that may occur in your implementation.

Feature Configuration. Some organizations require a cancel reason to be specified when a field order is cancelled. To achieve this, you must set up a fieldwork options [feature configuration](#) and ensure that the Cancel Reason Required option is set to Y.

Fieldwork Reschedule Reason

Some organizations require a reschedule reason to be specified when a field activity or field order's schedule date/time is changed. To achieve this, you must set up a fieldwork options [feature configuration](#) and ensure that the Reschedule Reason Required option is set to Y. The Default Reschedule Reason option should also be specified. This option value will be used when the system updates a field activity's schedule date/time behind the scenes. To define reschedule reasons, open **Admin > Field Work > Fieldwork Reschedule Reason**.

Description of Page

Enter a **Reschedule Reason** and **Description** for every field activity/field order reschedule reason.

Fastpath:

For more information on how to audit changes to a field activity or field order's schedule date/time, refer to the [Field Activity Rescheduling - Audit](#) and [Field Order Rescheduling - Audit](#) business objects.

Setting Up Field Activity Remarks

You may link remarks to a field activity using remark codes. To define field activity remark codes, open **Admin > Field Work > Field Activity Remark > Add**.

Description of Page

Enter a unique **Field Activity Remark** and a **Description** for every field activity remark.

Turn on **Eligible for Processing** if field activities marked with a given remark code should cause one or more algorithm to execute.

The grid contains **Algorithms** associated with the field activity remark. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|----------------------------------|---------------------|--|
| Field Activity Remark Activation | Optional | <p>These algorithms are executed when there are pending FA remarks linked to a field activity and the FACT (Field activity remark activation) background process runs.</p> <p>Refer to Field Activity - Characteristics/Remarks for more information.</p> |

Setting Up Outage Call Types

When you create an outage call, you must supply an outage call type. Outage call types contain a great deal of information that is defaulted onto the outage call, including the outage category group codes or trouble codes. To set up outage call types, open **Admin > Field Work > Outage Call Type > Add**.

Fastpath:

Refer to [The Big Picture of Outage System Integration](#) for a detailed description of how trouble calls are created and sent to NMS.

The topics in this section describe the base-package zones that appear on the Outage Call Type portal.

Outage Call Type List

The Outage Call Type [List zone](#) lists every outage call type, i.e. every service task type that has a service task type class of Outage Call. The following functions are available:

- Click a **broadcast** button to open other zones that contain more information about the adjacent outage call type.
- Click the Add link in the zone's title bar to add a new outage call type.

Outage Call Type

The Outage Call Type zone contains display-only information about an outage call type. This zone appears when an outage call type has been broadcast from the Outage Call Type [List zone](#) or if this portal is opened via a drill down from another page. The following functions are available:

- **Edit:** to start a business process that updates the outage call type.
- **Delete:** start a business process that deletes the outage call type.
- **Duplicate:** to start a business process that duplicates the outage call type.

Please see the zone's help text for information about this zone's fields.

Setting Up Service Call Communication Types

A Service Call Communication Type defines the rules and controls for creating service call communications.

Refer to [Asset Management System Integration](#) for more information.

To set up service call communication types, open **Admin > Field Work > Service Call Communication Type > Search**.

This is a standard [All-In-One Portal](#).

The information captured on the service call communication type depends on the business objects that your implementation supports. Refer to the embedded help text for more information.

Setting Up Service Categories

A service category represents a broad category of services.

Refer to [Asset Management System Integration](#) for more information.

To set up service categories, open **Admin > Field Work > Service Category — CCB > Search**.

This is a standard [All-In-One Portal](#).

The information captured on the service category depends on the business objects that your implementation supports. Refer to the embedded help text for more information.

Setting Up Service Codes

Service Codes are used to create the appropriate work record from the service call

Refer to [Asset Management System Integration](#) for more information.

To set up service codes, open **Admin > Field Work > Service Code — CCB > Search**.

This is a standard [All-In-One Portal](#).

The information captured on the service code depends on the business objects that your implementation supports. Refer to the embedded help text for more information.

Defining Credit & Collections Options

Note:

The functionality described in this section is meant to handle the collection of unpaid balances. If your organization practices [open-item accounting](#) and collects on unpaid bills, you will not use this functionality. Rather, you will use the functionality described under [Defining Overdue Processing Options](#).

The system periodically monitors how much your customers owe to ensure they haven't violated your collection criteria. When a violation is detected, the system generates the appropriate responses (e.g., letters, disconnect notices, collection agency referrals, and eventually write off). This section describes how to set up the tables that control your credit & collections processing.

Warning:

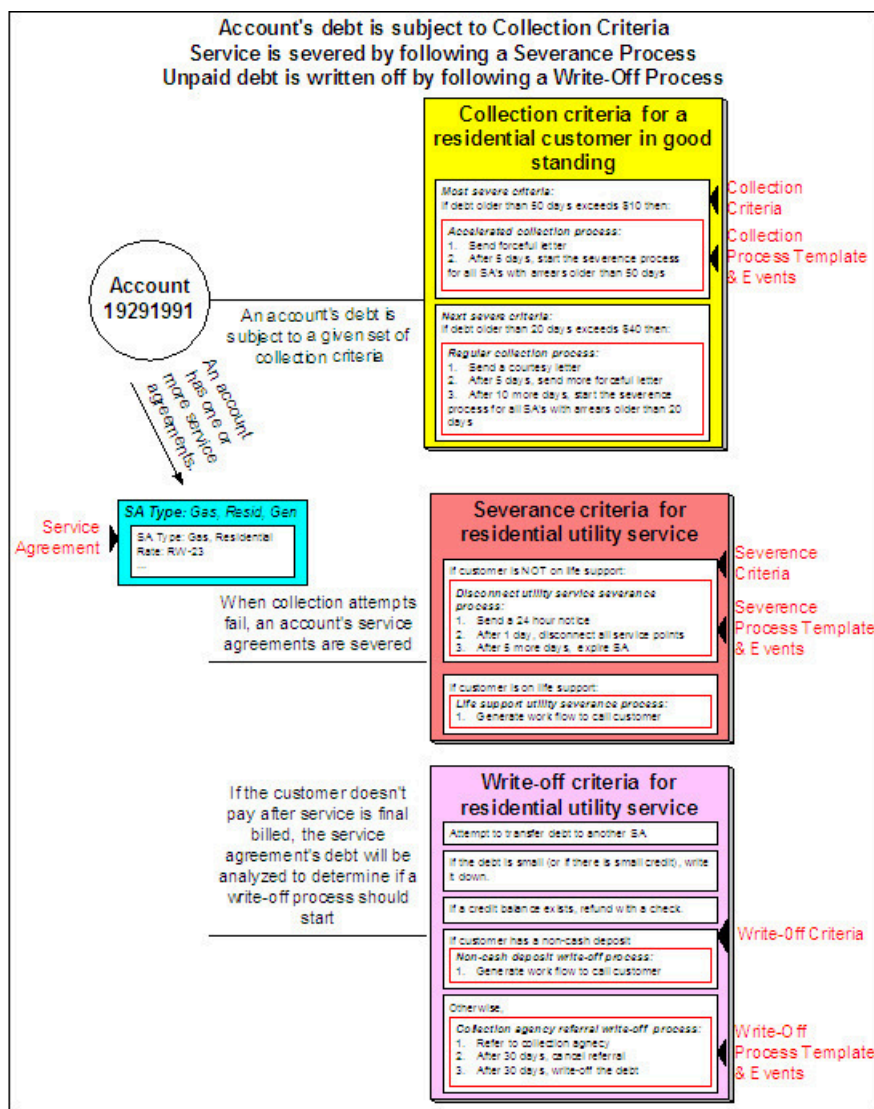

Setting up the credit & collections control tables is as challenging as your organization's collection rules. If you have simple rules then your setup process will be straightforward. If your collection rules are complicated (e.g., they differ based on the type of customer, the type of debt, the age of debt, the type of service, etc.), then your setup process will be more challenging.

The Big Picture Of Credit & Collections

This section provides an overview of important C&C concepts with which you should be familiar before you set up your C&C control tables.

Collection Criteria vs. Severance Criteria vs. Write Off Criteria

The following diagram introduces important concepts related to the C&C processes:

There are many important concepts illustrated above:

| | |
|---|--|
| An account's debt comes from its service agreements | An account's debt is managed at the service agreement level, i.e., the system keeps track of how much a customer owes in respect of each service agreement. In order to determine an account's balance, the system must add up the debt on each of the account's service agreements. |
| Collection criteria define intolerable debt | Collection criteria are control data that define intolerable debt. Most criteria are defined using a combination of number of days in arrears and a dollar amount. |
| Collection criteria may be compared to an account's total debt or to subsets of debt | If your organization has simple collection procedures, you will probably target collection criteria at an account's total debt. However, you have the option of segregating an account's debt into debt classes and targeting the collection criteria at each class. For more information about debt classes, see Different Collection Criteria For Different Customers And Different Debt . |
| Collection criteria also define what to do when the level of intolerable debt is exceeded | When you define collection criteria, you also define how the system should respond if an account violates your criteria. These collection events are defined in respect of a "collection process template". |
| There are usually several collection events that take place when criteria are violated | A collection process template usually has several collection events. Each event is meant to prod the customer to pay. The initial collection events are typically letters. If payment is not received after several such attempts, the last collection event typically starts a severance process for each service agreement in arrears. |
| A severance process template defines how to sever a service agreement | A "severance process template" defines how to sever a given type of service agreement. A severance process template usually contains several severance events. These events are a series of letters and / or disconnection field activities that eventually result in the expiration of a service agreement if payment is not received. |
| Severance criteria define how to sever service agreements | Severance criteria define the severance process to be executed for service agreements of a given SA type. The severance process may differ depending on some attribute of the customer (or premise). For example, you may have a different severance process if the customer has life support equipment. |
| After a service agreement is severed, it will be final billed | When the last active service agreement linked to an account is stopped, the system changes the account's bill cycle to bill that evening. If only one of many SAs is stopped, the SA will only be final billed as per the account's original bill cycle schedule. |

If a customer doesn't pay their final bill, the account's debt will be analyzed to determine if the system can reduce the debt to zero using a variety of mechanisms

The system will look at an account's finalized debt on its next scheduled credit review date (typically a few days after the bill's due date). The system will attempt to reduce the service agreement's debt to zero using all of the following methods:

- If the account has active service agreements, it will transfer the finalized debt to an active service agreement.
- If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit).
- If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).

If a customer's finalized debt cannot be reduced via any of the previous methods, the system creates a write-off process

A write-off process contains one or more write-off events. These events can generate a letter, send a To Do entry to a CSR, send a referral to a collection agency, etc.

When you set up the system, you define the type of write-off process to use for every collection class / write-off debt class combination. In addition, you can also indicate when the type of write-off process should differ depending on some attribute of the customer (or premise). For example, you may have a different write-off process if the customer has a non-cash deposit.

The last write-off event typically causes the debt to be written off

Ultimately, if the write-off events fail, the debt will have to be written off. When debt is written-off, the system creates a write-off service agreement and transfers the outstanding debt to it. This means the debt stays with the account for life and will have to be paid off if the customer ever returns.

Note:

Checkpoint. At this point, you should be familiar with the concept that an account's debt is compared to user-defined collection criteria. If the account violates the criteria, a series of events will ensue that prod the customer to pay. If the customer doesn't respond, every service agreement in arrears will be severed (i.e., disconnected). If lack of service doesn't inspire payment, the service agreement will be expired and a write-off process will be created to manage the write-off activities.

The C&C Monitors

Your collection, severance and write-off criteria described in the previous section exist to support the processes that manage the collection activities. The following diagram illustrates, at a high level, the major processes that manage the collection of overdue debt:

There are many important concepts illustrated above:

| | |
|---|---|
| <p>Bills, payments and adjustments affect an account's debt</p> | <p>An account's debt is the accumulation of all bills, payments and adjustments.</p> |
| <p>The Account Debt Monitor creates a collection process when an account violates collection criteria</p> | <p>Periodically, a background process referred to as the Account Debt Monitor determines if an account's debt violates your collection criteria. If so, a collection process is created using the violated criteria's collection process template. Refer to When Is An Account's Debt Monitored? for a description of when an account's debt is compared against collection criteria.</p> |

A collection process contains one or more collection events

The collection process contains a series of collection events. These events correspond with the collection event types associated with the collection process template. The initial collection events are typically letters. If payment is not received after several such communications, the last collection event typically starts a severance process for each service agreement in arrears.

The Collection Process Monitor cancels a collection process when warranted

The Collection Process Monitor cancels a collection process when its service agreements satisfy your cancellation criteria (e.g., when the service agreements have less than \$10 of debt older than 20 days). Refer to [How Are Collection Processes Cancelled](#) for more information about the cancellation process.

The last collection event starts one or more severance processes

The last collection event typically starts one or more severance processes. A severance process contains the activities necessary to sever a service agreement. The service agreement(s) that are severed may be all SAs that are associated with the collection process. Alternatively, you can nominate a service agreement to act as the primary service to cut (you'd do this if you cut electricity when the customer doesn't pay for their gas). The algorithm on the collection event that starts severance will control which service agreement(s) are severed. Refer to [How To Nominate A Single Service Agreement To Sever](#) for more information.

Each service agreement has its own severance process

Every service agreement that is severed has a severance process. The type of process is dependent on the severance criteria linked to the service agreement's SA type.

A severance process contains one or more severance events

The severance process contains a series of severance events. The events correspond with the severance process template's severance events.

The system cancels a severance process when warranted

The system cancels a severance process when its service agreement satisfies your cancellation criteria (note, it is possible to set up the system so that all service agreements in the debt class must satisfy your cancellation criteria before a severance process is cancelled).

It's important to note that the cancellation is real time (as opposed to the cancellation of collection processes, which happens in a background process). Refer to [How Are Severance Events Canceled?](#) for more information.

The last severance event should expire the service agreement

The last severance event typically expires its service agreement. When the last service agreement linked to an account is expired, the system will schedule the account for billing (outside of its normal bill cycle schedule).

If you nominate a single SA to sever when multiple SAs are in arrears...

Earlier we indicated that you can nominate a service agreement to act as the primary service to cut (you'd do this if you cut electricity when the customer doesn't pay for their gas). If you do this, you also need a severance event that will sever all other service agreements in the debt class if the severance of the nominated service agreement doesn't inspire payment. A severance event algorithm to do such is supplied with the base package. Refer to [How To Nominate A Single Service Agreement To Sever](#) for more information.

The Write-Off Monitor creates a write off process to collect stopped, unpaid debt

The Write-Off Monitor reviews stopped and reactivated service agreements after their closing bill's due date (plus grace period). The Write-Off Monitor attempts to reduce the service agreement's debt to zero using all of the following methods:

- If the account has active service agreements, it will transfer the finalized debt to an active service agreement.
- If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit).
- If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).

If the system is unsuccessful in reducing the account's debt to zero, a write-off process will be created using the appropriate write-off process template. Refer to [The Big Picture Of Write Off Processing](#) for more information about the write-off process.

A write-off process contains one or more write-off events

The write-off process contains a series of write-off events. These events correspond with the write-off event types associated with the write-off process template. The initial write-off events are typically collection agency referrals and/or letters. If payment is not received as a result of such efforts, the last write-off event typically writes off the customer's debt.

The system cancels a write-off process when warranted

The system cancels a write-off process when its service agreements no longer have debt (i.e., they become closed).

Another write-off process will be created if a closed service agreement ever reactivates

If a service agreement becomes reactivated (e.g., because the final payment bounces), the service agreement will be processed by the Write-Off Monitor and the whole write-off process starts again.

Note:

Checkpoint. At this point, you should be familiar with the concept that a collection process will be created for an account that violates collection criteria. The collection process consists of a series of events that typically generate letters and / or To Do entries. If the customer doesn't respond, a severance process will be started for one or more service agreements. A severance process consists of a series of events that typically generate letters and/or disconnection field activities. If lack of service doesn't inspire payment, the last severance event expires the service agreement (and a final bill will be scheduled when the last service agreement is expired). If the customer doesn't pay the final bill, a write-off process will be created for each type of unpaid debt. The write-off process consists of a series of events that ultimately result in the write-off of the customer's debt. When debt is written-off, the system creates a write-off service agreement and transfers the outstanding debt to it. This means the debt stays with the account for life (because the write-off service agreement is linked to the account) and will have to be paid off if the customer ever returns.

The Big Picture Of Collection Processes

The topics in this section describe how collection processes are created and cancelled.

Fastpath:

For more information refer to [The Lifecycle Of A Collection Process And Its Events](#).

How Does The Account Debt Monitor Work?

This section describes how the Account Debt Monitor uses your collection criteria and collection process templates to collect overdue debt.

Different Collection Criteria For Different Customers And Different Debt

Consider the following:

- You probably have different collection criteria for different jurisdictions (i.e., CIS Divisions). For example, if you have customers in different states / provinces, you may have different regulator-imposed criteria applied to each state's debt. You differentiate your debt in respect of the collection process via the **CIS division code on each customer's account**.
- You probably have different collection criteria for different customer segments. For example, customers with large bills probably have strict criteria, whereas you're probably more lenient with small customers (or vice versa). You differentiate your customers in respect of the collection process via a **collection class code on the customers' accounts**. An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.
- You probably have different collection criteria for different classes of debt. For example, if a single customer has both regulated and unregulated debt, you probably have commission-imposed criteria to be applied to the regulated debt, but you have the freedom to apply stricter criteria to the unregulated debt. You differentiate your debt in respect of the collection process via a **debt class code on the customers' service agreements** (note: the debt class is actually defined on the service agreement's SA type).
- You will have different criteria for every currency in which you work because the monitoring process always compares a customer's debt against some value and this value must be denominated in the customer's currency. A customer's currency is defined using a **currency code on the account**.

Given the above, you should understand that different collection criteria will exist for every combination of CIS division, collection class, debt class, and currency code. If you're confused, consider the following matrix (where we assume you have a single currency and division and therefore avoid the third and fourth dimensions):

| | | |
|------------------------|------------------------------------|------------------------------------|
| SA's Debt Class | Account's Collection Class: | Account's Collection Class: |
| | Commercial Customer | Residential Customer |

| | | |
|-------------------------|---|---|
| Regulated | N/A - there is no regulated, commercial customer debt. | Highest Priority: If > \$5 in arrears by more than 50 days, create the accelerated collection process for residential customers. Lower Priority: If > \$25 in arrears by more than 25 days, create the courtesy reminder collection process for residential customers. |
| Unregulated | Highest Priority: If > \$10 in arrears by more than 50 days, create the accelerated collection process for commercial customers. Lower Priority: If > \$1000 in arrears by more than 25 days, create the normal collection process for commercial customers. | Highest Priority: If > \$10 in arrears by more than 25 days, create the normal collection process for residential customers. |
| Charitable Contribution | Highest Priority: If > \$10 in arrears by more than 50 days, create the charitable collection process. | Highest Priority: If > \$10 in arrears by more than 50 days, create the charitable collection process. |

Also, notice that there can be multiple criteria for each cell in the matrix. What differentiates one collection criteria from another is its priority. The higher priority criteria will be compared first. If the debt meets the criteria, the collection process is initiated and no further comparisons are performed.

Fastpath:

For more information about maintaining this matrix, refer to [Setting Up Collection Class Controls](#). For more information about how the system handles an element in this matrix that has multiple criteria, see [How Is An Account's Debt Monitored?](#).

Override Conditions

Warning:

Your credit & collection requirements may not require any overrides and therefore this section may not be relevant for your organization.

The matrix presented in the previous section showed:

- You can have different collection criteria for different categories of debt and customers.
- When a collection criteria is violated, the system generates a specific collection process.

This works great for many organizations, but if your organization has other factors that affect either the collection criteria OR the collection process that is initiated when the criteria is violated, you may need to use override collection criteria. For example,

- If you have a different collection process for regulated, residential debt during the winter months, you'll need to use override collection criteria (where the override criteria is "if it's winter").
- If you have different collection criteria for customers with a poor credit score, you'll need to use override collection criteria (where the override criteria is "if the customer's credit rating is poor").

Fastpath:

Refer to [Designing Your Collection Class Control Overrides](#) for more information.

This section describes how and when the Account Debt Monitor analyzes an account's debt.

When Is An Account's Debt Monitored?

The account debt monitor (ADM) analyzes an account's debt at least every X days, where X is defined on the [customer class control](#) associated with the account's customer class and division (in the field Min Credit Review Freq (Days)).

In addition, an account's debt will also be monitored as follows:

- The ADM looks at an account's debt X days after an account's bill due date (X is defined on the account's customer class in the field Collection Grace Days).
- The ADM looks at an account's debt after a payment is canceled when the cancellation reason indicates NSF (non-sufficient funds).
- The ADM looks at an account's debt after a payment arrangement is broken (assuming you use the base package's break payment arrangement plug-in). Refer to [Monitoring Payment Arrangements](#) for more information.
- The ADM looks at an account's debt after a pay plan is broken. Refer to [The Pay Plan Monitor](#) for more information.

How Is An Account's Debt Monitored?

Assume the following collection control matrix exists for your organization:

| SA's Debt Class | Account's Collection Class: | |
|-----------------|---|---|
| | Commercial Customer | Residential Customer |
| Regulated | N/A - there is no regulated, large customer debt | Highest Priority: If > \$5 in arrears by more than 50 days, create the accelerated collection process for residential customers. Lower Priority: If > \$25 in arrears by more than 25 days, create the courtesy reminder collection process for residential customers. |
| Unregulated | Highest Priority: If > \$10 in arrears by more than 50 days, create the accelerated collection process for commercial customers. Lower Priority: If > \$1000 in arrears by more than 25 days, create the normal collection process for commercial customers. | Highest Priority: If > \$10 in arrears by more than 25 days, create the normal collection process for residential customers. |

This matrix contains the information used by the Account Debt Monitor.

Fastpath:

For more information about the information in this matrix, refer to [Different Collection Criteria For Different Customers And Different Debt](#).

This matrix can be overwhelming when viewed as a whole. So let's consider how to use it for a specific account's debt and things will become clearer.

First, because an account belongs to a unique collection class, we only have to worry about a single column in the matrix when monitoring an account's debt.

Next, we accumulate the total amount of aged debt for each unique debt class associated with the account's service agreements.

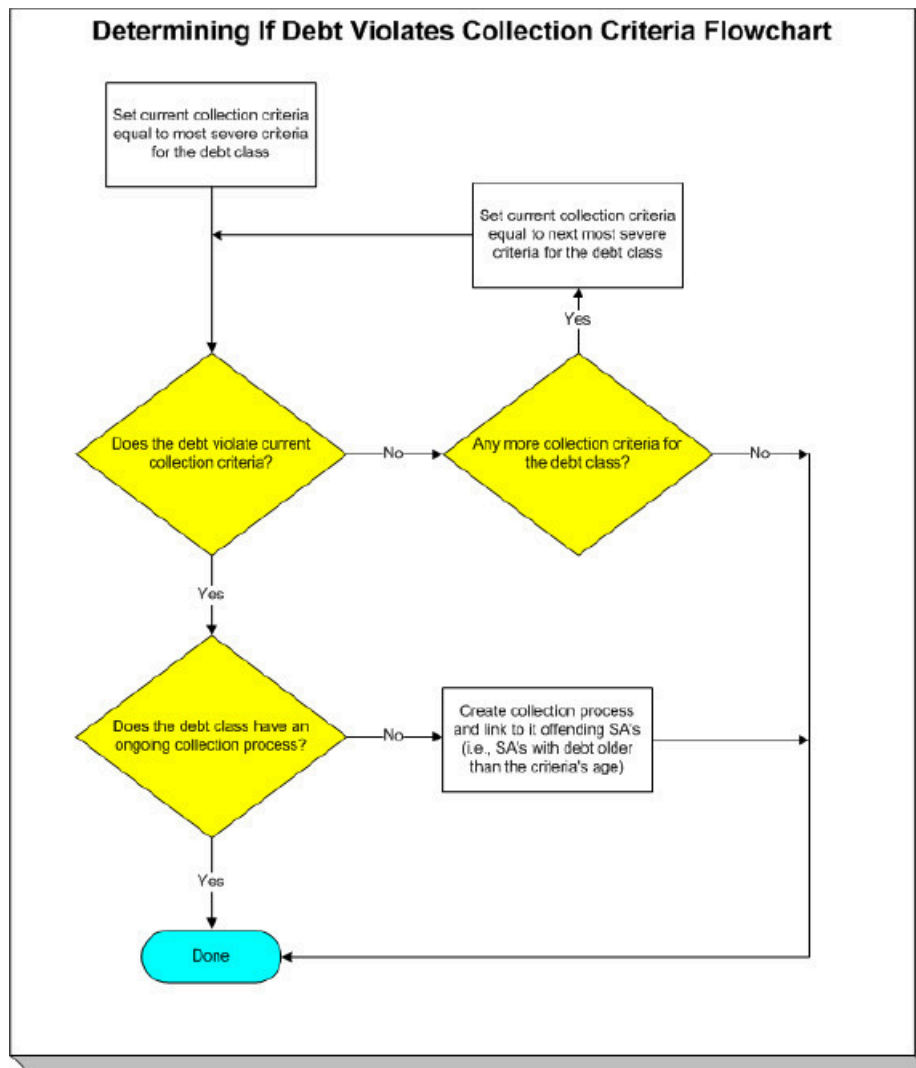

Next, we subject the accumulated aged debt to the override aged debt algorithm (plugged in on the debt class). This algorithm can cause aged debt to be reduced. This is an optional algorithm and is only used if you set up pay plans for customers. Refer to [How Pay Plans Affect The Account Debt Monitor](#) on page 803 for more information.

Next, we determine if the debt for the debt class violates the collection criteria in the respective matrix element. If so, we kick off a collection process and link the offending service agreements to it. The logic associated with the determination of whether to kick off a collection process is rather sophisticated. The following flowchart explains the exact details.

Note:

Important. If a service agreement is part of an ongoing severance process, it will NOT be considered by the Account Debt Monitor (it's already being severed). If a service agreement is stopped, closed, or reactivated, it also will NOT be considered by the Account Debt Monitor (it's already severed).

Note:

Multiple collection processes may be kicked off. It's important to be aware that if an account's service agreements reference multiple debt classes, a collection process will be started for each offending debt class.

One collection process per debt class. A given debt class for an account may only have one ongoing collection process at any point in time.

What Happens When A Collection Process Is Started?

When you define collection criteria, you must define the collection process template to use if the criteria are violated. The system uses this template to create the account-specific collection process.

Every service agreement that is part of the offending debt class that has debt older than X days will be linked to the collection process (where X is the debt age on the collection criteria).

Also linked to the collection process will be one or more collection events. These events are typically a series of letters meant to prod the customer (you can also create an event that sends a To Do entry to a user to highlight the offensive debt). You define exactly which letters are generated and when they are generated when you set up the events on your collection process templates.

It's important to note that all of the collection events will be created when the collection process is created. Each of these collection events contains a trigger date. The trigger date of the first event(s) will typically be the current date. The trigger date of the other events will be in the future. Refer to [Calendar vs Work Days](#) for information that describes how the trigger date is set.

A separate process, Activate Collection Events, is responsible for activating collection events whose date is on or before the current date. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, start a severance processes, etc.)

If adequate payments / credits are recorded in the system, the collection process will be cancelled.

Fastpath:

For more information about collection process templates, see [Setting Up Collection Process Templates](#). For more information about collection events, see [The Big Picture Of Collection Events](#). For more information about how a collection process is cancelled, see [How Are Collection Processes Cancelled](#).

Experimenting With Alternative Collection Process Templates

The system allows you to determine the efficacy of proposed collection process templates using a small subset of customers before implementing the templates on the entire customer base. We use the term "champion / challenger" to reference this functionality.

We'll use an example to explain. Let's assume your prevailing collection process template for residential customers starts with a "gentle reminder" letter followed 10 days later by a letter threatening collection agency referral if payment is not received. You may want to experiment with the impact of a change to this template. For example, you may want to change the "gentle reminder" to something more assertive and follow this up 5 days later with an even sterner warning. You can use the "champion / challenger" functionality to perform this experiment.

The following points describe how to implement "champion / challenger" functionality:

- Set up a "challenger" collection process template for each template that you want to experiment with.
- Insert a new **Champion/Challenger** option on the Collection Processing [Feature Configuration](#) for every champion template. Each option's value defines:
 - the "champion" collection process template code
 - the "challenger" collection process template code
 - the percentage of the time the system should use the "challenger" template
- Keep in mind that you can only experiment with one challenger template per champion template. For example, let's assume you have two prevailing collection process templates - one for residential customers and another for commercial customers. You can experiment with different challenger templates for the residential and commercial templates. However, you cannot experiment with two different challenger templates for the residential champion template (i.e., a champion template can have 0 or 1 challenger template).

After setting up the above, the [Account Debt Monitor](#) will use the challenger template X% of the time rather than the champion template.

If you are using the Oracle Utilities Analytics product, you can configure analytic zones in innumerable ways to compare the efficacy of the champion versus the challenger. For example,

- You can set up a graph to show the average duration of each type of process.
- You can set up a graph to show the average dollars that were successfully collected.
- You can set up a dimensional scorecard to show how each template performed in different regions (or customer classes or ...).
- Etc (the list is limited by your imagination).

How Are Collection Processes Cancelled?

A collection process may be cancelled via the mechanisms described in this section.

The Collection Process Monitor Can Cancel A Collection Process

The Collection Process Monitor (CPM or C1-CPM) is a background process that reviews a collection process when the debt associated with one of its service agreements is reduced. Financial events that can cause service agreement debt to be reduced are:

- The cancellation of a bill segment.
- The creation of a payment segment.
- The creation of an adjustment that credits a service agreement.

The review performed by the CPM occurs as follows:

- **Debt class cancel criteria.** In general, the sum of all debt associated with the collection process's debt class must be less than a given threshold amount for a collection process to be cancelled. If so, the collection process is cancelled.
- Please be aware that, if a [Pay Plan](#) exists for the account and debt class, the customer's debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount. Please be aware that this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

Note:

The above logic is not "hard coded". The CPM calls the Collection Process Cancel Criteria Algorithm defined on the debt class that is associated with the collection process. This algorithm will cancel a collection process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. However, because it's an algorithm, you can introduce whatever cancellation criteria you please.

- **Service agreement cancel criteria.** You can optionally introduce a special quirk to the cancellation logic. This quirk is a bit difficult to understand. To understand it, you should recall:
 - All service agreements that are in arrears in a given debt class are linked to the collection process.
 - The collection event called Start Severance creates a severance process for every service agreement that is in arrears on the collection process (the alternative is to [Nominate A Single Service Agreement To Sever](#)).
 - If you use the Start Severance collection event, you would want to remove a service agreement from a collection process when it no longer has intolerable debt (regardless of the state of the debt class's entire debt). You'd want to do this because, if you don't, the system would start a severance process for the paid up service agreement and if it's paid up, you wouldn't want a severance process created for it.
- To "remove" service agreements from a collection process when they no longer have intolerable debt, you should plug-in a Service Agreement-Oriented Cancel Criteria Algorithm on your collection process templates. The CPM will call this algorithm if you've plugged it in.

Note:

When all service agreements are "removed" from a collection process, the CPM cancels all pending collection events and cancels the collection process.

**Warning:**

Checking if individual service agreements should be removed from a collection process is optional (meaning that you don't have to plug one in on the collection process template).

A New Payment Plan Can Cancel A Collection Process

Refer to [Collection Process / Severance Process Cancellation When A Pay Plan Is Created](#) for the details.

**Note:**

Real time cancellation. Please be aware that the system will cancel a collection process real time when a pay plan is created (if the pay plan's scheduled payments are enough to pay-off the customer's outstanding debt).

A User May Cancel A Collection Process At Their Discretion

A user may cancel a collection process at their discretion.

Stopping A Service Agreement May Cancel A Collection Process

The system will "remove" a service agreement from a collection process when it is stopped (i.e., when the service agreement's status becomes Stopped). When the last service agreement is "removed" from the collection process, the collection process will be cancelled.

The Big Picture Of Collection Events

This section describes the various types of collection events and their lifecycle.

How Are Collection Events Created?

Collection events may be created as follows:

- The Account Debt Monitor creates a collection process when an account violates collection criteria. The collection process has one or more collection event(s). The number and type of events is controlled by the collection process template associated with the collection process.
- Collection events are created when a user creates an ad hoc collection process. The number and type of events is controlled by the collection process template defined when the collection process is created.
- An ad hoc collection event may be created and linked to an existing collection process by a user at their discretion.

**Note:**

Bottom line. Most collection events are created by the system when it creates a collection process for delinquent accounts. If you need to create an ad hoc collection event, you can either create a collection process whose template contains the desired event OR link the desired event to an existing collection process.

**Fastpath:**

For more information about the creation of events by the Account Debt Monitor refer to [What Happens When A Collection Process Is Started?](#). For more information about creating ad hoc collection processes, refer to [Collection Process Maintenance](#). For more information about creating ad hoc events, refer to [Collection Process - Events](#).

Types Of Collection Events

The following table describes the various types of collection events and what happens when they are completed:

| Type Of Collection Event | What Happens In The System |
|--------------------------------|--|
| Send Letter | <p>A customer contact is created for every financially responsible person linked to the account. The customer contact causes a letter to be produced.</p> <p>The type of letter is defined on the customer contact's contact type.</p> <p>The recipient of each letter is defined on Account / Person (those persons marked as Receiving Notifications).</p> |
| Create To Do Entry | A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries. |
| Affect Credit Rating/Cash-Only | An account credit rating demerit record is created. The number of demerits is defined on the collection event type. |
| Cancel Budget | <p>Every service agreement linked to the account that is on a budget is "removed" from the budget (i.e., the recurring charge amount for the service agreement is set to zero).</p> <p>In addition, a syncing adjustment is issued to cause each SA's current balance to be set equal to their payoff balance (the adjustment type is defined on the SA's SA type). Also, the Budget Plan field on the Account - Budget page is cleared.</p> |
| Generic Algorithm | The algorithm defined on the event's event type is executed. |
| Start Severance Process | A severance process is created for every service agreement linked to the collection process. The type of severance process is defined on the SA type table (every service agreement references an SA type). |

Fastpath:

Refer to [Setting Up Collection Event Types](#) for more information.

Collection Event Lifecycle

The following diagram shows the possible lifecycle of a collection event:

Collection events are initially created in the pending state.

When the system sees a pending event with a trigger date on or before the current date, the system executes the event's activity and completes the event.

Fastpath:

For more information about a collection event's trigger date, see [Collection Event Trigger Date](#).

A pending event will be cancelled automatically by the system when the account's debt no longer violates the collection criteria that sparked the event's collection process. A pending event may also be cancelled by a user at their discretion. Refer to [How Are Collection Processes Cancelled](#) for more information about how the system will cancel a collection process (and its events).

Collection Event Trigger Date

When a collection event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to [Calendar vs. Work Days](#) for more information.

How Are Collection Events Completed

A background process runs periodically (at least daily) that looks for collection events with a trigger date on or before the current date. For each triggered event, the system executes its activity and then completes it. Refer to [Collection Event Activator](#) for more information.

The Last Collection Event Should Kick Off Severance Process(es)

The last collection event will typically kick off the severance process for every service agreement linked to the collection process. This will only happen if you set up the collection process template accordingly (i.e., the last event type in the process template is the kind that starts a severance process for every service agreement linked to the collection process).

Note:

Nominating a service agreement to sever. Many organizations that have multiple services in arrears will NOT sever every service agreement that's in arrears. Rather, they will nominate one service agreement and use it to encourage the customer to pay for the other services. If your organization works this way, then your last collection event should call the Nominate A Service Agreement To Sever Algorithm.

How Are Collection Events Canceled?

Users can cancel a collection event at their discretion. In addition, the system can cancel a collection event when it automatically cancels a collection process. Refer to [How Are Collection Processes Cancelled](#) for the details.

The Big Picture Of Severance Process Cancellation

The topics in this section provide high level information about the cancellation of severance processes.

Fastpath:

For more information refer to [The Lifecycle Of A Severance Process And Its Events](#).

How Are Severance Processes Cancelled?

A severance process may be cancelled via the mechanisms described in this section.

Fastpath:

Refer to [What Happens When A Severance Process Is Cancelled?](#) for what happens when a severance process is cancelled.

The Freezing Of Certain Financial Transactions Can Cancel A Severance Process

Note:

The system will only cancel a severance process if its severance process template indicates that **Auto Cancel** is allowed. Typically, this switch is set on all severance process templates except for the odd ones that are used to [reconnect service](#).

The system reviews a severance process real-time whenever its service agreement's debt is reduced. Financial events that can cause service agreement debt to be reduced are:

- The cancellation of a bill segment.
- The creation of a payment segment.
- The creation of an adjustment that credits a service agreement.

Note:

Real time cancellation. Unlike collection processes, the system cancels severance processes real time (i.e., there is no background process that monitors severance processes). Why are severance processes canceled real time? Because a severance process may have events that create field activities to sever service. These events need to be canceled the moment the FT is frozen, we can't wait until a background process runs. This means that if a customer pays in person for a service agreement that is pending severance, the system will cancel the process and its field activities (if any) the moment the payment is entered.

The review takes place as follows:

- **Debt class cancel criteria.** In general, the sum of all debt associated with the severance process's debt class must be less than or equal to a given threshold amount for a severance process to be cancelled. If so, the severance process is cancelled.
- Please be aware that, if a [Pay Plan](#) exists for the account and debt class, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount. Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

Note:

The above logic is not "hard coded". The system calls the Severance Process Cancel Criteria Algorithm defined on the [debt class](#) that is associated with the severance process. This algorithm cancels a severance

process if the sum of ALL service agreements in the debt class have debt less than or equal to a given threshold amount. However, because it's an algorithm, you can introduce whatever cancellation criteria you please.

- **Service agreement cancel criteria.** You can optionally introduce a special quirk to the cancellation logic. This quirk is a bit difficult to understand. To understand it, you should recall:
 - The collection event called Start Severance creates a severance process for every service agreement that is in arrears. Note: you would only use this type of collection event if you do not Nominate A Single Service Agreement To Sever.
 - If you use the Start Severance collection event, then you would want to cancel a severance process when its service agreement no longer has intolerable debt (regardless of the state of the debt class's entire debt).
- To cancel a severance process when its related service agreement no longer has intolerable debt, you should plug-in a Cancel Criteria Algorithm on your [severance process templates](#). The system will call this algorithm if you've plugged it in.

Note:

Manual Creation. A user can create a severance process for an account that does not qualify to be on severance according to the cancel criteria algorithm. For example, perhaps your cancel criteria algorithm cancels a severance process when the account's debt falls below a threshold amount. A user can create a severance process for an account whose debt is already below this threshold. Because cancellation is real time, there is no action that will cause this severance process to be canceled. When a manual severance process is created, the system executes the appropriate cancellation criteria algorithm. If the algorithm indicates that the system would have canceled this severance process, a warning is issued.

A New Payment Plan Can Cancel A Severance Process

Refer to [Collection Process / Severance Process Cancellation When A Pay Plan Is Created](#) for the details.

Note:

Real time cancellation. Please be aware that the system will cancel a severance process real time when a pay plan is created that pays off enough debt.

A User May Cancel A Severance Process At Their Discretion

A user may cancel a severance process at their discretion.

Stopping A Service Agreement Will Cancel A Severance Process

The system will cancel a severance process if its service agreement is stopped (i.e., when the service agreement's status becomes Stopped).

What Happens When A Severance Process Is Cancelled?

The following takes place when a severance process is canceled by the system:

- The system cancels all pending severance events and deactivates the severance process.
- If there are any field activities linked to the severance process, an optional plug-in spot defined on the installation record allows you to plug in an algorithm to cancel these field activities.
 - The base package Severance Process Cancellation Algorithm will cancel all pending field activities that were created as a result of the severance process that are not linked to a dispatched field order.
- If there are any pending field activities left associated with the severance process, it is marked to trigger the creation of a To Do entry to highlight that field activities exist for a canceled severance process. (This happens

if you have not plugged in an algorithm to perform the cancellation or if the algorithm detected a condition that prevented cancellation.) To create the To Do entry, you must run the background process [TD-SPRO](#).

- There is an optional plug-in spot defined on the severance process' template. If an algorithm is plugged-in, it is called. The base package algorithm will create a reconnect process if there are completed field activities for a cut for nonpayment severance event associated with the severance process. Refer to Severance Post Cancellation Algorithm for more information about this algorithm.

The Big Picture Of Severance Events

This section describes the various types of severance events and their lifecycle:

How Are Severance Events Created?

Severance events may be created as follows:

- The process that completes (i.e., executes) collection events creates a severance process when it completes a "start severance process" collection event. The severance process has one or more severance event(s). The number and type of events is controlled by the severance process template associated with the severance process. Refer to [The Collection Event Activator](#) for more information about this process.
- Severance events will be created when a user creates an ad hoc severance process. The number and type of severance events is controlled by the severance process template associated with the severance process.
- An ad hoc severance event may be created and linked to an existing severance process by a user at their discretion.

Note:

Bottom line. Most severance events are created by the system when it creates a severance process for delinquent service agreements. If you need to create an ad hoc severance event, you can either create a severance process whose template contains the desired event OR link the desired event to an existing severance process.

Fastpath:

For more information about creating ad hoc severance processes and events, refer to [How To Perform Common Severance Process Functions](#).

Types Of Severance Events

The following table describes the various types of severance events and what happens when they are completed:

| Type Of Severance Event | What Happens In The System |
|-------------------------|--|
| Send Letter | <p>A customer contact is created for every financially responsible person linked to the service agreement's account. It is the customer contact that causes a letter to be produced.</p> <p>The type of letter is defined on the customer contact's contact type.</p> <p>The recipient of each letter is defined on Account / Person (those persons marked as Receiving Notifications).</p> |
| Create To Do Entry | <p>A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries.</p> |

| | |
|--------------------------------|--|
| Create Field Activities | A field activity is created for each service point associated with the service agreement being severed. The type of activity is defined on the service point's SP type's field activity type profile. |
| Generic Algorithm | The algorithm defined on the event's event type is executed. |
| Expire Service Agreement | The service agreement is expired and, if earlier severance events created "cut for non-payment" field activities, these field activities will be used as the basis for stopping service. Refer to Finalizing Pending Stops for how the system use the meter reads on these field activities as the "stop reads" on the service agreement. Note, you can see the field activities that are used to "cut" and "stop" service by viewing the Field Activities grid on Service Agreement - Service Point . |
| Affect Credit Rating/Cash-Only | An account credit rating demerit record is created. The number of demerits is defined on the collection event type. |

Fastpath:

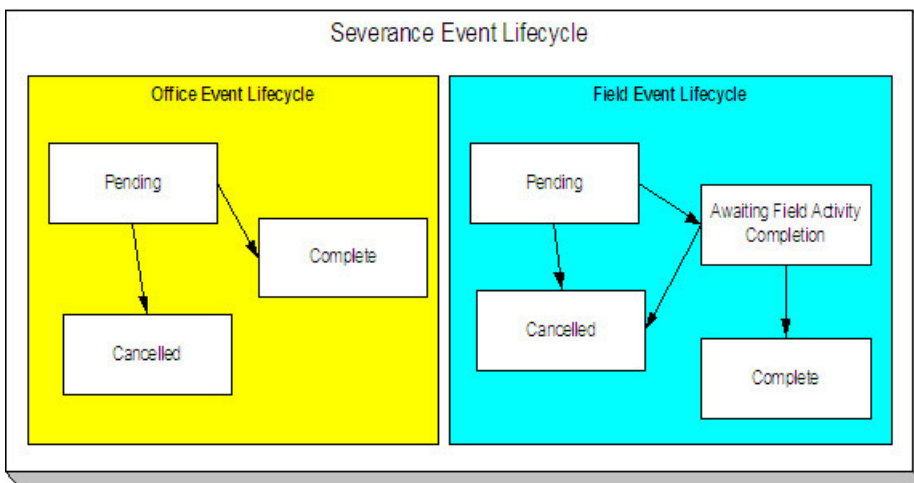

Refer to [Setting Up Severance Event Types](#) for more information.

Field Events Versus Office Events

Severance events are considered either field or office events. Office events are just like collection events in that they don't involve any type of field activity in their completion. Field events, however, are not like collection events because they create one or more field activities. These activities cause these events to have a different lifecycle. Refer to [Severance Event Lifecycle](#) for more information.

Severance Event Lifecycle

The following diagram shows the possible lifecycle of a severance event:

The following points explain the lifecycle of severance events of the office variety:

- Office events are initially created in the pending state.

- A pending office event becomes complete when the system sees that its trigger date is on or before the current date. At this time, the system executes the event's activity (e.g., create a letter, create To Do entry).

Fastpath:

For more information about a severance event's trigger date, see [Severance Event Dependencies & Trigger Date](#).

- A pending office event will be cancelled automatically by the system when the debt associated with the severance process's service agreement is sufficiently reduced. A pending office event may also be cancelled by a user at their discretion. Refer to [How Are Severance Processes Cancelled](#) for more information about how the system will cancel a severance process (and its events).

The following points explain the lifecycle of severance events of the field variety:

- Field events are initially created in the pending state.
- A pending field event becomes awaiting field activity completion when the system sees that its trigger date is on or before the current date. At this time, the system creates the field activities associated with the given event (e.g., disconnection warning, disconnect for nonpayment, etc.).

Fastpath:

For more information about a severance event's trigger date, refer to [Severance Event Dependencies & Trigger Date](#). For more information about the field activities that are created for a field severance event, refer to [Field Events And Their Activities](#).

- An awaiting field activity completion field event becomes complete when the system sees that its field activities are all complete or cancelled.
- A pending field event will be cancelled automatically by the system when the service agreement associated with the severance event's severance process has sufficient credits. A pending field event may also be cancelled by a user at their discretion.
- An awaiting field activity completion field event will be cancelled automatically by the system when the service agreement associated with the severance event's severance process has sufficient credits if the field activity has not been dispatched (refer to [Designing Your Reconnection Procedures](#) for information on how the system handles the situation if the field activity is completed or dispatched). An awaiting field activity completion event may also be cancelled by a user at their discretion.

