

Oracle Utilities Customer Care and Billing Cloud Service User Guides

Oracle Utilities Customer Care and Billing Cloud Service shares significant functionality with Oracle Utilities Customer Care and Billing. As such, both use the same user documentation. Oracle Utilities Customer Care and Billing Cloud Service User Guides comprise the following:

- Oracle Utilities Customer Care and Billing Business User Guide
- Oracle Utilities Customer Care and Billing Administrative User Guide

Release 24A

F92603-02

Business User Guide

Oracle Utilities Customer Care and Billing is a customer information system designed to meet the needs of electric, gas, and water utilities, and comprises of the following key functional areas:

- **Customer Information** - Create and maintain demographic, geographic, and contract information. Start and stop customer service. Capture customer interaction.
- **Sales and Marketing** - Create and maintain initiatives, marketing campaigns, and packages that can be offered to customers. Add eligibility criteria, as necessary, in order to target specific customer segments. Create and maintain leads and orders that can market and enroll eligible customers into initiatives and packages.
- **Device Management** - Create and maintain meter and item details including installation and removal information. Generate field work to initiate meter and item tests, and record their subsequent results.
- **Field Work** - Create and maintain field work requests. Dispatch field work to appropriate parties and record their outcome.
- **Meter Reading** - Generate and download meter read routes to meter readers. Upload meter read details and track of consumption trends to highlight anomalies.
- **Billing and Statements** - Create and maintain bills. Recalculate historical bills, as needed. Consolidate financial information from multiple accounts into a single statement.
- **Rates** - Configure and maintain rates that will be used to calculate charges that appear on bills.
- **Payments** - Post and maintain customer payments. Distribute payments based on balance-forward or open-item accounting practices. Manage automatic payments, as appropriate.
- **Credit and Collections** - Monitor customer debt. Create and maintain processes to encourage customers to pay overdue debt. Create and maintain payment arrangements and pay plans. Write-off debt, if necessary.

This documentation describes the features and functionality of the Oracle Utilities Customer Care and Billing system.

User Interface Standard Features

This section describes basic system concepts, features, and standards of the user interface.

Page Components

Oracle Utilities Application Framework screens are comprised of the following main areas:

1. The Application Toolbar
2. The Page Title Area
3. The Object Display Area
4. The Sidebar Area

| Keyboard Shortcuts | Description |
|--------------------|---|
| Alt+[| Moves the cursor focus to the next main page component based on the standard browser keyboard navigation "order". |
| Shift+Alt+[| Moves the cursor focus to the previous main page component based on the standard browser keyboard navigation "order". |

Note: The look and feel of the application may be modified after the product is installed. See [Custom Look and Feel Options](#) for customization information, including how to change colors, fonts, and other system features. The information provided in this document represents features and functionality available only in the delivered product.

The next topics provide more information about each component and the Script area, which appears in the Object Display area when applicable.

The Application Toolbar

This section describes the features available on the application toolbar.

Home Icon

Click the **Home** icon, , on the Application Toolbar to open your home page. Your home page is defined in [User Preferences](#).

| Keyboard Shortcut | Alternate Shortcut |
|-------------------|--------------------|
| Alt+O | Alt+Shift+O |

Note: Refer to [Shortcut Key Summary](#) for information about the alternate shortcut.

Menu

The Menu icon, , is available in the application toolbar to help you navigate to the different pages of the system. You only see the menu items that you have security access for.

Keyboard Shortcut

Ctrl+Alt+M

The menu list is organized by functional area. Clicking the Menu button displays each functional area. Clicking a functional area, in turn, displays a submenu that contains pages within that area.

The pages within each functional area *typically* have two options: Search and Add. If the menu item does not have an Add or Search option, select the menu item itself.

How the Search and Add option behaves depends upon whether the maintenance page is fixed or portal-based.