Severance Event Dependencies and Trigger Date

When a severance event is created by the system, its trigger date cannot be set. This is because, unlike collection events, the trigger date on severance events can only be set when ALL of the preceding severance events on which it depends are complete. An example will help explain why this design is necessary. Consider the following example that shows a standard severance process and its events:

| Event Number | Severance Event | Dependent On Event(s) | Trigger Date Set To X Days After Completion Of Preceding Events |
|--------------|---|-----------------------|---|
| 10 | Field activity - Disconnect for non-payment warning | N/A - first event | 0 |
| 20 | Field activity - Disconnect for non-payment | 10 | 2 |
| 30 | Create To Do entry | 20 | 0 |
| 40 | Send letter to customer | 20 | 0 |
| 50 | Expire service agreement | 20 | 10 |

This severance process is meant to execute as follows:

- On the first day, generate a 48-hour warning of impending disconnection. This is a field event as most organizations deliver this warning in person.
- After 2 days (i.e., 48 hours) have passed, create a field activity to disconnect for non-payment.
- When this is completed, generate a To Do entry to let a CSR know about the cutoff. Also, send a letter to the customer.
- If after 10 days from the cutoff, we still don't have payment, expire the service agreement.

As can be seen from the above example, the later events are dependent on the completion of the field activities in the earlier events. This means that when you set up a severance event, you must indicate the events on which it depends (and the number of days after their completion that the event should be triggered).

Note:

Bottom line. The system sets the trigger date on severance events when it detects that all of its dependent events are complete (this is the responsibility of the SED background process). Refer to [Calendar vs Work Days](#) for a description of your choices in respect of how the trigger date is calculated.

Field Events And Their Activities

When the system is told to start a severance event that creates field activities (e.g., disconnect for non-payment), it will generate a field activity for every service point linked to the service agreement.

The question is, where does it get the field activity type associated with the field activities? The answer is explained below:

- Every service point has an SP type.
- Every SP type references a field activity type profile.
- A field activity type profile contains a matrix defining activity types to generate under various situations. Some of these situations are those associated with severance.

Fastpath:

For more information, refer to [Setting Up Field Activity Type Profiles](#).

Severance Event Activation & Completion

A background process runs periodically (at least daily) that looks for severance events with a trigger date on or before the current date. This process executes the activity associated with each event. If the event is an office event, the event then becomes complete. If the event is a field event, the event becomes "awaiting field activity completion" until the field activities are complete. At this time, the severance event is completed. Refer to [Severance Event Activator](#) for more information.

How Are Severance Events Canceled?

Users can cancel a severance event at their discretion. In addition, the system can cancel a severance event when it automatically cancels a severance process. Refer to [How Are Severance Processes Cancelled](#) for the details.

The Big Picture Of Write Off Processing

Before you financially write-off debt, most companies go to some effort to collect the past due funds. You control exactly what happens by setting up the various write-off control tables. The topics in this section provide background information that will help you understand how the information in these control tables is used.

How Is Debt Financially Written-Off?

Before debt can be written-off, a write-off service agreement must exist for the account. Why? Because when you write-off a normal service agreement's debt, you are actually transferring its debt to a write-off service agreement.

A write-off service agreement is just like other service agreements in that:

- It holds debt.
- When a payment is received, the service agreement's debt is reduced.

Debt is transferred to a write-off service agreement (WO SA) from the customer's uncollectable service agreements (SAs). The following points highlight important characteristics about the uncollectable SAs and the WO SA:

- The WO SA and the uncollectable SAs should be linked to the same account (note: this isn't a strict rule, it just makes sense because an account's written off funds should be linked to the account).
- Debt may be transferred to a WO SA from any type of service agreement regardless of debt class, i.e., a WO SA can contain debt that originated in any debt class.
- When you transfer debt from the uncollectable SAs to the WO SA, the debt is removed from the uncollectable SAs (and their status becomes closed - assuming their balance becomes zero).
- If you use the system's automated write-off processing, the system will create WO SAs for you. The system's automated write-off processing can write-off revenue in a different manner than is used to write-off liabilities. Refer to [The Ramifications of Write Offs in the General Ledger](#) for more information.
- WO SAs are immune from the account debt monitor (assuming their debt class is marked as not being subject to collection activities).
- WO SAs are not billed (assuming their SA type is marked as being not billable).
- WO SAs start their life with a non-zero payoff and current balances (i.e., they have debt when first started). This debt is transferred from the normal service agreement(s) whose uncollectable debt necessitated the creation of the WO SA.
- If the customer pays off the write-off debt, the WO SA remains active in case you ever need to write-off debt in the future. If you don't like the WO SA remaining active after it's paid off, you can indicate on the WO SA's SA Type that it is a "one time charge", this will cause the WO SA to be automatically closed when it's paid off.
- You can transfer additional uncollectable debt to the WO SA.

Note:

Bankruptcy write-offs. If you have to write-off debt because a customer declares bankruptcy, everything stated above is true. The only thing you have to do is use a different SA type for bankruptcy write-offs as compared to "normal" write-offs. On the bankruptcy write-off SA type, simply leave the payment segment type blank - this way the system will never distribute a payment to the bankrupt debt (because bankrupt debt is legally uncollectable).

The Ramifications of Write Offs in the General Ledger

Warning:

If you practice cash accounting, refer to [Cash Accounting and Write-Offs](#).

When you write-off unpaid debt, you shouldn't book it all to a write-off expense account. Why? Because the debt that you're writing off typically contains both revenue and liabilities. At write-off time, you typically want to:

- Book the written off revenue to a write-off expense account, and
- Reduce the liabilities (you don't owe the liability if you don't get paid).

Consider the following example of a simple electric service agreement with two financial transactions:

| Event | GL Accounting |
|-------|---------------|
|-------|---------------|

| | |
|--|--|
| Customer is billed | A/R 1000 Revenue <900> State Tax Payable - Taxing State - California <80> City Tax Payable - Taxing City - San Francisco <20> |
| Customer is levied a late payment charge | A/R 50 Late Payment Revenue <50> |

After these two financial transactions are booked, the customer has debt of \$1050. Of this \$1,050; \$950 is revenue and \$100 is liability (money you owe the taxing authorities).

If the customer doesn't pay, you will eventually have to write-off this debt. Most organizations would issue the following types of financial transactions to do this:

| Event | GL Accounting |
|-----------------------------------|--|
| Write-off the bill | Write-off Expense 900 State Tax Payable - Taxing State - California 80 City Tax Payable - Taxing City - San Francisco 20 A/R <1000> |
| Write-off the late payment charge | Write-off Expense 50 A/R <50> |

Notice in the above transactions, the two separate revenue accounts are written off by booking to an expense account. However, the liability accounts are reversed. Why is revenue treated differently from liabilities at write-off time? There's a good reason for it (if you're an accountant), for the time being, just accept that this is how it works.

And finally, we need to worry about what happens if the customer eventually pays off their written off debt. If this happens, most organizations would pay off the write-off first, and, if there was still money left, they'd reimburse the taxing authorities. If we assume the customer pays off the entire written off debt, the following financial transactions would be issued:

| Event | GL Accounting |
|------------------------------|---|
| Pay off the written off debt | Cash 900 Write-off Expense <900> |
| Reinstate the liabilities | Cash 100 State Tax Payable - Taxing State - California <80> City Tax Payable - Taxing City - San Francisco <20> |

While the reinstatement of liabilities at payment time is possible in the system, the ramifications of doing such make this approach impracticable (the ramifications are a) if the check bounces, we would not be able to reduce the liabilities, and b) if there was a partial payment of the liabilities, the remaining unpaid amount could get written down). Therefore, when a write-off is paid the following financial transactions should be issued:

| Event | GL Accounting |
|-------|---------------|
|-------|---------------|

| | |
|------------------------------|------------------------------|
| Pay off the written off debt | Cash 900 |
| | Write-off Expense <900> |
| Reinstate the liabilities | Cash 100 |
| | Reinstated liabilities <100> |

Notice that rather than reinstating the individual liabilities, we simply reinstate all liabilities into a single account. This means your accountants will have to distribute this money to the appropriate liabilities manually.

So, how do we achieve the above in the system? This explanation is a little complicated, but it'll make sense if you keep the above financial transactions in mind:

- First of all, you'll need two different SA types - one to hold the written off revenue and another to hold the reduced liabilities.
 - On the SA type that holds written off revenue, indicate that it is not billable, indicate that it cannot have excess credits, and give it a high payment distribution priority. The distribution code on this SA type should reference your Write-off Expense account.
 - On the SA type that holds the reduced liabilities, indicate that it is not billable, indicate that it cannot have excess credits, and give it a high payment distribution priority. The distribution code on this SA type should reference a the "reinstated liabilities" GL account.

Next, you need to understand how the system's standard write-off logic works:

- The system accumulates the distribution codes from GL details associated with recent financial transactions linked to the service agreement being written-off.
- When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreement(s). The number and type of service agreements to which the bad debt is transferred is defined on the distribution codes. Refer to [Setting Up Distribution Codes](#) for how to define the type of write-off service agreement associated with a distribution code. In our example, we'd need the two SA types described above - one for the revenue accounts, the other for the liability accounts.
- At write-off time, for those distribution codes associated with revenue, the system will create a transfer adjustment from the normal service agreement to the write-off revenue service agreement. This will reduce (credit) the receivable on the normal service agreement and increase (debit) the expense account defined on the write-off revenue service agreement.
- However, if we do the above for the distribution codes associated with liabilities, we have a problem. The problem is a bit hard to explain unless you understand tax accounting, but it basically comes down to this - if we simply transfer the portion of the receivable balance associated with the liabilities to the write-off liability SA, we will always be debiting the distribution code defined on the SA type. This isn't correct because we really want to debit the liability account (and reference the characteristic type and value from the original credit) when we reduce the liability. So how do we do this? For those distribution codes associated with liabilities, you need to indicate that you want to override the distribution code on the "transfer to" side of the transfer adjustment with the distribution code / characteristic type / characteristic value that was originally booked. Refer to [Setting Up Distribution Codes](#) for how to indicate you want to override the distribution code at write-off time. If you do the above, then at write-off time the transfer adjustment will reduce (credit) the receivable on the normal service agreement and increase (debit) the original liability accounts from the original financial transactions.

If you followed the above, you'll see that we now have everything debited and credited appropriately. And, if a payment materializes for the written off debt, we will simply debit cash and credit the distribution code on the respective SA (either Write Off Expense or Reinstated Liabilities).

Note:

Batch and real-time write-offs may use the above processing. The above logic is executed real time when a user writes off debt using the [write-off transaction](#) (assuming the base package write off algorithm is plugged into the account's [customer class](#)). The above logic is executed in batch when a write-off event that references a Write Off Using Distribution Codes [event type](#) is executed. Write-off events are described in detail below.

Automated versus Manual Write Offs

The system will automatically create write-off SAs and transfer uncollectable debt to them during the automated write-off processing described below.

If necessary, you can write-off debt outside of the automated write-off process using either of the following methods:

- You can transfer bad debt from any service agreement to a write-off service agreement using a transfer adjustment.
- You can use the [write-off transaction](#) to write-off debt real-time. When this transaction is used, the system executes the logic embedded in the Write Off Method algorithm that's plugged in on the account's [customer class](#).

How Does The Write-Off Monitor Work?

This section describes how the [Write Off Monitor](#) uses your write-off criteria and write-off process templates to collect overdue debt.

Different Write-Off Criteria For Different Customers And Different Debt

Consider the following:

- You probably have different write-off criteria for different customer segments. For example, customers with large bills probably have strict criteria, whereas you're probably more lenient with small customers (or vice versa). You differentiate your customers in respect of the collection process via a **collection class code on the customers' accounts**. An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.
- You probably have different write-off criteria for different classes of debt. For example, if a customer has both regulated and unregulated debt, you probably have commission-imposed criteria to be applied to the regulated debt, but you have control over how to write-off unregulated debt. You differentiate your debt in respect of the collection process via a write-off **debt class on the customers' service agreements** (note the write-off debt class is actually defined on the SA type and every service agreement has a SA type).

Note:

Write Off Debt Class vs. Regular Debt Class. It's important to be aware that a SA type references both a regular debt class and a write-off debt class. The regular debt class controls the collection criteria applied against an account's service agreements. The regular debt class is also used to segregate an account's outstanding balance on several queries in the system. The write-off debt class controls the write-off criteria applied against an account's stopped service agreements. The reason the system supports two different debt classes is because you may categorize your service agreements differently when you try to collect overdue debt versus when you write-off debt.

Given the above, you should understand that different write-off criteria will exist for every combination of collection class and write-off debt class. If you're confused, then consider the following matrix:

| | | |
|---------------------------|--|---|
| SA's Write-Off Debt Class | Account's Collection Class: Commercial Customer | Account's Collection Class: Residential Customer |
|---------------------------|--|---|

| | | |
|-------------|---|--|
| Regulated | N/A - there is no regulated, commercial customer debt. | <p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Synchronize current balance with payoff balance.</p> <p>Attempt to transfer debt to another active service agreement linked to the account.</p> <p>If the debt is $< \\$10$ and $> \\$-1$, write down the debt using a write-down adjustment.</p> <p>If the debt is $\leq \\$-1$, create an A/P adjustment to refund the credit to the customer.</p> <p>If debt remains, create the default write-off process for regulated debt.</p> |
| Unregulated | <p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Synchronize current balance with payoff balance.</p> <p>Attempt to transfer debt to another active service agreement linked to the account.</p> <p>If the debt / credit is $< \\$10$ and $> \\$-10$, write down the debt using a write-down adjustment.</p> <p>If the debt / credit is $\leq \\$-10$, create an A/P adjustment to refund the credit to the customer.</p> <p>If debt still remains:</p> <p>Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process.</p> <p>Otherwise, create the default write-off process for unregulated commercial debt.</p> | <p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Synchronize current balance with payoff balance.</p> <p>Attempt to transfer debt to another active service agreement linked to the account.</p> <p>If the debt is $< \\$10$ and $> \\$-1$, write down the debt using a write-down adjustment.</p> <p>If the debt is $\leq \\$-1$, create an A/P adjustment to refund the credit to the customer.</p> <p>If debt remains, create the default write-off process for unregulated residential debt.</p> |

Notice that each cell in the matrix has the same pattern:

- The system first attempts to reduce the SA's current and payoff balances to zero using the following methods (assuming you have set up the write-off control appropriately):
 - Sync the current balance with the payoff balance. If the SA's payoff balance is zero, this will cause the current balance to become zero and therefore close the SA.
 - If there's a debit balance, transfer the debt to any pending start or active SA in the same write-off debt class.
 - If there's a credit balance, transfer the debt to any non-closed / non-cancelled SA in the same write-off debt class
 - If the remaining debit / credit balance is within a user-defined tolerance (this is defined on the respective algorithm on the write-off control), create an adjustment to write-down the small balance.

- If a credit balance remains, create an A/P adjustment to refund the balance with a check (the adjustment type is defined on the respective algorithm on the write-off control).
- All of the above points will cause the SA to close. If debt remains, the system starts some type of write-off process. The type of process is dependent on the respective criteria. What differentiates one write-off criteria from another is its priority. The higher priority criteria will be compared first. If the customer / debt meets the criteria, the write-off process is initiated; no further comparisons are performed.

Fastpath:

For more information about maintaining this matrix, refer to [Setting Up Write-off Control](#).

When Is Debt Monitored For Write Off Purposes?

The write-off monitor only reviews a service agreement when the following conditions are true:

- The service agreement is stopped and reactivated.
- If the service agreement is a "billable charge" SA (as identified on its SA type), all of its billable charges must appear on a bill segment AND the bill segment's bill's due date plus grace period must be on or before the business date.
- If the service agreement is not a "billable charge" SA AND it is billable (as identified on its SA type), the SA must have a closing bill segment (i.e., it must be final billed) and the bill segment's bill's due date plus grace period must be on or before the business date.
- If the service agreement is a sub SA, its master SA must abide by the above conditions.
- If the service agreement is not billable, it is possible that adjustments, which affect the SA's debt, exist. The write-off monitor will only review a non-billable SA if all FTs for this SA that have been marked to include on a bill have been swept onto a bill and the bill for any of these FTs has a bill due date plus grace period on or before the business date.

Note:

Postponing write-off processing. You can prevent the write-off process from processing an eligible service agreement by populating the account's C&C Postpone Date with a future date.

Attempt To Close The SA Before Creating A Write Off Process

Before the write-off monitor creates a write-off process for a stopped and reactivated service agreement, it attempts to reduce the service agreement's debt to zero using all of the following methods:

- If the account has active service agreements, it will transfer the finalized debt to a pending start or active service agreement.
- If the debt or credit amount on the service agreement is small, the system will generate an adjustment to 'write it down' (or up in the case of a small credit).
- If the service agreement has a large credit amount, the system will generate an A/P adjustment (resulting in a check being sent to the customer).

Note:

Plug-in algorithms do the work. Algorithms that are plugged-in on the [write-off control](#) responsible for managing the service agreement's debt actually perform the above effort. You can customize these algorithms to behave exactly how your collections staff desires.

If the algorithms responsible for the above effort are successful in reducing the service agreement's debt to zero, then the service agreement closes and will not be subject to write-off processing. If the above algorithms don't result in the service agreement's debt being reduced to zero, a write-off process will be started (as describe below).

What Happens When A Write-Off Process Is Started?

When you define write-off criteria, you must define the write-off process template to use if the criteria are violated. The system uses this template to create the account-specific write-off process.

Every stopped or reactivated service agreement that is part of the offending write-off debt class will be linked to the write-off process.

Also linked to the write-off process will be one or more write-off events. These events are meant to prod the customer. You define the types of events and when they are generated when you set up your write-off process templates.

It's important to note that all of the write-off events will be created when the write-off process is created. Each of these write-off events contains a trigger date. The trigger date of the first event(s) will typically be the current date. The trigger date of the other events will be in the future. Refer to [Calendar vs Work Days](#) for a description of how the trigger date is calculated.

A separate process, Activate Write-off events, is responsible for activating write-off events whose date is on or before the current date. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do to an operator, refer debt to a collection agency, etc.)

Note:

Multiple write-off processes may be kicked off. It's important to be aware that if an account's service agreements reference multiple write off debt classes, a write-off process will be started for each offending write off debt class that has stopped or reactivated service agreements.

Fastpath:

For more information about write-off process templates, see [Setting Up Write Off Process Templates](#). For more information about write-off events, see [The Big Picture Of Write-off Events](#). For more information about how a write-off process is cancelled, see [How Does A Write-Off Process Get Cancelled?](#).

How Does A Write-Off Process Get Cancelled?

The system "removes" a service agreement from a write-off process when its status becomes closed (i.e., when its balance is zero). When all service agreements are removed, the system cancels all pending write-off events and deactivates the write-off process. When the write-off process is deactivated, all collection agency referrals associated with the write-off process are cancelled.

Note:

Removing closed service agreements from a write-off process. Service agreements aren't actually removed from the process. Rather, they are inactivated so a proper audit exists.

How Do Collection Agency Referrals Work?

The following points describe how collection agency referrals work.

- A write-off process has one or more events. One type of event causes overdue debt to be referred to a collection agency.
- When a referral write-off event is activated, the system marks the event for processing by the event's Collection Agency Referral Algorithm (refer to [Setting Up Write Off Event Types](#) for more information).
- The next time the Collection Agency Referral process executes (the frequency is dependent on your background process schedule), it will refer the process' debt to a collection agency. The specific agency to which the debt is referred is controlled by the event type's Collection Agency Referral Algorithm. The sample algorithm supplied with the system simply refers debt to the collection agency with the least amount of referred debt. If you prefer different logic, you must write your own algorithm.
- Regardless of the manner in which a collection agency is selected for an account's debt, the referral involves the creation of a collection agency referral history record. Refer to [Collection Referral](#) for more information.
- A collection agency referral history record is linked to an account. It contains the amount of debt referred to the collection agency. It is the creation of this record that, in turn, triggers the interface of information to the collection

agency. The method used to interface the information to the agency is defined on the collection agency's record. Refer to [Setting Up Collection Agencies](#) for more information.

- If the collection agency is successful in obtaining the funds, simply add a payment. If the payment causes the SA's balance to become zero, the system will automatically close the service agreement. When the system closes a service agreement, it is "removed" from the write-off process. When a write-off process no longer contains active service agreements, the system cancels the write-off process. When a write off process is cancelled, all collection agency referrals are automatically cancelled.
- Collection agency referrals get cancelled by the creation of a new collection agency referral history record (with a type of cancel). This record will be interfaced to the agency in the same manner used to interface a new referral (see above).
- If the collection agency is not successful in obtaining your funds after a given amount of time, you probably want to cancel the referral and write-off the debt. The cancellation of the referral will happen automatically if you design your write-off process to generate a collection agency cancellation X days after the referral. Refer to [Setting Up Write Off Process Templates](#) for how to do this. You can cancel a referral manually by simply creating a new collection agency referral history record (with a type of cancel).

Fastpath:

When you enable the Control Central alert algorithm, C1-COLL-REF, an alert displays when an account has an active collection agency referral. This algorithm is plugged-in on the [installation record](#).

The Big Picture Of Write-off Events

This section describes the various types of write-off events and their lifecycle.

How Are Write-off Events Created?

Write-off events may be created as follows:

- The Write-Off Monitor creates a write-off process when an account has unpaid, final billed service agreements. The write-off process has one or more write-off event(s). Refer to [How Does The Write-Off Monitor Work?](#) for more information about how the system creates write-off processes and their events.
- Write-off events are created when an operator creates an ad hoc write-off process. The number and type of events is controlled by the write-off process template defined when the write-off process is created.
- An ad hoc write-off event may be created and linked to an existing write-off process by an operator at their discretion.

Note:

Bottom line. Most write-off events are created by the system when it creates a write-off process for unpaid, finalized service agreements. If you need to create an ad hoc write-off event, you can either create a write-off process using a template that contains the desired event OR link the desired event to an existing write-off process.

Fastpath:

For more information about creating ad hoc write-off processes and events, refer to [How To Perform Common Write-off Maintenance Functions](#).

Types Of Write-off Events

The following table describes the various types of write-off events and what happens when they are completed:

| Type Of Write-off Event | What Happens In The System |
|-------------------------|----------------------------|
|-------------------------|----------------------------|

| | |
|--------------------------------|--|
| Affect Credit Rating/Cash-Only | An account credit rating demerit record is created. The number of demerits is defined on the write-off event type. |
| Cancel Agency Referral | All collection agency referrals associated with the write-off process will be cancelled. |
| Refer to Agency | The debt associated with the SAs linked to the write-off process will be referred to a collection agency. |
| Send Letter | <p>A customer contact is created for every financially responsible person linked to the account.</p> <p>The customer contact causes a letter to be produced. The type of letter is defined on the customer contact type control table.</p> <p>The recipient of each letter is defined on Account / Person (those persons marked as Receiving Notifications).</p> |
| Send To Do | A To Do entry is created. Refer to The Big Picture of To Do Entries for more information about To Do entries. |
| Write Off using Distrib Code | <p>This type of event is used to write-off bad debt in accordance with the distribution codes associated with the financial transactions that caused the debt in the first place. You'd use this method for example if you want to write-off revenue differently than you write-off liabilities.</p> <p>The system accumulates the distribution codes from GL details associated with recent financial transactions linked to each write-off service agreement. When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreement. The type of service agreements to which the debt is transferred is defined on the distribution codes.</p> |
| Write Off using SA Type | The service agreements linked to the process will be written-off by transferring their debt to a new or existing write-off service agreement. Note: the SA type of the write-off service agreement is defined on the algorithm defined on events of this type. |
| Generic Algorithm | The system calls the algorithm defined on the write-off event type. This type of event is used when what you need to do isn't handled by one of the above event types. |

**Fastpath:**

Refer to [Setting Up Write Off Event Types](#) for more information.

Write-off Event Lifecycle

The following diagram shows the possible lifecycle of a write-off event:

Write-off events are initially created in the pending state.

When the system sees a pending event with a trigger date on or before the current date, the system executes the event's activity and completes the event.

Fastpath:

For more information about a write-off event's trigger date, see [Write-off Event Trigger Date](#).

A pending event will be cancelled automatically by the system when the service agreements linked to the process are all closed (i.e., they no longer have debt - either because it was paid or transferred to a write-off service agreement). A pending event may be cancelled by an operator at their discretion.

Write-off Event Trigger Date

When a write-off event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to [Calendar vs. Work Days](#) for more information.

How Are Write-off Events Completed

A background process runs periodically (at least daily) that looks for write-off events with a trigger date on or before the current date. For each triggered event, the system executes its activity and then completes it. Refer to [Write Off Event Activator](#) for more information.

The Last Write-off Event Should Write Off All Debt Associated With All SAs

The last write-off event will typically transfer all debt from the service agreement's linked to the process to a write off service agreement (linked to the account). This will only happen if you set up the write-off process template accordingly (i.e., the last event in the write-off process template is the kind that writes off debt for every service agreement linked to the write-off process).

How Are Write-off Events Canceled?

The system removes a service agreement from a write-off process when its status becomes closed (i.e., when its balance is zero). Be aware that any type of financial event could cause an SA's balance to fall to zero (e.g., the creation of an adjustment, the application or cancellation of a payment, the cancellation of a bill, ...). When all service agreements are removed, the system cancels all pending write-off events and deactivates the write-off process.

Note:

Real time cancellation. Unlike collection processes, the system cancels write-off processes real time when the service agreement becomes closed (i.e., there is no background process that monitors write-off processes).

Besides the automated cancellation process, an operator may cancel a write-off event at will.

Note:

Removing closed service agreements from a write-off process. Service agreements aren't actually removed from the process. Rather, they are inactivated so a proper audit exists.

Calendar vs. Work Days

When you set up your collection, severance and write-off process templates, you supply information that controls how the system determines the trigger date of each event in the related process. There are two different mechanisms for doing this:

- When you set up your severance process templates, you must define the number of days between each event. For example, the second event (send cutoff warning) may need to be triggered 7 days after the first event (send reminder letter).
- When you set up your collection and write-off process templates, you must define the number of days after the start of the process when each event should be triggered. For example, the second event (send cutoff warning) may need to be triggered 7 days after the start of the collection process.

The system uses this information in conjunction with the account's division's work calendar when it allocates a trigger date to the various collection, severance, and write-off events in your processes. The system offers you the following choices in respect of how it calculates an event's trigger date:

- You can indicate that the trigger date should be set to the next possible workday. For example, if you indicate that the second event is triggered 7 days after the first event, the system will add 7 days to the first event's completion date. It then checks if this is a workday (and not a holiday), if so, this is the trigger date of the event; if not, it assigns the trigger date to the next workday.
- You can indicate that the trigger date should be calculated by counting workdays. For example, if you indicate that the second event is triggered 7 days after the first event, the system will count 7 workdays (using the account's division's work calendar), and set the trigger date accordingly.

You must define which of the above methods is used in the following processes:

- Account Debt Monitor (ADM). Refer to [The Account Debt Monitor](#) for more information.
- Collection Event Trigger (CET). Refer to [The Collection Event Activator](#) for more information.
- Severance Event Set Trigger Date (SED). Refer to [Set Trigger Date](#) for more information.
- Write-off Monitor (WPM). Refer to [The Write Off Monitor](#) for more information.

The Big Picture Of Payment Arrangements and Pay Plans

The topics in this section describe two different mechanisms that allow a customer to payoff overdue debt in installments.

The Big Picture Of Payment Arrangement Requests

A Payment Arrangement Request is used to manage the process of starting a payment arrangement. It is a step-by-step process that can include:

- Checking the account's eligibility for payment arrangement
- Capturing the terms of the payment arrangement such as the included service agreements, down payment amount, number of installments and installment amount
- Evaluating whether or not the payment arrangement request requires approval
- User approval / rejection of the payment arrangement request
- Monitoring for the down payment, if applicable
- Creating the payment arrangement service agreement

The topics in this section describe how payment arrangement requests work.

Lifecycle Of A Payment Arrangement Request

The base product provides a Payment Arrangement Request (**C1-PARequest**) business object that supports the functions needed to create a payment arrangement. Its lifecycle allows for managing and monitoring of the prerequisites of a payment arrangement:

- The first step in the payment arrangement request process is typically to check that the account is eligible for a payment arrangement. One or more eligibility criteria are executed and an overall assessment is made on the results, to determine the account's eligibility/ineligibility. The request goes into the **Eligibility Checked** state. The results are shown on the user interface, for the user to determine the next step.
 - If the account is ineligible for a payment arrangement, the request process ends. The payment arrangement request goes into the **Denied** state.
 - If the account is eligible, the process can proceed with setting up the terms of the payment arrangement. The agreed upon terms are submitted and the request proceeds to the next step. If there are no prerequisites (approvals, down payment etc.), the request can automatically go to the **Granted** state, where the payment arrangement service agreement is created
- A payment arrangement request may be subject to prior approval if it meets certain criteria — e.g. the payment arrangement amount exceeds a threshold amount. The payment arrangement request goes into the **Approval In Progress** state, where an authorized user will need to review the request and **Approve** or **Reject** it accordingly.
 - If the user approves the request, the request will proceed to the next step — i.e. either another prerequisite (such as a down payment) or granting the request.
 - If the user rejects the request, the request will automatically go to the **Denied** state.
- If a down payment must be paid prior to starting the payment arrangement, the request will stay in the **Waiting for Down Payment** state until the payment is received or until the down payment due date.
 - If the down payment is paid (i.e. according to implementation-specific criteria for considering it paid), the payment arrangement request goes into the **Granted** state, where the payment arrangement service agreement is created. The account's SA balances to include in the payment arrangement are recalculated, based on the actual down payment that was received.
 - On the other hand, if the down payment is not received or is received but insufficient, the payment arrangement request goes into the **Unpaid Down Payment** state.
- A payment arrangement in a **Waiting for Down Payment** or **Approval In Progress** state can be **Withdrawn**. This is for cases where a customer decides to not proceed with the payment arrangement.
- Any issues encountered during the recalculation of the SA balances or during the creation of the payment arrangement service agreement can put the request into the **Error** state.

Refer to the Payment Arrangement Request business object, for more details on these lifecycle rules.

Payment Arrangement Eligibility

An account's eligibility for payment arrangement is typically checked at the start of the request process. Based on the results of these eligibility checks, a user can determine whether or not the payment arrangement request can proceed.

Since the eligibility rules can vary across implementations, the base product provides plug-in spots on the Payment Arrangement Request Type (**C1-PARequestType**) business object for eligibility checking:

- The **PA Request Type – Eligibility Criteria** algorithm spot is responsible for checking specific conditions or activity on the account, to determine payment arrangement eligibility. Algorithms of this type commonly return a simple Pass/Fail result. The base product supplies a sample algorithm that checks the account's past broken payment arrangements.
- The **PA Request Type — Criteria Assessment** algorithm spot is responsible for taking the results of the execution of **PA Request Type – Eligibility Criteria** algorithms and determining the overall result, which is whether or not the account is eligible for payment arrangement. The base product supplies two sample algorithms for this spot:
 - One algorithm type checks for at least one Fail result from the **PA Request Type – Eligibility Criteria** algorithms and if it finds one, returns an *Ineligible* result

- Another algorithm type simply returns an *Eligible* result. This is for implementations that do not need **PA Request Type – Eligibility Criteria** algorithms. This default algorithm would be the only algorithm to plug in.

Payment Arrangement Request Approval

A payment arrangement request may require prior approval, based on the terms specified on the request. For instance, if the total payment arrangement amount exceeds a set threshold amount, the request may have to be routed to another user for approval. That user will need to review the request and Approve or Reject accordingly.

Since the approval requirements are implementation-specific, the base product provides a **PA Request Type — Determine Approval Requirement** plug-in spot on the Payment Arrangement Request Type (**C1-PARequestType**) business object. Algorithms of this type return an indicator of whether or not approval is needed. If the algorithm indicates that approval is needed, the payment arrangement request will go into the **Approval In Progress** state until a user reviews and approves/rejects the request.

Your implementation must configure an algorithm with your specific approval criteria. The base product does not currently supply an algorithm type for this spot.

Payment Arrangement Down Payments

A down payment may be required/applicable as a prerequisite for starting the payment arrangement.

A setting on the Payment Arrangement Request Type controls whether down payments are required/optional/not applicable. If down payments are required or optional, the payment arrangement request type defines the down payment options, which are percentages of the total payment arrangement amount or a flat amount.

The down payment due date is calculated based on settings in the Payment Arrangement Request Type – e.g. number of days till due.

The down payment is monitored for the actual payment:

- If the down payment is paid, the request is granted. The SA balances are recalculated based on the down payment amount that was paid and the payment arrangement service agreement is created.
- If the down payment is unpaid or is insufficient (based on the implementation's rules), the request is denied and the payment arrangement service agreement will not be created.

Refer to the Payment Arrangement Request Type (**C1-PARequestType**) business object for more details on down payment option configuration and to the Payment Arrangement Request (**C1-PARequest**) business object, to see the monitor algorithm that checks if the down payment was made.

Setting Up Payment Arrangement Request Control Tables

This section describes the control tables needed to set up payment arrangement requests.

Setting Up Payment Arrangement Request Types

A payment arrangement request type defines properties that control how a request for payment arrangement is processed.

Refer to [The Big Picture Of Payment Arrangement Requests](#) on page 794 for an overview of payment arrangement request functionality.

To maintain payment arrangement request types, open **Admin > Credit & Collection > Payment Arrangement Request Type > Search**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information on the fields.

Setting Up Payment Arrangement Request Reasons

A payment arrangement request can capture the specific reason why a customer is asking to go on a payment arrangement. This reason is optional if using the base-owned Payment Arrangement Request (**C1-PARequest**)

business object and the Payment Arrangement Request Process Flow Type (**C1-PAREQUEST**) on your Payment Arrangement Request Types.

To use Payment Arrangement Request Reasons, configure your specific values on the **C1-PARequestReasonLookup** extendable lookup. No base values are supplied for this lookup.

Setting Up Payment Arrangement Request Status Reasons

The Payment Arrangement Request (**C1-PARequest**) base business object provides the option to specify the reason for the request going into the **Denied** or **Canceled** state.

A few base-owned status reasons are supplied. To add other reasons for payment arrangement request cancellation/denial, go to the Status Reason portal and update the **C1-PARequest** business object's status reasons for the Denied and Canceled states.

Automatically Cancelling Inactive Payment Arrangement Requests

The system is delivered with a batch process, Cancel Inactive PA Requests (C1-ACPAR), that can be used to cancel payment arrangement requests that have been open for more than a specified number of days. Refer to the batch control description for more detail.

The delivered process is built using the [Plug-in Driven Background Processes](#) framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. For example, you can introduce a process record algorithm to create a To Do Entry instead of cancelling the payment arrangement request. Adjust the batch parameters according to your custom logic, if needed.

The Big Picture Of Pay Arrangements

A payment arrangement is an agreement with a customer to payoff severely overdue debt in **billed** installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

Note:

Nomenclature. Some people refer to payment arrangements as "current bill plus" agreements because the customer's bills contain charges for both their current debt plus their installment amount. After the customer has paid off their overdue debt, the customer's bill only contains charges for their current debt.

The topics in this section describe how to set up a payment arrangement and how the system monitors the ongoing arrangements.

Creating Payment Arrangements

When you create a payment arrangement, you are actually creating a service agreement. This service agreement is just like other service agreements in that:

- It holds debt.
- It is periodically billed.
- When a payment is received, the service agreement's debt is reduced.
- If the service agreement becomes delinquent, a collection process is initiated to collect the overdue debt.

Debt is transferred to a payment arrangement service agreement (PA SA) from the customer's delinquent service agreements (SAs) at the inception of the payment arrangement.

When you transfer delinquent debt from the delinquent SAs to the PA SA, the debt is removed from the delinquent SAs. If you transfer all debt from the delinquent SAs, the customer will no longer be in arrears in a given debt class (and if the customer is no longer in arrears, active collection and severance processes will be cancelled).

Note:

Use the Payment Arrangement Request Transaction. You could do the above functions by adding a new service agreement and creating transfer adjustments. However, this is tedious. Rather, use the [Payment](#)

Arrangement Request process. This process is recommend when requests for payment arrangements require eligibility checking and other prerequisites such as down payments and approvals. When a payment arrangement request is granted, it creates the PA SA, transfers debt to it, and sets up the installment amount.

You can also create the payment arrangement service agreement directly using the **Payment Arrangement** transaction if you don't require any prior eligibility checks, down payments or approvals. This transaction is also used if you need to break or cancel the payment arrangement.

Installment, Payoff and Current Amounts

Warning:

If you do not understand the difference between payoff balance and current balance, refer to **Current Amount versus Payoff Amount**.

When you set up a payment arrangement service agreement (PA SA), you transfer delinquent debt to the PA SA using transfer adjustments. After moneys are transferred, the system sets the PA SA's current balance to zero. At this point, neither the original service agreements nor the PA SA have delinquent debt. If the customer neglects to pay their payment arrangement, the PA SA will fall into arrears and a collection process will ensue. If the customer neglects to pay their previously delinquent SAs, they will again fall into arrears and a collection process will ensue.

PA SAs start their life with a non-zero payoff balance (i.e., they have debt when first started). This debt is transferred from the normal service agreement(s) whose outstanding debt necessitated the creation of the PA SA.

The installment amount that the customer is billed is determined by the number of installments used to payoff the debt. For example, if the customer owes \$500 on their electric and water service agreements and they want to pay this off in 10 installments, you'd set up the installment amount to be \$50. The installment amount is saved on the PA SA's recurring charge amount. If the customer again falls into arrears on their normal service agreements, you can transfer additional delinquent debt to the PA SA. You can also change the installment amount as needed.

A PA SA's payoff balance typically differs from its current balance. The payoff balance is the amount of debt remaining to be paid off under the terms of the payment arrangement. The current balance is the installment amount that has been billed but not paid. For example, a customer who is paying off \$500 with 10 installments of \$50 would have an initial payoff balance of \$500 and a current balance of \$0. After the first bill, the PA SA would still have a payoff balance of \$500, but its current balance would be \$50. When the customer pays, the PA SA's payoff balance would fall to \$450 and its current balance would return to \$0.

The following table contains a financial example of a customer who sets up a payment arrangement to payoff \$1,000 of debt in \$10 installments.

| Event | Normal SA's GL Accounting | PA SA's GL Accounting | Normal SA's Current Balance | Normal SA's Payoff Balance | PA SA's Current Balance | PA SA's Payoff Balance |
|--|---------------------------|----------------------------|-----------------------------|----------------------------|-------------------------|------------------------|
| Prior to creation of payment arrangement | N/A | N/A | 1000 | 1000 | N/A | N/A |
| Transfer debt from normal SA(s) to PA SA | Xfer 1000 A/R <1000> | PA A/R 1000 Xfer <1000> | 0 | 0 | 1000 | 1000 |
| Set current balance to zero on PA SA | N/A | N/A | 0 | 0 | 0 | 1000 |

| | | | | | | |
|---|------------------------|------------------------|----|----|----|------|
| Customer is billed (\$50 for new debt and \$10 of payment arrangement debt) | A/R 50 Revenue <50> | N/A | 50 | 50 | 10 | 1000 |
| Customer pays \$60 | Cash 50 A/R <50> | Cash 10 PA A/R <10> | 0 | 0 | 0 | 990 |

When the customer pays off the payment arrangement debt, the system automatically closes the PA SA after it final bills (assuming the PA SA's SA type references a bill segment type that has a bill segment creation algorithm of Recurring Charge With Auto Stop).

Monitoring Payment Arrangements

The PA SA should belong to its own debt class (let's call it Payment Arrangement Debt) so that you can have stricter collection criteria for payment arrangement debt (as compared to normal SAs). Because there will be a new debt class, there will be a unique collection class control (CCC) for payment arrangements. This CCC will have debt criteria associated with payment arrangement debt. If these criteria are violated, we will kick off a collection process that should have 1 collection event - Start Severance.

The severance process template for PA SAs will have 1 severance event that calls the Break Payment Arrangement Event algorithm. This algorithm does the following:

- Cancels ALL adjustments that were used to transfer the debt to the payment arrangement (identified by the XFER adjustment type on the PA SA's SA type). When these are cancelled, the original arrearage will be reinstated under the original SAs - this debt should be rather old by this point.
- Syncs up current balance with payoff balance on the PA SA.
- Makes the PA SA pending stop (SA activation will stop the SA when it next runs).
- If there is a credit left on the PA SA (because payments were made against the arrangement), the credit will be distributed amongst the account's debt using the standard distribution algorithm. Because the payment arrangement debt that was reinstated should be rather old, it should get relieved first. This relief will occur via transfer adjustments from the PA SA to the original SAs.
- If there is a debit left (e.g., because LPC were issued or some other type of adjustment was created by an operator), the debt will be transferred back to one of the SAs from which the arrangement was originally created.
- Inserts a characteristic under the PA SA to indicate that it has been broken (we need this for the account debt monitor (ADM) a few steps down).
- Inserts a row on the account debt monitor trigger. This trigger will cause the account to be reviewed by the ADM the next time it runs.

Note:

The PA SA must final bill before it closes. The PA SA will only close after the PA SA is final billed. This is OK as it won't have any money left on it.

When the ADM next runs, it will analyze the account's reinstated debt. We recommend creating a new override collection criteria for the normal debt class that will return a value of true if the account has a closed payment arrangement that has been broken in the last X days (where X is a parameter of the override collection criteria's algorithm). If this algorithm returns a true, kick off a unique collection process template (that has nasty events). A sample algorithm of this type is supplied in the base package - COLL COND PA.

To complete this discussion, we have to worry about the situation when the final bill of a payment arrangement goes unpaid. In this situation, the payment arrangement is stopped and will therefore not be processed by the ADM. In this case, the write off monitor will process the PA SA after its final bill's due date and a write-off process will start. This

write off process will have a single event that calls the Break Payment Arrangement algorithm (described above). After the FT's are issued in this event, the SA will close (because it's been final billed and its balance will go to zero).

The Big Picture Of Pay Plans

A pay plan (PP) is an agreement with a customer to make payments on specific dates. Pay plans differ from payment arrangements in that pay plans have user-defined scheduled payment dates, which are independent from the customer's billing dates. In other words, payment arrangements appear on the customer's bills, pay plan scheduled payments do not.

If a customer is in arrears and you want to receive payments on specific dates (as opposed to with the customer's regular bills), you would set up a pay plan and define the dates on which you expect the payments.

The topics in this section describe how pay plans work.

A Pay Plan Has One Or More Scheduled Payments

When you create a pay plan for an account, you must define the number of scheduled payments and their respective amounts. There is no limit to the number of scheduled payments that may be set up under a pay plan.

Automatic Payments Can Be Created On The Scheduled Payment Dates

The system will create automatic payments on a pay plan's scheduled payment dates if:

- The account is set up for automatic payment (as described under [How To Set Up A Customer To Pay Automatically](#)), and
- The payment method defined on the pay plan indicates automatic payment is being used

The background process called PPAPAY is responsible for creating these automatic payments. It does this by calling the automatic payment creation algorithm plugged in on the installation record.

Note:

If the **Autopay Creation Option** on the [installation record](#) is set to Create On Extract Date, the automatic payment is NOT distributed and frozen when the automatic payment is initially created. Rather, a separate background process ([APAYDSFR](#)) distributes and freezes the automatic payment on the automatic payment GL distribution date (refer to [Automatic Payment Dates](#) for more information on how this date is calculated). Refer to [Automatic Payments](#) for more information.

A Pay Plan Insulates Overdue Debt From The Account Debt Monitor

A pay plan's scheduled payments are used by the account debt monitor as "pseudo payments" that relieve the account's debt before it is subjected to the collection criteria (refer to [How Does The Account Debt Monitor Work](#) for more information about collection criteria).

It's important to understand that a pay plan only insulates the account's debt that belongs to the pay plan's debt class. Therefore, if a customer has debt that belongs to two debt classes (e.g., normal debt and 3rd party pass through debt), you would need to set up a separate pay plan for each debt class (assuming both types of debt are covered by a pay plan). Refer to [Different Collection Criteria For Different Customers and Different Debt](#) for more information about debt classes.

A Pay Plan Must Reference A Pay Plan Type

When you create a pay plan, you must define its pay plan type. The pay plan type controls the following functions:

- The debt class whose debt is insulated by the pay plan.

- The type of algorithm (if any) that is executed when the pay plan is broken. You might use such an algorithm to affect the customer's credit rating when the pay plan is broken.

A Pay Plan May Reference A Third-Party Payor

In addition to referencing the account whose debt is insulated by the pay plan, the pay plan must also reference the account that is responsible for making the payments. We refer to this second account as the pay plan's "payor".

While the payor's account is typically the same as the account whose debt is insulated by the pay plan, you can indicate a third-party payor (e.g., a social service agency) is responsible for making the pay plan's scheduled payments.

If your organization allows third-party payors, you can define each on the third-party payor control table. This control table exists to simplify the data-entry effort when you create a pay plan (as it defines the account associated with the third-party payor).

Note:

If a pay plan does not reference a third-party payor, any non-third-party payor (i.e., any account that is not defined in the third-party payor control table) can make payments on behalf of the customer. If a pay plan references a third-party payor, only payments made by the third party on behalf of the customer are counted towards the fulfillment of the pay plan.

The Lifecycle Of A Pay Plan

The following diagram shows the possible lifecycle of a pay plan:

The following points explain this lifecycle:

- Pay plans are initially created in the active state. Active pay plans are monitored for compliance by [The Pay Plan Monitor](#).
- A pay plan may be cancelled as follows:
 - A user can cancel a pay plan at will.
 - When a SA is stopped AND there are no other active SAs in the same debt class, all **Active** pay plans associated with the account and debt class will be **Canceled**.
 - The activation of a collection event that calls the "cancel pay plan" algorithm will cancel all active pay plans associated with the collection process's debt class. You may want to use such a collection event if your organization cancels active pay plans when new debt causes a collection process to kick-off. Note, the base package algorithm that performs this function will not cancel the pay plan if it's associated with a 3rd party payor.