Fixed:

- **Search:** Displays a pop-up search window for the user to enter the search criteria and select the entity to display. Once the entity is selected, the user is taken to the maintenance map with the data populated in the fields.
- **Add:** Displays the maintenance page with empty fields so that the user can complete the information and save the entity.

Portal-Based:

- **Search:** Displays a search portal where the user can enter the search criteria and select the desired entity. Once the entity is selected, the user is typically taken to a maintenance portal or the information is broadcasted to other zones within the same portal.
- **Add:** Either navigates to a page where the user can select the entity type or business object, or directly to the input map where the user can enter and save the entity.

Users may also opt to use [Menu Item Search](#) to find a page.

Admin Menu

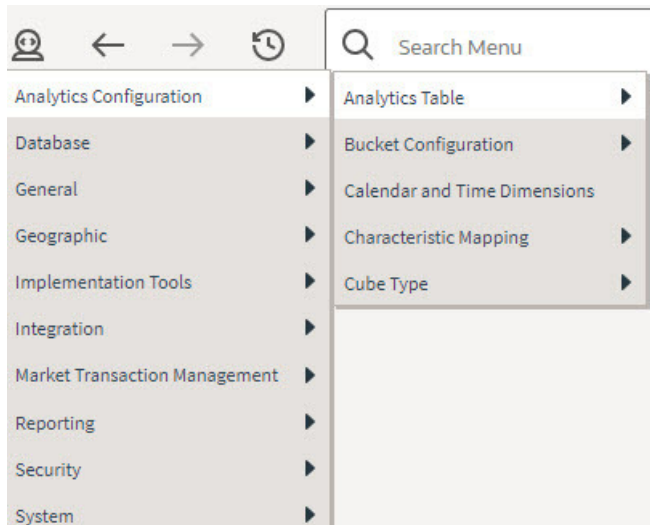

The Admin menu icon, , is available in the application toolbar to help you navigate to the different pages of the system. You only see the menu items that you have security access for. If you don't have security access to any of the entries in this menu, then the whole menu is suppressed.

Keyboard Shortcut

Ctrl+Alt+A

Depending on how your implementation has configured the Admin menu list, it may be organized either by functional area or alphabetically.

Clicking the Admin icon displays each functional area or alphabetical list. Clicking one of the options, in turn, displays a submenu that contains pages within that area. The following is an example of the Admin menu organized functionally.

Note: Menu navigation paths referenced in the administrative user guide provide the functional grouping. If your implementation uses the alphabetic grouping, the page can be found in the alphabetic letter that is the first letter of the page name.

Note: Refer to [Installation Options](#) for information about the admin menu configuration options.

The menu lines displayed for each menu entry *typically* have two options: Search and Add. If the menu item does not have an Add or Search option, select the menu item itself. See [Menu](#) for more information about these options.

Users may also opt to use the [Menu Item Search](#) to find a page.

Back and Forward Arrows

The back and forward arrows, , in the application toolbar allow you to navigate between the most recently viewed pages.

Back

Click the **Back** arrow to open the previously visited page.

| |
|--------------------------|
| Keyboard Shortcut |
| Alt+B |

Forward

Click the **Forward** arrow to return to the page that was most recently dismissed.

| |
|--------------------------|
| Keyboard Shortcut |
| Alt+G |

The **back** and **forward** arrows are enabled in the toolbar only when page use warrants their appearance.

Note: Under certain circumstances, such as revisiting a page that was left unsaved after being loaded with default data, a page may not appear as it did when you left it.

History Icon

Click the **History** icon, , to display a list of previously visited pages. When you click on an entry in the list to return to an earlier page, all items above the selected page are removed from the list.

The **back** and **forward** arrows, as well as the **History** list, appear in the application toolbar only when page use warrants their appearance.

Note that if the page has been configured to display an information string in the [page title area](#), that information will also be visible in the History dropdown.

| |
|--------------------------|
| Keyboard Shortcut |
| Ctrl+Alt+H |

Search

The toolbar Search field and search icon provide the ability to search for specific menu items or, depending on your product, certain business entities.