- [The Pay Plan Monitor](#) causes active pay plans to become broken if sufficient payments have not been made to satisfy the pay plan's scheduled payments.
- [The Pay Plan Monitor](#) causes active pay plans to become kept when it detects that sufficient payments have been made to satisfy the pay plan's scheduled payments.

Highlighting The Existence Of Broken / Kept / Active and Denied Pay Plans

You can define on the installation record plug-in algorithms that format alert messages. (Refer to [Installation Options - Algorithms](#) for additional information.) We recommend that you take advantage of the following algorithms to highlight pay plans:

- Highlight pay plans in a given status. This algorithm is used to highlight pay plans in a given state (broken, kept, cancelled) that were started within the last X days.
- Highlight customer contacts of a given type. This algorithm would be used to highlight customer contacts of a given type that were created within the last X days. This would be useful if you create a specific type of customer contact when you deny a pay plan. Some utilities do this to prevent customers from shopping around.

In addition, you can define account-specific alerts to highlight customers that should never be allowed to have a pay plan (for whatever reason).

A Pay Plan Must Reference A Payment Method

When you create a pay plan, you must define how the customer will make the payments be referencing a payment method. Examples of payment methods include: In Person , Wire Transfer, By Post, Express Mail, etc.

The payment method is more than just documentation as it defines the number of grace days the customer has to make the pay plan's scheduled payments. For example, if you set up the payment method control table to indicate that payments made By Post have 3 grace days, then the customer has up to 3 days after each scheduled payment date to make the payment. If payment is not received by the scheduled payment date plus the grace days, the pay plan will be marked as broken (and the ADM will be triggered).

The Pay Plan Monitor

Fastpath:

Please understand the concepts described in [The Lifecycle Of A Pay Plan](#) and [The Tendering Account May Differ From The Account Whose Debt Is Relieved](#) before reading this section.

The Pay Plan Monitor background process (referred to as PPM) is responsible for monitoring active payment plans. This process can cause a pay plan (PP) to become kept or broken (or being left as active).

Note:

When is a pay plan marked as broken / kept? It's important to understand that only the PPM can cause a pay plan to become kept or broken. This means that if a customer makes a payment that satisfies a pay plan, the pay plan will only be marked as kept when the pay plan monitor next runs. Analogously, if a payment is cancelled, nothing will happen to an active pay plan until the PPM next runs. When the PPM next runs, it will see that the scheduled payment was not kept and it will break the pay plan and schedule the ADM to be executed. When the ADM next executes, it will create a collection process (because the customer's debt will no longer be insulated by the pay plan's scheduled payments).

NSF Cancellations After A Pay Plan Is Kept. If a payment is cancelled due to non-sufficient funds (NSF) after a pay plan is marked as kept, the pay plan will remain kept. But keep in mind that the pay plan's account is scheduled for review by the ADM when a payment is cancelled due to NSF. When the ADM reviews the account's debt, it will no longer have an active pay plan to insulate it and the account's debt will likely trigger a new collection process. Refer to [How Pay Plans Affect The Account Debt Monitor](#) on page 803 for more information.

The following points describe, at a high level, how the PPM monitors a pay plan (PP) for compliance.

- The system selects all frozen, non-cancelled payment segments associated with the PP's account and debt class where:
 - The payment date is after the start date of the pay plan, and
 - The payment's pay event has at least one tender that references the pay plan's payor.
- The system logically reduces / removes past and current scheduled payments (starting with the earliest scheduled payment) until the total amount of payment segments is exhausted (or there are no more historical / current scheduled payments).

Note:

Paying pay plans in advance. Scheduled payments with a future date are not logically removed / reduced. This means that if a customer makes advance payments on a pay plan, it will not be marked as kept until all scheduled payment dates are in the past.

- If all scheduled payments have been logically removed, the pay plan is marked as kept.
- If there exist scheduled payments where the pay date + grace days (grace days are defined on the pay plan's payment method) is before the current date (i.e., a payment doesn't exist for a scheduled payment):
 - The pay plan is marked as broken.
 - The PP's break algorithm (if any) is called (note, for European / Australian pay plans, there are scenarios where the break algorithm can cause the pay plan to become unbroken - when there aren't at least two missed, historical scheduled payments).
 - An ADM trigger is stored for the PP's account. This will cause the account to be reviewed by the ADM the next time it runs. And because the pay plan is broken, its scheduled payments will no longer insulate the account's arrearage.

Important:

It's important that you schedule the PPM to run before the ADM so that it can break unpaid payment plans prior to the ADM subjecting the account's debt to collection criteria. Refer to [How Pay Plans Affect The ADM](#) for more information.

How Pay Plans Affect The Account Debt Monitor

As described under [A Pay Plan Insulates Overdue Debt From The Account Debt Monitor](#) on page 800, a pay plan's scheduled payments insulate an account's debt from the ADM. This section describes how this is accomplished.

Warning:

You should understand the concepts in [How Does The Account Debt Monitor Work](#) and [The Tendering Account May Differ From The Account Whose Debt Is Relieved](#) before reading the following.

Note:

The ADM will be triggered when a pay plan is broken. Refer to [The Pay Plan Monitor](#) for an explanation of how the ADM is triggered when a pay plan is broken.

Before the ADM subjects an account's debt to the collection criteria, it calls the debt's debt class's Override Arrears Algorithm (this is an optional plug-in spot on [Debt Class](#)). This algorithm is passed the debt class's aged debt and manipulates it as follows:

- First, a list of all past, present and future scheduled payments associated with the account and debt class's active pay plans is constructed.
 - If multiple payors are encountered (because the customer has multiple pay plans and these have different payors), a separate list of scheduled payments is maintained for each payor.
- Next, for each payor, retrieve the total amount of frozen, non-cancelled payment segments made on behalf of the pay plan's account and debt class.

- Select all frozen, non-cancelled payment segments associated with the pay plan's account and debt class whose pay date is >= pay plan's start date and the pay segment's event has at least one tendering account associated with the pay plan's payor.
- Next, logically reduce / remove past and current scheduled payments (starting with the earliest scheduled payment) until the payor's payment amount is exhausted (or there are no more historical / current scheduled payments). Future scheduled payments cannot be remove / reduced.
- Finally, reduce the passed in aged debt with any unpaid scheduled payments.

Note:

This logic is not "hard coded". Rather, the mechanism used to use a pay plan's scheduled payments to reduce debt is defined in an algorithm defined on the pay plan's debt class. The contents in this section describe how a base package algorithm works. Because it's an algorithm, you can introduce whatever logic you please.

The following is an example of how pay plans affect aged debt.

| Date | Event | SA's Arrears | SA's Balances | Scheduled Payments |
|---------------------------------------|--|--|-------------------------------------|--|
| Prior to creation of the PP 1/18/2000 | | \$1,000 - 90 days old \$1,600 - 60 days old \$1,900 - 30 days old | Current: \$4,500 Payoff: \$4,500 | |
| 1/18/2000 | Pay Plan created. The \$4,500 in future scheduled payments offsets the existing \$4,500 of aged debt. | \$1,000 - 90 days old \$1,600 - 60 days old \$1,900 - 30 days old De facto ADM debt: \$0 | Current: \$4,500 Payoff: \$4,500 | 1/20/2001 \$1,500 2/01/2001 \$1,500 2/07/2001 \$1,500 |
| 1/20/2001 | The customer pays \$1,500. There exists \$3,000 of future scheduled payments that offset the arrears | \$1,100 - 62 days old \$1,900 - 32 days old De facto ADM debt: \$0 | Current: \$3,000 Payoff: \$3,000 | 1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 Future 2/07/2001 \$1,500 Future |
| 1/20/2001 | ADM runs. The \$3000 in future scheduled payments offsets the Current Balance of \$3000, so CC events not created. | \$1,100 - 62 days old \$1,900 - 32 days old De facto ADM debt: \$0 | Current: \$3,000 Payoff: \$3,000 | 1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 Future 2/07/2001 \$1,500 Future |
| 1/24/2001 | A new bill is created for \$400 | \$1,100 - 62 days old \$1,900 - 32 days old \$400 - 1 day old De facto ADM debt: \$400 - 1 day old | Current: \$3,400 Payoff: \$3,400 | 1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 Future 2/07/2001 \$1,500 Future |

| | | | | |
|----------|---|--|-------------------------------------|--|
| 2/2/2001 | Pay Plan Monitor runs. PP marked as Broken because the 2/1/2001 scheduled payment has not been paid (assuming no grace period on the pay plan's payment method) | \$1,100 - 74 days old \$1,900 - 44 days old \$400 - 8 days old | Current: \$3,400 Payoff: \$3,400 | 1/20/2001 \$1,500 "Paid" 2/01/2001 \$1,500 "Late" 2/07/2001 \$1,500 Future |
| 2/2/2001 | ADM runs. There are no active pay plans and therefore there is nothing to insulate the customer's debt. Therefore the aged debt will be subjected to the collection criteria and an appropriate collection process will be created. | \$1,100 - 74 days old \$1,900 - 44 days old \$400 - 8 days old | Current: \$3,400 Payoff: \$3,400 | Pay plan is broken and therefore its scheduled payments cannot be used. |

Collection Process / Severance Process Cancellation

When a pay plan (PP) is created, the system determines if it can cancel active collection and severance processes associated with the pay plan's account and debt class. It does this because a pay plan's scheduled payments act as "pseudo payments" that relieve the account's debt (temporarily). The following points describe how this works:

- The system attempts to cancel collection processes by calling the Collection Process Cancel Criteria Algorithm defined on the debt class that is associated with the collection process. This algorithm is meant to cancel a collection process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. Because of the existence of the pay plan, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount (see [How Pay Plans Affect The Account Debt Monitor](#) on page 803 for more information about how debt is reduced). Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.
- It attempts to cancel severance processes by calling the Severance Process Cancel Criteria Algorithm defined on the debt class that is associated with the severance process. This algorithm is meant to cancel a severance process if the sum of ALL service agreements in the debt class have debt less than a given threshold amount. Because of the existence of the pay plan, the actual debt will be temporarily reduced by the amount of the pay plan's scheduled payments before it is compared to the threshold amount (see [How Pay Plans Affect The Account Debt Monitor](#) on page 803 for more information about how debt is reduced). Note: this temporary reduction will only occur if you have plugged in the appropriate pay plan debt reduction algorithm on the debt class.

If collection / severance processes still exist for the account / debt class associated with the pay plan, a warning is issued.

Interesting Pay Plan Facts

The following points describe a variety of interesting facts about pay plans (PP):

- An account may have many active pay plans. However, only 1 pay plan may be active for a given account / debt class / payor at any point in time.
- The existence of a pay plan has no impact on payment distribution.

- When a SA is stopped, if the SA's debt class has an active PP AND there are no other active SAs in the same debt class, the PP will be cancelled
 - The cancel reason will be "cancelled by system" (as opposed to "cancelled by user")
- If necessary, different collection / severance processes can be triggered if a broken PP is detected (via the override algorithms on CCC and write-off control - we do NOT provide such algorithms).

Setting Up Pay Plan Control Tables

This section describes the control tables needed to set up pay plans.

Setting Up Pay Plan Types

Pay plan types control what is done by a given pay plan. Open **Admin > Credit & Collection > Pay Plan Type** to define your pay plan types.

Fastpath:

For more information refer to [The Big Picture Of Pay Plans](#) for more information.

Description of Page

To modify a pay plan type, simply move to a field and change its value. To add a new pay plan type, press + to insert a row, then fill in the information for each field. The following fields display:

Pay Plan Type The name of the pay plan type.

Description A meaningful description of the pay plan type.

Broken Algorithm This algorithm is called when a pay plan is broken. Refer to [The Pay Plan Monitor](#) for more information about how pay plans are broken.

If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that breaks a pay plan.

Debt Class The debt class covered by pay plans of this type. Refer to [Setting Up Debt Classes](#) for more information.

Setting Up Payment Methods

Payment methods are used to describe how a customer intends to make their pay plan's scheduled payments. Open **Admin > Credit & Collection > Pay Method** to define your payment methods.

Fastpath:

For more information refer to [A Pay Plan Must Reference A Payment Method](#) for more information.

Description of Page

To modify a pay method, simply move to a field and change its value. To add a new pay method, press + to insert a row, then fill in the information for each field. The following fields display:

Pay Method The name of the payment method.

Description A meaningful description of the payment method.

Grace Days The number of days added to the scheduled payment date. The ADM will consider the pay plan to be broken if payment is not made by the scheduled date plus the grace days.

Auto Pay If the pay method is marked as being for **Auto Pay**, the PPAPAY background process will automatically create an automatic payment on the pay plan's scheduled payment dates IF the account has been set up for automatic payment.

Setting Up Third Party Payors

Pay plans support optional third-party payors. Open **Admin > Credit & Collection > Third Party Payor** to define your third-party payors.

Note:

A third-party payor refers to an account. You must set up the account before you can create a third-party payor.

Fastpath:

Refer to [A Pay Plan May Reference A 3rd Party Payor](#) for more information.

Description of Page

The following fields display for each third party payor:

Third Party Payor Provide a meaning id for the third-party payor that can be easily recognized when setting up a pay plan.

Description A meaningful description of the payor.

Account ID The account that is used for this payor. It is this account that is tracked as the "payee" of any payments made towards a third party payor's pay plan.

Active Check this box if the payor is currently available to participate in pay plans.

Creating Collection, Severance & Write-Off Procedures

Your collection procedures define how your organization collects overdue debt. Your severance procedures define how your organization severs service agreements when collection attempts fail. Your write-off procedures define how your organization writes off finalized debt. In this section, we describe how to set up the data that controls these procedures.

Fastpath:

For more information about collection, severance and write-off procedures, see [The Big Picture Of Credit & Collections \(C&C\)](#).

Warning:

There are innumerable ways to design your collection, severance and write-off procedures. Some designs will result in easy long-term maintenance, others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your production collection, severance and write-off procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

Designing Your Collection Procedures

The design of your collection procedures is an iterative process. Over time, you will develop intuitive skills that will allow you to skip some iterations. However, when you're starting out, we recommend you use the following matrix as your guide. When the matrix is complete, you're ready to set up the collection process control tables.

| SA's Debt Class | Account's Collection Class: | Account's Collection Class: |
|-----------------|-----------------------------|-----------------------------|
| | | |

The topics discussed below will gradually complete this matrix using a simple case study.

Fastpath:

For more information about how the information in this matrix is used to monitor your customers' debt, refer to [Different Collection Criteria For Different Customers And Different Debt](#).

Designing Your Debt Classes

Multiple debt classes are needed when you have different collection procedures for different types of service agreements. If all service agreement debt is collected the same way, then you'll have just one debt class (call it Generic). However, if you're like many organizations, you will have multiple debt classes. The following points will help you understand why:

- If you have both regulated and unregulated service, you probably have different debt classes for each type of service. Why? Because your local regulators control how you collect and cutoff overdue, regulated debt. For unregulated debt, your organization controls how overdue debt is collected.
- If your customers make charitable donations, you will have a charitable contribution debt class. Why? Because you probably send a different type of letter when the customer falls into arrears on their charitable contributions. You also can't cut off their water service if they don't make their charitable contributions.
- If you levy deposits, you will probably have a deposit debt class. Why? Because you probably respond differently if the customer doesn't pay their deposit (e.g., you may decide to cut off their electric service until the deposit is paid).
- If you allow customers to make payments on Non-Billed Budgets, you will probably have a Non-Billed Budget debt class. Why? Because you probably respond differently if the customer doesn't pay their Non-Billed Budget (e.g., you may decide to expire the Non-Billed Budget but not affect their other service since the Non-Billed Budget is a way for customers to prepay for upcoming bills).
- If you write-off uncollectable debt, you will need another debt class for write-off service agreements. Why? Because when you write-off debt in the system, you transfer the uncollectable debt from the original service agreement(s) to a write-off service agreement. The write-off service agreement holds this debt forever (or until it is paid). You need to use a different debt class for the write-off service agreements because they aren't subject to collection criteria.
- If you use the system to charge your organization's company usage, you'll need another debt class (we refer to it as the "N/A" debt class below). Why? Because all service agreements must have a debt class, even those that will never have debt.

| SA's Debt Class | Account's Collection Class | Account's Collection Class |
|-------------------------|----------------------------|----------------------------|
| Regulated | | |
| Unregulated | | |
| Charitable Contribution | | |
| Deposit | | |
| Non-Billed Budget | | |
| Write Off | | |
| N/A | | |

Designing Your Collection Classes

Multiple collection classes are needed when any debt class has different collection rules depending on the type of customer. If all customers within all debt classes are collected the same way, then you'll just have a single collection class (call it Generic). However, if you're like many organizations, you will have multiple collection classes.

Consider unregulated debt. For commercial/industrial customers, you probably don't worry until they owe you more than, say, \$100 after 20 days. For residential customers, you probably don't worry until they owe you more than, say, \$5 after 20 days. In this situation, you will have at least two collection classes: one for large customers, the other for residential customers.

In our example, we are assuming you have two collection classes: Residential and Commercial/Industrial.

| SA's Debt Class | Account's Collection Class: Residential | Account's Collection Class: Commercial/Industrial |
|-------------------------|--|--|
| Charitable Contribution | | |
| Regulated | | |
| Unregulated | | |
| Write Off | | |
| Company Usage | | |

Designing Collection Class Controls

At this point we have the rows and columns defined in our matrix. Now it's time to work on the individual cells.

Each cell should have a "collection class control" that defines its collection criteria and what to do if the criteria are violated. If a cell doesn't have a collection class control, this means you don't have any debt associated with that combination of collection class and debt class. So, we'll mark each cell without debt with "N/A".

| SA's Debt Class | Account's Collection Class: Residential | Account's Collection Class: Commercial/Industrial |
|-------------------------|--|--|
| Regulated | | N/A |
| Unregulated | | |
| Charitable Contribution | | N/A |
| Deposit | | |
| Write Off | | |
| N/A | | |

Next, we'll mark each cell for debt classes whose debt isn't collectable (i.e., the write-off and N/A debt classes).

| SA's Debt Class | Account's Collection Class: Residential | Account's Collection Class: Commercial/Industrial |
|-------------------------|--|--|
| Regulated | | N/A |
| Unregulated | | |
| Charitable Contribution | | N/A |

| | | |
|-----------|-----|-----|
| Deposit | | |
| Write Off | N/A | N/A |
| N/A | N/A | N/A |

Note:

If the Account Debt Monitor encounters debt associated with a non-existent collection class control, it will issue an error.

Determining the collection criteria in each remaining cell can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For charitable debt, if the customer is more than \$0 in arrears by more than 20 days, kick off the "charity reminder" collection process. We'll talk more about this collection process later.
- For regulated / residential debt, if the customer is more than \$15 in arrears by more than 20 days, kick off the Normal Regulated collection process. We'll talk more about this collection process later.
- For unregulated / residential debt, if the customer is more than \$5 in arrears by more than 20 days, kick off the Normal Unregulated collection process. We'll talk more about this collection process later.
- For unregulated / commercial-industrial debt we have multiple criteria:
 - Highest priority. If the customer is more than \$10,000 in arrears by more than 20 days, kick off the Large Overdue Debt collection process. We'll talk more about this collection process later.
 - Lower priority. If the customer is more than \$100 in arrears by more than 20 days, kick off the Normal Unregulated collection process. We'll talk more about this collection process later.
- For deposit debt (regardless of collection class) we have multiple criteria:
 - Highest priority. If the customer is more than \$5 in arrears by more than 50 days, kick off the Deposit Severely Overdue collection process. We'll talk more about this collection process later.
 - Lower priority. If the customer is more than \$15 in arrears by more than 20 days, kick off the Deposit collection process. We'll talk more about this collection process later.

Given the above, our matrix will look as follows:

| SA's Debt Class | Account's Collection Class: | |
|-------------------------|--|---|
| | Residential | Commercial/Industrial |
| Charitable Contribution | If > \$0 is older than 20 days, start Charity Reminder collection process. | N/A |
| Regulated | If > \$15 is older than 20 days, start Normal Regulated collection process. | N/A |
| Unregulated | If > \$5 is older than 20 days, start Normal Unregulated collection process. | Highest priority: If > \$10,000 is older than 20 days, start Large Overdue Debt collection process. Lower priority: If > \$100 is older than 20 days, start Normal Unregulated collection process. |

| | | |
|-----------|--|--|
| Deposit | Highest priority: If > \$5 is older than 50 days, start Deposit Severely Overdue collection process. Lower priority: If > \$15 is older than 20 days, start Deposit collection process. | Highest priority: If > \$5 is older than 50 days, start Deposit Severely Overdue collection process. Lower priority: If > \$15 is older than 20 days, start Deposit collection process. |
| Write Off | N/A | N/A |
| N/A | N/A | N/A |

Designing Your Collection Class Control Overrides

Warning:

Your collection needs may not require any overrides for your collection class control matrix and therefore this section may not be relevant.

The following matrix will help you design your collection class overrides. When the matrix is complete, you're ready to set up the collection class control tables.

Notice that the matrix has two dimensions: one is dependent on collection condition algorithms; the other is dependent on the collection class controls designed in the previous section. Collection condition algorithms are confusing. Think of them as optional conditions that, if met, will subject the collection class control's debt to different collection criteria.

Each cell in the matrix contains the collection criteria that will be applied to the account's debt when the collection condition is met (i.e., the same type of criteria - dollars and days and collection process - are defined in each cell).

We label the first collection condition as the Default. The collection criteria associated with this column will be used to analyze an account's debt when none of the other conditions applies. We'll start by indicating the Default collection criteria (this was defined in the previous section).

| SA's Debt Class | Account's Collection Class: Default | Account's Collection Class: Credit Rating < Threshold |
|-------------------------------------|--|---|
| Residential Charitable Contribution | See default collection criteria defined in previous section. | |
| Residential Regulated | See default collection criteria defined in previous section. | |
| Residential Unregulated | See default collection criteria defined in previous section. | |
| Commercial-Industrial Unregulated | See default collection criteria defined in previous section. | |
| Residential Deposit | See default collection criteria defined in previous section. | |
| Commercial-Industrial Deposit | See default collection criteria defined in previous section. | |

If a different collection process OR criteria should be used when other conditions are met, you should indicate such by defining the collection criteria in the cell. For example, if we assume that all unregulated residential debt has a different collection process when the account's credit score is less than the threshold credit rating on the installation record or the account's CIS Division, our matrix will look as follows:

| SA's Debt Class | Account's Collection Class: Default | Account's Collection Class: Credit Rating < Threshold |
|-------------------------------------|--|---|
| Residential Charitable Contribution | See default collection criteria defined in previous section. | |
| Residential Regulated | See default collection criteria defined in previous section. | |
| Residential Unregulated | See default collection criteria defined in previous section. | Override: If Credit Rating is lower than the credit rating threshold: If > \$5 is older than 15 days, start Risky Unregulated collection process. |
| Commercial-Industrial Unregulated | See default collection criteria defined in previous section. | |
| Residential Deposit | See default collection criteria defined in previous section. | |
| Commercial-Industrial Deposit | See default collection criteria defined in previous section. | |

Once the matrix is complete, you're ready to design your collection process and collection event types.

Note:

The collection conditions are limited by your imagination (and business requirements). We have provided the collection conditions you see above as an example; we don't expect you'll be able to use the exact conditions we supply. Your conditions will be based on any number of factors. For example, if you have different collection criteria that apply during winter months, you should add a new collection condition (called Winter Season). Or if you have different criteria based on years of service, you could have another condition.

New collection conditions may require programming. See [How To Add A New Algorithm](#) for more information.

Designing Collection Process Templates & Collection Event Types

The following table shows the collection process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

| Collection Process Template | Collection Event Template | Triggered X Days From Start Of Collection Process |
|----------------------------------|------------------------------------|---|
| Charitable Contribution Reminder | Charity courtesy reminder letter | 0 |
| | Start severance | 15 |
| Normal Regulated | Regulated courtesy reminder letter | 0 |

| | | |
|----------------------------|--------------------------------------|----|
| | Regulated second notice letter | 10 |
| | Start severance | 15 |
| Large Overdue Debt | Large debt courtesy reminder letter | 0 |
| | To Do for large overdue debt | 3 |
| | Large debt second notice letter | 10 |
| | Start severance | 15 |
| Normal Unregulated | Unregulated courtesy reminder letter | 0 |
| | Unregulated second notice letter | 5 |
| | Start severance | 10 |
| Risky Customer Unregulated | Unregulated risky letter | 0 |
| | Start severance | 5 |
| Deposit | Deposit reminder | 0 |
| Deposit Severely Overdue | Create To Do entry | 0 |

If we extract each unique event type from the above table, we end up with the following:

| Collection Event Type | Event Type |
|--------------------------------------|----------------------------|
| Charity courtesy reminder letter | Send Letter - CHARIT REMIN |
| Start severance | Start Severance Process |
| Regulated courtesy reminder letter | Send Letter - REGUL REMIN |
| Regulated second notice letter | Send Letter - REGUL second |
| Large debt courtesy reminder | Send Letter - LARGE REMIN |
| Risky debt courtesy reminder | Send Letter - RISKY REMIN |
| To Do for large overdue debt | Issue To Do |
| Large debt second notice letter | Send Letter - LARGE second |
| Unregulated courtesy reminder letter | Send Letter - UNREG REMIN |
| Unregulated second notice letter | Send Letter - UNREG second |
| Deposit reminder | Send Letter - DEPOS REMIN |
| To Do for deposit severely overdue | Issue To Do |

Now you're (almost) ready to set up your collection procedures.

Defining Cancellation Process Auto Cancellation Criteria

The topics in the section [How Are Collection Processes Cancelled](#) describe the two algorithms that play a part in the cancellation of a collection process. It also describes when to use what type of algorithm. Please read this section and then set up the appropriate cancellation criteria on your [Debt Classes](#), and optionally, on your [Collection Process Templates](#).

Setting Up Collection Procedures

In the previous section, [Designing Your Collection Procedures](#), we presented a case study that illustrated a mythical organization's collection procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

Setting Up Collection Event Types

Collection event types control what is done by a given collection event. Open **Admin > Credit & Collection > Collection Event Type > Add** to define your collection event types.

Description of Page

Enter a unique **Collection Event Type** and **Description** for the collection event type.

Enter the **Collection Event Type**. Permissible values are: Affect Credit, Rating/Cash-Only, Cancel Budget, Generic Algorithm, Send Letter, Create To Do Entry, Start Severance Process. The following discussion describes the parameters that must be defined for each type of collection event.

The Affect Credit Rating/Cash-Only collection event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- Use **Credit Rating Points** to define this event's affect on the account's credit rating. This should be a negative number. An account's credit rating is equal to the beginning credit rating amount defined on the installation record or the account's CIS Division plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the installation record or the account's CIS Division, the account's credit rating is displayed as an alert on Control Central.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Credit Rating Months** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

Fastpath:

For more information, refer to [Account - Credit Rating](#).

The Send Letter collection event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following **Parameters** for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

Note:

Letter creation is triggered via a customer contact. You must set up a customer contact type for each type of letter you generate. You specify the necessary customer contact type on the collection event. Refer to [Setting Up Letter Templates](#) for more information.

The Cancel Budget collection event type cancel an account's budget plan (if the account is on such a plan). When a budget plan is cancelled, adjustments are issued to synchronize every service agreement's current balance with its payoff balance and each applicable SA's recurring charge amount (i.e., budget amount) is set to zero.

The Generic Algorithm collection event type causes the algorithm defined in the **Collection Event Alg** to be executed. You use this type of algorithm when the standard types of collection events won't do what you need done. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the algorithm that will be called when events of this type of activated.

The Create To Do Entry collection event type causes a To Do entry to be issued. A good example of where this is used is when the collection event requires that the customer be called on the phone. Refer to [The Big Picture of To Do Entries](#) for more information about To Do entries (refer to the To Do type TD-CEVT for the type of To Do entry that's created).

The Start Severance Process type will start a severance process for every service agreement linked to the collection process. No parameters are needed for this type of event.

Enter a **Long Description** to fully describe the collection event type.

Setting Up Collection Process Templates

Collection process templates define the collection events that will be executed when a collection criteria rule is violated. Open **Admin > Credit & Collection > Collection Process Template > Add** to define your collection process templates.

Description of Page

Enter a unique **Collection Process Template** and **Description** for the collection process template.

Select a **Cancel Criteria Algorithm** if your organization allows individual service agreements to be "removed" from a collection process regardless of the debt associated with all service agreements in the debt class. In other words, if your cancel criteria are based on the debt associated with ALL service agreements in a debt class DO NOT SPECIFY THIS ALGORITHM. If this algorithm is specified, it is executed by the collection process monitor when it detects that a credit has been applied to a service agreement linked to an active collection process. This algorithm will indicate if the specific service agreement that has been credited no longer has debt that warrants a collection process. Refer to [How Are Collection Processes Cancelled](#) for more information. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that "removes" a service agreement from a collection processes if the service agreement's debt so warrants.

The **Response** grid contains an entry for every collection event that will be created when a collection process that references this template is created. The following information must be defined for each event:

Event Sequence controls the order in which the collection event types appear under the collection process template. The sequence number is system-assigned and cannot be changed. If you have to insert a collection event type between two existing templates, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Collection Event Type Specify the type of collection event to be generated.

Days After Process Creation Specify the number of days after the creation of the collection process that the related collection event will be triggered. Refer to [Calendar vs Work Days](#) for a description of how this system uses this information to set the trigger date on the respective collection events.

Fastpath:

For more information about collection event types, see [Setting Up Collection Event Types](#). For more information about trigger dates, see [Collection Event Trigger Date](#).

Setting Up Collection Classes

Every account has a collection class. This class is one of several fields that control the collection method applied to the account's debt. Open **Admin > Credit & Collection > Collection Class** to define your collection classes.

Fastpath:

For more information about collection classes, see [Designing Your Collection Classes](#).

Description of Page

Enter a unique **Collection Class** code and **Description** for each collection class.

Indicate which method is used to monitor the member accounts' unpaid debt:

- If you practice [balance-forward accounting](#) for accounts belonging to this collection class, select Collection, Severance & Write-Off. This method of collection is described throughout this chapter.
- If you practice [open-item accounting](#) for accounts belonging to this collection class, select Overdue. This method of collection is described under [Defining Overdue Processing Options](#).
- If accounts belonging to this collection class are not subject to either of the above collection methods, select Not Eligible For Collection. Please be aware that these accounts will NOT be reviewed for overdue debt.

Setting Up Debt Classes

Every SA type has a debt class. This class is one of several fields that control the collection criteria applied to the service agreement's debt. Open **Admin > Credit & Collection > Debt Class > Add** to define your debt classes.

Fastpath:

For more information about debt classes, see [Designing Your Debt Classes](#).

Description of Page

Enter a unique **Debt Class** and **Description** for the debt class.

Turn on **Eligible for Collection** if service agreements belonging to this debt class have their debt monitored by the collection process. This should only be turned off if this debt cannot be collected, e.g., write-off debt.

The grid that follows contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to an arbitrary number as only one algorithm for each system event is allowed in this case.

Warning:

These algorithms are typically significant system processes. The absence of an algorithm may prevent the system from operating correctly.

You can define algorithms for the following **System Events**:

| System Event | Optional / Required | Description |
|---------------------------------|---|--|
| Collection Process Cancellation | Required if debt class is eligible for collection | This algorithm determines if a collection process can be canceled, and if so, it cancels it. Refer to How Are Collection Processes Cancelled for more information. |

| | | |
|----------------------------------|---|---|
| Severance Process Cancellation | Required if debt class is eligible for collection | This algorithm determines if a severance process can be canceled, and if so, it cancels it. Refer to How Are Severance Processes Cancelled for more information. |
| Override Arrears Due to Pay Plan | Required if you use Pay Plans | <p>This algorithm is called to temporarily override a customer's arrears using a pay plan's scheduled payments when the system looks at an account's debt from a credit & collections perspective (i.e., the ADM calls this algorithm before it subjects a customer's debt to the collection criteria and when a pay plan is created). It does not actually change any data, but overlays the current arrears with the pay plan scheduled payments.</p> <p>This algorithm is also called by the above algorithms when a pay plan is created in order to evaluate if the scheduled payments actually cover the arrears (if so, the collection / severance processes are cancelled). It is also called periodically by the ADM in order to establish if the current state of the pay plan still covers the arrears. Refer to How Pay Plans Affect The Account Debt Monitor on page 803.</p> |

Setting Up Collection Class Controls

The topics in this section describe the windows on which you set up your collection class control information.

Warning:

The information in this page is what controls how the system analyzes your customer's debt. The flexibility of this control information provides you with almost unlimited options. This is very powerful, but it requires careful analysis. Refer to [Designing Your Collection Procedures for more information](#).

Collection Class Control - Main Information

The information on this transaction defines the conditions that will be checked by the [Account Debt Monitor](#) when it checks if an account has violated your debt criteria.

Open **Admin > Credit & Collection > Collection Class Control > Add** to define this information.

Fastpath:

For more information about collection class control, refer to [Designing Collection Class Controls](#).

Description of Page

Enter a unique **Collection Class Control** code and **Description** for the collection class control (CCC).

Enter the **CIS Division** to which the CCC's criteria applies.

Enter the **Collection Class** to which the CCC's criteria applies.

Enter the **Debt Class** to which the CCC's criteria applies.

Enter the **Currency Code** in which the CCC's criteria are denominated.

Use **Long Description** to further describe the CCC.

Fastpath:

The information in the following grid is not intuitively obvious. Refer to [Designing Collection Class Controls](#) and [Designing Your Collection Class Control Overrides](#) for more information.

The grid which follows contains the conditions that are checked by the **Account Debt Monitor** (ADM) to determine the type of criteria (defined on the next tab) that will be applied against an account's debt. In other words - the ADM will check each condition (from highest to lowest **Priority**). The first condition that returns a value of true will cause the system to compare the account's debt against the debt criteria defined on the next tab.

Multiple conditions may be defined if different conditions result in a different type of debt thresholds (or a different type of collection process). The following fields are required for each condition:

Collection Condition Priority The priority controls the order in which the ADM checks if a collection condition applies (the lower the number, the higher the priority). Higher priorities are checked before lower priorities.

Note:

The values for this field are customizable using the Lookup table. This field name is COLL_CAT_PRIO_FLG.

Condition Algorithm Define the algorithm used to check if an account should be subject to the collection criteria defined on the next tab. If the algorithm returns a value of true (i.e., the condition is met), the ADM will compare the account's debt against the **Debt Criteria** (defined on the next tab) and start a collection process if the account has debt that violates these criteria.

You must have at least one collection condition; otherwise the system will not have criteria against which to compare the account's debt. This entry should have the lowest priority code and reference the "default" algorithm. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that references the "default" collection condition algorithm type (COLL COND DF).

If you have other conditions that should be checked before the default condition, you must create an entry for each in this grid. Each entry should have a priority consistent with your business requirements (and this priority should be higher than the default condition's priority). In addition, you should reference an algorithm that contains the conditions that will be checked to determine if the account should be subject to the debt criteria (defined on the next tab). The system is supplied with many additional algorithm types. In order to take advantage of them, you will need to create an algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that references one of the collection condition algorithm types.

Where Used

Collection class controls contain the data that controls the Account Debt Monitor. Refer to [How Does The Account Debt Monitor Work?](#) for more information.

Collection Class Control - Debt Criteria

The information on this page defines the debt and age thresholds used by the **Account Debt Monitor** when it checks if an account has violated your acceptable levels of debt. Open **Admin > Credit & Collection > Collection Class Control > Search** and navigate to the **Debt Criteria** page to define this information.

Note:

The information on this page is not intuitively obvious. Refer to [Designing Collection Class Controls](#) and [Designing Your Collection Class Control Overrides](#) for more information.

Description of Page

The **Debt Criteria** scroll contains an entry for each collection criteria algorithm defined on the **Main** tab. The following information appears

The **Collection Condition Priority** controls the order in which the Account Debt Monitor (ADM) checks if a collection condition applies. Higher priorities are checked before lower priorities.

The **Condition Algorithm** is called by the ADM to determine which collection criteria should be applied to the account's debt. If this algorithm returns a value of true (i.e., the condition is met), the ADM will compare the account's debt against the **Debt Criteria** defined below. If the account violates any criteria, a collection process will be started (using the respective **Collection Process Template**).

The grid that follows contains the debt age and amount of debt that must be violated by the account in order for the ADM to create a collection process template. The following fields should be defined:

Arrears Priority controls the order in which the arrears criteria will be checked by the Account Debt Monitor (the lower the number, the higher the priority). The first criteria, if any, that is met will cause a collection process to be created (using the **Collection Process Template**).

Note:

The values for this field are customizable using the Lookup table. This field name is CRIT_PRIO_FLG. Be aware that this field is used for multiple tables: [Collection Class Control](#), [Severance Criteria](#), [Write Off Control](#), and [Workflow Process Profiles](#) .

Collection Process Template If the Account Debt Monitor determines that the account's debt violates the corresponding criteria, it creates a collection process using the specified collection process template.

Arrears Amount When the Account Debt Monitor checks an account's debt, it determines if the account has debt older than "> Number of Days" (the next field) AND the debt exceeds "> Arrears Amount". If so, a collection process is started.

Days When the Account Debt Monitor checks an account's debt, it determines if the account has debt older than **Days** AND the debt exceeds **Arrears Amount**. If so, a collection process is started.

Where Used

Collection class controls contains the data that controls the [Account Debt Monitor](#).

Designing Your Severance Procedures

The following matrix will help you design your severance procedures. When the matrix is complete, you're ready to set up the severance process control tables.

Notice that the matrix has two dimensions: one is dependent on severance criteria algorithms; the other is dependent on the SA type of the service agreement being severed. The number and type of SA types is dependent on how your organization sets up the SA type table (the SA types shown below are characteristic of those used by a simple utility).

| SA Type | Severance Criteria Algorithm: Default | Severance Criteria Algorithm: Customer On Life Support |
|-------------------------|--|---|
| Electric Residential | | |
| Electric Commercial | | |
| Gas Residential | | |
| Gas Commercial | | |
| Charitable Contribution | | |

Once you know the values of each dimension, you fill in each cell with its respective severance events. We've completed the sample matrix with some characteristic events.

| SA Type | Severance Criteria Algorithm: | Severance Criteria Algorithm: |
|----------------------|---|---|
| Electric Residential | <p>Default</p> <p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection, expire the service agreement.</p> | <p>Customer On Life Support</p> <p>Create a To Do entry asking a collection rep to call the customer.</p> <p>5 days later, create a 72-hour warning field activity.</p> <p>2 days after completion, create a To Do entry telling collection rep of impending life support cutoff.</p> <p>3 days after completion of warning, create a disconnect service field activity AND generate a To Do entry informing a collection agent of such.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection expire the service agreement.</p> |
| Electric Commercial | <p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection, expire the service agreement.</p> | <p>N/A</p> |
| Gas Residential | <p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection, expire the service agreement.</p> | <p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection, expire the service agreement.</p> |

| | | |
|-------------------------|--|--------------------------|
| Gas Commercial | <p>Create a 48-hour warning field activity.</p> <p>2 days after completion, create a disconnect service field activity.</p> <p>Immediately after completion of the disconnect field activity, send a letter to the customer.</p> <p>10 days after completion of disconnection, expire the service agreement.</p> | N/A |
| Charitable Contribution | Expire service agreement | Expire service agreement |

Once the matrix is complete, you determine the severance process templates needed to implement your severance procedures. The following table shows the severance process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

| Severance Process Template | Event Number | Severance Event Template | Dependent On Event(s) | Trigger Date Set To X Days After Completion Of Dependent Events |
|---|--------------|---|-----------------------|---|
| Utility severance - default | 10 | Field activity - 48 hour disconnect for non-payment warning | N/A - first event | 0 |
| | 20 | Field activity - disconnect for non-payment | 10 | 2 |
| | 30 | 'Service has been disconnected' letter | 20 | 0 |
| | 40 | Expire service agreement | 20 | 10 |
| Electric life support residential severance | 10 | Generate delinquent life support customer To Do entry | N/A - first event | 0 |
| | 20 | Field activity - 72 hour disconnect for non-payment warning | 10 | 5 |
| | 30 | Generate impending life support cutoff To Do entry to C&C rep | 20 | 2 |
| | 40 | Field activity - cut for non-payment | 20 | 3 |
| | 50 | Service has been disconnected letter | 40 | 0 |

| | | | | |
|-----------------------|----|--------------------------|-------------------|----|
| | 60 | Expire service agreement | 40 | 10 |
| Just expire severance | 10 | Expire service agreement | N/A - first event | |

If we extract each unique severance event type from the above table, we end up with the following:

| Severance Event Template | Event Type |
|--------------------------------------|--|
| 48-hour warning | Generate Field Activity - Disconnect Warning |
| 72-hour warning | Generate Field Activity - Disconnect Warning |
| Disconnect for non payment | Generate Field Activity - Cut For Non-Payment |
| Delinquent life support customer | Create To Do Entry - C&C Rep Role |
| Impending life support cutoff | Create To Do Entry - C&C Rep Role |
| Service has been disconnected letter | Send Letter - Customer Contact Type is Disconnect Letter |
| Expire service agreement | Expire Service Agreement |

Warning:

The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter is off.) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to [Setting Up Field Activity Type Profiles](#) for how to set up the specific disconnect field activity types for your various types of service points.

Now you're (almost) ready to set up your severance procedures.

Defining Severance Process Auto Cancellation Criteria

The topics in the section [How Are Severance Processes Cancelled](#) describe the two algorithms that play a part in the cancellation of a collection process. It also describes when to use what type of algorithm. Please read this section and then set up the appropriate cancellation criteria on your [Debt Classes](#), and optionally, on your [Severance Process Templates](#).

Designing Your Reconnection Procedures

If a customer pays for a service agreement after the service has been cut for non-payment AND BEFORE THE SA HAS BEEN EXPIRED, they need to be reconnected. Counter-intuitively, you must set up a severance process to initiate the field activities to reconnect service.

Note:

Why do you use a severance process to reconnect service? Because a severance process is nothing more than a series of events that take place one after another. Some of the events create field activities, others send

letters, others create To Do entries. So, why not use a severance process? You just have to send different letters and perform different field activities.

Warning:

The system will automatically create a reconnection process if a severance process is cancelled as a result of a payment (or other credits). Please note that this will only happen if you plug-in the appropriate post cancellation algorithm on your severance process templates. Refer to [What Happens When A Severance Process Is Cancelled?](#) for more information.

While you don't define the reconnect procedures for an SA type, we recommend you think about the reconnection steps for each of your SA types that can be disconnected for nonpayment. We've completed the sample matrix with some characteristic events.

| SA Type | Steps |
|----------------------|---|
| Electric Residential | Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer. |
| Electric Commercial | Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer. |
| Gas Residential | Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer. |
| Gas Commercial | Create a reconnect service field activity. Immediately after completion of the reconnect, send a letter to the customer. |

Once the matrix is complete, you determine the severance process templates needed to implement your reconnection procedures. Notice each SA type has the same reconnection steps. This means you just need one severance process. The following table shows this severance process template and its events.

| Severance Process Template | Event Number | Severance Event Template | Dependent On Event(s) | Trigger Date Set To X Days After Completion Of Dependent Events |
|----------------------------|--------------|-------------------------------------|-----------------------|---|
| Reconnect | 10 | Field activity - reconnect service | N/A - first event | 0 |
| | 20 | Service has been reconnected letter | 10 | 0 |

If we extract each unique severance event type from the above table, we end up with the following:

| Severance Event Template | Event Type |
|--------------------------|-------------------------------------|
| Reconnect | Generate Field Activity - Reconnect |

Service has been reconnected letter

Send Letter

**Warning:**

The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter is off.) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to [Setting Up Field Activity Type Profiles](#) for how to set up the specific disconnect field activity types for your various types of service points.

**Important:**

If you want the system to automatically create a reconnection process if a customer pays after they have been cut, you must specify the appropriate post cancellation algorithm on your severance process templates.

And now you're ready to set up your severance (and reconnection) procedures.

Setting Up Severance Procedures

In the previous section, [Designing Your Severance Procedures](#), we presented a case study that illustrated a mythical organization's severance procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

Setting Up Severance Event Types

Severance event types control what is done by a given severance event. Open **Admin > Credit & Collection > Severance Event Type > Add** to define your severance event types.

**Fastpath:**

For more information refer to [Designing Your Severance Procedures](#).

Description of Page

Enter a unique **Severance Event Type** code and **Description** for the severance event type.

Enter the Severance **Event Type**. Permissible values are: Affect Credit Rating/Cash-Only, Send Letter, Generic Algorithm, Create To Do Entry, Create Field Activities, Expire Service Agreement. The following discussion describes the parameters that must be defined for each type of severance event.

The Affect Credit Rating/Cash-Only collection event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- account debt monitor.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Cash-Only Points** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.

The Send Letter severance event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following **Parameters** for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

The Generic Algorithm severance event type causes the algorithm defined in the **Sev. Event Algorithm** to be executed. You use this type of algorithm when the standard types of severance events won't do what you need done.

The Create To Do Entry severance event type causes a To Do entry to be created. Refer to [The Big Picture of To Do Entries](#) for more information about To Do entries (refer to the To Do type TD-SEVT for the type of To Do entry that's created).

The Generate Field Activities severance event type causes one or more field activities to be generated. Enter the following **Parameters** for this type of event:

- Select the **Customer Event** associated with the field activity. Valid values are: Cut For Non-Payment (CNP), Disconnect Warning (Disc Warn), Reconnect for Payment (Reconn), Start Service (Start) , Start/Stop Service (Start/Stop), Stop Service (Stop), Reread (Reread).
- The system uses the **Customer Event** to select the appropriate field activity type(s) from the field activity type profile associated with the service points linked to the service agreement.

Warning:

The field activity types are NOT specified directly on the severance event type. Why? Because each service point linked to the service agreement being severed could necessitate a different type of field activity. Therefore, the system uses the type of service point, its state (e.g., connected, meter off) and the desired customer event (e.g., Disconnect Warning, Cut For Non-Payment) to determine which field activity type(s) to generate. Refer to [Setting Up Field Activity Type Profiles](#) for how to set up the specific disconnect field activity types for your various types of service points.

The Expire Service Agreement severance event type causes the service agreement to be moved to the pending stop state (it also populates the service agreement's stop date). Refer to [Finalizing Pending Stops](#) for how the system will eventually stop the service agreement (and then final bill it). There are no parameters for this type of event.

Note:

Cut for non-payment field activities are special. The Expire Service Agreement severance event type also makes any "cut for non-payment" field activities created by earlier severance events available to stop service. Specifically, it changes the linkage type of the field activities from Severance Activity to Stop Activity. You can see a service agreement's service points' field activities and their respective linkage type on [Service Agreement - Service Point](#).

Enter a **Long Description** to fully describe the severance event type.

Setting Up Severance Process Templates

Severance process templates define the severance events that will be executed when a service agreement is severed. Open **Admin > Credit & Collection > Severance Process Template > Add** to define your severance process templates.

Description of Page

Enter a unique **Severance Process Template** and **Description** for the severance process template.

If severance processes of this type should be automatically canceled when the customer pays the collection amount on the severance, turn on **Auto Cancel**. This switch would typically only be turned off for severance processes used to reconnect a cut service because you don't want such a reconnection process to be canceled when a payment is made. Refer to [Designing Your Reconnection Procedures](#) for more information.

In addition to turning on the **Auto Cancel** switch, specify a **Cancel Criteria Algorithm** if your organization allows a severance process to be cancelled regardless of the debt associated with all service agreements in the debt class. In other words, if your cancel criteria are based on the debt associated with ALL service agreements in a debt class DO NOT SPECIFY THIS ALGORITHM.

If the **Cancel Criteria Algorithm** is specified, it is executed when a credit is posted to the service agreement associated with a severance process. This algorithm will indicate if the service agreement no longer has debt that warrants a severance process. Refer to [How Are Severance Processes Cancelled](#) for more information. If you haven't

done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that cancels a severance process if the service agreement's debt so warrants.

If you wish to perform any special processes after a severance process is canceled, specify a **Post Cancel Algorithm**. This can be used to start a reconnection in case the severance process was canceled too late to stop the disconnection. If you haven't done so already, you must set up this algorithm in the system. To do this, create a new algorithm (refer to [Setting Up Algorithms](#)). On this algorithm, reference an Algorithm Type that cancels a severance process if the service agreement's debt so warrants.

When a service agreement is to be severed due to non-payment, the system creates a severance process and links to it one or more severance events based on the **Event Types** entered here. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event:

Event Sequence controls the order in which the severance event types appear under the severance process template. The sequence number is system-assigned and cannot be changed. If you have to insert a severance event type between two existing templates, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Severance Event Type Specify the type of severance event to be generated.

Dependent On Other Events Turn this indicator on if the trigger date of the event can only be determined after earlier events are complete. For example, you would turn this switch on for the event that initiates the field activity to disconnect service. Why? Because you only want to disconnect service after the preceding event that warned the client of impending disconnection is complete.

Days After Prev Response Specify the number of days after the completion / cancellation of the dependent events on which the severance event will be triggered. If this event is not dependent on the completion of other events, this field contains the number of days after the creation of the severance process that the related severance event will be triggered. Refer to [Severance Event Dependencies and Trigger Date](#) and [Calendar vs Work Days](#) for a description of how the system uses this information to set the trigger date on the respective severance events.

When the **Dependent On Other Events** switch is on, use the grid to define the events on which this event is dependent. If multiple events are specified in the grid, all such events must be completed or cancelled before the event will be triggered.

Sequence is system-assigned and cannot be specified or changed.

Dependent On Sequence Specify the sequence number of the severance event on which the above severance event depends.

Fastpath:

For more information about severance event types, see [Setting Up Severance Event Types](#). For more information about trigger dates, see [Severance Event Dependencies & Trigger Date](#).

Designing Your Write-Off Procedures

The design of your write-off procedures is relatively straightforward. Simply follow the instructions in the following topics.

Designing Your Write-Off Debt Classes

Multiple write-off debt classes are needed when you have different write-off procedures for different types of service agreements. If all service agreement debt is written-off the same way, then you'll have just one write-off debt class (call it Generic). However, if you're like many organizations, you will have multiple write-off debt classes. The following points will help you understand why:

- If you bill for 3rd parties, you probably have different write-off debt classes for the 3rd party service agreements. Why? Because you probably treat 3rd party uncollectable debt differently from your own debt.

- You will need a separate write-off debt class for service agreements whose debt cannot be written off. Why? Because there is a switch on the write-off debt class control table that controls if service agreements in the write-off debt class are eligible for write-off processing. Given that you will have some service agreements that hold debt that aren't eligible for write-off processing (e.g., service agreements that hold written-off debt and service agreements that overpayments), you will need at least one other write-off debt class.
- If you use the system to calculate charges for your organization's company usage, you'll need another write-off debt class (we refer to it as the "N/A" write-off debt class below). Why? Because all service agreements must have a write-off debt class, even those that will never have debt.

| SA's Write-Off Debt Class | Account's Collection Class | Account's Collection Class |
|---------------------------|----------------------------|----------------------------|
| Normal W/O | | |
| N/A | | |

Designing Write-Off Controls

Set up a matrix using the collection classes you designed when you were designing your collection procedures ([Designing Your Collection Procedures](#)).

| SA's Write-Off Debt Class | Account's Collection Class | Account's Collection Class |
|---------------------------|----------------------------|----------------------------|
| | Residential | Commercial/Industrial |
| Normal Write Off | | |
| N/A | | |

Each cell should have a "write-off control" that defines what to do when the system detects finalized debt that hasn't been paid. This is true even of the "N/A" write-off debt class. Why? Because you may want the system to write-down these stopped SAs when they have a small balance. For example, if you have a write-off service agreement that subsequently receives a partial payment that leaves a small amount owing, you probably want the system to generate a write-down adjustment (so that the write-off service agreement will close). We'll initially fill in the matrix for the "N/A" write-off debt class.

| SA's Write-Off Debt Class | Account's Collection Class | Account's Collection Class |
|---------------------------|---|---|
| | Residential | Commercial/Industrial |
| Normal Write Off | | |
| N/A | Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment. | Attempt to reduce the SA's balance to zero using the following methods: Synchronize current balance with payoff balance. If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment. |

Note:

If the Write Off Monitor encounters debt associated with a non-defined collection class and write-off debt class, it will issue an error.

For each cell that isn't designated as N/A, you need to answer the following questions:

- Are you allowed to transfer debt to other non-closed service agreements linked to the account? If so, you need to define the algorithm used to do such. Refer to [Setting Up Write-off Control](#) for more information about this algorithm.
- Are you allowed to write-down small amounts of debt (or small credits)? If so, you need to define the algorithm used to do such. Refer to [Setting Up Write-off Control](#) for more information about this algorithm.
- Should you refund credit balances with a check? If so, you need to define the algorithm to do such. Refer to [Setting Up Write-off Control](#) for more information about this algorithm.
- If debt remains after doing the above, how do you write it off (e.g., do you first refer the debt to a collection agency and only write it off after waiting 30 days)?

We'll fill in the above matrix with our assumptions:

| SA's Write-Off Debt Class | Account's Collection Class | Account's Collection Class |
|---------------------------|---|--|
| | Residential | Commercial/Industrial |
| Normal Write-Off | <p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Attempt to transfer debt to another active service agreement linked to the account.</p> <p>If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.</p> <p>If the debt is <= \$-1, create an A/P adjustment to refund the credit to the customer.</p> <p>If debt remains:</p> <p>Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process.</p> <p>Otherwise, create the default write-off process for residential debt.</p> | <p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Attempt to transfer debt to another active service agreement linked to the account.</p> <p>If the debt / credit is < \$10 and > \$-10, write down the debt using a write-down adjustment.</p> <p>If the debt / credit is <= \$-10, create an A/P adjustment to refund the credit to the customer.</p> <p>If debt remains:</p> <p>Highest priority: If customer has a non-cash deposit, create the non-cash deposit write-off process.</p> <p>Otherwise, create the default write-off process for commercial debt.</p> |
| N/A | <p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Synchronize current balance with payoff balance.</p> <p>If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.</p> <p>Because this debt class isn't eligible for further write-off processing, criteria used to process debt are not necessary.</p> | <p>Attempt to reduce the SA's balance to zero using the following methods:</p> <p>Synchronize current balance with payoff balance.</p> <p>If the debt is < \$10 and > \$-1, write down the debt using a write-down adjustment.</p> <p>Because this debt class isn't eligible for further write-off processing, criteria used to process debt are not necessary.</p> |

We can now use the information in the above matrix to design the necessary Write Off Process Templates and Write Off Event Types.

Designing Write Off Process Templates & Write Off Event Types

The following table shows the write-off process templates referenced in the previous section's matrix. Adjacent to each process are its events and an indication of when they are triggered.

| Write Off Process Template | Write Off Event Type | Triggered X Days From Start Of Write Off Process |
|----------------------------|--|--|
| Residential | Refer to collection agency | 0 |
| | Letter notifying customer of referral | 0 |
| | Cancel collection agency referral | 60 |
| | Write off | 60 |
| Non-Cash Deposit Exists | To Do for non-cash deposit redemption | 0 |
| | To Do to highlight unpaid SA(s) still exist (and they will be reconsidered for write-off processing) | 10 |
| Commercial | Refer to collection agency | 0 |
| | Letter notifying customer of referral | 0 |
| | To Do to check up on collection agency's efforts | 30 |
| | Cancel collection agency referral | 60 |
| | Write off | 60 |

If we extract each unique event type from the above table, we end up with the following:

| Write Off Event Type | Event Type |
|--|---|
| Notification of write-off referral | Send letter - Debt referred to a collection agency |
| Refer to collection agency | Refer to collection agency |
| Cancel collection agency referral | Cancel collection agency referral |
| Write off | Write off |
| To Do for non-cash deposit redemption | Generate To Do - Redeem non-cash deposit |
| To Do to highlight unpaid SA(s) still exist | Generate To Do - SA(s) linked to a non-cash deposit remain unpaid (and will be reconsidered for write-off processing) |
| To Do to check up on collection agency's efforts | Generate To Do - Check up on collection agency's efforts |

And now you're ready to set up your write-off procedures.

Setting Up Write-Off Procedures

In the previous section, [Designing Your Write-Off Procedures](#), we presented a case study that illustrated a mythical organization's write off procedures. In this section, we'll explain how to set up the control tables to implement these procedures:

Setting Up Write Off Debt Classes

Every SA type has a write-off debt class. This class is one of several fields that control the write off criteria applied to the service agreement's debt. Select **Admin > Credit & Collection > Write Off Debt Class** to define your debt classes.

Fastpath:

For more information about debt classes, see [Designing Your Write-Off Debt Classes](#).

Panel controls

To modify a write-off debt class, simply move to a field and change its value. To add a new write-off debt class, click + to insert a row, then fill in the information for each field. The following fields display:

Write Off Debt Class Code The unique identifier of the write off debt class.

Eligible for Write Off Indicates if service agreements belonging to this write off debt class are eligible for write-off processing. This should only be turned off if this debt cannot be written off, e.g., write off debt.

Description The description of the write off debt class.

Setting Up Write Off Event Types

Write-off event types control what is done by a given write-off event. Select **Admin > Credit & Collection > Write Off Event Type > Add** to define your write-off event types.

Description of Page

Enter a unique **Write Off Event Type** code and **Description** for the write-off event type.

Select the **Write Off Event Type**. Permissible values are: Affect Credit Rating/Cash-Only, Cancel Agency Referral, Generic Algorithm, Refer to Agency, Send Letter, Create To Do Entry, Write Off using Distrib Code, and Write Off using SA Type. The following discussion describes the parameters that must be defined for each type of write-off event.

The Affect Credit Rating/Cash-Only write-off event type causes a credit rating demerit record to be linked to the account. This record is constructed using the following **Parameters**:

- Use **Affect Credit Rating By** to define this event's affect on the account's credit rating. This should be a negative number. An account's credit rating is equal to the beginning credit rating amount defined on the installation record or the account's CIS Division plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the installation record or the account's CIS Division, the account's credit rating is displayed as an alert on Control Central.
- Use **Affect Cash-Only Score By** to define this event's affect on the account's cash-only score. This should be a positive number. When an account's cash-only score exceeds the cash-only threshold score defined on the installation record or the account's CIS Division, the account is flagged as cash-only during payment processing and on Control Central.
- Use **Months Affecting Credit Rating** to define the length of time the demerit remains in effect. This information is used to define the effective period of the credit rating demerit record.

Fastpath:

For more information, refer to [Account - Credit Rating](#).

The Cancel Agency Referral event type will cancel previous collection agency referrals. No parameters are needed for this type of event.

The Generic Algorithm write-off event type causes the algorithm defined in the **Generic Algorithm** to be executed. You use this type of algorithm when the standard types of write off events won't do what you need done. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the algorithm that will be called when events of this type are activated.

The Refer to Agency event type will refer the debt associated with the process' SAs to a collection agency. You must supply the **Agency Selection Algorithm** that is used to determine the collection agency associated with the referral. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines the collection agency to which bad debt should be referred.

Note:

Letters. You must set up a customer contact type for each type of letter you generate. You specify the necessary customer contact type on the write off event type. Refer to [Setting Up Letter Templates](#) for more information.

The Send Letter write-off event type causes a customer contact to be generated that, in turn, generates a letter. Enter the following parameters for this type of event:

- Select the **Contact Class** used to categorize the customer contact.
- Use **Contact Type** to define the type of customer contact to create. The type of customer contact controls the type of letter that is generated.

The Create To Do Entry write-off event type causes a To Do entry to be issued. Refer to [The Big Picture of To Do Entries](#) for more information about To Do entries (refer to the To Do type TD-WOEV for the type of To Do entry that's created).

The Write Off using Distrib Code event type causes bad debt to be written off in accordance with the distribution codes associated with the financial transactions that caused the debt in the first place. Use this method if, for example, you want to write-off revenue differently than you write-off liabilities. When this type of event is activated, the system accumulates the distribution codes from GL details associated with recent financial transactions linked to each write-off service agreement. When the system has accumulated enough distribution codes (i.e., where the amount associated with the distribution code equals or exceeds the amount to write off), the debt will be transferred to a new or existing write-off service agreements. The type of service agreements to which the debt is transferred is defined on the distribution codes. Refer to [Setting Up Distribution Codes](#) for more information.

The Write Off using SA Type event type causes all debt associated with the process' SAs to be transferred to a write-off service agreement linked to the account. Enter the following **Parameters** for this type of event:

- **CIS Division / SA Type** is the type of write-off service agreement to which the debt will be transferred. Note well,
 - The system will reuse an existing service agreement if an active SA of this type is already linked to the account; otherwise the system will create a new service agreement of this type.
 - The adjustment type used to set the offending service agreement's current balance equal to its payoff balance is defined on the write-offable SA Type. Refer to [SA Type - Main Information](#) for more information.
 - The adjustment type used to transfer the delinquent debt to the write-off service agreement is defined on the write off SA type. Refer to [SA Type - Detail](#) for more information.

Enter a **Comment** to fully describe the write-off event type.

Setting Up Write Off Process Templates

Write-off process templates define the write-off events that will be executed when a write-off criteria rule is violated. Select **Admin > Credit & Collection > Write Off Process Template > Add** to define your write-off process templates.

Description of Page

Enter a unique **Write Off Process Template** code and **Description** for the write-off process template.

The rows in the following grid define the events that will be created when a write off process is created using this template. The following fields display:

Event Sequence Controls the order in which the write-off event is executed. The sequence number is system assigned and cannot be changed. If you need to insert a write-off event between two existing events, you must remove the latter events, insert the new event, and then re-enter the removed events.

Write-off Event Type Code Specify the type of write-off event to be generated. The event type's description is displayed adjacent.

Days After Process Creation Specify the number of days after the creation of the write-off process that the related write-off event will be triggered. Refer to [Calendar vs Work Days](#) for a description of how this system uses this information to set the trigger date on the respective write-off events.

Fastpath:

For more information about write-off event types, see [Setting Up Write Off Event Types](#). For more information about trigger dates, see [Write-off Event Trigger Date](#).

Setting Up Write Off Control

Write-off controls define how the system handles finalized, unpaid debt belonging to a given collection class and write off debt class.

Write Off Control - Main

Select **Admin > Credit & Collection > Write Off Control > Add** to define basic information about a write-off control. After entering basic information, navigate to the **Criteria** tab to define the type of write-off process to start when given criteria are met.

Fastpath:

For more information about write-off control, refer to [Designing Write-Off Controls](#).

Panel controls

Enter a **Write Off Control** code and **Description** for the write-off control (WOC).

Enter the **Collection Class** to which the WOC applies.

Enter the **Write Off Debt Class Code** to which the WOC applies.

Enter general **Comments** to further describe the WOC.

Define the **Synch All Algorithm** used by the system to generate adjustments that cause current balance to equal payoff balance on the service agreements to be written off. This type of algorithm is issued before you actually start a write-off process as current balance is meaningless at write-off time (the customer owes you the payoff balance). If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that synchronizes current and payoff balances.

Define the **Debt Transfer Algorithm** used by the system when it attempts to transfer the unpaid debt to another active service agreement linked to the stopped SA's account. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that transfers unpaid balances.

Define the **Write Down Algorithm** used by the system when it attempts to write-down small debt and/or credit balances. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that writes down small amounts.

Define the **Credit Refund Algorithm** used by the system when it refunds a credit balance to a customer. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that refunds credit balances.

Write Off Control - Criteria

Select **Admin > Credit & Collection > Write Off Control > Search** and navigate to the **Criteria** page to define the type of write-off process to start when given criteria are met.

Fastpath:

The following information is not intuitively obvious. Refer to [Designing Write-Off Controls](#) for more information.

Panel controls

The information in the grid defines the write-off process to be executed for debt belonging to the previously defined collection class and write off debt class. The type of write-off process may differ depending on some condition. For example, you may have a different write-off process if the customer has a non-cash deposit. You must have at least one entry in this collection otherwise the system will not start a write-off process. This entry should have the lowest priority code and should reference a **Write Off Criteria Algorithm** that references the WO CRIT DFLT the algorithm type.

The following fields display:

Priority controls the order in which the criteria will be checked by the Write Off Monitor (higher priorities are checked before lower priorities). The first criteria algorithm that is met (i.e., returns a value of *True*) will cause the associated write-off process to be initiated.

Note:

The values for this field are customizable using the Lookup table. This field name is CRIT_PRIO_FLG. Be aware that this field is used for multiple tables: [Collection Class Control](#), [Severance Criteria](#), [Write Off Control](#), and [Workflow Process Profiles](#).

Write Off Criteria Algorithm The Write Off Monitor checks if the condition defined by the W/O Condition Algorithm applies to the account whose debt is being analyzed. If a condition is met, a write-off process is created using the associated write-off process template.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines if a customer's bad debt should be processed using the associated **Write Off Process Template**.

Important:

You must have at least one entry in this grid otherwise the system will not start a write-off process. This entry should have the lowest priority code and should reference a **W/O Criteria Algorithm** that references the WO CRIT DFLT algorithm type.

Write Off Process Template If the Write Off Monitor determines the condition defined by the w/o condition algorithm applies, a write-off process is created using the associated write-off process template.

Where Used

Write-off controls contain the data that controls the Write Off Monitor. Refer to [How Does The Write-Off Monitor Work?](#) for more information.

Setting Up Collection Agencies

You must set up a collection agency for each such organization to which you refer delinquent debt. To define a collection agency, select **Admin > Credit & Collection > Collection Agency**.

Description of Page

Enter an easily recognizable **Collection Agency** code and **Description** for each collection agency.

A collection agency must be associated with a Person. Choose the **Person ID** of the organization from the prompt.

Fastpath:

Information about how to set up persons is discussed in [Maintaining Persons](#).

Turn on the **Active** switch if the collection agency is actively receiving referrals.

Specify the **Batch Control** that's used to route new and cancelled referrals to the collection agency. The batch control's description is displayed adjacent.

Where Used

Collection agencies get assigned to collection agency referrals when the collection agency referral background process executes. Refer to [How Do Collection Agency Referrals Work?](#) for more information.

Setting Up Feature Configuration

You must set up a [Feature Configuration](#) if you use the [champion / challenger](#) functionality.

The following describes the various **Option Types** that must be defined:

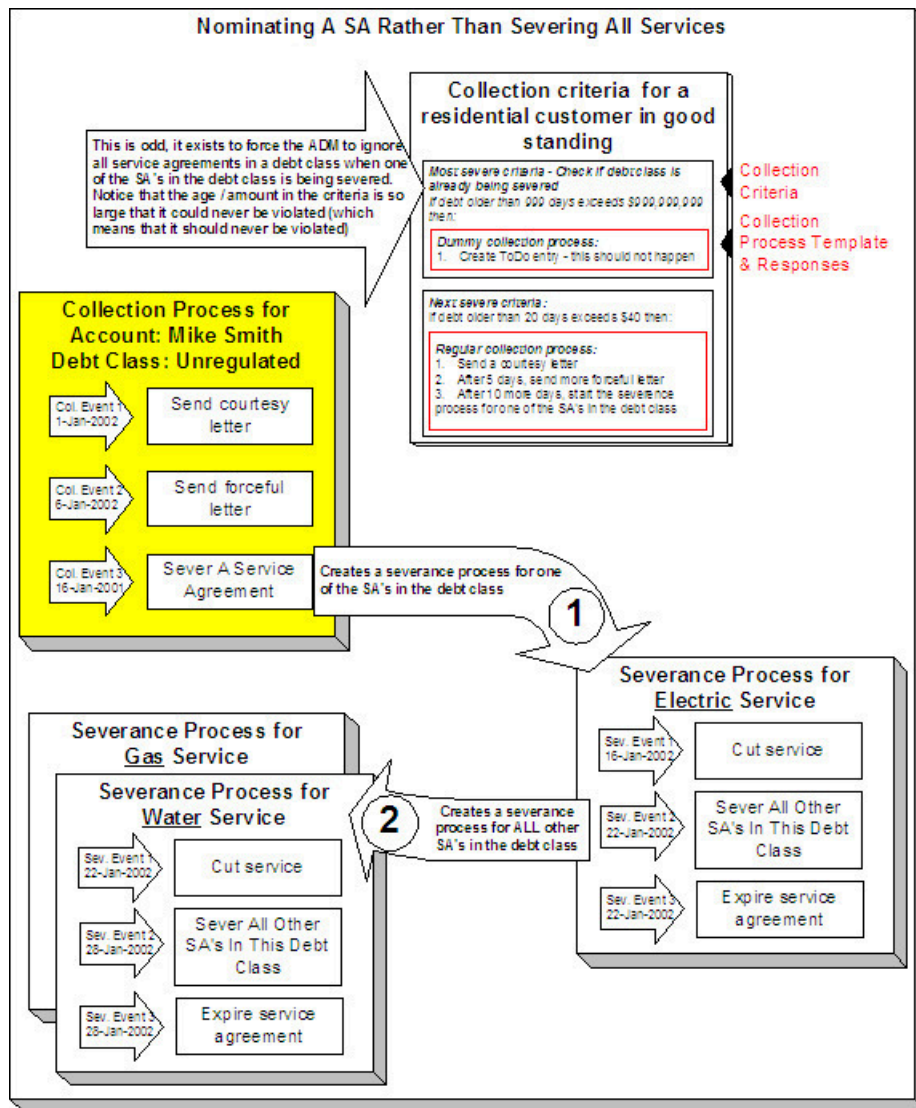

Champion Template\$Challenger Template\$Percentage(1-100). You need only set up options of this type if your implementation implements [Champion / Challenger](#) functionality. Options of this type are entered in the format A \$B\$nnn where A is the collection process template of the champion template, B is the collection process template of the challenger template, and C is the percent of the time that the system should create the challenger template. The collection monitor uses this option to override the champion collection process template X% of the time with the challenger template. You may enter any number of these options (but only one per Champion Template).

How To

The contents of this section describe how to set up various credit and collections scenarios.

How To Nominate A Single Service To Sever (Rather Than Sever Everything That's In Arrears)

Some organizations that offer multiple services do not sever all services when the customer falls into arrears. Rather, they nominate a single service agreement to sever in the hopes that the lack of service will cause the customer to remit payment. The following diagram illustrates the control tables values required to implement this type of requirement.

The following important concepts are illustrated above:

- The collection process's last event does NOT sever all services. Rather, it calls an algorithm that selects a single service to sever. A base package algorithm allows you to define the primary service to sever and a secondary service to sever (if the customer does not have the primary service). If you sold electricity and gas, you would probably define the primary service as electricity and the secondary as gas (because electricity is easier to cutoff than gas).
- The severance process that is started for the primary service cuts service. If the customer doesn't remit what is owed, the second severance event calls an algorithm that severs all other service agreements in the debt class.
- Because you are nominating a single service to sever, you must set up a special value in collection class control to force the ADM to ignore all service agreements in a debt class when one of the SAs in the debt class is being severed. Notice that the age / amount in the criteria is so large that it could never be violated.
- In addition, because the entire debt class must no longer be in arrears to stop the collection and severance processes, you must plug-in the appropriate collection process and severance process cancellation criteria on the debt class. Refer to [How Are Collection Processes Cancelled](#) and [How Are Severance Processes Cancelled](#) for more information about how these algorithms are used. Also note, you do not need service agreement cancellation criteria defined on your collection process templates and severance process templates (because cancellation is controlled at the debt class level).

Defining Meter & Item Options

Located at a premise's service points are the various meters, items and equipment that regulate and measure consumption. Before you can define meters, items and equipment you must set up the control tables defined in this section.

Fastpath:

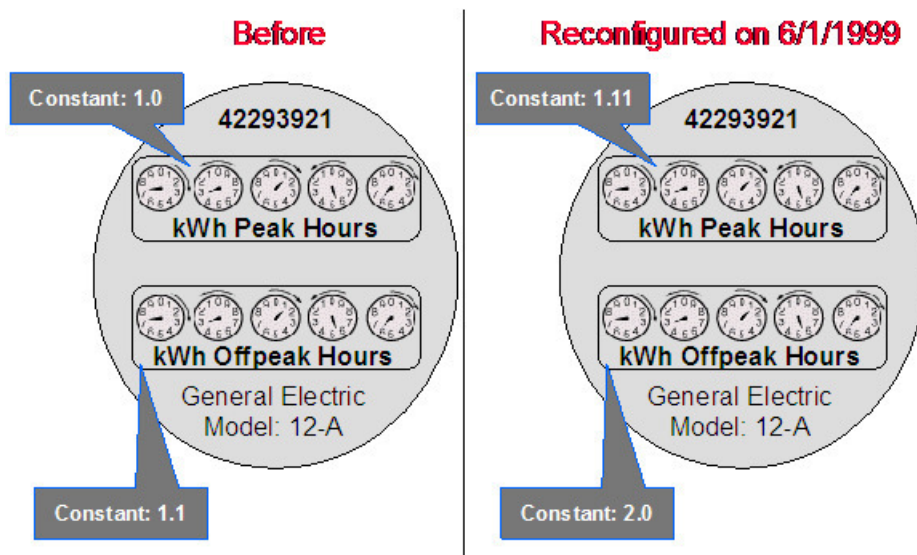

Refer to [An Illustration Of A Premise](#) for an illustration of how meters, items and equipment are related to the service points.

The Big Picture of Meters, Items and Equipment

The topics in this section provide background information about meters, items and equipment.

The Structure Of A Meter

A customer's consumption is measured using a meter. What a meter measures and how it measures it can change over time. The following example illustrates a simple meter before and after a reconfiguration.

The system maintains how a meter looks over time so that it can reproduce bills using historical consumption. Information about this meter is recorded in the following tables:

- Every meter has a single **meter** record that contains information about the meter that doesn't change over time. For example, its meter number and manufacturer.
- A **meter configuration** record is required whenever something changes about what the meter measures. The meter shown above has two configurations - the original and the one effective on 1-June-1999.
- Every meter configuration contains one or more **registers**. Each register references the unit being measured and how the measured quantity is manipulated before it is billed.

Fastpath:

Information about how to set up meters is discussed in [Maintaining Meters](#).

Items Are Used For Other Devices Associated With A Customer's Service

In addition to meters, there are many other devices that can be involved with a customer's service. We refer to these other devices as "items".

We purposefully use the ambiguous term *item* because items are used for many different devices including lamps, poles, current transformers, backflow devices, pulse initiators, etc. Refer to the diagram in [An Illustration Of A Premise](#) for an example of the various items that could be associated with a customer's service.

The topics in this section provide more information about items.

Equipment versus Badged Items

This is a rather confusing subject, but there are two notional types of items:

- **Equipment.** An item that is considered to be "equipment" is a physical device that regulates consumption; it does NOT measure consumption. You would only define equipment if it is of interest to your organization. For example, if your organization periodically tests the pulse initiators associated with your meters, you will need to set up items for each pulse initiator and link them to their respective meters. Equipment can be linked to either a service point (e.g., a current transformer, a backflow device), a meter (e.g., a pulse initiator), or an item (e.g., the components of an installation).
- **Non Equipment.** An item that is not considered to be "equipment" is a physical device that does NOT measure consumption, but impacts billing in some way (i.e., there are charges in your rates based on the number and type of items installed at a service point). Examples include street lights, light poles, and security cameras. These types of items are related to service points. Refer to [Chargeable Items Must Be Associated With Service Points](#) for information about the two types of items that may be linked to service points.

The topics that appear below provide more information about both types of items.

Meters May Have Equipment

If you have physical devices that are intrinsically associated with meters (but aren't meters), you can set up an item for each such device. For example, if you have pulse initiators linked to your meters, you would set up an item for each pulse initiator. After creating these items, you would update each meter's collection of equipment to include the respective pulse initiator.

Items May Have Equipment

If you have physical devices that are intrinsically associated with other non-metered devices, you can set up an item for each such device. For example, you could set up an item for an "installation" (an installation is a group of devices that work together to regulate electric consumption) and link to it the individual items that do the work. To do this, you would set up items for each individual piece of equipment in the installation. After creating these items, you would update the collection of equipment associated with the installation's item to include each piece of equipment.

Service Points May Have Equipment

If you have physical devices that don't have line item charges but are intrinsically associated with a service point, you can set up an item for each such device. For example, if you have voltage regulators linked to your service points, you would set up an item for each voltage regulator. After creating these items, you would update each service point's collection of equipment to include the respective voltage regulator.

Chargeable Items Must Be Associated With Service Points

If there are charges in your rates based on the number and type of items installed at a service point, you can use either of the following techniques:

- If the item is badged (i.e., uniquely identified), you would set up an item and link it to an **item - based** service point. An item-based service point may have zero or one item installed at any instant in time. Over time, an item-

based service point may have many badged items installed and removed. Refer to [Installing / Removing An Item](#) for more information.

- If the item does not have a unique identifier, you do NOT have to set up phony items for it. Rather, you can use the system's multi-item functionality and simply define the number of each TYPE of item that is installed at a service point. Refer to [Service Points With Multiple Items](#) for an illustration of such a service point.

Start/Stop and Items

When a customer start or stops service at an **item - based** service point, it takes into account whether an item is currently installed at the SP and whether the item is on or off. Start/Stop does not concern itself with equipment.

Billing and Items

It's important to note that billing ignores equipment relationships when it constructs the snapshot of number and types of items associated with a service agreement's service points. In other words, billing constructs the item snapshot as follows:

- It inserts an entry into the item snapshot for every item type referenced in the service agreement's service points' multi-item collection.
- It inserts an entry into the item snapshot for every badged item linked to service points with an SP type of Item.

Fastpath:

Refer to [Item Snapshot](#) for more information.

Note:

Equipment and billing. Be aware that the only way equipment can impact billing would be if you develop a pre-processing calculation group that analyzed the equipment associated with a service point (directly or indirectly via the meters and items) and manipulated billed consumption accordingly. Refer to [All Calculation Rule-Based Rates Share a Common Structure](#) for more information about pre-processing calculation groups.

Generic Equipment

Some companies do not badge their equipment, but they still need to keep track of the type of equipment that is linked to service points, meters and badged-items. For example,

- You may want to keep track of the type of modem linked to a meter, but you don't care about the individual modem or pulse-initiator
- You may want to keep track of the type of backflow device linked to a water meter

Note:

Why is generic equipment recorded in the system? Generic equipment gets linked to SP's / meters / items when the type of equipment linked to an SP / meter / item affects bill calculations. For example, some water companies charge extra if a backflow device is present at a service point.

If you encounter the need for generic equipment, do the following:

- Create an Item Type for each type of unbadged equipment. On this item type, indicate that items of this type may be linked to multiple SP's / meters / items. Note: we recommend suffixing the description of the item type with the word "generic".
- Update the relevant meter type(s) / SP type(s) / item type(s) to indicate that they may use equipment associated with the generic item type.
- Create one (1) item for each type of unbadged equipment. Note: we recommend suffixing the description of the item type with the word "generic".
- Link the generic item to the relevant SP's / meters / items.

Setting Up Meter Options

This section describes tables that must be set up before you can define meters.

Setting Up Meter Configuration Types

Every meter configuration must reference a meter configuration type. The meter configuration type indicates the valid (required or optional) unit of measure and time of use registers for the configuration.

Navigate to **Admin > Meter Configuration Type > Add** to set up valid meter configuration types.

Description of Page

Enter an easily recognizable **Meter Configuration Type** and **Description** for the meter configuration type.

Choose the **Service Type** associated with the meter configuration type. Refer to [Setting Up Service Types](#) for more information.

Use **Prepaid Meter** to indicate whether or not the meter configuration is used to record prepaid usage.

If you have set up a **TOU Group** to indicate your collection of time of use codes for the meter configuration, enter it here. Use the **Default TOU Registers** button to have the system build the collection of registers for you based on the TOU codes linked to the TOU group. Refer to [Setting Up TOU Groups](#) for more information.

In the grid, specify the attributes of the collection of valid registers. If the register is **Interval**, put a check in the checkbox. For any register, indicate the valid **UOM**. For interval registers, indicate the **Interval Register Type**. If a **TOU** is applicable for the register, enter the TOU code. Finally, specify a **Validation** for each register. The register pair can be Optional or Required.

Note:

In certain markets, registers with the same **UOM** and **TOU** combination or, for **Interval** meters, the same **UOM** and **Interval Register Type** combination may need to be defined under a single meter configuration. If your implementation is in one of these markets, add the Allow Duplicate UOM/TOU Combination **Option Type** on the Meter Management Options [Feature Configuration](#) and set its value to Y.

Attributes related to interval registers may not appear. These attributes are suppressed if Meter Data Management module is [turned off](#).

Setting Up Meter Types

Every meter references a meter type. The meter type defines the type of service and common characteristics shared by its meters. The meter type also controls the characteristics that may be specified on meters of a given type.

Note:

When a new meter type is added. After adding a new meter type, you must define the SP types at which meters of this type can be installed.

The topics in this section describe how to maintain your meter types.

Meter Type - Main

To define a meter type, open **Admin > Meter Type > Add**.

Description of Page

Enter an easily recognizable **Meter Type** and **Description** for the meter type.

Choose the **Service Type** associated with all meters of this type. Refer to [Setting Up Service Types](#) for more information.

Turn on **Allow Duplicate Meter Badges** if more than one meter of this type may have the same badge number.

Turn on **Prepaid-Capable** if meters of this type are used to record prepaid usage.

Turn on **Allow Interval Registers** if meters of this type may contain interval registers. Refer to [The Big Picture of Raw Data Collection and Aggregation](#) for more information.

Indicate in **Track Location** whether you Track or Do Not Track the location of meters of this type. Refer to [The Big Picture of Asset Inventory](#) for more information.

Use the **Characteristic Values** collection to define **Characteristic Types** and their respective **Characteristic Values** and **Adhoc Values** to describe characteristics common to all meters of this type. This grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the Meter Type Characteristics table.

Note:

You can only choose characteristic types defined as permissible on the meter type record.

Meter Type - Meter Characteristics

To define characteristics that can be defined for meters of a given type, open **Admin > Meter Type > Search** and then navigate to the **Meter Characteristic** page.

Description of Page

Use the **Meter Characteristics** collection to define characteristics that can be defined for meters of a given type. Turn on the **Required** switch if the **Characteristic Type** must be defined on meters of a given type. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on. Use **Sequence** to control the order in which characteristics are defaulted.

Meter Type - Equipment Types

Open **Admin > Device > Meter Type > Search** and then navigate to the **Equipment Types** page to define the types of equipment that can be linked to meters of a given type. Refer to [Equipment versus Badged Items](#) for more information about equipment.

Description of Page

Use the collection to define the item types of **Equipment** that can be linked to meters of this type.

Note:

Item types are being specified. There is no equipment type control table. Rather, items are used to define equipment and therefore you are actually defining item types rather than equipment types. Refer to [Equipment versus Badged Items](#) for more information about equipment.

Meter Type - Test Types

Open **Admin > Device > Meter Type > Search** and then navigate to the **Test Types** page to define the types of device tests that can be performed on meters of a given type. Refer to [The Big Picture Of Device Testing](#) for more information about device tests.

Description of Page

Use the **Device Test Type** collection to define the types of [device tests](#) that can be performed on meters of a given type.

Meter Type - Meter Configuration Type

Open **Admin > Device > Meter Type > Search** and then navigate to the **Meter Configuration Type** page to define the types of meter configurations that are allowed for this type of meter.

Description of Page

Use the **Meter Configuration Type** collection to define the types of meter configurations that can be used for this type of meter.

Setting Up Manufacturers & Their Models

When you set up a meter (or an item) you must define the manufacturer and model number of the meter / item. To define a manufacturer and its models, open **Admin > Manufacturer > Add**.

Description of Page

Enter an easily recognizable **Manufacturer** and **Description** for the manufacturer.

Enter a **Model** and **Description** for every model supplied by the manufacturer. Enter the **Service Type** with which the model is associated. Refer to [Setting Up Service Types](#) for more information.

If the model is associated with a meter, turn on **Use On Meter**. If the model is associated with an item, turn on **Use On Item**.

Setting Up Meter ID Types

A meter may have alternate ID's other than its badge number. If so, it will reference one or more meter ID types (one for each alternate form of ID). To define meter ID types, open **Admin > Meter ID Type**.

Description of Page

Enter a unique **Meter ID Type** and **Description** for every meter ID type.

Where Used

A meter may have alternate ID's other than its badge number. If so, it will reference one or more meter ID types (one for each alternate form of ID). Refer to [Meter - Meter ID Information](#) for more information.

Setting Up Read Out Types

Every register has a read out type that defines how the register's measurements are physically displayed (e.g., circular dials, digital, n/a-electronic transmission, and so on). To define read out types, open **Admin > Device > Read Out Type**.

Description of Page

Enter a unique **Read Out Type** code and a **Description** for every read out type.

Setting Up Protocol Codes

Every register has a protocol code that defines the method used to record the register's measurements (e.g., visual, probe, AMR, modem). To define protocol codes, open **Admin > Device > Protocol**.

Description of Page

Enter a unique **Protocol** and **Description** for every protocol.

Setting Up Unit Of Measure Codes

You must create a unit of measure (UOM) for:

- Every UOM that is measured by your meters' registers.

- Every UOM in which your rates' prices are expressed.
- Every UOM in which your items' estimated consumption is expressed.

**Note:**

Typically, the measured UOM is the same as the UOM in which the prices are expressed. However, there are instances where the UOM of the price is not measured by a meter's registers. Natural gas is a good example - the prices are expressed in an amount per therm, but the gas meters measure some volume (e.g., cubic feet, cubic meters).

**Fastpath:**

For more information about UOM's, refer to [UOM versus TOU versus SQI](#) .

To define unit of measure codes, open **Admin > General > Rates > Unit of Measure**.

Description of Page

The following fields display for each unit of measure:

UOM The unique identifier of the unit of measure.

Description The full description of the UOM.

Service Type The type of service (e.g., electric, gas, water, and so on.) associated with this UOM. This value controls the UOMs that may be referenced on meters belonging to a given service type. Refer to [Setting Up Service Types](#) for more information.

Decimal Positions The number of decimal positions that appear on bill lines that show consumption.

**Note:**

Suppression of trailing zeroes. If you wish to suppress trailing zeroes in the consumption that appears on bill lines, you must set up the Allow Zero Suppression Of Consumption In Bill Description option type on the Financial Transaction Options [Feature Configuration](#).

Allowed on Register Turn on this switch if the UOM can be referenced on a meter's register. A unit of measure may not be allowed on a register when it exists purely because there is a price in a rate expressed in this UOM. (For example, prices of natural gas are frequently expressed in therms, but it is rare to find a meter that measures gas in therms.)

Measures Peak Quantity Turn on this switch for UOMs that exist to record the peak amount of consumption, e.g., kW and kVar. Peak UOMs are treated differently by billing when determining the amount of consumption. They are also treated differently if rating has to prorate consumption.

Setting Up Time-Of-Use Codes

You will only create time of use (TOU) codes if your meters measure consumption in respect of broad time bands. For example, some electric meters measure consumption in respect of WHEN the power was used - peak period, off peak period, or partial peak period.

If you have "time of use" meters, then you must create TOU codes for:

- every TOU that is measured by your meters, and
- every TOU in which your rates' prices are expressed.

**Note:**

Typically the measured TOU is the same as that in which the prices are expressed. However, there are instances where the TOU of the price is not measured directly by a meter's registers. A simple example is where the meter measures peak hours consumption and total consumption but there are prices in the rate for off peak consumption. In this situation, the peak hours consumption would have to be subtracted from the total consumption to derive off peak consumption. In this situation, you would need TOU codes for both peak (measured) and off-peak (derived) periods.

**Fastpath:**

For more information about TOU's, refer to [UOM versus TOU versus SQI](#) .

Time-of-use codes will also be needed if your company offers interval billing with TOU mapping. Refer to [Designing Your Time of Use Options](#) for more information.

To define time-of-use codes, open **Admin > Rates > Time of Use**.

Description of Page

Enter a unique **TOU** code and **Description** for every time of use code.

Setting Up TOU Groups

TOU Groups may be used to group together time of use codes, which are included in a meter configuration. It is also used in TOU mapping and pricing functionality.

**Fastpath:**

Refer to [Grouping of TOU Codes](#) for more information about the TOU group's role in TOU mapping and pricing.

Open **Admin > TOU Group > Add** to define your TOU Groups.

Description of Page

Enter a unique **TOU Group** and **Description** for the TOU group.

Enter the Collection **Time of Use** codes. This is a list of time of use codes that define the time of use periods to be used for certain TOU maps. For each time of use code, you may indicate a **TOU Sequence** to indicate the relative order or relative priority of each TOU for the TOU group. Refer to [Grouping of TOU Codes](#) for more information.

Setting Up Retirement Reasons

When you change a meter or item's status to Retired, you must supply a retirement reason. To define retirement reasons, open **Admin > Devuce > Retire Reason**.

Description of Page

Enter a **Retire Reason Code** and **Description** for every retirement reason.

Setting Up Metered Service Point Options

This section describes tables that must be set up before you can define metered service points.

Defining Meter Location Codes

When you set up a metered service point you must define where the meter's service point is located on the property.

**Note:**

The meter location code is provided to meter readers and field workers to help locate the meter.

To define meter location codes, open **Admin > Meter Location**.

Description of Page

Enter a unique **Meter Location** and **Description** for every meter location.

Setting Up Service Cycles And Routes

Fastpath:

Refer to [Designing Service Cycles, Routes, And Schedules](#) for more information.

Setting Up Metered Premise Options

This section describes tables that must be set up before you can define premises.

Setting Up Meter Read Instructions

When you set up a premise you may define instructions to be supplied to the individuals who read the meters located at the premise. To define meter read instruction codes, open **Admin > Geographic > Meter Read Instruction**.

Description of Page

Enter a unique **Meter Read Instruction Code** and **Description** for every meter read instruction.

Setting Up Meter Read Warnings

When you set up a premise you may define warnings to be supplied to the individuals who read the meters located at the premise. To define meter read warning codes, open **Admin > Geographic > Meter Read Warning**.

Description of Page

Enter a unique **Meter Read Warning** and a **Description** for every meter read warning.

Setting Up Consumption Estimation Parameters

The system estimates consumption under the following situations:

- At billing time, when "real" consumption cannot be computed due to the lack of a meter read, the system estimates how much the customer used assuming the following conditions are true:
 - The service agreement allows estimation.
 - The rate schedule allows estimation.
 - The bill cycle schedule (if one is being used) allows estimation.
 - The register is not a peak register (this is an artificial constraint, but most organizations do not estimate peak consumption). Note that the base product estimation algorithms may attempt to estimate peak registers.
 - The register is subtractive. This is because only subtractive registers are self-correcting. For example, assume we estimate a reading of 100 and the next real read is 102, the customer will only be charged for 2 units. But consider what would happen if we estimated a consumptive register, the consumption associated with the next real read will be billed in its entirety.
- When a meter read is added, the system verifies that the resultant consumption is congruous with historical consumption trends (i.e., high / low checks are performed).

This section describes the tables that must be set up to estimate consumption.

Estimating Consumption

How the system generates estimated consumption is up to you because a plug-in algorithm is called when it's time to estimate consumption. The identity of the plug-in algorithm is defined on the *trend area* of the premise at which the meter is installed.

The base package is supplied with two algorithm types that you may use to estimate consumption:

- The TSMRE-LA algorithm type first tries to estimate consumption using historical data for the account and service point. If this is unsuccessful, it uses trend data to estimate consumption.

- The MR EST TREND algorithm type uses trend data to estimate consumption.

If neither of these algorithms works for your organization, you will need to write a new algorithm and plug it in on your trend areas.

The following discussion explains how the sample estimation plug-ins work.

Estimating Using Historical Consumption

One of the sample estimation algorithms provided with the base package attempts to estimate consumption using historical data for the account and service point.

When you estimate consumption using historical data, you assume that the customer will have current consumption that is similar to their historical usage. For example, if you need to estimate consumption for the month of February of the current year, you could assume that the customer has similar consumption during the month of February of the previous year or that they have similar consumption to the previous month.

The base package algorithm type that uses a customer's historical data to estimate consumption is called TSMRE-LA (three-step meter read estimation). It makes three attempts to estimate consumption stopping at the first successful attempt.

First, it tries to estimate consumption using a bill segment for the service point from the previous year that covers a similar period to the one being estimated. The year-old bill segment can be used for estimation if it is for the same account AND the bill segment's end read is not a system estimate AND there are enough days in the bill segment for estimation (as defined by the algorithm).

If the year-old bill segment cannot be used for estimation, the system attempts to use the bill segment for the account and service point that immediately precedes the start date of the estimation period. Again, this bill segment must not have an estimated end read and it must have a sufficient number of days for estimation.

Once a historical bill segment that can be used for estimation is located (using one of the above methods), the estimation occurs as follows:

- If the register is non-peak, the system calculates the average amount of consumption per day on the historical bill segment and multiplies this by the number of days in the current estimation period. For example, if the customer averaged 30.350877 kWh per day in the historical bill period and there are 30 days in the current period, the estimated consumption is: 911 kWh.
- If the register is peak, the estimation amount is the same as the peak amount on the historical bill segment.

If the system is unsuccessful in estimating consumption using the historical data for the previous year or the previous bill period, the system estimates consumption *using trends*.

Estimating Using Trends

Warning:

The topics that appear below explain how the MR EST TREND sample estimation algorithm works. Another algorithm is also available in the base package. It attempts to estimate consumption using the customer's historical consumption; if historical consumption does not exist, it estimates using the logic described below (refer to *Estimating Using Historical Consumption* for the information about this algorithm).

The Theory Behind Consumption Estimation Using Trends

The following discussion explains how the sample estimation plug-ins use trend data. If you decide to create your own version of one of these plug-ins, you still have to set up trend areas and trend classes as these are required fields on premises and SP types.

The standard estimation plug-ins assume that if a customer historically used, say, twice as much as customers of a similar profile, then the customer should use twice as much in the current period. Therefore, to estimate consumption for any period of time the system needs to know:

- A. How much the specific customer used in the previous consumption period.
- B. How much the average customer in the customer's trend profile used in the previous consumption period.
- C. How much the average customer in the customer's trend profile used in the period being estimated.

Once the above are known, estimated consumption for the specific customer equals $(A/B) * C$.

Knowing how much the specific customer used in the previous consumption period simply involves looking at the customer's previous readings (or reading, in the case of consumptive meters).

Knowing how much the average customer used requires consumption trend data. Consumption trend information is continuously updated behind-the-scenes using meter reads. A consumption trend is identified by a unique combination of:

- **Trend area.** Trend areas are used to differentiate consumption trends in different geographic areas. If your service territory doesn't have appreciable differences based on geography, then you will have just one trend area.
- **Trend class.** Trend classes are used to differentiate consumption trends based on the type of service and the type of property. At a minimum, you would probably have a trend class to differentiate between residential, commercial, and industrial usage.
- **Unit of Measure and Time of Use.** All consumption in the system is identified using a unit of measure code and, optionally, a time-of-use code.

Fastpath:

For more information about unit of measure codes, see [Setting Up Unit Of Measure Codes](#) . For more information about time-of-use codes, see [Setting Up Time-Of-Use Codes](#) . Trend areas, trend classes, and consumption trends are described later in this section.

Note:

Bottom line. A separate consumption trend is maintained behind-the-scenes for every combination of trend area, trend class, unit of measure and time of use.

Consumptive Register Where UOM Does Not Measure Peak Quantity

The algorithm used to estimate consumption for a consumptive, non peak unit of measure is identical to [Subtractive Register Where UOM Doesn't Measure Peak Quantity](#) ; the only difference is that we don't have to find the previous, previous read in order to determine the customer's usage in the previous period.

Subtractive Register Where UOM Does Not Measure Peak Quantity

Assume the following read history exists for a subtractive register (i.e., one where you have to subtract the previous read from the current read in order to derive consumption) where the register's unit of measure doesn't measure a peak quantity.

| Read Date | Reading | Derived Consumption |
|--------------|---------|---------------------|
| 15-Jan- 1999 | 1000 | N/A (first read) |
| 15-Feb-1999 | 3000 | 2000 |
| 15-Mar-1999 | 4500 | 1500 |

Next, assume the meter's trend profile looks as follows:

| Read Date | Total Qty (Assume kWh) | No of Units (Total Days) | Number of Reads | Average Consumption (Per Day) |
|-----------|------------------------|--------------------------|-----------------|-------------------------------|
|-----------|------------------------|--------------------------|-----------------|-------------------------------|

| | | | | |
|-------------|-----------|---------|-------|-----------|
| 13-Mar-1999 | 6,000,000 | 135,000 | 4,500 | 44.444444 |
| 14-Mar-1999 | 900,000 | 15,000 | 500 | 60 |
| 15-Mar-1999 | 5,000,000 | 137,750 | 4,750 | 36.297641 |
| ... | | | | |
| 13-Apr-1999 | 4,000,000 | 135,000 | 4,500 | 29.629630 |
| 14-Apr-1999 | 4,650,000 | 155,000 | 5,000 | 30 |

**Note:**

The system keeps a separate trend for every combination of trend area, trend class, unit of measure and time of use code. Trend area comes from the premise at which a meter is installed. Trend class comes from the SP type of the service point at which a meter is installed. Unit of measure and time of use come from the register read's register.

Next, assume a new register read is recorded on 15-Apr-1999 with a value of 5000.

In order to calculate estimated consumption for this register read, we have to calculate average daily consumption using the following formula:

$$\frac{\text{This customer's usage in previous period}}{\text{Avg customer's usage in previous period}} \times \text{Avg customer's usage in current period}$$

The following points describe exactly how the system calculates each variable in this formula:

- Determine **Average Customer's Usage In Current Period:**
 - Extract the number of reads from the meter's service point's SP type's trend class. We'll assume this is set to 7,500 reads.
 - Read trend records in reverse chronological order from the read date (assuming there is no trend record on 15-Apr-1999, we'll start amassing trends from 14-Apr-1999).
 - Read enough trend records until the number of reads is greater than or equal to the trend class' number of reads. We will have to read 2 trends records to amass this value (the ones on 14-Apr-1999 and 13-Apr-1999). We remember how many reads we extracted from the trend table for use a little later. In this case, we used 9,500 reads.
 - Divide **Total Qty** by **No of Units**. Using our example, we'd divide 8,650,000 kWh by 290,000 days to get 29.827586 kWh per day.
- Determine **This Customer's Usage In Previous, Non-Estimated Period:**
 - Find the consumption associated with the previous, non-estimated read for the register's unit of measure / time of use codes at the service point. In this case, we'd find the read on 15-Mar-1999. Because this register is subtractive, we'd also need to find the previous, previous non-estimated read in order to calculate consumption. In this case, we'd find the read on 15-Feb-1999.

**Note:**

Minimum Days Between Readings. The algorithm parameter Minimum Days Between Readings controls the minimum number of days needed between the previous non-estimated read and the "previous, previous" non-estimated read.

- Divide the total consumption by the number of days. Using our example, we'd divide 1,500 kWh by 28 days to get 53.571429 kWh per day.
- Note: if the customer doesn't have consumption in the previous, non-estimated period, e.g., if it's a meter at a new premise, the system assumes the customer uses the same as the average customer's usage in the previous period (see next point).
- **Determine Average Customer's Usage In Previous Period:**
- Read trend records in reverse chronological order from the read date of the previous reading (15-Mar-1999).
- Read enough trend records until the number of reads is greater than or equal to the number of reads amassed when determining the Average Customer's Usage In The Current Period (the first point). Using our example, we'd have to read 3 trends records (the ones on 15-Mar-1999, 14-Mar-1999 and 13-Mar-1999).
- Divide **Total Qty** by **No of Units**. Using our example, we'd divide 11,900,000 kWh by 287,750 days to get 41.355343 kWh per day.
- Next, determine the number of days of estimated consumption. This will be equal the number of days between the estimation date and the prior reading (note, the prior reading could have been estimated). Using our example, we'd have 31 days (the number of days between 15-Apr-1999 and 15-Mar-1999).
- At this point, we have everything we need to estimate consumption. This will equal $((53.571429 / 41.355343) * 29.827586) * 31$ days. This is equal to 1,198 kWh.
- If we need to calculate high and low boundaries, we multiply 1,198 kWh by the high and low values defined for the register's unit of measure, the service point's service type and the read's read type.

Consumptive Register Where UOM Measures A Peak Quantity

The algorithm used to estimate consumption for a consumptive, peak unit of measure is identical to [Subtractive Register Where UOM Measures A Peak Quantity](#) with the exception that we don't have to find the previous, previous read in order to determine the customer's usage in the previous period.

Subtractive Register Where UOM Measures A Peak Quantity

The algorithm used to estimate consumption for a subtractive, peak unit of measure is identical to [Subtractive Register Where UOM Doesn't Measure Peak Quantity](#) the previous example except:

- The No of Units on the trend table is not the number of days. Rather, it's the number of reads that contributed to the trend.
- Because we don't care about number of days, we don't have to multiply final estimated consumption by the number of days in the estimation period.

Tips for Consumption Estimation Using Trends

The quality of the trend information and setup impacts your estimation results (depending on your estimation algorithm) and this in turn impacts any estimated bills you send your customers. When you are setting up consumption estimation parameters keep the following guidelines in mind.

Make Sure the Number of Reads on Trend Class Is Large Enough

You should make the Number of Reads on the [trend class](#) is large enough that individual reads do not cause statistical anomalies. For example, assume that a "normal" read in a trend class is 500 kWh and, that within the trend class, there is one "abnormal" customer using 500 percent of normal:

- If the number of reads in the class is 10, the average read is calculated to be 700 kWh. The abnormal read causes a 40 percent increase in the average.

- If the number of reads in the class is 100, the average read is calculated to be 520 kWh. The abnormal read causes a 4 percent increase in the average.
- If the number of reads in the class is 1000, the average read is calculated to be 502 kWh. The abnormal read causes a 0.4 percent increase in the average.

By sizing the number of reads in a trend class appropriately, you can reduce the impact of statistical anomalies.

Note:

Example Values. The example above is meant to illustrate the importance of using an appropriate number of reads in a trend class. The numbers used in the example should not be viewed as recommended values when setting up your trend classes.

Trend Classes and Trend Areas Should be Defined Appropriately

In addition to defining a large enough number of reads on the trend class, you want to make sure that the system can collect the number of reads in a relatively short period of time or the benefit of trends is diluted. For example, if the system collects the number of reads over a period of two days as opposed to two months, the seasonal trend information is better represented in your estimates.

Consider the following example. Assume the number of reads required in the trend sample is 1000 and your system collects the following trend information for the area/class:

| Month | Number of Reads | Average |
|-------|-----------------|---------|
| March | 400 | 200 kWh |
| April | 400 | 300 kWh |
| May | 400 | 500 kWh |

The trended average in May is 333.33 kWh $((80000 + 120000 + 200000) / 1200)$.

However, if the number of reads required in the trend sample is 1000 and your system collects the following trend information for the area/class:

| Month | Number of Reads | Average |
|-------|-----------------|---------|
| March | 1100 | 200 kWh |
| April | 1100 | 300 kWh |
| May | 1100 | 500 kWh |

The trended average in May is 500 kWh $(550000/1100)$, which is a more accurate representation of the trend in May.

Note:

Example Values. The examples above are meant to illustrate the importance of ensuring that the system collects enough reads in a short enough time span to accurately capture trends. The values are summarized by month and do not represent actual records in a trend profile.

The collection of an appropriate number of reads is a function of the number of reads defined for a trend class and the number of customers who are in each trend class/trend area combination. Make sure that the number of reads is not too large for the number of customers who are in each trend class/trend area combination and that the trend class/trend area combinations do not create groups of customers that are too small to calculate accurate trends.

Customers Should Be Classified Into Appropriate Trend Classes and Areas

Make sure that your customers are classified into appropriate trend area/trend class categories. If a customer's actual usage does not follow the trend (within a certain percentage) for the area/class in which the customer is classified, the consumption estimates for that customer may be inaccurate. For example, a residential customer should not be in a trend class with industrial customers.

A customer's premise references the trend area in which the customer is classified. A customer's service point type references the trend class in which the customer is classified.

Estimation and Negative Consumption

In some cases, a service point may be fitted with its own renewable energy source such as wind turbines or solar panels. The energy generated at this service point, as well as any energy used, could possibly be measured by a single meter, with the energy generated being netted against the energy used (a situation also referred to as net-metering). When the energy generated exceeds the energy used, negative consumption can result.

The possibility of negative consumption occurring at a particular SP/meter combination is indicated by the presence of a characteristic on the SP that identifies it as one that has generation capacity, as well as a characteristic on the meter type that identifies the meter as one capable of rolling backwards. Both characteristics must be present before negative consumption is allowed for that SP/meter combination. These characteristic types and values are defined on the Meter Management Options [Feature Configuration](#). The following points describe the various **Option Types** that must be defined if negative consumption is allowed by your implementation:

- Negative Consumption SP Characteristic Type. This option indicates the characteristic type used on service points to denote generation capacity.
- Negative Consumption SP Characteristic Value. This option indicates the characteristic value used on service points to denote generation capacity.
- Negative Consumption Meter Type Characteristic Type. This option indicates the characteristic type used on meter types to identify meters capable of rolling backwards.
- Negative Consumption Meter Type Characteristic Value. This option indicates the characteristic value used on meter types to identify meters capable of rolling backwards.

Because the factors that cause a meter to roll forward are very different from the factors that cause it to roll backward, it is impracticable for the estimation algorithms to try to derive an estimate in situations where negative consumption is allowed. The estimation rules simply cannot combine the effects of all these disparate factors into one meaningful figure. By extension, the same issue applies to the determination of high/low factors. Besides the fact that high/low validation is impossible without first obtaining an estimate, a meaningful set of high/low factors cannot be determined when it is not known how energy generated at the service point may have affected the consumption in the first place. Therefore, no estimation is done by the system for SP/meter combinations that allow negative consumption. Reads that belong to these SP/meter combinations are also excluded from the trending process so as not to skew the rest of the estimates for a certain trend area and trend class.

Setting Up Trend Areas

When you set up a premise, you must define the consumption trend area in which it is located. This categorization matters when consumption trends differ across your service territory AND you want the system to estimate consumption in different areas differently.

This categorization does not have to be done in respect of classic geographic boundaries like cities and counties. Rather, trend areas may be based on economic factors, climatic conditions, or anything else related to geography that affects consumption.

Note:

A premise's trend area will default based on its postal code. See [Setting Up Premise & Service Point Postal Defaults](#) for more information.

To define trend areas, open **Admin > Consumption > Trend Area**.

Description of Page

Enter a unique **Trend Area** and **Description** for every trend area.

Define the **Meter Read Estimate Algorithm** that is used to estimate consumption for meters installed at premises associated with this trend area. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that performs meter read estimation.

Setting Up Trend Classes

When you set up an SP type, you must define the consumption estimation trend class in which its consumption will be categorized. This categorization matters when consumption differs based on the type of property AND you want the system to estimate consumption in different classes differently.

These categories could be the classic divisions of residential versus commercial versus industrial consumers. Alternatively, they could be finer-grained divisions: single family residence, versus duplex, versus triplex, versus medical office, versus grocery store.

To define trend classes, open **Admin > Consumption > Trend Class**.

Description of Page

Enter a unique **Trend Class** and a **Description** for every trend class.

Enter the **Number of Reads** that must be amalgamated to create a statistically significant sample when amassing the average customer's consumption. The system uses this number to determine the number of consumption trend records to amalgamate.

Note:

Don't worry. The Number of Reads is not the number of rows that will be read when the system estimates consumption. This is because the total consumption from many reads is stored on a single consumption trend record.

Setting Up High / Low Factors

When consumption estimation is done for the purpose of meter read validity, the system checks if the meter read's consumption is reasonable. The High / Low Meter Read algorithm type (HILO-FACTBL) supplied with the base package uses the factors defined in this table to calculate the high / low values.

High and low factors are defined for every measurable unit of measure (UOM) and read type combination. The word measurable was underlined because some UOMs exist purely for pricing purposes and are never measured by a meter (e.g., a therm of gas).

Fastpath:

For more information, refer to [High / Low Checks](#).

To define high / low factors, open **Admin > Device > High Low Factor**.

Description of Page

Enter the **Unit of Measure** (UOM) for which the high / low factors are used.

Enter the **Read Type** for which the high / low factors are used. Valid values are: Billing Force, Customer Read, Office Estimate, No Read, Service Provider Estimate, System Estimate, Regular, and Verified.

Enter the **Low Factor** for the UOM and Read Type. This value will be multiplied by estimated consumption to derive the acceptable low value of a meter read with this UOM and read type.

Enter the **High Factor** for the UOM and Read Type. This value will be multiplied by estimated consumption to derive the acceptable high value of a meter read with this UOM and read type.

Where Used

This information is used by the High / Low Meter Read algorithm type (HILO-FACTBL) when the system calculates the low and high consumption amounts against which a meter read's consumption is compared when the read is added to the system.

Note:

Detecting Theft Of Service. When the status of a meter is Off, the system sets the high and low read values equal to the previous register read. This catches any consumption activity at the service point after a meter has been turned off. However, for some implementations, a small amount of consumption trickle at the service point is acceptable. In this case, you would want to relax the high/low thresholds so that the reads are not constantly flagged to have failed high/low validation. To do this, you can add the Always Estimate And Apply High/Low Factors **Option Type** under Meter Management Options [Feature Configuration](#) and set its value to Y .

Setting Up Trends

Fastpath:

Refer to [Setting Up Trends](#) for more information.

Setting Up Meter Read Options

This section describes tables that must be set up before you can enter a meter read.

Setting Up Meter Reader Remarks

When you enter a meter read, you may define remarks using remark codes. The topics in this section describe how to set up meter reader remark codes.

Meter Reader Remark - Main

To define meter read remark codes, open **Admin > Device > Meter Reader Remark > Add**.

Description of Page

Enter a unique **Meter Reader Remark** and a **Description** for every meter read remark.

Turn on **Eligible for Processing** if meter reads marked with a given remark code should cause one or more **Action Algorithms** to execute. For example, if you need a "reread" field activity to be created when a "high bill" remark is uploaded, you'd create an algorithm called "reread" and associate it with the "high bill" remark code. Then, whenever such a meter read with a "high bill" remark is recorded in the database, the system will execute the algorithm (and generate the field activity). If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that is associated with a meter read remark special activity.

Meter Reader Remark - Bill Messages

To define bill messages to appear on bills that use a meter read that references a given meter reader remark code, open **Admin > Device > Meter Reader Remark > Search** and navigate to the **Bill Messages** tab.

Description of Page

Use the **Bill Messages** collection to define **Bill Message** codes that should appear on bills that use a meter read that references a given meter reader remark code. For each message, also specify the **Start Date** and **End Date** when such a message should appear on the bill (leave **End Date** blank if the message should appear indefinitely).

Where Used

The system snaps bill messages on a bill during bill completion. Refer to [The Source Of Bill Messages](#) for more information.

Setting Up Meter Read Sources

When you add or upload a meter read, you may define the source of the meter read. The source could reference a specific reader, a meter reading agency, or any other possible source. To define meter read sources, open **Admin > Meter Read Source**.

Description of Page

Enter a **Meter Read Source** code and **Description** for every meter read source.

Setting Up Items

This section describes tables that must be set up before you can define items.

Setting Up Item Types

Every item has an item type that defines characteristics common to all items with this type. The topics in this section describe how to set up your item types.

Item Type - Main

To define item types, open **Admin > Item Type > Add**.

Note:

When a new item type is added. After adding a new item type, you must define the SP types at which items of this type can be installed.

Fastpath:

Refer to [Service Points \(SPs\)](#) for information about the difference between badged and non-badged items. Refer to [Items Are Used For Other Devices Associated With A Customer's Service](#) for more information about items in general.

Description of Page

Enter an easily recognizable **Item Type** and **Description** for the item type.

Choose the **Service Type** associated with all items of this type. Refer to [Setting Up Service Types](#) for more information.

Turn on **Use Estimates** if estimated consumption is recorded for this type of item (e.g., lamps have estimated consumption that is used to calculate billable charges for these types of items). When this switch is turned on, also define the **Unit Of Measure** in which the estimated consumption is expressed.

Fastpath:

For more information about estimated consumption, refer to [Setting Up Estimated Consumption For Items](#).

Turn on **Summarize For Billing** if billing is supposed to summarize all items of this type on a customer's bill. If billing is supposed to show a separate bill line for every individual item of this type, turn this switch off.

Warning:

The Summarize For Billing switch is only pertinent if badged items are linked to the service points being billed. If unbadged items are linked to the service points, the bill will contain a summary of items by item

type regardless of the value of this switch. Refer to [Metered versus Item-Based versus Non-Badged Service Points for more information](#).

Turn on **Multiple Equipment Assignment** if equipment of this type can be linked with more than one service point / meter / item at any instant in time.

Turn on **Billable** if billing should amalgamate items of this type when it calculates a bill segment. This switch would typically only be turned-off for items used to describe [equipment](#) and other non-billable items linked to a service point.

Warning:

If this switch is turned on, rates linked to service agreements used to bill for items of this type must include an [Item Type Calculation Rule](#) that references this item type. Why? Because we assume that a bill line should be produced for "billable" items (and bill lines are produced for items using "item type" calculation rules). If you neglect to have such a calculation rule, a bill segment error will be produced.

If your organization bills for items of this type using [Estimated Consumption](#) rather than on a "per item" basis, you'll still need an "item type" calculation rule in these rates (otherwise billing will generate an error). In order to prevent the system from calculating a charge for such an "item type", make sure to indicate the calculation rule is "for calculation purposes only" (FCPO). Refer to [Common Parameters](#) for Calculation Rules for more information about FCPO's. Also note that you might also want to indicate that the calculation rule is not printable if you want to suppress the item type's description on the printed bill. Refer to [How to Use Description on Bill](#) for more information about printable calculation rules.

Indicate in **Track Location** whether you Track or Do Not Track the location of items of this type. Refer to [The Big Picture of Asset Inventory](#) for more information.

Use the **Characteristic Values** collection to define **Characteristic Types** and their respective **Characteristic Values** to describe characteristics common to all items of this type. This grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the Item Type Characteristics table.

Note:

You can only choose characteristic types defined as permissible on the item type record.

Item Type - Item Characteristics

To define characteristics that may be defined for items of a given type, open **Admin > Item Type > Search** and navigate to the **Item Characteristics** page.

Description of Page

Use the **Item Characteristics** collection to define characteristics that can be defined for items of a given type. Turn on the **Required** switch if the **Characteristic Type** must be defined on items of a given type. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on. Use **Sequence** to control the order in which characteristics are defaulted.

Item Type - Equipment Types

Open **Admin > Device > Item Type > Search** and navigate to the **Equipment Types** page to define the types of equipment that can be linked to items of a given type. Refer to [Equipment versus Badged Items](#) for more information about equipment.

Description of Page

Use the collection to define the item types of **Equipment** that can be linked to items of this type.

Note:

Item types are being specified. There is no equipment type control table. Items are used to define equipment; therefore, you define item types instead of equipment types. Refer to [Equipment versus Badged Items](#) for more information about equipment.

Item Type - Test Types

Open **Admin > Device > Item Type > Search** and navigate to the **Test Types** page to define the types of device tests that can be performed on items of a given type. Refer to [The Big Picture Of Device Testing](#) for more information about device tests.

Description of Page

Use the collection to define the types of **Device Tests** that can be performed on items of a given type.

Setting Up Manufacturers and Models

When you set up an item (or a meter) you must define the manufacturer and model number of the meter / item.

Fastpath:

Refer to [Setting Up Manufacturers & Their Models](#) for more information.

The Big Picture Of Device Testing

The topics in this section describe meter and item (i.e., device) testing at a high level.

We strongly recommend examining the demo data to see how the concepts explained in this section could be used in real life.

Warning:

Setting up the device testing control tables is as challenging as your organization's business rules. If you don't test your devices, you don't have to setup anything. If you have sophisticated testing requirements, your setup process will be more challenging.

The Level of Complexity Depends On What You Test and Your Record Keeping Requirements

Every organization's device testing requirements are different. Consider the following:

- Some organizations simply use the CIS system to create and dispatch field activities when it's time to test devices. After the field activities are dispatched, the test results are maintained in a separate system. You can set up the system to work this way for you.
- Some organizations maintain very detailed test result records, others don't. For example, some organizations record both "as found" and "as left" test results, i.e., they test the meter in its "as found" state, then they recalibrate it and test it again and record the "as left" state. You can set up the system to work this way for you.
- Some organizations maintain separate test results for every individual register on a meter. For example, they might record 3 separate test results for an electric meter with kWh, kW, and kVar registers (and, if they recorded both "as found" and "as left" results, they would have 6 separate test results, at least, for this meter). You can set up the system to work this way for you.
- The type of information that can be recorded in respect of a test varies widely. Some organizations simply record if the test passed or failed. Other organizations keep track of a great deal of information about the test results. Consider the following examples:
 - Most organizations record who performed the test, the state of the seals on the meter, and whether or not a repair is necessary.
 - A company with gas meters might record the ambient air temperature, the temperature of the oil used in the test, the test spin time, the actual meter reading, the "chart" (should be) reading and the percent accuracy.
 - A company with electric meters might record the following information: meter reading at full capacity, meter reading a light capacity, meter reading with a power factor of 50%, and the percent accuracy.
- You can set up the system to work this way for you.

Given that the system supports the above disparate requirements, you can understand why the set up process is either straightforward or challenging. The remaining topics in this section provide some guidelines to help you through this setup process.

A Device Test Records Test Results

You create a device test each time you test a meter or item. The device test keeps track of when the test was conducted, who conducted it, and the results of the test. Every device test references a *device test type*.

When you design your device test types, you are actually defining the type of information that can / must be recorded when such a device test is saved in the system. The following picture illustrates a device test type used for tests of simple electric meters.

Notice that the above device test type example uses two different mechanisms to record test results:

- **Component tests.** If your organization maintains the test results from individual registers, you will use component tests. In the above example, two different types of component tests can be recorded for this type of device test: one is used to record a register's accuracy before calibration (the "as found" component test), another is used to record the register's accuracy after calibration (the "as left" component test).
- The component test type controls the type of information that is recorded for a component test. In the above example, each component test type requires the same result types - a register reading and a percent accuracy. Note, the fact that these two test types require the same results is coincidental.

You have to set up a component test types and test result types to satisfy your organization record keeping requirements.

- **Characteristics.** If your organization doesn't keep register-specific test results, you don't have to use component tests. Rather, you can simply use characteristics to record test results. In the above device test type, characteristics are used to record whether the seals were in placed and a repair code (if the test results in a repair). Refer to [Setting Up Characteristic Types & Their Values](#) for more information about characteristics.

Field Activities And Device Testing

Most device tests occur as a result of a field activity. The field activity is associated with the service point at which the device is currently installed. Refer to [Examples of Device Testing Activity Types and their Steps](#) for an overview of how these types of field activities look.

You can create device testing field activities manually OR you can take advantage of the [Device Test Selection](#) page. This page will generate field activities to test meters and items based on a user-defined Test Selection Algorithm. The system comes with a sample Test Selection Algorithm type that selects meters of a given manufacturer / model that haven't been test for a given number of months. In all likelihood, you or your implementer will have to develop other algorithms to meet the test selection requirements of your organization. For example, if you test all meters that generate more than \$100,000 of revenue per annum every 6 months, you will have to write a new Test Selection Algorithm Type.

After defining which test selection algorithm types you need, you must set up Test Selection Algorithms that make use of them (these algorithms are specified by the operator on the [Device Test Selection](#) page). To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that is associated with a device test selection.

Device Test Validation

After entering the test results for a device test, some organizations want the system to analyze the test results and determine if the meter / item passed or failed the test. If your organization does this, you will have to determine the characteristic values and test result values associated with "passing the test". You will then have to design an algorithm that contains logic that determines if a device test contains the appropriate characteristic and test result values.

After developing your device test algorithms, you associate them with the appropriate device test types. The system invokes the respective algorithm when an operator pushes the Validate Device Test button on the device test page.

Setting Up Device Test Options

The topics in this section describe how to set up the control tables that must exist before a device test can be recorded.

Setting Up Component Test Types

If you organization records component test results, you must set up a component test type for each type of component test. Refer to [A Device Test Records Test Results](#) for more information about component test types.

Open **Admin > Device > Device Test Component Type > Add** to define the type of information that must be recorded on a component test of a given type.

Note:

When a new component test type is added. After adding a new component test type, you must define the device test types that make use of it.

Description of Page

Enter an easily recognizable **Test Component Type** and **Description**.

Turn on **Meter Test** if this type of component test is associated with a meter. If this type of component test is associated with an item, this switch should be off.

If **Meter Test** is on, turn on **Register Required** if a register must be referenced on component tests of this type. You would require a register if a) you keep component tests for individual registers, or b) if your component tests require the entry of register readings (as defined in the following grid).

The grid that follows defines the type of test results that are recorded.

Result Seq Result sequence controls the order in which the test results are captured.

Description Enter the prompt that is displayed for this type of test result.

Result Required Turn this switch on if a result must be specified on a test component of this type.

Validation Algorithm The validation algorithm controls how the test result is validated. Leave this field blank if no validation should be imposed.

Prompt For Read Turn on this switch if a user can enter a register read for this type of test result.

Setting Up Device Test Types

Every device test references a device test type. The device test type controls business rules associated its device tests. The topics in this section describe how to set up your device test types.

Device Test Type - Main

Open **Admin > Device > Device Test Type > Add** to define general business rules shared by device tests of a given type.

Note:

When a new device test type is added. After defining your device test types, you must update your meter and item types to define their valid test types. This is what prevents a gas test from being performed on an electric meter.

Description of Page

Enter an easily recognizable **Test Type** and **Description**.

Turn on **Meter Test** if this type of test is associated with a meter. If this type of test is associated with an item, this switch should be off.

Turn on **Validation Required** if tests of this type use a **Validation Algorithm** to determine if the test results (and therefore the device test) are of a passing grade. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that is associated with a device test validation algorithm.

Define **Characteristic Types** and their respective **Characteristic Values** to describe characteristics common to all tests of this type. This grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the Device Test Type Characteristics table. Note that you can also define characteristic types for which values are required to be entered when the device test is created (see [Device Test Type - Characteristics](#)).

Note:

You can only choose characteristic types defined as permissible on a device test type record.

Device Test Type - Component Types

Open **Admin > Device > Device Test Type > Search** and navigate to the **Component Types** page to define the types of component tests (if any) that can be performed for device tests of a given type.

Description of Page

Use **Sequence** to define the relative order of each **Test Component Type** that can be performed during device tests of a given type.

Device Test Type - Characteristics

Open **Admin > Device > Device Test Type > Search** and navigate to the **Characteristics** page to define required and optional characteristics for device tests of a given type.

Description of Page

Define **Characteristic Types** to describe characteristics that might be entered for all tests of this type. Turn on **Required** if this type of characteristics must be specified on tests of this type, otherwise, the characteristic will be optional. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on. Use **Sequence** to control the order in which characteristics are defaulted.

Note:

You can only choose characteristic types defined as permissible on a device test type record.

Defining Usage Options

This section describes concepts and common tasks related to usage administration.

The Big Picture of Usage Requests

Oracle Utilities Meter Data Management is used by some organizations who use a meter data management (mdm) system to record meter reading information. Since meter reads are not available in Oracle Utilities Customer Care and Billing to calculate consumption during the billing process, usage (or bill determinants) must be requested by Oracle Utilities Customer Care and Billing from the mdm system, Oracle Utilities Meter Data Management.

The following sections describe how the base-package usage request process works.

Requesting Bill Determinants

The term bill determinant request is another way to refer to a usage request. These usage requests are created during the batch billing process, and also when a user generates an online bill segment or performs cancel / rebill. The get consumption algorithm specified on the SA Type's Bill Segment Type is responsible for creating the usage request.

Batch Billing Usage Requests

Batch billing usage requests are created and held in the initial pending state. A separate batch process is responsible for transitioning these requests and sending them to the MDM system. Here's how this works:

- The get consumption algorithm specified on the SA Type's Bill Segment Type is responsible for creating the usage request. These batch billing usage requests are held in the Pending state until the batch Usage Scheduled Monitor Process is executed
- Similarly, once a response is received from MDM, the usage request will not transition to the Bill Determinants Processed state until the batch Usage Scheduled Monitor Process is executed
- In addition to the standard MDM usage request elements, the system captures the bill cycle and window start date.

Online Billing Usage Requests

- Usage requests created from an online billing request are not held in the initial state. These usage requests are transitioned through their lifecycle resulting in the request being sent to the meter data management system (mdm) and, once a response is received, the bill segment is regenerated.
- The bill segment remains in the Freezable state until the user freezes the bill segment and completes the bill. If the freezable bill segment is regenerated, however, the system cancels the usage request and creates another usage request for the bill segment.
- In addition to the standard mdm usage request elements, the system captures the responsible user id.

Note:

External Reference ID. When creating a usage request, the external reference id is populated based on the version of MDM that your implementation integrates with. This is defined as the MDM Version MO option on the Usage maintenance object. If integrating with MDM 1, the system populates the external reference id using the batch run thread scheduler id to facilitate processing in the external system. Otherwise, the external reference id is left blank and may be updated on the response from the external system.

Multi Cancel/Rebill — Usage Requests

When online multi-cancel/rebill involves bill segments for service agreements that require bill determinants from Oracle Utilities Meter Data Management, an off cycle bill generator (OCBG) is created to perform the cancel/rebill.

The OCBG is created using the business object that is defined as OCBG Multi-Cancel/Rebill option on the Off Cycle Bill Generator maintenance object. It orchestrates the creation of usage requests for the specific bill segments being rebilled. Each bill segment needs to be successfully rebilled before the next bill segment can be rebilled. If a bill segment's usage request sits in waiting status, the following will occur:

- The original bill segment sits in Pending Cancel state.
- The new (rebill) bill segment is linked to both the usage request that is in the Awaiting Bill Determinants state and the Multi Cancel/Rebill OCBG in Processing Request state.
- Subsequent bill segments that were selected for rebilling stay in the Frozen state until the previous bill segment is successfully rebilled. Each will be linked to its own Multi Cancel/Rebill OCBG in Pending state.

The user will need to refresh the Multi Cancel/Rebill page, to see if any of the bill segments have progressed in rebilling.

If cancel/rebill of a bill segment results in an error, the system discards any non-final OCBGs for that service agreement.

Refer to the **C1-MultiCancelRebill** business object for more details on the OCBG processing.

Usage Request Lifecycle

The usage request business object (BO) contains the rules that govern the processing of a usage request. The base product provides the BO C1-UsageRequest which serves as a parent BO and contains the following lifecycle:

- All usage requests are created in the initial Pending state. If the usage request was created from the batch billing process, the batch Usage Scheduled Monitor Process must be executed to transition the usage request.
- If there are pending sync requests for the usage request's service agreement, the usage request is held in the Awaiting Data Sync state until the sync is processed.
- Once all pending sync requests related to the usage request have been processed, the usage request transitions to the Send Request state. An enter algorithm on this transitory state is responsible for sending the usage request to Oracle Utilities Meter Data Management (MDM). The base algorithm creates a JMS Queue outbound message. This outbound message is configured to not persist on the database.
- Once the outbound message has been successfully sent, the usage request sits in the Awaiting Bill Determinants state until a response is received from MDM, or a time out is encountered.
- When a response is received from the external system, the usage request is transitioned to either the Bill Determinants Received state, or the Error state. In the case of an error, the following occurs:
 - If the usage request was created from the batch billing process and the billing window is still open, a new usage request will be created the next time billing runs and the process is repeated. If however, the billing window is no longer open, a to do entry is created for manual follow up.
 - If the usage request was created from an online billing process, the user will be notified. The bill segment remains in the error state and the user can either delete the bill segment, or attempt to generate it again. If the bill segment is regenerated, a new usage request is created and the process is repeated.
 - The system transitions usage requests in the Bill Determinants Received state to the Bill Determinants Processed state. An enter algorithm on this final state is responsible for generating the bill segment. If the usage request was created from the batch billing process, the bill segment is frozen and the bill is completed. For online billing usage requests, the user is responsible for freezing the bill segment and completing the bill.

Summary Billed Accounts and Usage Requests

A "summary" account refers to an account with service agreements that cover more than one premise. If these premises are linked to service points that span different service cycle routes scheduled for reading on different dates, there's no guarantee that all the account's SAs will be billed at the same time. This is because batch billing for manually read meters is based on the meter's scheduled reading date.

For example, assume a summary account has two SAs each linked to a different premise. One is on route X, scheduled for reading every first of the month and the other is on route Y, scheduled for reading every 20th of the month. Assume that the account's bill cycle is cycle X (which matches the schedule of premise/SP on route X). When billing runs on the first of the month, the service agreements tied to route Y won't have any reads. And because route Y is not scheduled for reading, the system will not estimate the consumption. Instead, it will skip billing the route Y SAs until the next month. This means some SAs are always one billing cycle behind.

If your implementation maintains meters and meter reads in CCB, then the base get consumption algorithm called ***Get Consumption From SP's Linked To SA*** handles the skipping of a summary billed account's service agreements based on bill cycle and service cycle schedules. The remainder of this section describes how this works in a CCB-MDM integrated environment.

Requesting Bill Determinants for Summary Billed Accounts

Usage requests for summary billed accounts are handled as follows:

- On the first night of the billing window usage requests are created for each SA and sent to Oracle Utilities Meter Data Management (MDM). MDM then checks what the next schedule read date is for each service point.
- Assuming Oracle Utilities Meter Data Management owns meter read schedules; when batch billing executes Oracle Utilities Customer Care and Billing (CCB) cannot determine whether a summary account's service agreement should be included on the bill or not.
- If MDM determines that an SA/usage subscription should be skipped from billing, it notifies CCB by including a skip indicator and reason on the usage response, as well as the SA's next scheduled read date. This date is captured as a ***MDM Next Scheduled Read Date*** characteristic on the SA, and the usage request is cancelled. The system still attempts to complete the bill since this might be the last outstanding usage request for the bill
- When billing next runs, the base ***Get bill segment consumption using a usage request*** algorithm first checks if the SA should be skipped as follows (Note that this check is also performed in first billing run):
- Get the ***MDM Next Scheduled Read Date*** characteristic on the SA. If this date is after the bill segment end date, we'll skip the SA from billing

If your implementation would like to wait until the bill cycle window end date before attempting to complete summary account's bills, ensure that the ***Complete Summary Bill at End of Bill Cycle*** pre-bill completion algorithm is defined on customer class. This is useful if scheduled reads are expected in the bill cycle window, but not necessarily on the window start date.

Corrected Read Notifications

If a read that was used for bill determinant calculations is modified in the mdm system, notification is sent to Oracle Utilities Meter Data Management.. Resulting in the creation of an off cycle bill generator. The system uses the business object defined as the OCBG Corrected Read BO MO option on the Off Cycle Bill Generator maintenance object to create the OCBG. If any errors are encountered while attempting to create the OCBG, the system sends a message to the external system using the Outbound Message Type and External System defined as BO options on the OCBG Corrected Read BO

What happens next depends on the lifecycle that your implementation has configured for the OCBG Corrected Read BO. Here are examples of what might occur:

- Create a To Do entry for manual follow up.
- Find any frozen bill segments that might be affected by the corrected read and perform cancel/rebill.

Configuring The System For Usage Request Integration

Oracle Utilities Customer Care and Billing sends usage requests to Oracle Utilities Meter Data Management (MDM) in the form of an xml message. These messages are transformed by the integration layer and then sent to MDM. Similarly, MDM sends responses to the integration layer so that the data can be transformed and sent to Oracle Utilities Customer Care and Billing. MDM sends responses back to Oracle Utilities Customer Care and Billing.

The following sections describe at a high level the data setup required to send usage requests to an mdm system.

Define the Outbound Message Type

An outbound message type is required for the batch billing usage request outbound message. This outbound message type must reference the base C1-CyclicalUsgReqOutMsg business object. The outbound message type must also be specified as a BO option on the base C1-CyclicalUsgReqOutMsg business object so the system knows which outbound message type to use when sending usage requests to MDM.

An outbound message type is required for the online billing usage request outbound message. This outbound message type must reference the base C1-NonCyclicalUsgReqOutMsg business object. The outbound message type must also be specified as a BO option on the base C1-NonCyclicalUsgReqOutMsg business object so the system knows which outbound message type to use when sending usage requests to MDM.

Note:

Defining the Usage Business Objects. The business objects used by the get consumption algorithm when creating a batch or online billing usage request are defined as MO options on the Usage maintenance object.

Define the Message Sender

A Message Sender is required to define how to send usage requests to MDM. Use the context of the Message Sender to define the web service interface.

Define the External System and Configure the Messages

Define an external system and configure the valid outbound message types and the method of communication for each. You will also need to select the appropriate XSLs to format the request for usage. The external system must also be specified as a BO option on the base C1-CyclicalUsgReqOutMsg and C1-NonCyclicalUsgReqOutMsg business objects so the system knows which external system to use when sending usage requests to Oracle Utilities Meter Data Management.

Fastpath:

Refer to the *Oracle Utilities Customer Care and Billing - Meter Data Management Integration Implementation Guide* for more information.

Designing Your SA Types For Usage Requests

SA Types used to bill service agreements that require bill determinants from a meter data management system must have the following characteristics:

- The SA Type must have a special role flag of Bill Determinants Required
- Bill segment type:
 - Reference the bill segment creation algorithm that creates a bill segment from a usage request.
 - Reference the bill segment get consumption algorithm that gets bill segment consumption using a usage request.

Start and End Times for Billing

As you know, there is logic in billing to determine the start date and end date for a bill segment. Refer to [Ways To Control The Start Date Of A Bill Segment](#) and [Ways To Control The End Date Of A Bill Segment](#) for more information. When billing for a customer with interval data, the system also needs to know the time.

The time used by billing, referred to as the cutoff time, is stored on the service agreement. There is also a control on the service agreement called Start Day Option that determines which day to use for the start time. Billing uses the billing date, the cutoff time, and the start day option to determine the correct interval data to process.

When integrating with a meter data management system, Oracle Utilities Customer Care and Billing lacks knowledge of the type of meter installed at a service point. Thus, both interval processing period as well as scalar processing information is captured on a usage request. Oracle Utilities Meter Data Management (MDM) then uses the appropriate period to calculate bill determinants based on the type of meter installed.

MDM returns the true usage period used to calculate bill determinants on the usage response. This usage period is captured on the bill segment.

Fastpath:

Refer to [Start and End Times for Billing](#) for more information.

Navigating To MDM

It might be necessary for Oracle Utilities Customer Care and Billing users to navigate to MDM to view detailed read information for a service point. For example, a user may want to see the unbilled consumption that's available in MDM. The following is required to implement this:

- Add a menu entry to the service point context menu. This menu item must reference the base Go To MDM From SP navigation option
- Add a menu entry to the service agreement context menu. This menu item must reference the base Go To MDM From SA navigation option
- Set up the MDM URL option type on the General System Configuration [Feature Configuration](#). The MDM URL option must contain the URL for the MDM application.

Once configured, users should be able to launch the MDM system from these context menus with either a service point or service agreement id in context.

The Big Picture of Time of Use Mapping and Pricing

This section provides an overview of the concepts related to setting up your control tables to support time of use mapping and pricing with the rates.

Note: Time of use mapping is supported to enable low volume interval data manipulation (for example, for mapping electric vehicle charging events into time of use quantities). A meter data management application, such as Oracle Utilities Meter Data Management, must be used to manipulate high volumes of interval data and calculating bill determinants for billing purposes.

Mapping to Time of Use (TOU) Periods

Many customers choose not to price their interval data using interval prices. Customers may choose for their interval data to be mapped into time of use (TOU) periods. This option for interval data might be preferred because:

- Typically it involves fixed prices for the use periods
- It is more manageable than direct billing
- It is easier for a customer to forecast and budget

A TOU map's purpose is to define the TOU codes for a collection of time period definitions (i.e. given dates and times). The TOU Map has a TOU Map Type, which defines the interval size between TOU map data rows.

Time of use periods can (and often do) change during the year.

| Map #123 (TOU Group 2) | | |
|------------------------|-------|-----------------|
| Effective 1 Jan 2000 | | |
| Interval Date/Time | | |
| 30/Apr/00 | 16:30 | On Peak/Winter |
| 30/Apr/00 | 16:45 | On Peak/Winter |
| 30/Apr/00 | 17:00 | Off Peak/Winter |
| 30/Apr/00 | 17:15 | Off Peak/Winter |
| --- | | |
| 01/May/00 | 7:45 | Off Peak/Summer |
| 02/May/00 | 8:00 | On Peak/Summer |
| 02/May/00 | 8:15 | On Peak/Summer |
| --- | | |

All the possible TOU codes for a given map are grouped together in a TOU group. Refer to [Grouping of TOU Codes for TOU Mapping](#) for more information.

Grouping of TOU Codes for TOU Mapping

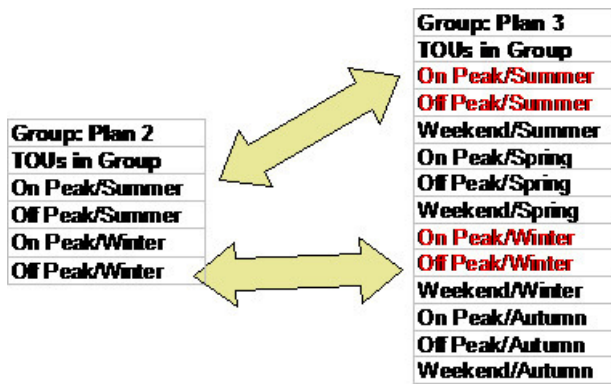

This section describes the relationship between TOU Codes and TOU Mapping.

Overview of TOU Codes and TOU Mapping

A TOU map's purpose is to define the TOU codes for a collection of time period definitions (i.e. given dates and times).

Time of use codes or TOU codes (for example, "Off Peak/Winter", "Off Peak/Summer") are user-defined. Refer to [Setting Up Time-Of-Use Codes](#) for more information.

TOU Sequence for TOU Mapping and Pricing

If desired, you may use sequence number to indicate the relative position or relative priority of each TOU code within a TOU group. This sequence number is not used by any system functionality, but is available for you to use in a plug-in algorithm.

Time of Use (TOU) Mapping and Pricing

The following section describes the logic used by the system to map an interval data curve to TOU periods using a TOU map, and subsequently apply prices to these mapped quantities.

At some point during billing, the system will take an interval data curve and will map the interval values to TOU periods based on a TOU Map. The interval data curve is retrieved from either a specific usage request or from the new rate engine buffer populated prior to calling the rate engine.

This type of data manipulation is typically handled using a calculation rule based on the 'math' calculation rule type.

Once the interval data curve values have been mapped to TOU periods, prices can be applied to the time of use period quantities using calculation rules based on the 'service quantity' calculation rule type.

Calculation Rules for TOU Mapping & Pricing

Calculation Rules are used to perform time of use mapping and time of use pricing.

Time of Use Mapping

Time of use mapping will be typically handled using a calculation rule based on the 'math' calculation rule type. Calculation rules of this type can perform many functions. Two examples include:

- Applying a TOU map to an interval data curve to produce service quantities that will be added to the bill segment's SQ collection.

- Applying a TOU map to a derived interval data curve. For example, after deriving the power factor curve, perform TOU mapping on the resultant curve.

For further details on the 'math' calculation rule type, refer to [Base Package Math Calculation Rule](#) for more information.

Time of Use Pricing

Time of use pricing will be typically handled using calculation rules based on the 'service quantity' calculation rule type. Calculation rules of this type can perform many functions. For example:

- Add or update a service quantity in the bill segments SQ collection
- Create bill calculations lines that levy charges based on some type of consumption. For example, applying a price to a specific service quantity in the bill segment's SQ collection

For further details on the 'service quantity' calculation rule type, refer to [Base Package Service Quantity Calculation Rule](#) for further information.

Note: Calculation rules are implemented using algorithms that contain the logic to be performed. If your implementation requires a new type of calculation rule, you can configure a new calculation rule type and reference the appropriate algorithm on it.

TOU Map Used For Mapping

An interval data curve is mapped into time-of-use periods using a TOU map. The TOU map used by the calculation rule for mapping interval data curve values to time of use periods is defined directly on the calculation rule.

Attributes of TOU Maps

TOU map types define attributes shared by TOU maps of a given type. The essential attributes of any TOU Map Type are the interval sizes between TOU map data rows, associated TOU map template(s) to use, and whether the TOU data will follow any seasonal time shifting.

Designing Your Time of Use (TOU) Mapping and Pricing Options

This section provides an overview for designing your control tables to support time of use (TOU) mapping and pricing with the new rating engine.

Designing Your Time Of Use (TOU) Mapping and Pricing Calculation Rules

As you know from the rates chapter, the system can handle mapping of interval data curve values into different time of use periods and pricing these quantities using the 'math' and 'service quantity' calculation rule types respectively. Refer to [Base Package Calculation Rule Descriptions](#) for more information.

The following guidelines provides a high level outline on how you should go about designing a rate schedule that involves time of use mapping and pricing.

- Obtain copies of existing bills that use the rate in question. If the rate is new, then write up exactly how the information should appear on the customers' printed bills.
- Identify all the lines that represent charges for individual time of use periods.
- Determine how the quantities for the time of use periods are calculated. Which time of use map is used to define the time periods?
- In order to perform time of use mapping and pricing, calculation rules need to be designed
 - A calculation rule based on the 'math' calculation rule type may be used to map an interval data curve into time of use periods. This calculation rule must know the TOU map to apply to the interval data curve to map into the relevant time of use periods. The time of use period quantities are populated in the bill segments SQ collection.
 - Calculation rules based on the 'service quantity' calculation rule type may be used to apply prices to each mapped time of use period quantity. These calculation rules each require either a price or regular bill factor for pricing each time of use period quantity. The bill factor may contain the price directly, or may indicate that the price is customer specific and can be found as contract quantities for the service agreement.

Once you have your calculation rules designed, you will be able to design the other control tables needed to set up your time of use billing customer.

Designing Your TOU Codes for TOU Mapping

The next most logical step in designing your time of use mapping controls is to define your time of use codes. To do this, look at the time of use periods to which your usage needs to be mapped. These values will likely correspond to the time of use quantities that your rate bills for. It should be noted that it's possible that will not bill for every time of use period.

For more information about time of use, refer to [UOM versus TOU versus SQL](#).

Designing Your TOU Groups for TOU Mapping

To further aid in designing time of use mapping, the TOU Group enables you to group together all the time of use codes that are available to be used in a single map. You must also decide if you want to use a sequence number to define the relative order of a TOU code within a TOU group.

When TOU data is created for a TOU map, only TOU periods defined on a specified TOU group can be specified.

Designing Your TOU Map Types for TOU Mapping

Now that you have your TOU groups defined, you can begin defining TOU map types. Recall that the TOU map type defines the attributes that may be shared by TOU maps of the same type.

The essential attributes of any TOU Map Type are the interval sizes between TOU map data rows, associated TOU map template(s) to use, and whether the TOU data will follow any seasonal time shifting. Refer to [Designing Your Time Options](#) for more information.

TOU Map Type Interval Size

The interval size of a TOU map must divide evenly into the interval size of the interval data curve that uses the map (because the system joins the date/time of the interval data curve values to the date/time of the TOU data). This means that it is possible to use a 15 minute TOU map with a 60 minute interval data curve. However, it is not OK to have a 60 minute TOU map used with a 15 minute interval data curve because the join will miss 3 out of 4 interval data curve values.

TOU Map Type Override Template

While most TOU maps will use the TOU map template defined on the TOU map type, TOU maps also support override templates. Refer to [Designing Your TOU Map Templates](#) for TOU Mapping for more information.

- A TOU map's TOU map type defines the default TOU map template that's used to generate its TOU data.
- A TOU map's type defines the TOU map templates that can be referenced on individual TOU maps to override the default template.
- An individual TOU map can have override templates. If the TOU map doesn't have an override template, the default template defined on the TOU map type is used to generate the map's TOU data.

Refer to [Creating TOU Map Types](#) for further information.

Designing Your TOU Map Templates for TOU Mapping

In order to help your users to create and maintain data for TOU maps, you may define TOU map templates, which can be used to generate data for a TOU map. The templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. TOU map types reference TOU map templates.

Every TOU map references a TOU map template that defines the rules for generating TOU data from that TOU map. Specifically, TOU map templates define:

- The TOU group (defines the valid TOU periods for the template) used for the TOU map
- The default TOU period used for periods not explicitly defined. (This means you don't have to specify dates and times for all periods. For example, if your default TOU period is "Off Peak" you only need to define dates and days and times for On Peak or other TOU periods.)

- The specific date ranges, days of the week, and time periods designated for each TOU period. The system periodically generates TOU map data for TOU maps by interpreting the rules defined in the template.

Holidays

Many utilities categorize consumption on holidays differently than on the day of week on which the holiday falls. For example, holiday consumption might be categorized as Off-Peak regardless of the day it falls on. TOU map templates can define rules for different TOU periods for holidays by specifying the following:

- A Work Calendar that defines when holidays start and end
- Either:
 - A Holiday TOU period for consumption on holiday
 - A Holiday TOU Map Template that defines the TOU codes to use for different times in the year

TOU Map Template Interval Size

TOU map templates can also specify an interval size. This value specifies the duration of the individual TOU map data records, and also controls the values allowed in the Start and End Times. For example, if a TOU map template sets the interval size at 15 minutes, Start and End times must be in units of the interval size (10:00, 10:15, 10:30, etc.).

A TOU map template can be used to generate TOU map data for TOU maps whose interval size is divisible by the template's interval size. For example, a 60 minute template can be used to generate TOU data for TOU maps with an interval size of 60 minutes, 15 minutes, 5 minutes, etc. This means separate map templates are not needed for every interval size.

Refer to [Creating TOU Map Templates](#) for further information.

Setting Up Time of Use (TOU) Mapping and Pricing Control Tables

This section provides an overview of setting up your control tables to support time of use mapping and pricing with rates.

TOU Codes

Refer to [Setting Up Time of Use Codes](#) for further information

TOU Groups

Refer to [Setting Up TOU Groups](#) for further information

Creating TOU Map Templates

TOU map templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. TOU map types reference TOU map templates and used for TOU map data generation.

Prerequisites: You must define TOU groups and work calendars before you can create TOU map templates. Refer to the Oracle Utilities Application Framework online help for more information about creating work calendars.

To maintain existing TOU map templates, select **Admin > Consumption > TOU Map Template > Search** then use standard actions to edit, duplicate, or delete a TOU map template.

To define a new TOU map template, follow these steps:

1. Select **Admin > Consumption > TOU Map Template > Add**. If your system supports more than one TOU map template business object, you will be prompted to select a business object for this TOU map template.
2. Enter a name and a meaningful description for the TOU map template.
3. Select the TOU group to be used by the TOU map template.
4. Select the default TOU for the TOU map template (from the TOU Group). This is the TOU used when creating TOU map data for dates not accounted for in the TOU Schedules section.
5. Select the work calendar for the TOU map template. Work calendars define the days of the week on which work is performed, and specify holidays.
6. Select the holiday TOU for the TOU map template (from the TOU Group).
7. Select the TOU map template used for holidays (if applicable).

8. Specify the interval size for TOU map data created from the map template. Interval size is designated as hours:minutes:seconds (HH:MM:SS)
9. To specify TOU schedule's date ranges and which TOUs should be used for this TOU map template, click the + or - sign in the TOU Schedule Section and enter or select the following:
 - Start and End Dates for a specific date range
 - Start and End Days of the Week: To add or remove Start and End Days of the Week pairs, click the + or - sign and select the appropriate weekdays
 - Start and End Times: To add or remove Start and End Times within a Start and End Days of the Week pair, click the + or - sign and enter the appropriate times
 - TOU
10. Click **Save**.

Now you can use the TOU map template when creating TOU types.

Creating TOU Map Types

An interval data curve is mapped into time-of-use periods using a TOU map. The TOU map used by the calculation rule for mapping interval data curve values to time of use periods is defined directly on the calculation rule. TOU map types define attributes shared by TOU maps of a given type.

Prerequisites: You must define TOU map templates and time zones before you can create TOU map types. Refer to the Oracle Utilities Application Framework online help for more information about creating time zones.

To maintain existing TOU map types, select **Admin > Consumption > TOU Map Type > Search** then use standard actions to edit, duplicate, or delete a TOU map type.

To define a new TOU map type, follow these steps:

1. Select **Admin > Consumption > TOU Map Type > Add**

Note: If your system supports more than one TOU map type business object, you will be prompted to select a business object for this TOU map type.

2. Enter a name and a meaningful description for the TOU map type.
3. Select the business object to use when creating TOU maps of this type
4. Select the time zone for the TOU map type.
5. Specify the interval size for TOU map data created from the map type. Interval size is designated as hours:minutes:seconds (HH:MM:SS)
6. Select the default TOU map template for the TOU map type
7. To add or remove override TOU map templates for this TOU type, click the + or - sign in the Override TOU Map Templates section and select the TOU map template.
8. Click **Save**.

Now you can use the TOU map type when creating TOU maps.

Defining Premise and Service Point Options

A premise is where a customer consumes the services supplied by your company. Located at a premise are the various devices that consume energy and measure consumption. Before you can define premises and devices, you must set up the control tables defined in this section.

Warning:

The topics in this section do not describe every table that must exist in order to set up premises and service points. Many premise and service point control tables are described in [Defining Meter and Item Options](#) , and [Defining Field Order Options](#) . The tables described in this section are those that must be set up regardless of the type of service.

For more information about the control tables that must be set up before you can define service points refer to [Setting Up Generic Service Point Options](#), [Defining Meter and Item Options](#) .

Field activities may be dispatched to all types of service points.

Meter A meter is a physical device used to measure the amount of gas, water, or electricity used by a customer. While most meters measure consumption in a single unit of measure (e.g., gallons, cubic feet, kilowatt-hours), some electric meters are extremely sophisticated and measure several different factors. For example, some electric meters measure how much was used, when it was used, the efficiency of consumption, the maximum amount used, and a few other unusual things.

Fastpath:

For more information about the control tables that must be set up before you can define a meter, refer to [Setting Up Meter Options](#) , and [Setting Up Consumption Estimation Parameters](#).

Item (Equipment) An item that is considered to be "equipment" is a physical device that regulates consumption; it does NOT measure consumption. You would only define equipment if it is of interest to your organization. For example, if your organization periodically tests the pulse initiators associated with your meters, you will need to set up items for each pulse initiator and link them to their respective meters. Equipment can be linked to either a service point (e.g., a current transformer, a backflow device), a meter (e.g., a pulse initiator), or an item (e.g., the components of an installation).

Note:

Equipment and billing. Be aware that the only way equipment can impact billing would be if you developed pre-processing calculation groups that analyzed the equipment associated with a service point (directly or indirectly via the meters and items) and manipulated billed consumption accordingly. Refer to [Understanding Calculation Groups and Rules](#) for more information.

Item (NOT Equipment) An item is a physical device that does NOT measure consumption, but impacts billing in some way (i.e., there are charges in your rates based on the number and type of items installed at a service point). Examples include street lights, light poles, and security cameras. Items are related to service points and a service point can have one or more items linked to it.

Fastpath:

For more information about the control tables that must be set up before you can define an item, refer to [Setting Up Items](#) on page 853 .

For more information about premises and service points, refer to [Understanding The "V"](#).

Setting Up Premise Options

This section describes tables that must be set up before you can define premises.

Defining Premise Types

Open **Admin > Geographic > Premise Type** to define the premise types used to categorize your premises.

Description of Page

Enter a unique **Premise Type** and a **Description** for every premise type.

Allow CIS Division controls whether premises of this type can use the CIS Division on the premise page. Valid values are Not Allowed, Optional, and Required.

If your implementation requires restricting data by CIS Division, it is recommended that Allow CIS Division be set to Required.

Implementing Address Validation

In order to set up address validation, you must ensure that the following Option Types are defined with their corresponding values on the General System Configuration – Feature Configuration page:

| Option Type | Description |
|---------------------------|---|
| Address Validation Script | Indicates the name of the BPA script to invoke when a user clicks on the validate address button. This option is required if the Allow Address Validation option is set to Y. The base product includes sample script C1-ValAddr that uses Oracle Spatial procedures and functions to geocode an address and return its matching quality code. |
| Allow Address Validation | Indicates whether an integration with address validation software is implemented. If set to Y, the system will render a validate button along with the address fields displayed throughout the application to trigger address validation. Valid values are 'Y' and 'N'. If set to Y, the Address Validation Script to invoke must be specified. |

As described in the above table, the base product includes sample script C1-ValAddr uses Oracle Spatial procedures and functions to geocode an address and return a matching quality code. To use this script, ensure that the Oracle Spatial Geocoding (F1-ORAGEOCD) algorithm is plugged in on installation options for the geocoding service system event. A data source containing the geocoding data must also exist on the database.

If your implementation uses something other than Oracle Spatial for address validation, you'll need to create a new address validation BPA script to specify on the General System Configuration feature configuration. For additional information about creating this script, see the steps descriptions for the C1-ValAddr script in the application. The new script should contain the following move step to update the page:

- If the calling page is an old style page, the move from the BPA to the page can be achieved by specifying a move step from a source field to a User Interface Field.
- If the calling page is a display map, the move from the BPA to the page can be achieved by specifying a step to read the Business Object, modify the values as returned by the validation software, and then update the BO.

Setting Up Generic Service Point Options

This section describes tables that must be set up before you can define service points.

Facility Levels

Every type of service tends to use a different mapping philosophy to designate the facility hierarchy that supplies service to the service point. For example, electric service typically uses a substation / feeder / node facility hierarchy to define how electricity is supplied to a service point (the substation is the highest level in the hierarchy, the feeder comes next, and finally the node). Whereas gas service uses a city gate / main / feeder hierarchy.

If your organization maintains this type of information on service points, you will set up your facilities and their interrelationships using 3 windows. On the first you set up the number and type of facility levels used for every service and you define the valid values for each facility level (you define these when you define your Service Types). On the second and third you define the values that may coexist in each level. After these set up tasks are complete, you're ready to enter facility levels on your service points.

Note:

A service point's facility levels are used to help pinpoint problems and dispatch service crews during outages.

Setting Up Facility Levels 1 & 2 Combinations

To define which values of facility level 2 may be used with a given value of facility level 1, open **Admin > Geographic > Facility Level 1 to 2**.

Description of Page

Choose a **Service Type** and **Facility Level**, then use the **Facility Level 2** collection to define the level 2 facility levels that may coexist with the selected level 1 facility level.

Setting Up Facility Levels 2 & 3 Combinations

To define which values of facility level 3 may be used with a given value of facility level 2, open **Admin > Geographic > Facility Level 2 to 3**.

Description of Page

Choose a **Service Type** and **Facility Level 2**, then use the **Facility Level 3** collection to define the level 3 facility levels that may coexist with the selected level 2 facility level.

Setting Up Service Point Types

Every service point must reference a service point (SP) type. The SP type controls almost all aspects of the service point's behavior (e.g., the type of field activity that may be dispatched to it, the type of service agreement that may be linked to it, the type of meter that may be installed at it).

The topics in this section describe the windows used to set up your SP types.

Warning:

Setting up SP types requires careful analysis of your company's SA types, field activities, and its consumption estimation philosophy. Refer to [Designing SP Types](#) for more information about this design process.

SP Type - Main

You begin to define a service point type by selecting **Admin > Geographic > SP Type > Add**.

Warning:

You may find that your desire to use some of the more sophisticated control functions in the system will necessitate many SP types. For example, notice that one of the other windows on this group allows you to define the meter types that can be installed in service points of a given type. If you have many different types of meters and many restrictions as to the types of service points in which they can be installed, you will end up with many SP types.

Description of Page

Enter an easily recognizable **SP Type** for the service point type. This value will appear on many windows throughout your system as a "shorthand" for how the SP is used, so think carefully about the format. We recommend using a consistent format for all of your SP types. You should include the service type, an indication if it's metered or item-based, and the trend classification. For example, you might enter "E-M-RES", for an electric, metered, residential SP type.

Select the **Service Type**. Refer to [Setting Up Service Types](#) for more information.

Enter a **Description**.

Select the **Sub Type** to indicate the type of device that may be installed at service points of this type: Meter, Item, Unbadged.

Turn on the **Allow Service Route** switch if service points of this type should have a route. This switch would typically be turned on for metered service points.

Multiple Route Usage controls whether a service point can reference multiple service routes. Select Allowed if multiple service routes are allowed on service points of this type. Select Not Allowed if multiple service routes are not allowed on service points of this type. This switch would typically be turned on for garbage service points.

If this SP type is for metered service, select the **Trend Class** to define how to categorize this SP type's consumption for estimation and high / low validation purposes. This field will be gray for item-based services because items don't have meter reads that can be estimated or that are subject to high / low validation. Refer to [Setting Up Trend Classes](#) for more information.

If this SP type is for fieldwork that is managed by an external system, specify the external system in **Fieldwork Orchestration**.

If field activities are created for this SP type's service point, select the **Field Activity Type Profile** that controls which type of field activities may be linked to the service points. This Profile will also control which field activities are automatically generated by the system under various circumstances. Refer to [Setting Up Field Activity Type Profiles](#) for more information.

If a geographic type is used to identify individual service points of this SP type, select the **Identifying Geographic Type** used. You typically have an identifying geographic type if you refer to a service point using an identifier that is assigned by a third party. Refer to [Defining Geographic Types](#) for information on setting up geographic types.

Use the **SP Type Characteristic** collection and their respective **Characteristic Values** to describe characteristics common to all service points of this type. This grid supports all standard characteristic types (such as, Adhoc, Predefined, File Location, and Foreign Key) from the SP Type Characteristics table.

Note:

You can only choose characteristic types defined as permissible on an SP Type record. Refer to [Setting Up Characteristic Types and Their Values](#) for more information.

SP Type - Meter Type

Open **Admin > Geographic > SP Type > Search** and navigate to the **Meter Types** page to define the types of meters that may be installed at service points belonging to this SP type.

Description of Page

The **Meter Types** collection contains the types of meters that may be installed at service points belonging to this SP type. This collection is not relevant if the SP sub type is Item or Unbadged.

Note:

You can connect meters with different service types to your SP Type. For example, a metering device such as a recorder can be used on both gas and electric service points.

SP Type - SA Type

Open **Admin > Geographic > SP Type > Search** and navigate to the **SA Types** page to define the SA types that may be linked to (and therefore pay for) service points belonging to this SP type.

Description of Page

The following fields display:

CIS Division / SA Type Indicate the type of service agreement that may be linked to service points of this type.

Initial Turn on this switch if the Start Service process should default this SA type when service is initially started at a service point of this type. Multiple SA types may be marked as Initial if you want multiple service agreements created when service is initially started. For example, if you have both wastewater and water service agreements linked to the water service point.

SP Type - Item Type

Open **Admin > Geographic > SP Type > Search** and navigate to the **Item Types** page to define the types of items that may be installed at service points belonging to this SP type.

Description of Page

The **Item Types** collection contains the types of items that may be installed at service points belonging to this SP type. This collection is not relevant if the SP sub type is Meter or Unbadged.

Note:

You can connect items with different service types to your SP Type. For example, an item like a cell phone can be used on both gas and electric service points.

SP Type - SP Characteristic

To define characteristics that may be defined for service points of a given type, open **Admin > Geographic > SP Type > Search** and navigate to the **SP Characteristic** page.

Description of Page

- Use the **SP Characteristics** collection to define characteristics that can be defined for service points of a given type.
- Use **Sequence** to control the order in which characteristics are defaulted.
- Turn on the **Required** switch if the **Characteristic Type** must be defined on service points of a given type.
- When the **Default** switch is turned on, enter a **Characteristic Value** to use as the default for a given **Characteristic Type**

SP Type - Equipment Type

Open **Admin > Geographic > SP Type > Search** and navigate to the **Equipment Types** page to define the types of equipment that can be linked to service points of a given type.

Open **Admin > Device Installation > SP Type > Search** and navigate to the **Equipment Types** page to define the types of equipment that can be linked to service points of a given type.

Description of Page

Use the collection to define the item types of **Equipment** that can be linked to service points of this type.

Note:

Item types are being specified. There is no equipment type control table. Rather, items are used to define equipment and, therefore, you define item types rather than equipment types. Refer to [Equipment versus Badged Items](#) for more information about equipment.

SP Type - FA Type Review

Open **Admin > Geographic > SP Type > Search** and navigate to the **FA Type Review** page to review the field activities that are allowed for the SP type.

Note:

Four dimensions. For every **field activity type** that is eligible for dispatch, you define the **dispatch group** that performs the activity at every **SP type** located in every **operations area**. This information is maintained on the field service control page. This is a rather complex relationship because it involves the four dimensions highlighted in bold. Due to this complexity, we have provided review trees on the SP Type, Dispatch Group, and Field Activity Type windows to help you understand what you've set up.

Description of Page

This window is dedicated to a tree that shows the field activities allowed for this SP type. For each field activity type that is eligible for dispatch, you can view the dispatch group that will perform the activity at every operations area.

Setting Up Premise & Service Point Postal Defaults

You set up postal defaults if your company is able to default field values onto new premises and service points based on the premise's postal code. The topics in this section describe how to maintain postal defaults.

Fastpath:

For more information about where these default values are used, refer to [Maintaining Premises](#) and [Maintaining Service Points](#).

Postal Defaults - Main

To define premise postal defaults, open **Admin > Geographic > Postal Code Default > Add**.

Description of Page

Enter the **Country Code** and range of postal codes to which the default values apply using the **From Postal** and **To Postal**.

Note:

You may not have postal defaults whose from / to postal codes overlap.

Select the **Trend Area** to be defaulted onto new premises located in this postal code range. The trend area is used to categorize premises into geographic areas when consumption estimation is controlled, in part, by where the customer lives. Refer to [Setting Up Trend Areas](#) for more information.

Enter the **County** to be defaulted onto new premises located in this postal code range.

Enter the **City** to be defaulted onto new premises located in this postal code range.

Enter the **CIS Division** to be defaulted onto new premises located in this postal code range.

Enter the **State** to be defaulted onto new premises located in this postal code range.

Enter the **Time Zone** to be defaulted onto new premises located in this postal code range.

Use the **Characteristic Types and Values** collection to define the **Characteristic Types** and their respective **Characteristic Values** to be defaulted on premises located in this postal code range. In addition to providing interesting information, these characteristics may also determine the prices and tax rates on the bills generated for the services consumed at a premise.

Fastpath:

For more information about characteristics, see [Setting Up Characteristic Types & Their Values](#) and [An Illustration Of A Bill Factor And Its Characteristics](#) .

Use the **Geographic Types and Values** collection to define the **Geographic Types** and their respective **Values** to be defaulted on premises located in this postal code range. In addition to providing interesting information, these values may be used to sort field activities in geographic value order.

Where Used

This information is defaulted when a new Premise is added. Characteristics and geographic values are also defaulted when the postal code for a Premise is changed. Refer to [Maintaining Premises](#) for more information.

Postal Defaults - Service Default

To define values to be defaulted for a service point located in a postal range, open **Admin > Geographic > Postal Code Default > Search** and navigate to the **Service Defaults** page.

**Fastpath:**

For more information about where these default values are used, refer to [Maintaining Service Points](#).

Description of Page

Use the **Service Defaults** collection to define values to be defaulted on service points located in a given postal code range belonging to a given **Service Type** (note, a service point's Service Type comes from its SP Type).

The following values may be defined per **Service Type**:

- When a meter or item is removed from a service point located in this postal code range, the system assigns it by default to **Stock Location**. Note that this is only used if the meter's meter type or item's item type indicates that stock locations are tracked.

**Fastpath:**

For more information about location history, refer to [Stock Location History Is Created Behind The Scenes](#).

- Use the **Field Services** collection to define the **Field Service Classifications** and their respective **Operation Area** to be defaulted on new service points located in this postal range. Refer to [Designing Field Service Classifications](#) for more information.
- Use the **Characteristic Types and Values** collection to define the **Characteristic Types** and their respective **Characteristic Values** to be defaulted on new service points located in this postal code range. In addition to providing interesting information, these characteristics may also determine the prices and tax rates on the bills generated for the services consumed at a service point.
- Use the **Geographic Types and Values** collection to define the **Geographic Types** and their respective **Values** to be defaulted on new service points located in this postal code range. In addition to providing interesting information, these values may be used to sort field activities in geographic value order.

Where Used

Information is defaulted when a new Service Point is added to a Premise. Refer to [Service Point - Main Information](#) for more information.

Stock Location is defaulted when a Meter or an Item is removed from a Service Point. For details see [SP/Meter Installation](#) and [SP/Item Installation](#).

Designing SP Types

Every service point must reference an SP type. When you set up an SP type, you define how the system manages many aspects of its service points' behavior.

**Note:**

Perfect foresight. In a perfect world, the other control tables would have been set up with perfect foresight of setting up your SP types. In reality, setting up your SP types may invalidate some of your earlier decisions. Don't feel bad if this happens, some amount of iteration is natural.

Designing your SP types is an iterative process. To minimize the number of iterations, we recommend using the steps outlined in this section to complete the following table. When the table is complete, you're ready to set up your SP types.

| | |
|---------|--------------|
| SP Type | Service Type |
|---------|--------------|

Service Segmentation

At a minimum, you will have one SP type for every different type of service that exists at your premises. If we assume that your organization sells gas, water, waste water and electricity services, you will need four SP types.

| | |
|--------------------|---------------------|
| SP Type | Service Type |
| GAS | Gas service |
| WATER | Water service |
| WASTE WATER | Waste water service |
| ELECTRIC | Electric service |

Device Segmentation

For each service, determine if there exist meters, badged items, or non-badged items at the service points. For example, if we assume:

- Electric service has service points with meters, badged lamps, and parking lots.
- Gas and water services just use meters.
- Waste water service doesn't actually have a meter installed at it (it uses the water consumption measured by the water service point's meter)

Then your SP types will be:

| SP Type | Service Type | SP Sub Type |
|-------------------------------|---------------------|-------------|
| GAS - METERED | Gas service | Meter |
| WATER - METERED | Water service | Meter |
| WASTE WATER | Waste water service | Unbadged |
| ELECTRIC - METERED | Electric service | Meter |
| ELECTRIC - BADGED LAMP | Electric service | Item |
| ELECTRIC - PARKING LOT | Electric service | Unbadged |

Meter Read Estimation Trend Class Segmentation

When you set up a metered SP type, you must define the consumption estimation trend class in which its consumption will be categorized. This categorization matters when consumption differs based on the type of property AND you want the system to estimate consumption in different classes differently.

These categories could be the classic divisions of residential versus commercial versus industrial consumers. Alternatively, they could be finer-grained divisions: single family residence, versus duplex, versus triplex, versus medical office, versus grocery store.

Fastpath:

Refer to [The Theory Behind Consumption Estimation](#) for more information about how trend class is used to estimate consumption.

If we assume you differentiate between residential and commercial service for all of your metered services, then your SP types will be:

| SP Type | Service Type | SP Sub Type | Trend Class |
|---------|--------------|-------------|-------------|
|---------|--------------|-------------|-------------|

| | | | |
|-----------------------------------|---------------------|----------|-------------|
| GAS - METERED - RESID | Gas service | Meter | Residential |
| GAS - METERED - COMM | Gas service | Meter | Commercial |
| WATER - METERED - RESID | Water service | Meter | Residential |
| WATER - METERED - COMM | Water service | Meter | Commercial |
| WASTE WATER - RESID | Waste water service | Unbadged | N/A |
| WASTE WATER - COMM | Waste water service | Unbadged | N/A |
| ELECTRIC - METERED - RESID | Electric service | Meter | Residential |
| ELECTRIC - METERED - COMM | Electric service | Meter | Commercial |
| ELECTRIC - BADGED LAMP | Electric service | Item | N/A |
| ELECTRIC - PARKING LOT | Electric service | Unbadged | N/A |

Notice that the non-metered service points don't use a trend class. This is because they don't have meters (and only meters have estimated consumption).

Field Activity Type Profile Segmentation

When you set up any type of service point that can have field activities, you must define the field activity type profile. This profile defines:

- The type of field activities that may be dispatched to the service points.
- The type of field activity to be defaulted by the start/stop process given the condition of the service point.

Field activity type profiles should not impact your SP type design as these profiles should be designed after the SP types are designed.

Fastpath:

Refer to [Designing Your Field Activity Profiles & Types](#) for more information about how field activity profiles are used.

SA Type Segmentation

Every SP Type whose service points can be linked to a service agreement has one or more SA types. These define which type of service agreements can pay for the service point's service. If different service points have different valid SA types, you will need to split the SP types accordingly.

The SA Type segmentation of SP Types is the most complicated design decision you'll have to make. Unfortunately, the decision making process is subjective and iterative. The iterations are caused by the fact that the number of SA

types is dependent on the number of SP types (and vice versa). We recommend the following to help work your way through this conundrum:

- Design your SA types using the information in [Defining Service Agreement Types](#).
- Return to your SP types and determine if, given the proposed SA types, you can define a list of valid SA types for each SP type. If you find the population of SA types (and their valid rates) could result in invalid rates paying for service at a service point, divide your SA types further.

Meter Type Segmentation

Every metered SP Type has one or more meter types. These define which type of meter can be installed at a service point of a given type. If different service points have different valid meter types, you will need to split the SP types accordingly.

For example, if you have 3-phase electric service points and you want to make sure that only 3-phase meters are installed in these service points, you will need to split the electric SP types accordingly.

Fastpath:

Refer to [Setting Up Meter Types](#) for more information.

Item Type Segmentation

All SP Types may have item types. These define which type of item can be installed at a service point of a given type. If different service points have different valid item types, you will need to split the SP types accordingly.

Fastpath:

Refer to [Setting Up Item Types](#) for more information.

Defining Bill & Meter Read Cycles

This chapter is dedicated to issues related to defining cycles, routes and schedules in the system.

Defining Bill and Service Cycles

Every account references a bill cycle. An account's bill cycle controls when it is billed.

Every metered service point references a service cycle. A service point's service cycle controls when a service point's meter is read.

The design of your meter read and bill cycles is inextricably linked because you probably want to bill your customers shortly after their meters are read.

In this section, we describe how to design and set up these cycles. In addition, we discuss how to set up bill period schedules. These are used to define the bill segment end date for special types of non-metered service agreements.

Note:

Recommendation. We recommend reading [Bill Frequency - Bill Cycle vs Bill Segment Duration](#) before setting up this information.

The Big Picture Of Bill Cycles, Service Cycles and Bill Periods

The topics in this section provide background information about a variety of bill cycle, service cycle, and bill period issues.

Designing Cycles for Metered Services

The topics in this section provide background information about a variety of service cycle issues.

A Description of the Cyclical Meter Read Process

Meter readers using handheld devices record most meter reads in the field. These meter reads are uploaded into the system for use by billing.

A service point's meter is read due to the following data relationships:

- Every metered service point references a service route (henceforth called "route").
- A route references a service cycle.
- A service cycle has service schedules that define when the service points in the cycle are read.
- Every service cycle schedule contains two dates:
 - **Scheduled selection date.** This is the date the system selects the service points in the cycle for download to your handheld software.
 - **Scheduled work date.** This is the date the meter is expected to be read.

Note:

Overriding a route within a specific schedule. Rather than downloading all routes within a cycle, you can set up the system so that only specific routes are downloaded on any given date. This is a very powerful feature. You can use it, for example, to estimate specific cycles every other month or indicate the customer reads the meter every third month. Refer to [Designing Service Cycles, Routes, And Schedules](#) for more information.

- On the scheduled selection date, the system creates a download file containing information to be sent to your handheld software. This download file contains information about every register on every meter in the routes being downloaded.
- Your handheld software distributes this information to the handheld devices and then your meter readers do their job. When they finish, the resultant meter reads are uploaded into the system for subsequent use by billing.

Warning:

It is very important to create a service cycle schedule for every expected read date regardless of whether the cycle's routes are downloaded. Why do you have to do this? Because billing uses the scheduled work date on the service cycle to know when to look for a reading. If it can't find a reading on or near this date, billing estimates consumption (given estimation is allowed on the service agreement). Without a service cycle schedule, billing wouldn't know when to look for readings. So, for example, if you estimate a given cycle's consumption EVERY OTHER MONTH, you must create a service cycle schedule for EVERY month. On each month's schedule, you must define if the routes should be downloaded.

Fastpath:

For more information about the how to control when a cycle is read, refer to [Setting Up Service Cycle Schedules](#).

Designing Service Cycles, Routes, And Schedules

The topics in this section provide information describing how to design your service cycles, routes, and schedules.

- [Designing Service Cycles For Meter Reading](#)
- [Designing Service Routes For Meter Reading](#)
- [Designing Metered Service Cycle Schedules](#)

Designing Service Cycles for Meter Reading

The criterion that affects the number of service cycles has nothing to do with when meter readers physically read your meters. Rather, the frequency that you bill the meter's consumption (real or estimated) is what controls the number of service cycles.

So, for example, if you bill every month, but read every OTHER month, you'll have 20 service cycles - one for each bill day during the month. If you bill bimonthly, you'll have 40 service cycles. If you bill quarterly, you'll have 60 service cycles. Etc.

Note:

Different billing frequencies are possible for different service points. If you have different billing frequencies for your different types of metered service, you'll need a different set of cycles for each billing frequency. For example, if you bill water quarterly and electricity monthly, you'll have 20 bill cycles (one for each bill day during a month), but you'd need 60 quarterly service cycles for your water service points, and 20 monthly service cycles for your electric service points. This would result in a customer getting billed every month. However, four times a year, their bill would contain a charge for both electricity and water.

[Top of the Page](#)

Designing Service Routes For Meter Reading

The following points describe the relationship between a meter read, a route and a service cycle:

- A service cycle contains one or more routes.
- A route has one or more service points.
- A service point holds a meter.
- And a meter is what is read.
- Therefore, the number of meters a person can read in a day limits the number of service points in a route.

Warning:

If your company supplies electric service and uses MV90's, you will need to take advantage of "notional" routes. A "notional" route's service points are never actually read by a human. Rather, the service points' consumption is fed to the system by a sophisticated device (e.g., an MV90). These service points still need to be linked to a route because billing is dependent on the route's cycle to determine the expected meter read date.

[Top of the Page](#)

Designing Metered Service Cycle Schedules

The process of designing your service schedules is either easy or complicated. It will be easy if all routes within a cycle are downloaded when the service cycle is scheduled for download. It will be complicated if you download a subset of routes within a cycle on any given download date. We'll provide a few examples to help explain why.

If you download all cycles in a route whenever the cycle is downloaded, your service cycle schedule will look as follows.

Note:

Bill cycles. We've included each service cycle's related bill cycle to help you understand when the service cycle's consumption will be billed. Bill cycles are discussed in [Bill Cycles](#).

| Service Cycle | Download Date | Sched MR Date | Which Routes To Download | Bill Cycle | Bill Window | Estimation Date |
|---------------|---------------|---------------|--------------------------|------------|-----------------------|-----------------|
| 1 | 28-May-99 | 31-May-99 | All | 1 | 31-May-99 to 2-Jun-99 | 2-Jun-99 |
| 2 | 31-May-99 | 1-Jun-99 | All | 2 | 1-Jun-99 to 3-Jun-99 | 3-Jun-99 |

| | | | | | |
|------------|----------|----------|-----|---|-------------------------|
| 3 | 1-Jun-99 | 2-Jun-99 | All | 3 | 2-Jun-99 to 4-Jun-99 |
| 4 | 2-Jun-99 | 3-Jun-99 | All | 4 | 3-Jun-99 to 7-Jun-99 |
| Etc. to 20 | | | | | |

Now let's complicate life. If we assume you physically read your routes every other month (but bill monthly using estimated consumption), then you'll need the following service schedule.

| Service Cycle | Download Date | Sched MR Date | Which Routes | Bill Cycle | Bill Window | Estimation Date |
|---------------|---------------|---------------|--|------------|---------------------------|-----------------|
| 1 | 30-May-99 | 31-May-99 | 1, 2, 3 - Download 4, 5, 6 - Estimate | 1 | 31-May-99 to 2-Jun-99 | 2-Jun-99 |
| 2 | 31-May-99 | 1-Jun-99 | 1, 2, 3 - Download 4, 5, 6 - Estimate | 2 | 1-Jun-99 to 3-Jun-99 | 3-Jun-99 |
| 3 | 1-Jun-99 | 2-Jun-99 | 1, 2, 3 - Download 4, 5, 6 - Estimate | 3 | 2-Jun-99 to 4-Jun-99 | 4-Jun-99 |
| 4 | 2-Jun-99 | 3-Jun-99 | 1, 2, 3 - Download 4, 5, 6 - Estimate | 4 | 3-Jun-99 to 7-Jun-99 | 7-Jun-99 |
| Etc. to 20 | | | | | | |
| 1 | 29-Jun-99 | 30-Jun-99 | 1, 2, 3 - Estimate 4, 5, 6 - Download | 1 | 30-Jun-99 to 2-Jul-99 | 2-July-99 |
| 2 | 30-Jun-99 | 1-July-99 | 1, 2, 3 - Estimate 4, 5, 6 - Download | 2 | 1-July-99 to 3-Jul-99 | 3-July-99 |
| 3 | 1-July-99 | 2-July-99 | 1, 2, 3 - Estimate 4, 5, 6 - Download | 3 | 2-July-99 to 4-July-99 | 4-July-99 |

| | | | | | |
|------------|-----------|-----------|-----------------------|---|---------------------------|
| 4 | 2-July-99 | 3-July-99 | 1, 2, 3 - Estimate | 4 | 3-July-99 to 7-July-99 |
| | | | 4, 5, 6 - Download | | |
| Etc. to 20 | | | | | |

Notice the following:

- You still have 20 service cycles even though you only read the meters every other month. Why? Because billing uses the scheduled read date on the service cycle to know when to look for a reading. If it can't find a reading on this date, billing estimates consumption (given estimation is allowed on the service agreement). Without a service cycle schedule, billing wouldn't know when to look for readings.
- Every other month you download half the routes in each cycle and estimate consumption for the other half.
- If you don't download all routes when a service cycle is scheduled, you have to indicate how to handle every route in the cycle.

The above design is infinitely flexible. You can use it to handle any number of requirements:

- Estimate consumption every seventh month.
- Bill every month, but only read once a quarter.
- Etc.

Designing Cycles for Waste Collection Services

The topics in this section describe how to design service cycles to support your waste collection requirements.

A Description Of The Cyclical Waste Collection Process

Waste collection equipment (e.g., garbage trucks) travel from service point to service point using a predefined schedule. This schedule defines which groups of service points are collected by a given truck on a given day (we use the term "route" to define a group of service points that are collected by a given truck on a given day).

Waste service points tend to belong to multiple routes because they can be collected in a different order depending on a wide variety of factors:

- A service point may have one truck responsible for collecting recycling and a different truck responsible for collecting non-recyclable waste.
- A service point that is collected on Mondays, Wednesdays and Fridays may be on a different route on each day of the week.
- Etc.

Note:

Contrary to metered service points, the service schedules linked to your waste collection service cycles / route groups do not affect billing. Why? Because billing doesn't need to look for a read for these types of service points and therefore it doesn't need a schedule to know when to look for a read.

Bill Cycles

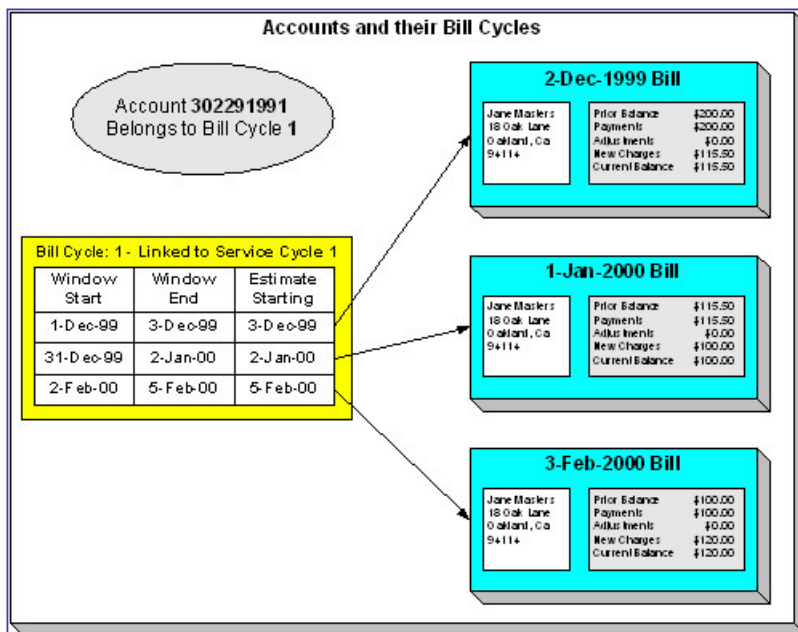

The topics in this section provide background information about a variety of bill cycle features.

The Cyclical Billing Process & Window Billing

The cyclical bill creation process creates most bills. This process works as follows:

- Every account references a bill cycle. The bill cycle's schedule controls WHEN the system attempts to create bills for the account.
- Every bill cycle has a bill cycle schedule that defines the dates when a cycle's accounts are to be billed. Rather than attempt to create bills on one evening, most bill cycles use a concept of "window billing" where the system attempts to produce bills for accounts over a few nights. The first night (i.e., the day the window opens) should be the earliest day on which meter reads for the account can enter the system. The last night (i.e., the day the window closes) should be the last possible day in which a meter read can enter the system. This concept of window billing allows you to start billing accounts on the earliest possible day and then bill the stragglers over successive evenings. This results in much better cash flow.
- When the bill cycle creation process runs, it looks for bill cycles with open bill windows. It then attempts to create bills for the accounts in each such cycle. If a bill is created, it will send it out that evening. If a bill cannot be created, the system will create a bill in the "error" state with a message that can be analyzed by your billing staff. The next day, your staff can either correct the problem or not. When the bill cycle creation process next runs, it deletes all "error" bills and attempts to recreate them. It continues this throughout the bill window. If bills are in error at the end of the window, they will remain in this state until a user fixes them. If the bills are still in error when the cycle's next window opens, a billing error will be generated.

The following diagram should help clarify the above.

Fastpath:

For more information about the how to control when bills are produced for a cycle, refer to [Bill Cycle - Bill Cycle Schedule](#).

Designing Your Bill Cycle

The number of bill cycles is determined by the frequency that you bill your customers. So, for example, if you bill every month, you'll have 20 bill cycles - one for each bill day during the month. If you bill bimonthly, you'll have 40 bill cycles. If you bill quarterly, you'll have 60 bill cycles. Etc.

Keep in mind the following:

- You may need additional bill cycles if you allow customers to be billed off-cycle. For example, you could create a bill cycle called "Seniors" and link this to every senior citizen. You would set up this bill cycle's schedule to create bills shortly after social security checks are issued.
- You may need other bill cycles for customers with non-metered services (e.g., land leases, one time invoices).

**Important:**

An account's bill cycle should attempt to create bill segments at least as often as the shortest service agreement duration. For example, if an account has both monthly and quarterly service agreements, the account should be placed on a monthly bill cycle. Refer to [Bill Frequency - Bill Cycle vs Bill Segment Duration](#) for more information.

The Relationship Between Metered Service Cycles and Bill Cycles

As you can deduce, a service point's service cycle is related to an account's bill cycle.

The following table is an example of how you would set up the various dates on the various schedules that control meter reading and billing.

| Service Cycle | Download Date | Sched MR Date | Bill Cycle | Bill Window | Estimation Date |
|---------------|---------------|---------------|------------|-----------------------|-----------------|
| 1 | 28-May-99 | 31-May-99 | 1 | 31-May-99 to 2-Jun-99 | 2-Jun-99 |
| 2 | 31-May-99 | 1-Jun-99 | 2 | 1-Jun-99 to 3-Jun-99 | 3-Jun-99 |
| 3 | 1-Jun-99 | 2-Jun-99 | 3 | 2-Jun-99 to 4-Jun-99 | 4-Jun-99 |
| 4 | 2-Jun-99 | 3-Jun-99 | 4 | 3-Jun-99 to 7-Jun-99 | 7-Jun-99 |
| Etc. | | | | | |

Notice the following about this example:

- The bill cycle code is the same as the meter read (MR) cycle. This is not necessary, it's just good practice.
- The bill window starts on the first date on which a meter read could be uploaded.
- The bill window ends on the day after the last possible day a read could be uploaded for the bill cycle.
- Billing is only allowed to estimate consumption on the last day of the bill window.

**Fastpath:**

For more information about the bill cycle schedule, refer to [Bill Cycle - Bill Cycle Schedule](#). For more information about the service cycle schedule, refer to [Setting Up Service Cycle Schedules](#).

How Does An Account Get Its Bill Cycle?

Most accounts are created behind-the-scenes when a user uses the "add account" option on [Person - Main Information](#). An account created like this doesn't have a bill cycle. Rather, it sits in limbo awaiting the activation of its first service agreement. When a service agreement is activated, the system populates the account's bill cycle using the following algorithm:

- If an account's bill cycle is protected, the activation of a service agreement will not affect an account's bill cycle. Refer to [Protecting An Account's Bill Cycle](#) for more information.
- If the service agreement being activated is for metered service, the account is given a bill cycle that will generate bills shortly after the service point is read. The route the system follows to get this bill cycle is a bit indirect:
 - A metered service agreement references one or more metered service points.

- Every metered service point references a service cycle (the service cycle controls when the meter at the service point is read).
- Every service cycle references a default bill cycle. It is this bill cycle that is populated on the account paying for service at the service point.
- If the service agreement being activated is not metered, the system cannot populate the account's bill cycle because there is no service cycle from which to default the bill cycle. This means the account's bill cycle will be blank until a user specifies a bill cycle for the account (using the Account page).

Note:

A To Do entry highlights accounts without a bill cycle. A To Do entry highlights those accounts that require a user to specify a bill cycle. This entry is generated for accounts without a bill cycle that have active service agreements.

When the last service agreement linked to an account is stopped, the account's bill cycle will be changed so that the account will be final billed when billing next executes. Refer to [What Happens At Finalization Time?](#) for more information.

When a service point's service cycle is updated, and the account's bill cycle is not protected, the system automatically updates the account's bill cycle to be in sync with the service cycle. Note that this will only take place if the Allow Bill Cycle Synchronization **Option Type** on the General System Options [Feature Configuration](#) is set to Y.

Protecting An Account's Bill Cycle

Over time, as a customer moves from premise to premise, their bill cycle is changed behind-the-scenes to be in sync with the latest service point's service cycle (as described in the previous section). If you do not want the system to change an account's bill cycle when a metered service agreement is activated, you need to turn on the account's **protect bill cycle** flag. You would do this if a customer liked to be billed at the start of the month regardless of when their meter was read.

When the last service agreement for an account is stopped, the protect bill cycle flag is reset. This is to ensure that if the customer returns to start new service again, the bill cycle can be set based on [How Does An Account Get Its Bill Cycle](#).

What Happens If An Account Has Service Agreements Spanning Metered Service Cycles?

A single account can have service agreements that are in several service cycles. The bill cycle on such an account will default based on the last activated metered service agreement.

It's important to be aware that an account will only have bills created when its bill cycle schedule so indicates. This means that the consumption for some service points could remain unbilled for a few weeks.

Designing Bill Periods

Bill periods are used by non-metered service agreements whose bill end dates need to fall on strict dates. You need only set up this information if you have this type of service agreement.

Fastpath:

Refer to [Ways To Control The End Date Of A Bill Segment](#) for more information.

Every bill period has a calendar that defines when bill segments are created for service agreements that use the bill period. Examples of bill periods include:

- Quarterly Bill - Last Day Of Quarter
- Quarterly Future Bill - Last Day Of Quarter
- Monthly - 15th Day Of Month.
- Monthly Future Bill - Last Day Of Month.

The Quarterly Bill - Last Day Of Quarter bill period would have a schedule that looked as follows:

| Earliest Date On Which To Create A Bill Segment | Bill End Date |
|---|---------------|
| 1-Oct-1998 | 30-Sep-1998 |
| 1-Jan-1999 | 31-Dec-1998 |
| 1-Apr-1999 | 31-Mar-1999 |
| 1-Jul-1999 | 30-Jun-1999 |
| ... | |

The Quarterly Future Bill - Last Day Of Quarter bill period would have a schedule that looked as follows:

| Earliest Date On Which To Create A Bill Segment | Bill End Date |
|---|---------------|
| 15-Dec-1998 | 31-Mar-1999 |
| 15-Mar-1999 | 30-Jun-1999 |
| ... | |

The remainder of this section provides examples using the above calendars.

The following example assumes the following:

- The service agreement starts on 18-Dec-1998.
- The service agreement's SA type references the Quarterly Future Bill - Last Day Of Quarter bill period.

The following table shows when bill segments will be produced (assuming the account's bill cycle attempt to create segments as soon as possible) for several bill periods:

| Earliest Date Segment Will Be Produced | Bill Period |
|--|------------------------------|
| 18-Dec-1998 | 18-Dec-1998 thru 31-Mar-1999 |
| 15-Mar-1999 | 1-Apr-1999 thru 30-Jun-1999 |
| ... | |

The following example assumes the following:

- The service agreement starts on 18-Dec-1998.
- The service agreement's SA type references the Quarterly Bill - Last Day Of Quarter bill period.

The following table shows when bill segments will be produced (assuming the account's bill cycle attempts to create segments as soon as possible) for several bill periods:

| Earliest Date Segment Will Be Produced | Bill Period |
|--|------------------------------|
| 1-Jan-1999 | 18-Dec-1998 thru 31-Dec-1998 |
| 1-Apr-1999 | 1-Jan-1999 thru 31-Mar-1999 |

...

Fastpath:

Refer to [Setting Up Bill Periods](#) for information about how to define this information.

Setting Up Bill Cycles

An account references a bill cycle. The bill cycle defines when the account is billed and when the account's debt is checked to determine if it's overdue. To define a bill cycle and its bill cycle schedule, open **Admin > Billing > Bill Cycle > Add**.

Description of Page

Enter a unique **Bill Cycle** and **Description** for every bill cycle.

If your implementation requires restricting bill cycles to accounts by CIS Division, specify a **CIS Division** on the bill cycle.

Use the **Bill Cycle Schedule** collection to define when bills are produced for the accounts in a given bill cycle. The following fields are required for each instance:

Window Start Date Specify the date on which the system should start trying to create bills for accounts in the cycle.

Window End Date Specify the last day on which the system will create bills for accounts in the cycle. This should be the last possible date on which a meter read could be loaded into the system for the account.

Accounting Date Specify the financial date associated with the bills' financial transaction. The accounting date defines the financial period(s) to which the bills will be booked in your general ledger.

Estimate Date The date on which the system is allowed to start estimating consumption if a real read cannot be found. Leave this date blank to inhibit consumption estimation. When specified, this date is typically on or shortly before the window end date.

The system will only estimate a service agreement's consumption if: 1) the bill cycle schedule allows estimation, and 2) the service agreement allows estimation.

Freeze and Complete Turn on this switch if the system should freeze and complete any bill that is created without errors. If this switch is turned off, all bills created by the billing process will be left in the unfinished state. You would only turn this switch off if you want to verify an entire bill run prior to freezing it (e.g., if you are introducing a new version of a rate). If you turn this off, you will need to return to this page after verifying a bill run and turn it back on for the customers to receive bills. When the system next runs, it deletes all unfrozen bills and recreates them as per the instructions on the bill cycle schedule.

The batch bill creation process uses this schedule to define the bill cycles for which it should create bills.

Note:

Don't forget. After you set up the bill cycles that correspond with service cycles, go to [Setting Up Service Cycle Schedules](#) and update the service cycles accordingly.

Setting Up Service Route Types

Every route within a service cycle references a route type. The route type controls:

- The batch process used to download and upload a route's meter reads.
- Whether a route is downloaded as part of the service cycle schedule download process.

Open **Admin > Consumption > Service Route Type > Add** to define your route types.

Description of Page

The following fields display:

Route Type The unique identifier of the route type.

Description The description of the route type.

Batch Control This defines the batch process used to download the meter reads for routes of this type. If you have multiple meter reading device formats you will have multiple batch processes - one for each format.

Process Routes In Cycle Turn this switch on if routes of this type have their meter reads downloaded when their service cycle is downloaded. This switch will be on for most types of routes. A classic example of a type of route where this switch is off would be a route containing translators (a translator sends in reads when it is polled).

Setting Up Service Cycles And Routes

When you set up a metered service point you must define its service cycle, route and sequence within the route. To define a service cycle and its routes, open **Admin > Service Cycle > Add**.

Note:

Every service cycle has a calendar that defines when the service points in the cycle are read. For more information about this calendar, see [Setting Up Service Cycle Schedules](#).

Description of Page

Enter a unique **Read Cycle** and **Description** for the service cycle.

Enter the **Bill Cycle** to populate on accounts with service points in this service cycle. The system updates an account's bill cycle when a service agreement is activated (assuming the account's bill cycle is not protected). Refer to [How Does An Account Get Its Bill Cycle?](#) for more information.

If the service cycle is associated with a **Service Provider** (rather than your own company's), define the owner of the cycle. Refer to [MDMAs And Service Cycles](#) for more information about service providers and their service cycles.

Use the **Service Routes** collection to define the routes within a given service cycle. The following fields display for each service route:

Service Route The unique identifier of the route within the cycle (you can use the same route ID in many cycles).

Description The route's description.

Route Type The type of route. This controls if and how the route's meter reads are downloaded. Refer to [Setting Up Service Route Types](#) for more information.

Characteristics

The **Characteristics** collection contains information that describes miscellaneous information about the service route.

The following fields display:

Effective Date Indicate the effective date for this characteristic.

Characteristic Type Controls the order in which characteristics of the same type are displayed.

Characteristic Value Indicate the value of the characteristic.

Setting Up Service Cycle Schedules

The service cycle schedule defines when the service points in a given cycle are scheduled to be read. Open **Admin > Consumption > Service Schedule > Search** to maintain this information.

Fastpath:

Refer to [Designing Cycles for Metered Services](#) for more information about service cycle. Refer to [The Relationship Between Metered Service Cycles and Bill Cycles](#) for more information about how service cycles are linked to bill cycles.

Description of Page

When you want to add a new service cycle schedule, you must specify the following information:

Service Cycle Enter the service cycle ID of the cycle whose routes will be downloaded.

Scheduled Selection Date Specify the date on which the system is meant to download information about the cycle's meters. This date should be a day or two before the scheduled work date.

Define the date the meters in the route are scheduled to be read using **Scheduled Work Date**. This date is extremely important as billing uses it when it looks for meter reads for service points in this cycle. If billing can't find a reading, consumption will be estimated as of this date (assuming the service agreement allows estimation).

Click **Pre-Generate Routes** if you need to finesse the cycle's routes on this Scheduled Selection Date (e.g., because some of the routes shouldn't be downloaded on a given date because the system is meant to estimate consumption). If you don't click this button, the system will create the routes on the scheduled selection date. It does this by creating a route extract for each downloadable route within the cycle (as defined by the route type). If you click this button, the system shows all routes within the cycle in the grid below. You must then define how the system is supposed to download each route on the scheduled selection date.

Click **Delete Routes** if you have pre-generated the routes and you want to remove them and allow the system to create the routes on the scheduled selection date.

Use the **Service Schedule Routes** to define how individual routes within the cycle should be handled during the download. The following fields are required for each schedule read date:

Service Route The unique ID of the service route. The route's route type is displayed adjacent.

Schedule Type This defines if and how the system is supposed to download the route's meter reads. Valid values are: Cust Read, Download, Estimate. Only those routes defined as Download will have meter reads downloaded. The other values are used to document why the route won't be downloaded.

Schedule Status This defines the download status of the route. Valid values are Pending and Complete. This value is only displayed for routes with a schedule type of Download.

Where Used

This information is used by the meter read download process to determine which meter reads to download.

This information is used by the billing process to determine the date on which it expects to find a read. If it cannot find a read on or around this date, and it's OK to estimate consumption, consumption will be estimated as of the scheduled work date. The system uses the service agreement's rate schedule's frequency to determine the period of time around the scheduled work date in which it looks for a read. Refer to [Defining Frequency Codes](#) for more information.

Setting Up Bill Periods

Some SA types reference a bill period. The bill period defines when the service agreement's bill segments are produced and the respective end date of each bill segment.

Fastpath:

Refer to [Designing Bill Periods](#) for more information.

To define a bill period and the bill period schedule, open **Admin > Billing > Bill Period > Add**.

Description of Page

Enter a unique **Bill Period** and a **Description** for every bill period.

Use the **Bill Period Schedules** collection when the system should create bill segments for service agreements that use a given bill period. It also defines the end date of each respective bill segment. The following fields are required:

Bill Date Specify the earliest date on which the system is allowed to create a bill segment for service agreements using this bill period.

Bill Seg End Date Specify the end date of the bill segment. For future bills, this will be after the bill date. For retro bills, this will be before the bill date.

This information is used by the bill segment creation process to determine the end date of service agreements that use a bill period.

Defining Statement Cycles

If you have persons set up in the system to receive statements with financial information, you will need to assign them to a statement cycle and define a schedule for the statement cycle.

Fastpath:

Refer to [The Big Picture of Complex Statements](#) for more information about statements.

The Big Picture Of Statement Cycles

A statement cycle has a similar purpose to that of a bill cycle. It controls when statements will be produced.

The Cyclical Statement Process

Persons who wish to receive statements will work with you to determine how often these statements should be produced. Some persons may want a monthly statement, some a quarterly and some annually. For each unique schedule that is designed for your various statement persons, you will set up a Statement Cycle and its schedule.

Designing Your Statement Cycles

The number of statement cycles is determined by a combination of the frequency that you will send statements to the statement persons and how many statement cycles you wish to manage within the same frequency.

So, for example, for all the statement persons who wish to receive a monthly statement, will you create only one monthly Statement Cycle so that all monthly statements are produced the same day? Or will you have several monthly statement cycles scheduled throughout the month? The answer will depend on the volume of statements being produced and on how you want to manage the statement production.

Lifecycle of a Statement Cycle Schedule

Pending The statement cycle schedule is added in this state. The Create Statements background process find records in this state to process on the appropriate date.

Fastpath:

Refer to [Create Statements Background Process](#) for more information.

In Progress Records in this state are currently being processed by the Create Statements background process.

Completed Records in this state have already been processed by the Create Statements background process. If a problem occurs with the Create Statements background process and it needs to be rerun, simply change the status back to pending and rerun the process.

Setting Up Statement Cycles

A Statement Construct references a statement cycle. The statement cycle defines when the statement person will receive statements with financial information related to the accounts and service agreements linked to the statement construct. To define a statement cycle and its statement cycle schedule, open **Admin > Billing > Statement Cycle > Add**.

Description of Page

Enter a unique **Statement Cycle** and **Description** for every statement cycle.

Use the **Statement Cycle Schedule** collection to define when statements are produced for the persons with statement construct records in the given statement cycle. The following fields are required for each instance:

Processing Date Specify the date on which the system should create statements for persons with statement construct records in the cycle.

Status Indicates the status of the cycle schedule. Refer to [Lifecycle of a Statement Cycle Schedule](#) for more information.

The batch statement creation process uses this schedule to determine which statement cycles for it should create statements for the statement construct records. Refer to [Create Statements Background Process](#) for more information.

Defining Service Agreement Type (SA Types)

Every service agreement must reference a SA type. The SA type defines what you sell, how much you sell it for, to whom you sell it, how overdue debt is collected, and how sales will be booked in your general ledger.

Note:

Perfect foresight. In a perfect world, the other control tables would have been set up with perfect foresight of setting up your SA types. In reality, setting up your SA types may invalidate some of your earlier decisions. Don't feel bad if this happens, some amount of iteration is natural.

Designing SA Types For Service Agreements With Service Points

Designing your SA types is an iterative process. To minimize some iterations, we recommend using the steps outlined in this section to complete the following table. When the table is complete, you're ready to set up your SA types.

| Division/SA Type | Service Type |
|------------------|--------------|
| | |

The topics in this section provide guidelines describing how to fill in this table for SA types associated with service agreements that charge for service point-oriented services.

CIS Division Segmentation

A CIS division is typically associated with a jurisdiction. The definition of a jurisdiction is a geographic-oriented entity with unique business rules. For example, if you conduct business in California and Nevada, and each state has different collection rules, you will need a separate jurisdiction for each state. You must set up a CIS division for each jurisdiction in which you conduct business.

If we assume that you are located in a single jurisdiction - say California - we will need a single CIS division for all of our SA types.

| |
|----------------------|
| CIS Division/SA Type |
|----------------------|

| |
|----|
| CA |
|----|

Service Segmentation

At a minimum, you will have one SA type for every different type of utility service offered by your organization. If we assume you sell electricity, gas, water, wastewater and cable; your SA Types will be as follows:

| CIS Division/SA Type | Service Type |
|----------------------|---------------------|
| CA/G | Gas service |
| CA/W | Water service |
| CA/E | Electric service |
| CA/WW | Waste water service |
| CA/CABLE | Cable |

Note:

Non Utility Services. Earlier in this manual, service types are discussed in respect of meters and items. However, you may require additional service types if you have non-utility services. In the above table, we have only shown utility oriented services and their respective CIS Divisions. Later in this section, we will encounter a few more service types. Refer to [Setting Up Service Types](#) for more information.

Receivable Segmentation

Many organizations segregate their receivable balances in the general ledger. For example, the receivable amount associated with gas and water service may be maintained in separate GL accounts.

If your organization does this, you will probably have at least one SA type for each such receivable account because each SA type references a distribution code that typically contains the receivable account.

- The word *probably* is underlined because this is a rule of thumb. There are situations where the number of receivable accounts isn't directly related to the number of SA types. This happens when an organization maintains very detailed receivable accounts in the general ledger and maintaining a one-to-one relationship between SA types and distribution codes would lead to a massive proliferation of SA types (and you don't want this!). If your organization maintains very detailed receivable accounts, please speak to your implementers, they should be able to introduce a small customization to generate the appropriate receivable account rather than extract it from the distribution code.
- The word *typically* is underlined because there are several SA types that don't book to a receivable account when bill segments are generated. For example, company usage and charitable contributions. Refer to [Company Usage Segmentation](#) and [Charitable Contribution Segmentation](#) for examples of SA types that don't book to receivable accounts.

We'll simplify our example and assume your organization has one receivable account for all types of utility service. Given this, we won't need additional SA types to support receivable segmentation:

| CIS Division/ SA Type | Service Type | Distribution Code |
|--------------------------|---------------------|-------------------|
| CA/G | Gas service | A/R-UTIL |
| CA/W | Water service | A/R-UTIL |
| CA/E | Electric service | A/R-UTIL |
| CA/WW | Waste water service | A/R-UTIL |
| CA/CABLE | Cable service | A/R-UTIL |

Revenue Segmentation

Look at your rates and determine which rates can be used by each SA type. The following table shows the sample rates that can be used for each service:

| CIS Division/ SA Type | Service Type | Distribution Code | Rates |
|--------------------------|---------------------|-------------------|---|
| CA/G | Gas service | A/R-UTIL | GALL-1 |
| CA/W | Water service | A/R-UTIL | WALL-1 |
| CA/E | Electric service | A/R-UTIL | ERES-1, ERES-2, ECOM-1, EIND-1, ELAMP-1 |
| CA/WW | Waste water service | A/R-UTIL | WWALL-1 |
| CA/CABLE | Cable service | A/R-UTIL | CABLE |

Now, look at the rates' calculation rule GL Distribution window. You're looking for calculation rules whose GL distribution is affected by revenue class. If there are no revenue classes referenced on the calculation rules, this means that the revenue associated with the rate will be booked to a single GL account regardless of the type of customer. If you see revenue classes, this means that the revenue account associated with the calculation rule(s) differs depending on the SA type's revenue class. If revenue classes are used in the rates, you must create a different SA Type for every revenue class.

Let's assume the following:

- The gas rate (GALL-1) references the RESIDENTIAL, COMMERCIAL and INDUSTRIAL revenue classes in order to differentiate revenue based on the type of customer.
- None of the other rates differentiate revenue based on customer class.

Our SA types will now look as follows:

| CIS Division/ SA Type | Service Type | Distribution Code | Revenue Class | Rates |
|--------------------------|--------------|-------------------|-----------------|--------|
| CA/G-RES | Gas service | A/R-UTIL | R - residential | GALL-1 |

| | | | | |
|-----------------|---------------------|----------|----------------|---|
| CA/G-COM | Gas service | A/R-UTIL | C - commercial | GALL-1 |
| CA/G-IND | Gas service | A/R-UTIL | I - industrial | GALL-1 |
| CA/W | Water service | A/R-UTIL | N/A | WALL-1 |
| CA/E | Electric service | A/R-UTIL | N/A | ERES-1, ERES-2, ECOM-1, EIND-1, ELAMP-1 |
| CA/WW | Waste water service | A/R-UTIL | N/A | WWALL-1 |
| CA/CABLE | Cable service | A/R-UTIL | N/A | CABLE |

Notice that we created new SA types for gas in order to specify the respective revenue class. We didn't do this for the other services because it isn't necessary. However, you should feel free to do this if it feels right or if you need it for reporting purposes. For example, if you want to report on all *residential* service agreements, but you differentiate only gas by residential versus commercial, you'll be in trouble.

Rate Segmentation

Every SA Type whose service agreements have their charges calculated with a rate must have one or more rates linked to it. These define which rates can be linked to the SA type's service agreements. If different service agreements have different valid rate combinations, you will need to split the SA types accordingly.

For example, look at the electric rates. If we assume:

- the RES rates can only be used for residential customer,
- the IND rates can only be used for industrial customers,
- the COM rates can only be used for commercial customers,
- the LAMP rates can only be used for lamp customers

Then you might want to set up a new SA type to indicate such. The advantage of doing this is that you get more control over which rates can be used on a given SA type. The disadvantage is that you proliferate SA types. Unfortunately, it's really a question of taste.

| CIS Division/ SA Type | Service Type | Distribution Code | Revenue Class | Rates |
|--------------------------|------------------|-------------------|-----------------|----------------|
| CA/G-RES | Gas service | A/R-UTIL | R - residential | GALL-1 |
| CA/G-COM | Gas service | A/R-UTIL | C - commercial | GALL-1 |
| CA/G-IND | Gas service | A/R-UTIL | I - industrial | GALL-1 |
| CA/W | Water service | A/R-UTIL | N/A | WALL-1 |
| CA/E-RES | Electric service | A/R-UTIL | N/A | ERES-1, ERES-2 |
| CA/E-COM | Electric service | A/R-UTIL | N/A | ECOM-1 |
| CA/E-IND | Electric service | A/R-UTIL | N/A | EIND-1 |
| CA/LAMP | Electric service | A/R-UTIL | N/A | ELAMP-1 |

| | | | | |
|----------|---------------------|----------|-----|---------|
| CA/WW | Waste water service | A/R-UTIL | N/A | WWALL-1 |
| CA/CABLE | Cable service | A/R-UTIL | N/A | CABLE |

**Warning:**

Don't be too specific in your analysis in respect of rate segmentation because you could end up with a separate SA type for every rate (and you don't want this). We understand this is a very subjective warning, but we recommend that you start out with broad bands of rates that can be used on a SA type and narrow it down if you end up unhappy with the results. For example, you don't have to set up a separate SA type for low-income residential gas customers just because they have a special rate. Rather, you can leave your SA types as they are and treat low-income gas customers as a subset of your residential gas customers. **For more information,** refer to [Setting Up Start Options](#).

**Note:**

Rate override. If a service agreement of this type may be linked to a terms of service record, you must also consider whether or not the [rate schedule could be overridden](#) by a template SA linked to the terms of service record. Refer to [SA Type - Rate](#) for information about the possible values for this field.

Service Point (SP) Type Segmentation

Every SA Type whose service agreements exist to bill for service point-oriented service has one or more SP types. These define which type of service points can be linked to the SA type's service agreements. If different service agreements have different valid SP types, you will need to split the SA types accordingly.

For each service point-oriented SA type, determine if there are any restrictions in respect of the types of service points that can use the SA type's rates. For example, if we assume that only commercial SP types can be used by commercial customers, industrial SP types by industrial customers, residential SP types by residential customers, your SA types will be:

| CIS Division/ SA Type | Service Type | Distribution Code | Revenue Class | Rates | SP Type |
|--------------------------|-----------------------|-------------------|-----------------|----------------|-------------------|
| CA/G-RES | Gas service | A/R-UTIL | R - residential | GALL-1 | G-RES |
| CA/G-COM | Gas service | A/R-UTIL | C - commercial | GALL-1 | G-COM |
| CA/G-IND | Gas service | A/R-UTIL | I - industrial | GALL-1 | G-IND |
| CA/W-RES | Water service | A/R-UTIL | N/A | WALL-1 | W-RES |
| CA/W-COM | Water service | A/R-UTIL | N/A | WALL-1 | W-COM |
| CA/W-IND | Water service | A/R-UTIL | N/A | WALL-1 | W-IND |
| CA/E-RES | Electric service | A/R-UTIL | N/A | ERES-1, ERES-2 | E-RES |
| CA/E-COM | Electric service | A/R-UTIL | N/A | ECOM-1 | E-COM |
| CA/E-IND | Electric service | A/R-UTIL | N/A | EIND-1 | E-IND |
| CA/WW-RES | Wastewater service | A/R-UTIL | N/A | WWALL-1 | W-RES, WW- RES |

| | | | | | |
|------------------|--------------------|----------|-----|---------|---------------|
| CA/WW-COM | Wastewater service | A/R-UTIL | N/A | WWALL-1 | W-COM, WW-COM |
| CA/WW-IND | Wastewater service | A/R-UTIL | N/A | WWALL-1 | W-IND, WW-IND |
| CA/CABLE | Cable service | A/R-UTIL | N/A | CABLE | CABLE |

Notice the wastewater SA types reference both water and waste water service points. This is intentional as wastewater service uses the consumption from the water service to calculate some part of the wastewater charge.

Company Usage Segmentation

Up to now, we've discussed SA types associated with service agreements linked to your customers. The system has also been designed to keep track of the expenses associated with your company's use of power. If you want the system to do this, you must create at least one SA type for each service consumed by your organization.

For example, if we assume your organization consumes electric, gas, and water service; your SA types will now be as follows:

| CIS Division/ SA Type | Service Type | Distribution Code | Revenue Class | Rates | SP Type | Bill Seg Type |
|--------------------------|--------------------|----------------------|-----------------|-------------------|---------------|---------------|
| CA/G-RES | Gas service | A/R-UTIL | R - residential | GALL-1 | G-RES | SP-RATED |
| CA/G-COM | Gas service | A/R-UTIL | C - commercial | GALL-1 | G-COM | SP-RATED |
| CA/G-IND | Gas service | A/R-UTIL | I - industrial | GALL-1 | G-IND | SP-RATED |
| CA/W-RES | Water service | A/R-UTIL | N/A | WALL-1 | W-RES | SP-RATED |
| CA/W-COM | Water service | A/R-UTIL | N/A | WALL-1 | W-COM | SP-RATED |
| CA/W-IND | Water service | A/R-UTIL | N/A | WALL-1 | W-IND | SP-RATED |
| CA/E-RES | Electric service | A/R-UTIL | N/A | ERES-1, ERES-2 | E-RES | SP-RATED |
| CA/E-COM | Electric service | A/R-UTIL | N/A | ECOM-1 | E-COM | SP-RATED |
| CA/E-IND | Electric service | A/R-UTIL | N/A | EIND-1 | E-IND | SP-RATED |
| CA/WW-RES | Wastewater service | A/R-UTIL | N/A | WWALL-1 | W-RES, WW-RES | SP-RATED |
| CA/WW-COM | Wastewater service | A/R-UTIL | N/A | WWALL-1 | W-COM, WW-COM | SP-RATED |
| CA/WW-IND | Wastewater service | A/R-UTIL | N/A | WWALL-1 | W-IND, WW-IND | SP-RATED |

| | | | | | | |
|-----------------|------------------|----------|-----|----------|----------|----------|
| CA/CABLE | Cable service | A/R-UTIL | N/A | CABLE | CABLE | SP-RATED |
| CA/E-COY | Electric service | EXP-COMP | N/A | E CO USE | E-CO USE | COMPUSAG |
| CA/G-COY | Gas service | EXP-COMP | N/A | G CO USE | G-CO USE | COMPUSAG |
| CA/W-COY | Water service | EXP-COMP | N/A | W CO USE | W-CO USE | COMPUSAG |

Notice the three company usage SA types do not reference an A/R account as their distribution code. This is because when bill segments are created for these types of service agreements, the system must debit an expense account (or contra-revenue account) rather than a receivable account.

Also notice we introduced a new column - Bill Segment Type. Notice that the customer-oriented SA types use the SP-RATED bill segment type and the company usage SA types use the COMPUSAG bill segment type. Different bill segment types are necessary because company usage SA types use a different algorithm to calculate their bill segment's financial transaction algorithm because they don't affect either payoff or current balance.

Fastpath:

For more information, refer to [Designing and Defining Bill Segment Types](#).

Debt Class Segmentation

Every SA Type has a debt class. The debt class is used to categorize a service agreement's debt for the purpose of credit and collections (C&C) analysis. If a given SA Type has different categories of debt from C&C's perspective, you will have to split the SA Type.

Fastpath:

For more information about debt class, refer to [Designing Your Collection Procedures](#).

If we assume that your residential services are regulated and your commercial and industrial services are deregulated, we won't have to introduce additional SA types.

| CIS Division/ SA Type | Distribution Code | Revenue Class | Rates | SP Type | Bill Seg Type | Debt Class |
|--------------------------|----------------------|-------------------|-------------------|---------|---------------|------------|
| CA/G-RES | A/R-UTIL | R - residential | GALL-1 | G-RES | SP-RATED | REGU |
| CA/G-COM | A/R-UTIL | C - commercial | GALL-1 | G-COM | SP-RATED | UNRE |
| CA/G-IND | A/R-UTIL | I - industrial | GALL-1 | G-IND | SP-RATED | UNRE |
| CA/W-RES | A/R-UTIL | N/A | WALL-1 | W-RES | SP-RATED | REGU |
| CA/W-COM | A/R-UTIL | N/A | WALL-1 | W-COM | SP-RATED | UNRE |
| CA/W-IND | A/R-UTIL | N/A | WALL-1 | W-IND | SP-RATED | UNRE |
| CA/E-RES | A/R-UTIL | N/A | ERES-1, ERES-2 | E-RES | SP-RATED | REGU |
| CA/E-COM | A/R-UTIL | N/A | ECOM-1 | E-COM | SP-RATED | UNRE |
| CA/E-IND | A/R-UTIL | N/A | EIND-1 | E-IND | SP-RATED | UNRE |

| | | | | | | |
|-----------|----------|-----|----------|---------------|----------|---------|
| CA/WW-RES | A/R-UTIL | N/A | WWALL-1 | W-RES, WW-RES | SP-RATED | REGU |
| CA/WW-COM | A/R-UTIL | N/A | WWALL-1 | W-COM, WW-COM | SP-RATED | UNRE |
| CA/WW-IND | A/R-UTIL | N/A | WWALL-1 | W-IND, WW-IND | SP-RATED | UNRE |
| CA/CABLE | A/R-UTIL | N/A | CABLE | CABLE | SP-RATED | UNRE |
| CA/E-COY | EXP-COMP | N/A | E CO USE | E-CO USE | COMPUSAG | No debt |
| CA/G-COY | EXP-COMP | N/A | G CO USE | G-CO USE | COMPUSAG | No debt |
| CA/W-COY | EXP-COMP | N/A | W CO USE | W-CO USE | COMPUSAG | No debt |

Notice the three company usage SA types do not have a debt class. This is because their bill segment type's FT algorithm doesn't cause debt to be created and therefore there is no reason to have a debt class. However, you'll need to create a "dummy" debt class - call it N/A - for these SA types because every SA type must reference a debt class.

Budget Billing Segmentation

Many utilities offer their customers levelized payment plans to smooth out the seasonal bill variations. We call this levelized amount the *budget amount*.

Fastpath:

Refer to [Budget Billing](#) for more information about budgets in general. Refer to [Billing - Current Balance versus Payoff Balance](#) for an example of budget billing accounting.

If we assume that you only allow budget billing on the electric and gas residential services, then you'll need to update your CA/G-RES and CA/E-RES SA types:

| CIS Division/ SA Type | Dist Code | Rev Class | Rates | SP Type | Bill Seg Type | Debt Class | Recurring Charge Control Info |
|--------------------------|-----------|-----------|--------|---------|---------------|------------|---|
| CA/G-RES | A/R-UTIL | R | GALL-1 | G-RES | SP-RATED | REGU | Amount to bill is Not Allowed Amount is Optional Frequency is Monthly Recurring Amount Label is Budget Amount: |
| CA/G-COM | A/R-UTIL | C | GALL-1 | G-COM | SP-RATED | UNRE | |

| | | | | | | | |
|------------------|----------|-----|-------------------|------------------|----------|---------|---|
| CA/G-IND | A/R-UTIL | I | GALL-1 | G-IND | SP-RATED | UNRE | |
| CA/W-RES | A/R-UTIL | N/A | WALL-1 | W-RES | SP-RATED | REGU | |
| CA/W-COM | A/R-UTIL | N/A | WALL-1 | W-COM | SP-RATED | UNRE | |
| CA/W-IND | A/R-UTIL | N/A | WALL-1 | W-IND | SP-RATED | UNRE | |
| CA/E-RES | A/R-UTIL | N/A | ERES-1, ERES-2 | E-RES | SP-RATED | REGU | Amount to bill is Not Allowed Amount is Optional Frequency is Monthly Recurring Amount Label is Budget Amount: |
| CA/E-COM | A/R-UTIL | N/A | ECOM-1 | E-COM | SP-RATED | UNRE | |
| CA/E-IND | A/R-UTIL | N/A | EIND-1 | E-IND | SP-RATED | UNRE | |
| CA/WW-RES | A/R-UTIL | N/A | WWALL-1 | W-RES, WW-RES | SP-RATED | REGU | |
| CA/WW-COM | A/R-UTIL | N/A | WWALL-1 | W-COM, WW-COM | SP-RATED | UNRE | |
| CA/WW-IND | A/R-UTIL | N/A | WWALL-1 | W-IND, WW-IND | SP-RATED | UNRE | |
| CA/CABLE | A/R-UTIL | N/A | CABLE | CABLE | SP-RATED | UNRE | |
| CA/E-COY | EXP-COMP | N/A | E CO USE | E-CO USE | COMPUSAG | No debt | |
| CA/G-COY | EXP-COMP | N/A | G CO USE | G-CO USE | COMPUSAG | No debt | |
| CA/W-COY | EXP-COMP | N/A | W CO USE | W-CO USE | COMPUSAG | No debt | |

Notice the following:

- We updated the two SA types to allow recurring charge information.
- The Recurring Charge Amount is Optional. Why? Because those customers who aren't on a budget plan won't have a recurring charge amount. Those customers on a budget will have a recurring charge amount.

Note:

Turn on Eligible for Budget. Besides indicating that these SA types use recurring charges, you also need to turn on the Eligible for Budget switch on the SA type to indicate that this type of SA participates in budget processing.

Override Budget Eligibility. You may plug in an override budget eligibility algorithm on an SA type that is configured to be Eligible for Budget if certain service agreements of this type are not eligible.

Fastpath:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes.

Designing SA Types For SAs Without Service Points

The topics in this section provide guidelines describing how to design the SA types associated with your service agreements that don't have service points.

Overpayment Segmentation

When a customer pays more than they owe, you must decide what to do with the excess money. The following points describe two possibilities:

- You could create a new service agreement to hold the excess (let's call it an overpayment SA). The credit would be transferred from this service agreement to the billable service agreements when the next bill is completed. This means that all billable service agreements have the same opportunity to receive the overpayment when they are billed in the future.
- You could amalgamate the excess payment on one of the existing, billable service agreements. For example, if a customer has both electric and gas service, the excess funds could be kept on either the gas or the electric SA. This would result in the following:
 - The service agreements that do NOT receive the overpayment will have debt when they are next billed.
 - The service agreement that receives the overpayment could have its future debt offset by the overpayment (meaning that it could have a credit balance until the service agreement's future bill segments offset the overpayment amount).
- The above situation is not desirable unless the customer intentionally overpaid one service agreement. The first method (keeping the overpayment on a separate service agreement) obviates this potential problem. Obviously, if your organization sells a single service (and therefore your customers have a single service agreement) you would choose the second method.

You control which method is used by plugging in the appropriate Overpayment Distribution algorithm on each [Customer Class](#) (i.e., you can choose a different method for different customer classes). If you choose to hold overpayments on a separate SA, then you must set up an SA Type as described in the following table:

| CIS Division/ SA Type | Service Type | Distrib. Code | Eligible for Billing | Debt Class | Pay Seg Type | Do Not Overpay | One-time |
|-----------------------|--------------|---------------|----------------------|------------|--------------|----------------|----------|
| CA/ OVERPAY | Other | A/P - OVER | Not billed | N/A | Normal | No | Yes |

Notice the following about the new overpayment SA type:

- It has an interesting distribution code. This is because when a payment segment is created for this type of service agreements, the system must credit a liability (an overpayment is a liability).
- It's important to indicate that the overpayment SA is a one-time service agreement. Why? Because this means that the system will automatically close the SA when it's balance falls to zero (i.e., when all of the overpayment has been used to satisfy future bills).
- A bill segment type is not needed because the system never creates bill segments for such service agreements (they exist only to hold excess credits).
- You may also want to turn on the alert message

- You must plug-in a bill completion algorithm on this SA type. This bill completion algorithm will transfer the credit balance to the account's other service agreements when the bill is completed. Refer to The Credit Transfer Algorithm for more information about this algorithm.
- You must also reference this overpayment SA type as the parameter value on your overpayment algorithm (this algorithm is plugged in on the desired customer classes). Refer to Overpayment Algorithm for more information about this algorithm.

Note:

If overpayment means charitable contribution. Some organizations sponsor a program that works as follows - if a customer overpays a bill by a given amount (say \$5), this amount is assumed to be a charitable contribution. If you have this requirement, you will create another SA type to hold a customer's charitable contributions. This SA type will look similar to the one described below (see [Charitable Contribution Segmentation](#)) except it is not billable. The funds will be credited to this service agreement by creating a new overpayment algorithm that is similar to the base package Overpayment Algorithm. This new algorithm will be very similar to the existing algorithm. The main difference will be that it will have to check if the overpayment amount is an exact value (say \$5). If so, it will create a payment segment for the charitable contribution SA type; otherwise it will create a payment segment for the overpayment SA.

Write Off Segmentation

When you write off non-collectable debt, you transfer the receivable from a "normal" service agreement onto one or more write-off service agreements. When the debt is transferred to a write-off service agreement, the distribution code on the "normal" service agreement is credited (typically an A/R GL account), and the distribution code on the write-off service agreement is debited.

You will almost always need a write-off service agreement whose distribution code is the write-off expense. However, you probably don't book all of the write-off amount to a write-off expense account. Why? Because the debt that you're writing off typically contains both revenue and liabilities. At write-off time, you want to book the written off revenue to a write-off expense account and you want to reduce the liabilities (you don't owe the liability if you don't get paid). This means you'll need another SA type for the liabilities. Refer to [The Ramifications of Write Offs in the General Ledger](#) for a complete explanation.

The following table contains the minimum number of SA Types that you'll need to hold your write-offs.

| CIS Division/ SA Type | Service Type | Distrib. Code | Bill Seg Type | Debt Class | Pay Seg Type | Do Not Overpay |
|--------------------------|--------------|---------------|---------------|------------|--------------|-------------------|
| CA/WO-STD | Other | EXP-W/O | Not billed | WO | Normal | Yes |
| CA/WO-LIA | Other | LIA-General | Not billed | WO | Normal | Yes |

Notice the following about the new write-off SA types:

- They have interesting distribution codes. This is because when debt is transferred to these types of service agreements, the system must debit either an expense account (i.e., write-off expense) or a liability account. It's important to note that in [The Ramifications of Write Offs in the General Ledger](#) we explain how this liability account may be overwritten with the liability account that was originally booked.
- Neither needs a bill segment type because the system never creates bill segments for such service agreements (they exist only to hold uncollectable debt)
- Even though the debt is not collectable, it still has a debt class. Why? Because the system shows a customer's debt on many inquiries by debt class and it's important to show write-off debt on these queries.
- The combination of Payment Segment Type and Do Not Overpay are important. Refer to [The Ramifications of Write Offs in the General Ledger](#) for a complete explanation.

Note:

The adjustment type used to set the offending service agreement's current balance equal to its payoff balance is defined on each write-offable SA type. The adjustment type used to transfer the delinquent debt to the write-off service agreement is defined on the write-off SA type.

An Alternative. If you have a limited number of liability accounts, you may decide to have a separate write-off service agreement for each liability account. Doing this would proliferate the number of service agreements created at write-off time. However, it would simplify the remittance of payment to the taxing authority if the reversed liability is ever paid.

Connection Charge Segmentation

If you levy connection charges, you have two options:

- You can create a SA type that exists purely to handle connect charge debt. After doing this, you'd create a start option for this SA type that causes an adjustment to be levied as part of the start service process. This adjustment would contain your standard connection charge. This approach would be used by a utility that had multiple services (e.g., a combined electric, gas, water utility) that only levies a single connection charge regardless of the number of services started. If you use this approach, make sure to indicate the SA type is non billable.
- You can levy a start adjustment on one of your existing SA types (e.g., CA/E-RES). The easiest way to do this is with a start option. On the start option you'd indicate an adjustment to be levied as part of the start service process. This adjustment would contain your standard connection charge. This approach would be used by a utility that had a single service offering (e.g., an electric-only utility). Refer to [Setting Up Start Options](#) for more information.

In the table below, we show what would be necessary if you want to have a separate service agreement for the connection charge.

| CIS Division/ SA Type | Service Type | Distrib. Code | Bill Seg Type | Debt Class |
|--------------------------|--------------|---------------|---------------|------------|
| CA/CONNECT | Other | A/R-UTIL | Not billed | REGU |

Notice the following about the new connection charge SA type:

- It has a normal receivable distribution code.
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (its charged via an adjustment).
- The debt class is interesting - REGU (for regulated). We are intentionally linking the connection charge debt to the same debt class as the regulated debt from which it originates. This way, the C&C process will consider the connection charge debt the same as regulated debt and therefore perform the regulated collection (which results in the severance of all regulated service agreements).

Charitable Contribution Segmentation

If your organization accepts charitable contributions made by your customers, you must create a SA type to hold these contributions.

| CIS Division/ SA Type | Service Type | Distrib. Code | Debt Class | Bill Seg Type | Recurring Charge Control Info |
|--------------------------|--------------|---------------|------------|---------------|----------------------------------|
|--------------------------|--------------|---------------|------------|---------------|----------------------------------|

| | | | | | |
|------------|-------|----------|------|-------|---|
| CA/CHARITY | Other | A/P-CHAR | CHAR | RECUR | Amount to bill is Not Allowed |
| | | | | | Amount is Required |
| | | | | | Frequency is Monthly |
| | | | | | Recurring Amount Label is Contrib. Amount |

Notice the following about the new charitable contribution SA type:

- It has an interesting distribution code. This is because when a payment is distributed to these types of service agreements, the system must credit a payable account (i.e., charitable contribution payable) rather than a receivable account. Note well, we have assumed a receivable is not incurred when the bill segment for the charitable contribution is created.
- It uses an interesting bill segment type - RECUR. This bill segment type was set up to create recurring charges that don't automatically stop at some point in time.
- The debt class is interesting - CHAR (for charity). This is done so that past due charitable contribution debt is treated separately from other types of debt.
- The recurring charge control information is set up as defined.

Fastpath:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Warning:

It's important that you assign the charitable contribution SA type with a payment segment type that only affect current balance (as opposed to affecting current AND payoff balance). This is because there is no receivable recognized when the contribution is billed and therefore there is no payoff balance to relieve when it's paid.

Payment Arrangement Segmentation

If your organization allows customers to payoff outstanding debt using payment arrangements (e.g., current bill plus \$X), you will need a new SA type for every debt class that can have a payment arrangement. If we assume you can have payment arrangements for both regulated and unregulated debt, then you'll need at least two more SA types (you may have more SA types if you need to segregate the payment arrangement receivable amount by utility type (or some other type)).

| | | | | | |
|--------------------------|--------------|---------------|------------|---------------|-------------------------------|
| CIS Division/ SA Type | Service Type | Distrib. Code | Debt Class | Bill Seg Type | Recurring Charge Control Info |
|--------------------------|--------------|---------------|------------|---------------|-------------------------------|

| | | | | | |
|-------------------|-------|----------|------|----------|---|
| CA/PA-REGU | Other | A/R-ARRG | REGU | RECUR-AS | Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Arrange Amount |
| CA/PA-UNRE | Other | A/R-ARRG | UNRE | RECUR-AS | Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Arrange Amount |

Notice the following about the new payment arrangement SA types:

- They have an interesting distribution code. This is because when funds are transferred to these types of service agreements, the system must debit a receivable (i.e., payment arrangement receivable).
- They use an interesting bill segment type - RECUR-AS. This bill segment type was set up to create recurring charges that stop when the customer no longer has a payoff balance.
- Each new SA type references the debt class whose debt it will pay off. We are intentionally linking the payment arrangement debt to the same debt class as the regulated debt from which it originates. This way, the C&C process will consider the arrangement debt as the same as regulated debt and therefore perform the regulated collection (which results in the severance of all regulated service agreements).
- The recurring charge control information is set up as defined.

Fastpath:

Refer to the Description of Page under [SA Type - Billing](#) for the definition of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use Start Options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Merchandise Segmentation - Installment Billing

If your organization allows customers to purchase merchandise using an installment plan, you must create a SA type for this.

Note:

No installments. If the customer must pay for the merchandise in one lump amount, you'd create an SA type similar to the [Connection Charge Segmentation](#) example.

| | | | | | |
|--------------------------|--------------|------------------|------------|---------------|----------------------------------|
| CIS Division/ SA Type | Service Type | Distrib. Code | Debt Class | Bill Seg Type | Recurring Charge Control Info |
|--------------------------|--------------|------------------|------------|---------------|----------------------------------|

| | | | | | |
|------------|-------|----------|------|----------|---|
| CA/MERCH-I | Merch | A/R-MRCH | UNRE | RECUR-AS | Amount to bill is Not Allowed Amount is Required Frequency is Monthly Recurring Amount Label is Install Amount |
|------------|-------|----------|------|----------|---|

Notice the following about the new merchandise SA type:

- It has a normal receivable distribution code.
- It uses an interesting bill segment type - RECUR-AS. This bill segment type was set up to create recurring charges that stop when the customer no longer has a payoff balance.
- The recurring charge control information is set up as defined.

Fastpath:

Refer to the Description of Page under [SA Type - Billing for the definition](#) of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for **how** you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started. Refer to [Start Option Considerations For SA Types That Use Initial Adjustments](#) for **how** you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Deposit Segmentation - Installment Billing

If your organization allows customers to pay deposits using an installment plan, you must create an SA type for this.

Note:

No installments. If the customer must pay for the deposit in one lump amount, you'd create an SA type similar to the [Connection Charge Segmentation](#) example. Just make sure the adjustment that's levied to charge for the deposit amount doesn't affect payoff balance (when you bill a deposit, the customer doesn't really owe anything because it's not a true receivable from an accountant's perspective).

| CIS Division/ SA Type | Service Type | Distrib. Code | Debt Class | Bill Seg Type | Recurring Charge Control Info |
|--------------------------|--------------|------------------|------------|---------------|--|
| CA/DEP-I | Other | A/P-DEPO | DEP | RECURATB | Amount to bill is Required Amount is Required Frequency is Monthly Recurring Amount Label is Install Amount |

Notice the following about the new deposit SA type:

- It has an interesting distribution code. This is because when a payment is distributed to these types of service agreements, the system must credit a payable account (i.e., deposit payable) rather than a receivable account. Note well, we have assumed a receivable is not incurred when the bill segment for the deposit is created.
- It uses an interesting bill segment type - RECURATB. This bill segment type was set up to create recurring charges that stop when the system has billed the Total Amount to Bill.
- The debt class is interesting - DEP (for deposit). This is done so that past due deposit "debt" is treated separately from other types of debt.
- The recurring charge control information is set up as defined. Note well, the Amount to bill is Required.

Fastpath:

Refer to the Description of Page under [SA Type - Billing for the definition](#) of the recurring charge attributes. Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for how you can use start options to automatically populate a service agreement's recurring charge fields with appropriate values when service is started.

Note:

Bill messages on receipt of deposit in full. The base package includes a special FT Freeze algorithm that can be specified on deposit SA Types. It recognizes when a deposit has been paid in full, and creates a bill messages to inform the customer. Refer to algorithm DEP PIF MSG in [Algorithm Types](#) for more information.

Billable Charge Segmentation

You create a billable charge whenever a customer should be charged for a service that occurs outside the normal course of business. For example, you would create a billable charge to charge a contractor for the repair of a ruptured gas line. You can also use billable charges to "pass through" other bill ready charges generated outside the system, by another application, or by a 3rd party supplier.

A billable charge must reference a service agreement. This service agreement behaves just like any other service agreement:

- **Bill segments are created for the service agreement.** Whenever billing is performed for an account with billable charge service agreements, the system creates a bill segment for each service agreement with unbilled charges. If multiple unbilled charges exist for a given service agreement, only one bill segment will be created and it will contain details about all of the billable charges.
- **Payments are distributed to the service agreement.** Payments made by an account are distributed to its billable charge service agreements just like any other service agreement.
- **Overdue debt is monitored.** The credit and collections process monitors billable charge service agreements for overdue debt and responds accordingly when overdue debt is detected.

Therefore, you must set up at least one SA type to hold your billable charge debt. You may have multiple charges based on billing frequencies, A/R booking, debt monitoring, etc. It's really up to you.

The easiest way to determine how many billable charge SA types you'll need is to define every conceivable billable charge (which you should have done when you designed your [billable charge templates](#)). Then ask yourself if they have the same billing and payment behavior, if so, you'll have one SA type. If not, you'll need one SA type for each combination.

We will assume your billable charges are all used to levy unusual one-off charges that can be collected in the same way, therefore we'll need one SA type.

| CIS Division/ SA Type | Service Type | Distrib Code | Debt Class | Bill Seg Type | Billable Charge Templates | Rate |
|--------------------------|--------------|--------------|------------|---------------|---------------------------------|------|
|--------------------------|--------------|--------------|------------|---------------|---------------------------------|------|

| | | | | | | |
|-------------------------|-------------|-----------|----------|----------|--------------------|-------|
| CA/ ONETIME | Other | A/R-UTIL | UNRE | BILLCHRG | TREETRIM DAMAGE | None |
| CA/ PASSTHRU | Electricity | A/R-OTHER | UNRE | BILLCHRG | None | None |
| CA/ADDON | Electricity | A/R-OTHER | EXTERNAL | BILLCHRG | None | TAXES |

Notice the following about the new one time SA type:

- It has a normal receivable distribution code.
- Its debt class is unregulated.
- It uses an interesting bill segment type - BILLCHRG. This bill segment type was set up to create bill segments using billable charges.
- It references the valid billable charge templates that can be used on this SA type.

Note:

One Time Charge. The ONE TIME example shown above implies this SA type exists to hold one-time charges. Because of this, you should turn on the One Time Charge switch on the SA type so that service agreement's of this type are automatically closed when final payment is received. You don't have to do this because a customer could have a single billable charge service agreement that is perpetually active for pass through charges (i.e., it doesn't have a stop date). If you do this, the system will create a bill segment for this service agreement whenever it finds an unbilled billable charge linked to the service agreement.

Notice the following about the pass through SA Type:

- It doesn't use the normal distribution code or debt class. This is done so that the debt and receivable can be tracked separately. If these charges were being pass through from another system, you might want to track these financial values separately.
- It still uses the normal bill segment type - BILLCHRG. From a billing perspective, there is no difference between this and the one time SA Type.
- Templates are not relevant - these charges are not created on-line using templates, but are loaded via the [Billable Charge Upload Staging](#).

Notice the following about the add on charges SA Type:

- This is an example of bill-ready charges (similar to pass through) to which the system adds on other charges, for example, taxes.
- It still uses the normal bill segment type - BILLCHRG. From a billing perspective, there is no difference between this and the one time SA Type.
- It also uses a Rate. In this case, the bill creation algorithm (specified on the bill segment type) will take any billable charge lines and attach them to a bill. In addition, these billable charges will include billable charge service quantities (SQs). These service quantities will also be swept onto the bill segment, and the Rate (TAXES in this example) will be applied. In order for taxes to be calculated, the billable charge SQs must include the total taxable amount - the system is not able to apply the rate on top of the other billable charges. But, it can apply the tax rate to the SQs that are supplied.
 - You can also use this technique to bill other rate-ready service quantities, like kWh, CCF, *etc.* This is a way to process rate-ready data for which you have a contract, but you do not know the meter (and therefore, cannot collect real meter reads).
 - If the rate has pre-processing calculation groups, these will be applied as well.

Fastpath:

For more information about billable charge templates, refer to [Setting Up Billable Charge Templates](#).

Over/Under Cash Drawer Segmentation

In order to balance a tender control that is out-of-balance, your organization must set up an account with a service agreement whose SA type references the over/under expense account. You will probably only have one service agreement that references this SA type, but you still must have it if you remit funds via a cash drawer.

Fastpath:

For more information about over/under processing, refer to [How To Get An Unbalanced Tender Control In Balance \(Fixing Over/Under\)](#).

| CIS Division/ SA Type | Service Type | Distrib. Code | Debt Class | Bill Seg Type |
|--------------------------|--------------|---------------|------------|---------------|
| CA/OVR UNDR | Other | EXP-OV/UND | N/A | Not billed |

Notice the following about the new SA type:

- It has an interesting distribution code. This is because when a payment segment is applied to this type of service agreement, the system must debit an expense account for under amounts (and credit it for over amounts).
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (it only has over/under payment segments linked to it).
- It uses the N/A debt class because the credit and collections process should never consider debt associated with service agreements of this type (because it's not really debt).

Payment Upload Error Segmentation

If the payment upload process detects an invalid account on a payment upload record, it will create a payment for the suspense service agreement defined on the upload process' tender source (see [Setting Up Tender Sources](#)). You should create a special SA type for this service agreement.

Fastpath:

For more information about the payment upload process, refer to [Phase 3 - Create Payment Events, Tenders, Payments, and Payment Segments](#).

| CIS Division/ SA Type | Service Type | Distrib. Code | Debt Class | Bill Seg Type |
|--------------------------|--------------|---------------|------------|---------------|
| CA/SUSPENSE | Other | EXP-MISC | N/A | Not billed |

Notice the following about the new SA type:

- It has an interesting distribution code. This code should probably be a suspense account. All payment segments that are created for this service agreement will eventually be transferred to a "real" service agreement and therefore this GL account's balance should be zero when no payments are in suspense.
- It doesn't need a bill segment type because the system never creates bill segments for such service agreements (it only has invalid account payment segments linked to it).
- It uses the N/A debt class because the credit and collections process should never consider debt associated with service agreements of this type (because it's not really debt).

CIAC Segmentation

If your company bills and refunds Contribution In Aid of Construction (CIAC) contracts, you must create one or more SA types. CIAC contracts are typically used to levy charges associated with line extensions. These types of service agreements are different from other service agreements because the initial amount charged is refunded to the original payee when new properties (or extensions) are added to the extension (or when the new properties are subsequently billed for service).

Note:

Billable charges are used for the original CIAC service agreement. CIAC SA types are always Billable Charge SA types because an operator must specify the exact amount to charge the contractor using a billable charge. Refer to [Billable Charge Segmentation](#) for more information.

The following points describe how CIAC processing is implemented in the system:

- When a new line extension is build, you will create a new service agreement that references your CIAC SA type. This service agreement should be linked to a service point associated with the extension. The easiest way to create this service agreement and link it to the service point is by using the Start Account transaction. It's important to remember to define your CIAC SA type as a valid SA type for the SP type used to represent the line extension.
- When a new premise / service point is built that "hangs" off the original extension, the new service point should be linked to the original service point. This can be done by referencing the original service point as the "parent" service point of the new service point using a [foreign key value characteristic](#).
- The system periodically monitors the original CIAC service agreement. The process that performs this monitoring is referenced on the original CIAC service agreement's SA type. The exact processing that takes place during this monitoring is up to your organization's specific business requirement. For example, if you refund 10% of every bill produced for the "downstream" service points to the original contractor, you would have logic in your CIAC monitoring process that looks for recent bill segments produced for the "downstream" service agreements and then creates an adjustment for the master service agreement.

Note:

CIAC refunds are idiosyncratic. Because CIAC refund processing is idiosyncratic, we do not supply any CIAC monitoring processes in the base package. This is because the likelihood that they could be used is extremely low because of your organization's unique requirements.

Therefore, if your organization performs CIAC processing, you should create a special SA type.

| CIS Division/ SA Type | Service Type | Distrib. Code | Debt Class | CIAC Process | Bill Seg Type |
|-----------------------|--------------|---------------|------------|---|-----------------|
| CA/CIAC | Other | A/R - CIAC | UNRE | Refund based on percent of future bills | Billable Charge |

Loan Segmentation

If you loan money to customers that is recouped using an amortization schedule, you need to set up an SA type for the loan service agreement.

| CIS Division/ SA Type | Service Type | Distrib. Code | Loan A/R Distrib. Code | Debt Class | Bill Seg Type |
|-----------------------|--------------|---------------|------------------------|------------|---------------|
| CA/LOAN | Other | A/R - LOAN | A/R - STLN | UNRE | LOAN |

Fastpath:

Refer to [Setting Up The System To Enable Loans](#) for more information.

Non-Billed Budget Segmentation

If you allow your customers to pay set amounts at specified intervals (e.g. every two weeks), you need to set up SA types for Non-Billed Budget service agreements. Non-billed budgets are typically used when your company bills

on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. You may implement two types of Non-Billed Budgets monitored and unmonitored, each type requiring a different SA type. You may also implement different renewal options for Non-Billed Budgets.

| CIS Division/ SA Type | Service Type | Distrib. Code | Non Billed Budget Monitoring | Debt Class | Renewal | Bill Seg Type |
|--------------------------|--------------|---------------|------------------------------------|------------|----------|---------------|
| CA/NBB- MON | Other | A/P - OVPY | Monitored | NBB | Optional | Not billed |
| CA/NBB- UNMON | Other | A/P - OVPY | Unmonitored | N/A | Optional | Not billed |

Fastpath:

For more information about monitored and unmonitored Non-Billed Budgets, refer to [Defining Non-Billed Budget Options](#).

Designing SA Type For Other Segmentations

The earlier parts of this discussion described the most common factors that cause the creation of SA Types. However, many obscure factors could cause the introduction of more SA Types. In this section, we explain these more obscure factors.

Warning:

We strongly recommend not being too pedantic when considering the factors described in this section. If you can only think of a few strange situations that would necessitate a SA type, think carefully before you introduce it. It's better to be a little less than perfect than end up with large number of obscure SA types.

Cash Distribution Segmentation

Every SA Type has a payment segment type. The payment segment type defines the cash account to which the SA type's payments should be booked. If different service agreements have different cash accounts, you will need to split the SA types accordingly.

Adjustment Profile Segmentation

Every SA Type has one or more adjustment profiles. These profiles define the valid adjustment types that can be booked to the SA type's service agreements. If different service agreements within an SA type have different mixtures of valid adjustment types, you must split the SA types accordingly.

Late Payment Charge Segmentation

An option exists on SA Type that causes the system to generate a late payment charge if payment is not received on time. If you don't levy late payment charges on all service agreements, you will need to determine when you do and design your SA types accordingly.

In addition, if you levy late payment charges, the percentage levied and the algorithm that defines the amount of the outstanding balance subject to the charge is defined on the SA type.

Debt Classification Segmentation

Every SA Type has a debt class. The debt class is used to categorize a service agreement's debt for the purpose of credit and collections (C&C) analysis. If a given SA Type has different categories of debt from C&C's perspective, you must split the SA Type.

Fastpath:

For more information about debt class, refer to [Designing Your Collection Procedures](#).

Note:

Write Off Debt Class vs. Normal Debt Class. An SA type references both write off debt class and normal debt class. An SA type's write-off debt class controls the write-off rules imposed on service agreements of a given type. An SA type's normal debt class controls the collection rules imposed on service agreements of a given type. Refer to [Different Collection Criteria For Different Customers And Different Debt](#) for more information about collection rules. Refer to [Different Write-Off Criteria For Different Customers And Different Debt](#) for more information about write-off rules.

Allow Estimates Segmentation

Every SA Type has a switch that controls whether the system estimates consumption if meter reads are missing at billing time. If a given SA Type has different situations when the system should and should not estimate, you will have to split the SA Type.

Note:

Override. You can override the value of the SA Type's estimation switch on an individual service agreement. This means that if only a few service agreements don't abide by the SA Type's estimation switch, you can change the switch value of these service agreements.

Fastpath:

For more information about estimation, refer to [Setting Up Consumption Estimation Parameters](#).

Severance Criteria Segmentation

Every SA Type has severance criteria. The severance criteria define the severance process used to sever service if the customer doesn't pay. You can have multiple severance processes if different conditions warrant a different process. For example, you may have a different severance process if the customer has life support.

If you have a SA Type that requires different severance conditions other than those currently supported, you can make a programmatic change to introduce the additional conditions OR you can split the SA Type.

Fastpath:

For more information about severance, refer to [Designing Your Severance Procedures](#).

Deposit Class Segmentation

Every SA Type that exists to hold a cash deposit will reference a deposit class. The deposit class defines the business rules that control various functions including interest calculation and refund criteria. You will need multiple deposit SA Types if any of the deposit class' rules / conditions differ for different types of deposits. For example, if residential customers use a different recommended deposit algorithm as compared to commercial customers, you'd need one SA type for residential deposits and another for commercial deposits (where the residential deposit SA type will reference the residential deposit class and the commercial deposit SA type will reference the commercial deposit class).

You will need additional deposit SA types if your customers can have multiple deposits where each deposit is restricted to a specific type of debt. For example, if separate deposits are held for regulated and unregulated debt (and a customer could hold a combination of regulated and unregulated debt), you'd need one SA type for regulated deposits and another for unregulated deposits.

**Fastpath:**

For more information about deposit class, refer to [Designing and Defining Deposit Classes](#).

Sub SA Types

If you operate in a deregulated environment AND if you provide billing services for other service providers, you will need to create SA types to handle the billing of the service providers' charges.

**Fastpath:**

Refer to [Designing Your SA Types And Start Options For Sub SAs](#) for more information.

Financial Settlement SA Types

If you operate in a deregulated environment, you may have to create financial settlement service agreements for the service providers. As explained in [Service Providers Have Service Agreements Too, We Bill For Them and They Bill For Us](#) service providers require a service agreement to hold adjustments used to increase how much you owe the service provider (or how much they owe you).

**Fastpath:**

Refer to [Designing SA Types For Service Provider Financial Settlements](#) for more information.

Interval Billing SA Types

If you have customers with interval meters, the SA types for these customers will require special setup.

**Fastpath:**

Refer to [Designing Your SA Interval Billing Options](#) for more information.

Usage Request SA Types

If your organization uses a meter data management system to store meter reading information and the mdm is responsible for calculating bill determinants during billing, the SA types for these customers will require special setup.

**Fastpath:**

For more information about usage requests, refer to [The Big Picture Of Usage Requests](#).

Initial Consumption Period Considerations

Bill segments produced for a service agreement have two time periods:

- The bill segment period. The bill segment period defines the entire period of time covered by a bill segment's charges.
- The consumption period. The consumption period defines the period of time used to calculate the number of days for daily charges.

The consumption period almost always starts one day after the bill segment period. The consumption period always ends on the bill segment's end date. For example, a bill segment period that spans 5-Jan-2002 through 6-Feb-2002 will almost always have a corresponding consumption period of 6-Jan-2002 through 6-Feb-2002. The reason that the start dates don't match is because a bill segment's start date equals the end date of the prior bill segment (i.e., the start date was already counted in the previous bill segment's consumption period and we don't want to count it twice).

The only time when the previous paragraph isn't true is the first bill segment that's produced for a new service agreement. This is because different utilities count the first day of a new service agreement differently than others.

Because of this, a flag exists on SA Type called **Initial Start Date Option**. This flag controls whether the service agreement's start date is included in the consumption period in a service agreement's first bill segment.

The following table describes the ramifications of the options you can set for this flag.

| Flag Value | Consumption Period Calculation | Use This Option When |
|----------------------------|--|--|
| Add 1 Day Always | The consumption period's start date is calculated by adding 1 day to the service agreement's start date. (The SA start date is never included in the consumption period for the first bill segment.) | You want the initial bill and all subsequent bills to have a consistently calculated consumption period (i.e., the consumption period for the first and all other bills is always one day less than the bill segment's period). |
| Add 1 Day for Back-to-back | <p>A back-to-back occurs when any service point for this service agreement was previously linked to a different service agreement that was stopped on the same date that the new service was started (i.e., there is no gap in the service).</p> <p>If a back-to-back is detected, the consumption period start date is calculated by adding 1 day to the SA start date.</p> <p>If no back-to-back is detected, the start date of the consumption period is the SA start date.</p> | You want to flexibly handle consumption period calculation. If you start customers on the same date as the stop date of the previous customer, billing does not include the SA start date in the consumption period. However, if you start a new customer one day (or more) after the stop date of the previous customer, billing includes the first day of the service agreement in the consumption period. |
| Include First Day | The start date of the consumption period is the service agreement start date. (The SA start date is always included in the consumption period.) | You want to always include the first day AND you will never encounter a back-to-back situation. |

The example below shows how the consumption period would be calculated with the various options for a customer who starts service on January 1.

| | First Bill | Second Bill | Third Bill |
|---|---|--|--|
| | Meter Read: Jan 31 | Meter Read: Feb 28 | Meter Read: Mar 31 |
| | Bill Segment Period: Jan 1 to Jan 31 | Bill Segment Period: Jan 31 to Feb 28 | Bill Segment Period: Feb 28 to Mar 31 |
| Consumption period using Add 1 Day Always | Jan 2 to Jan 31 (30 days) | Feb 1 to Feb 28 (28 days) | Mar 1 to March 31 (31 days) |
| Consumption period using Add 1 Day for Back-to-back when back-to-back is detected | Jan 2 to Jan 31 (30 days) | Feb 1 to Feb 28 (28 days) | Mar 1 to March 31 (31 days) |

| | | | |
|---|------------------------------------|---------------------------|-----------------------------|
| Consumption period using Add 1 Day for Back-to-back when back-to-back is NOT detected | Jan 1 to Jan 31 (31 days) | Feb 1 to Feb 28 (28 days) | Mar 1 to March 31 (31 days) |
| Consumption period using Include First Day | Jan 1 to Jan 31 (31 days) | Feb 1 to Feb 28 (28 days) | Mar 1 to March 31 (31 days) |

There may be SA types for which the value of this flag does not affect the consumption period calculation and still other SA types where this flag is never used. For example,

- For billable charge service agreements, the consumption period is equal to the start and end dates on the billable charge and therefore this flag is not applicable.
- A sub SA either inherits the consumption period from the master SA or it uses billable charges. As a result, billing does not use this flag.
- For some service agreements, the charges on the rate are not affected by the consumption period. For example, if you have a customer with a simple meter and a simple usage-based charge, billing calculates the amount of consumption between the start reading and end reading and applies the rate (i.e., the number of days in the consumption period doesn't impact the charges in some rates).
- Some service agreements are not billed, for example, [overpayment service agreements](#). For this type of service agreement and other types of service agreements that are not billed, this flag is not applicable. However, the system does not prevent a value from being entered in these cases to allow for an implementation process to use the flag if needed.

Setting this flag to an appropriate value is significant for certain types of service agreements.

- For services whose rate includes daily charges, the configuration of this flag may impact the first bill segment for the service agreement. For example, if the first bill period is October 1st through October 31st, do you consider consumption period to be 31 days or 30 days? How you want to bill the customer on the first bill determines how you set this flag.
- For interval billing service agreements, the interval usage recordings typically begin on the first day of service. If you add 1 to the start date, you miss billing for intervals on the first day. In this case, you should set the value to Add 1 Day for Back-to-back.

Fastpath:

Refer to [Determine the Consumption Period](#) for more information.

Processing Sequence Considerations

You may have customers with a complex collection of contracts such that the calculation for one bill segment relies on information calculated by another bill segment for the same account. For example, perhaps you need to process your bill segments as follows:

- Step 1: Calculate bill segments for all the account's "single site" service agreements (i.e., each service agreement related to a single premise)
- Step 2: Calculate the bill segment for additional charges for the "head office" service agreement where the charges are based on the aggregated consumption of all premises from all bill segments (calculated in the first step).

To create the "head office" bill segment for the account, you must control the order in which the system creates the bill segments for each service agreement.

The SA type allows you to indicate a billing processing sequence that controls the order in which the service agreements are processed. The processing sequence is optional and service agreements are processed in ascending order of their SA type's billing processing sequence. As a result, SA Types with a processing sequence of zero are processed first, then 1, then 2, etc.

Note:

If you have sub SAs linked to a master SA, the billing processing sequence is used first to order the creation of bill segments for the master SAs. If you populate a processing sequence on an SA type for a sub SA, it is used to control the order in which the sub SAs for a given master SA are processed relative to each other. Refer to [Designing Your SA Types And Start Options For Sub SAs](#) for more information.

The billing processing sequence also controls the order of service agreements in the following other processes:

- Execution of pre bill completion algorithms. The system processes each service agreement in the billing processing sequence order. Within each service agreement, the pre bill completion algorithms on its [SA type](#) are processed in the order of the algorithm's sequence.
- Execution of bill completion algorithms. The system processes each service agreement in the billing processing sequence order. Within each service agreement, the completion algorithms on its [SA type](#) are processed in the order of the algorithm's sequence.
- Interval Data Creation. For interval service agreements linked to interval profiles with profile creation algorithms defined, the system processes each service agreement in the processing sequence order. Within each service agreement, the [data creation algorithms](#) are processed in the order of the creation priority on the [profile type](#).

Designing Prepayment Billing Options

This section provides guidelines describing how to design service agreements that handle smart meter prepaid billing.

When a customer is subject to prepayment, normal cycle-based billing is not used to calculate the bill segments for their service. Rather, a prepay billing (PPB) process creates bill segments frequently (for example, daily) and periodically requests funds to maintain an adequate payoff balance. Bills will only be used to periodically inform the customer of the various financial transactions that have occurred since the last bill was produced.

Implementing prepayment billing requires the configuration of the following objects:

- SA Type
- Adjustment Types
- Bill Segment Type
- Service Task Type

These configuration tasks are described below.

Note: For additional information, see the detailed descriptions in the application for the C1-PrepayBillerTaskType and C1-PrepayBillerTask business objects.

SA Type for Prepay Billing

To configure a prepay billing SA Type, create a new SA type with the following attributes:

- Set the Special Role flag to **Bill Determinants Required**. The Prepay Option should be set to **Prepaid Smart Meter**.
- Specify the SA Creation system event with the algorithm CI_CREATEPPB to create the service agreement's prepay biller.
- Specify the Payment Freeze system event with the algorithm STPZ-RMVC to set current amount to zero on a payment.
- If required, specify the Bill Completion system event with an algorithm of the type C1-CREPPBBM to add a bill message that informs an end customer of their prepaid charges for the period. You may need to create an algorithm of this type if it does not exist in your system.
- **Eligible for Budget** should be set to false.
- Reference a new **Prepay Bill Segment Type**, which is described below.

The following adjustment types must also be defined on the prepay SA type:

- **Adjustment Type (Xfer)** specifies the type of adjustment used to transfer funds from the delinquent service agreements to the prepaid service agreement
- **Adjustment Type (Current=0)** specifies the type of adjustment used to set the prepaid current balance to zero after debt has been transferred

- **NSF Adjustment Type** specifies the type of adjustment used to levy an NSF charge. The NSF Adjustment Type is described in greater detail below.

The new SA types must be added to the data value mapping between CCB and MDM. This is to enable the synchronization of SAs of this type to MDM. The new CCB SA types can be mapped to existing US types in MDM. For additional information about this configuration, please see the integration documentation.

Adjustment Types for Prepay Billing

- **Funds Request Adjustment Type:** This adjustment type captures the type of adjustment used to request more prepaid funds. This adjustment type is specified on the prepaid biller task type. Specify the following algorithms on this adjustment type:
 - **Adj. Financial Algorithm** should reference the Adjustment FT creation algorithm ADJT-CA (Payoff=0/Current=Adj Amount (No GL)).
 - **Adjustment Freeze Algorithm** should reference an algorithm of the type C1-PPBADJFRZ (Set Prepaid Funds Request FT Details). You may need to create an algorithm of this type if it does not exist in your system.
- **NSF Adjustment Type:** For prepaid customers on autopay, when a user cancels an autopay tender the cancel reason must indicate that an NSF charge should be levied. The system invokes the NSF Charge algorithm specified on the tender's account's customer class which creates the NSF adjustment on the appropriate SA. The charge is levied using the NSF Adjustment Type specified on the SA's SA type. This adjustment type must reference the new adjustment freeze algorithm that will disable automatic payments on the PPB. This algorithm must be based on the algorithm type C1-DISPPBAP (Disable PPB's Automatic Payment). You may need to create an algorithm of this type if it does not exist in your system.

Bill Segment Type Required for Prepay Billing

Configure a new bill segment type for prepaid service agreements. This bill segment type should have the following attributes:

- **Create Algorithm** should be set to C1-BSBS-UR to create bill segment using a usage request.
- **Financial Algorithm** should be set to a new algorithm with algorithm type C1-NEM-GL (Payoff Amt = Bill Amt / Current Amt = 0 (GL affected)). You may need to create an algorithm of this type if it does not exist in your system.
- **Get Consumption Algorithm** should be set to C1-BSGC-USG to get bill segment consumption using a usage request.

Service Task Type for Prepay Billing

Configure a new service task type for prepay billing. This task type should reference the Prepay Biller (PPB) Task Type Business Object (C1-PrepayBillerTaskType). The task type must be specified on the new prepay billing SA creation algorithm. The task type captures the adjustment type used when an adjustment is created to request additional funds from the customer. Ensure that this adjustment type references the adjustment freeze algorithm (C1-PPBADJFRZ) that populates the financial transaction's arrears date.

SA Types And The Financial Design

In this section, we provide an example of how our SA Types map to Bill Segment Types, Payment Segment Types, and Adjustment Profiles. This example is meant to help solidify the power of the financial model, it is not necessarily indicative of how your specific implementation will look.

Warning:

If you are not comfortable with the topics described in [Defining Financial Transaction Options](#), the following table will not make sense.

| Division/SA Type | Distribution Code | Bill Segment Type | Payment Segment Type | Adjustment Profiles |
|------------------|-------------------|-------------------|----------------------|---------------------|
| | | | | |

| | | | | |
|-------------------|----------|----------|---------|---------------------------------|
| CA/G-RES | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES, BUDGET |
| CA/G-COM | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/G-IND | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/W-RES | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/W-COM | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/W-IND | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/E-RES | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES, BUDGET |
| CA/E-COM | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/E-IND | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/WW-RES | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/WW-COM | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/WW-IND | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/CABLE | A/R-UTIL | SP-RATED | NORMAL | BALXFER, MISCFEES |
| CA/E-COY | E-COMP | COMPUSAG | | |
| CA/G-COY | E-COMP | COMPUSAG | | |
| CA/W-COY | E-COMP | COMPUSAG | | |
| CA/WO-STD | | | NORMAL | BALXFER |
| CA/WO-LIA | | | NORMAL | BALXFER |
| CA/CONNECT | | | NORMAL | BALXFER, MISCFEES |
| CA/CHARITY | A/P-CHAR | RECUR | CHARITY | CHARITY |

| | | | | |
|-------------|------------|----------|--------|----------------------------------|
| CA/PA-REGU | A/R-ARRG | RECUR-AS | NORMAL | BALXFER, MISCFEES, DPA |
| CA/PA-UNRE | A/R-ARRG | RECUR-AS | NORMAL | BALXFER, MISCFEES, DPA |
| CA/MERCH-I | A/R-MRCH | RECUR-AS | NORMAL | BALXFER, MISCFEES, MERCH |
| CA/DEP-I | A/P-DEPO | RECUR-AS | NORMAL | BALXFER, MISCFEES, DEPOSIT |
| CA/ONETIME | A/R-UTIL | BILLCHRG | NORMAL | BALXFER, MISCFEES |
| CA/OVR UNDR | EXP-OV/UND | | NORMAL | |
| CA/OVERPAY | A/P-OVER | | NORMAL | BALXFER |
| CA/SUSPENSE | A/R-SUSP | | NORMAL | |
| CA/NBB | A/P-OVPY | | NORMAL | BALXFER, MISCFEES, NBB |

If you operate in a deregulated environment, you will also have additional SA types as described under [Designing Your SA Types And Start Options For Sub SAs](#) and [Designing SA Types For Service Provider Financial Settlements](#) you may have additional SA types.

Setting Up SA Types

In the previous section, Designing SA Types, we presented a case study that illustrated a mythical organization's SA types. In this section, we explain how to use the windows on the SA Type window group to maintain your SA Types.

Note:

When a new SA type is added. When you add a SA type whose service agreements use service points, you must update the respective SP types if the new SA type is defaulted when service is initially started at the service points of a given SP type. Refer to [SP Type - SA Type](#) for more information.

SA Type - Main Information

Open **Admin > Customer > SA Type > Add** to define core information about your SA Types.

Warning:

Every SA Type is owned by a CIS Division. This Division controls many values that can be referenced on the SA Type. If you don't understand Divisions and their place in the application, do NOT attempt to set up your SA Types. Rather, refer to [Setting Up CIS Divisions](#) on page 595 before proceeding.

Description of Page

Enter a unique combination of **CIS Division** and **SA Type** for every service agreement type.

Enter a **Description** for the SA type.

Service Type defines the type of service associated with the SA type. If the SA type has rates, only rates belonging to this service type may be linked to the SA type.

Fastpath:

For more information about service types, refer to [Setting Up Service Types](#).

Select the **Distribution Code** and **GL Division** that defines the receivable account for receivable-oriented service agreements. For non-receivable oriented service agreements, this distribution code is typically as follows:

- Charitable contributions. The distribution code is a charity payable account.
- Deposits. The distribution code is a deposit payable account.
- Non-Billed Budgets. The distribution code is an overpayment payable account.
- Company usage. The distribution code is a company usage expense account.
- Write off. The distribution code is a write-off expense account.
- Payment arrangements. The distribution code is a payment arrangement receivable account.

Fastpath:

For more information about GL accounts, refer to [The Source Of GL Accounts On Financial Transactions](#).

Select the **Revenue Class** associated with the SA Type (and its service agreements). The revenue class may affect the revenue account(s) generated by the service agreement's rate.

Fastpath:

Refer to [Designing Calculation Groups and Rules](#) for more information about revenue class.

Turn on **Start Options Required** if you want to force a customer service rep to choose a start option when they start service for this SA Type (on the Start Account window). If this switch is off and a rate is required for the SA Type, the system defaults the SA type's default rate on new service agreements. The default rate is defined on the SA Type - Rate page.

Fastpath:

Refer to [Setting Up Start Options](#) for more information about the pros and cons of requiring start options.

Select the **Pay Segment Type** that defines how payment segments linked to service agreements of this type affect:

- The service agreement's payoff and current balances

Fastpath:

For more information about payment segment types, refer to [Setting Up Payment Segment Types](#).

When a tender is canceled, a cancellation reason must be supplied. If the cancellation reason indicates a NSF (non sufficient funds) charge should be levied, the system invokes the Levy an NSF Charge algorithm specified on the tender's account's [customer class](#). Because adjustments must be linked to a service agreement, the algorithm must determine the appropriate service agreement to use to levy the adjustment based on business rules. The charge is levied using the **NSF Adjustment Type** of the appropriate service agreement's SA type.

Warning:

You must specify adjustment type profiles on the SA type (on the Adjustment Type window) before adjustment types will appear in the above drop downs.

Fastpath:

For more information about adjustment types, refer to [Setting Up Adjustment Types](#). For more information about cancellation reasons, refer to [Setting Up Payment Cancellation Reasons](#).

Select the **Payment Priority**. This field is available for use by the algorithms that distribute partial payments amongst an account's service agreements. Higher priority service agreements will have their debt relieved before lower priorities. Refer to Distribution Based on Payment Priority and Delinquent Payment Distribution Algorithm for information about payment distribution algorithms that use this field.

**Note:**

The values for this field are customizable using the Lookup table. This field name is PAY_PRIORITY_FLG.

**Fastpath:**

For more information about distribution priority, refer to [Distributing A Payment Amongst An Account's Service Agreements](#).

Select the **Delinquent Payment Priority**. This field is available for use by the algorithms that distribute partial payments amongst an account's service agreements. Higher priority service agreements will have their debt relieved before lower priorities. Refer to Delinquent Payment Distribution Algorithm for information about a payment distribution algorithm that uses this field.

**Note:**

The values for this field are customizable using the Lookup table. This field name is DEL_PRIORITY_FLG.

Turn on **Do Not Overpay** if the system is not allowed to distribute an overpayment to this type of service agreement (i.e., the service agreement is not allowed to have a system-created credit balance). This field is available for use by algorithms that distribute overpayments. Refer to Overpayments Held On Highest Priority Service Agreement for information about an overpayment algorithm that uses this field.

Turn on **Late Payment Charge** if the system should generate a late payment charge for this type of service agreement if payment is not received on time. If this is turned on, you must define the **LPC Calc. Algorithm** used to calculate the late payment charge amount. Refer to [Defining Late Payment Charge Options](#) for more information about late payment charges. Examples of algorithm types used for calculating late payment charges are BILPC-SPRC and BILPC-TOTAL.

Define the **Adjustment Type (Synch Curr)** that will be used to synchronize (make equal) the current amount with the payoff amount on a service agreement of this type. This type of processing happens as follows:

- Most [write-off](#) algorithms that perform financial efforts (e.g., writing off debt), will issue an adjustment of this type if the service agreement's current and payoff balances are not equal.
- If a user stops a customer on a [budget plan](#), the system issues adjustments of this type to synchronize the customer's current and payoff balances.
- If a user stops a service agreement covered by a [Non-Billed Budget](#), the system issues adjustments of this type to synchronize the customer's current and payoff balances.
- If a [cancellation of a bill segment](#) occurs after a customer has stopped participating in a budget plan, an adjustment of this type is issued to synchronize the imbalance created when the bill segment's financial transaction is canceled.

Turn on **CIAC SA Type** and specify an appropriate **CIAC Refund Process** if service agreements of this type are used to bill for Contribution In Aid of Construction (CIAC) charges. Refer to [CIAC Segmentation](#) for more information.

SA Type - Detail

Open **Admin > Customer > SA Type > Search** and navigate to the **Detail** page to define additional details about a given SA type.

Description of Page

Turn on **Display As Alert** if Control Central should display an alert if an account has a service agreement of this type that isn't Closed or Canceled. If this switch is on, also enter the **Alert Information** to appear on Control Central. We recommend only using this feature on unusual SA types (e.g., payment arrangements, write-offs) so that a CSR is not presented with an alert for every SA type.

If this SA Type is used for any of the **Special Roles**, defined in the dropdown, indicate which one. Valid values are: Billable Charge, Cash Deposit, Interval, Loan, Non-Billed Budget, Payment Arrangement, Write Off, Bill Determinants Required. This information is used on windows with functionality that can only be used by service agreements used for specific roles. For example, the Billable Charge window group can only reference Billable Charge service agreements.

If Special Role is Cash Deposit, you must define the **Deposit Class** of the deposit. You should also define a **Deposit Class** on every SA type to which a given deposit can be distributed.

Fastpath:

Refer to [What Do Deposit Classes Do?](#) for more information.

If the Special Role is Loan, you must also define the following fields:

- Use the **Interest Bill Factor** to define the bill factor code for the loan interest rate.
- Use **Override Interest** to indicate whether the interest rate defined on the interest bill factor may be overridden at the SA level. If you select Allowed, the interest rate may be overridden by a contract value on a start option or the SA.
- Use the **Loan A/R Distribution Code** to define the distribution code to be used when posting the short-term receivable amount to the general ledger (the normal distribution code is used for the long-term receivable). If the normal distribution code is the same as the **Loan A/R Distribution Code**, the SA type does not differentiate between long- and short-term receivables. If the two distribution codes are different, the SA type differentiates between long- and short-term receivables.

Fastpath:

Refer to [Defining Loan Options](#) for more information about **Interest Bill Factor**, **Override Interest** and **Loan A/R Distribution Code**.

If the Special Role is Non-Billed Budget , you must also define the following:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to the transfer accumulated credit from the Non-Billed Budget SA to the SAs covered by the Non-Billed Budget when the account is billed or the Non-Billed Budget SA is stopped.
- Use the **Non-Billed Budget Monitoring** to specify whether the Non-Billed Budget is monitored by the account debt monitor.

If the SA type is defined as Eligible for Non-billed Budget, you must also define the following:

- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the service agreement's current balance to zero when a service agreement of this type is linked to an active, monitored Non-Billed Budget.

If the Special Role is Payment Arrangement and you have not enabled Use Alternate PA Creation Logic, you must also define two adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the delinquent service agreements to the payment arrangement service agreement.
- Set **Use Alternate PA Creation Logic** if your payment arrangement SA Types share a debt class with other SA Types. When this is set, the current balance on the transfer adjustment on the payment arrangement SA is set to zero instead of using the below adjustment type to set the current balance to zero. When payment arrangements are in their own debt class, the additional credit adjustment offsets the transfer adjustment. This results in an offsetting credit and debit in the payment arrangement debt class and a single credit on the non-payment arrangement debt class. However, when a single debt class is used, the two credits inaccurately impact the way debt age (arrears) is calculated and presented. Using the alternate PA creation logic ensures that debt age is calculated and displayed accurately when a single debt class is used.
- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the payment arrangement's current balance to zero after funds have been transferred.

If the Special Role is Write Off, you must also define the following adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the uncollectable service agreements to the write off service agreement.

Note:

It may be important to your organization to track the original source of debt that is being written off. The system is delivered with three characteristic types: C1-WODST, C1-WOCHT, and C1-WOCHV that can record the distribution code, characteristic type and characteristic value from the FT GL(s) being written

off onto the write off adjustment. To enable this logic, specify these characteristic types as allowable characteristic types on your write off transfer adjustment type.

If the Prepay Option is **Prepaid Smart Meter**, you must also define two adjustment types:

- Use **Adjustment Type (Xfer)** to specify the type of adjustment used to transfer funds from the delinquent service agreements to the prepaid service agreement.
- Use **Adjustment Type (Current=0)** to specify the type of adjustment used to set the prepaid current balance to zero after debt has been transferred.

Warning:

You must specify adjustment type profiles on the SA type (on the Adjustment Type window) before adjustment types will appear in the above drop downs.

The **Stop Option** can be used to automatically stop a service agreement when all other service agreements of an account are stopped. Valid values are: Automatically Stop SA. When all service point related service agreements of an account are stopped then all additional service agreements where the **Stop Option** is set to Automatically Stop SA will also be stopped. This is useful, for example, with charitable contribution service agreements. The charity service agreement should be stopped when all utility related services are stopped.

Fastpath:

Refer to [The Lifecycle of a Service Agreement](#) for more information on the **Stop Option**.

Turn on **One Time Charge** if this SA type is used for one-time invoices. When a one-time invoice service agreement is created, the system sets the stop date of the SA to be equal to the start date.

Turn on **Sub SA** if this SA type is used to define the business rules for sub service agreements.

Fastpath:

Refer to [Sub Service Agreements](#) for more information about sub service agreements.

Renewal of SAs of this type may be Optional, Not Allowed or Required depending on your business processes. If renewal is not allowed, the SA expires on the expiration date. Renewal treatment is an important consideration for SAs that require an expiration date, such as [non-billed budget SAs](#).

If renewal is required or optional, specify the **Days Before Expiration for Renewal**. Note that currently this is only used by Non-Billed Budgets to calculate the renewal date based on the expiration date.

If the Special Role is Non-billed Budget, **Non-Billed Budget Monitoring** must indicate whether the Non-Billed Budget is monitored by the account debt monitor.

Fastpath:

Refer to [Credit and Collections and Non-Billed Budgets](#) for more information about monitoring Non-Billed Budgets.

Set **Eligible for Payment Arrangement** to Eligible if this SA type can be included in a payment arrangement.

Note: This is automatically set to Ineligible on SA types with a Special Role of Payment Arrangement.

Where Used

The alert information is used by Control Central to alert a CSR when unusual service agreements exist for an account. Refer to [Control Central - Search](#) for more information.

Only SA types designated as being Billable Charge may have billable charges linked to them. Refer to [Maintaining Billable Charges](#) for more information.

Only SA types designated as being Cash Deposit are processed by the various deposit-related background processes (e.g., interest calculation, automatic refund, etc.). Refer to [The Big Picture Of Deposits](#) for more information.

Only SA types designated as being Interval may define Contract Option Types, Profile Relationship Types and TOU Map Types. Refer to [Designing Your SA Interval Billing Options](#) for more information. This role also ensures that a

service agreement of this type defines the cutoff time and start day option required by billing. Refer to [Start and End Times for Billing](#) for more information.

Only SA types designated as Loan are used to define the loan terms for a loan SA. Refer to [Loans](#) for more information.

Only SA types designated as Non-billed Budget may be used to set up Non-Billed Budgets. Refer to [Non-Billed Budgets](#) for more information.

Only SA types designated as being Payment Arrangement may be used on the payment arrangement window group. Refer to [Setting Up Payment Arrangements](#) for more information.

Only SA types designated as being Write Off may be specified as the write off SA type on distribution codes. Refer to [Setting Up Distribution Codes](#) for more information.

Only service agreements whose SA type is designated as being Write Off appear on the Write Off SAs query. Refer to [Write Off - Write Off SAs](#) for more information.

SA Type - Billing

Open **Admin > Customer > SA Type > Search** and navigate to the **Billing** page to define how the system manages bill segments for service agreements of a given SA type.

Description of Page

Turn on **Eligible for Billing** if the system should create bill segments for service agreements of this type. This will typically be turned on for all service agreements except for those used to hold write-off amounts or to levy one-off adjustments.