Menu Item Search

This search allows a user to enter the description of a menu item entry to navigate directly to the corresponding page or BPA script rather than using the menus to navigate to the desired page or script. If you start the search text with a slash "/", the search is confined to menu items. If you search for a menu item without a slash, the menu items are searched along with other unified search results.

| Keyboard Shortcut |
|-------------------|
| Ctrl+Alt+F |

Typing text in the field preceded by a slash shows menu items whose descriptions include the typed text.

- Bucket Configuration
- Add Bucket Configuration
- Feature Configuration
- Add Feature Configuration
- Master Configuration
- Maintenance Object Configuration
- Market Configuration

Note that only menu items within the [Menu](#) and [Admin Menu](#) that the user has security access for are included in the results. The text included in the search is taken from the menu item description. As described in [Menu](#), menu lines often have two sub item: Search and Add. In most instances, the description of the "Search" menu item is simply the menu entry text, for example **To Do Entry**. The description of the "Add" menu entry includes the word Add in front of the menu entry text, for example **Add To Do Entry**.

As mentioned in [Menu Item Suppression](#), menu items will not appear if it is associated with a module that is suppressed.

Note: When operating in debug mode, the description of the parent menu is displayed in parentheses after the menu item description.

Unified Search

If your product has implemented unified search, you may use the toolbar search box to search for business entities. The unified search feature is a simplified version of your product's main search that allows you to lookup up records using free form text without leaving your current page. For more complex queries, use the link provided as part of the search box to navigate to your product's advanced search portal.

 [Advanced Search](#)

The type of business entities you may query and the filters you may use depend on the specific unified search implementation of your product. For example, if your product supports a search for customers based on their name or address, you may type in part of a name or an address to find matching results. If a unified search option is not

configured for your product or you do not have security access to use it then the search box may only be used for searching for menu items.

To search for business entities, you may enter your search criteria in the following ways:

- Type in your search text in **free form**. For example, if your product's unified search option supports a search for customers by name or address, the text you enter may be considered as part of a name or an address.
- Depending on your product's unified search configuration, you may use specific **hints** to explicitly identify your filtering criteria. For example, an address filter may be associated with the hint name "ad:" allowing you to be more explicit and enter "ad: main" to find records by their address. Click the search icon in the search input area to view the hints that are configured for this search. You can also click the up arrow adjacent to the hint to automatically populate the hint text into the search.

- You may use free form text or hints but not both.

As you type in your text, the application attempts to find matching records and presents the top most results for your review. You may select a record from the results list to navigate to the corresponding portal.

If your product has configured more than one unified search that you are allowed to use, one of the searches is the default search. Click the search icon in the search input area to choose a different search option. After selecting a different option, the hints for the selected search are shown and the Advanced Search link will navigate to the query portal configured for the selected search.

Other Searches

Refer to your specific product documentation for more information about your product's unified search features.

Refer to [Understanding Unified Search](#) to better understand unified search configuration.

Help Menu

The Help menu is available in the application toolbar to provide access to the following product support options.

Open the menu by clicking the Help icon .

Help

Select the **Help** entry in the menu to launch the Oracle Help Center in a new tab. The application will automatically navigate to the context-sensitive help information within the help center. Alternatively, use the following shortcut key to launch help directly.

| Keyboard Shortcut |
|-------------------|
| Alt+F1 |

Prepare Issue Details

Select the **Prepare Issue Details** entry in the menu to launch a script to capture details of an error that needs to be reported. Refer to [Prepare Issue Details](#) for more information on this option.

Release Notes

Select the **Release Notes** entry in the menu to launch in a new tab the What's New content (for cloud customers) or the Release Notes (for on premises customers), for your product and version.

Enable | Disable Debug

If you have security access to the application service **F1OUIDBUG**, you will see an option in the menu related to [debug mode](#) depending on its current state. If debug mode is currently not enabled, the entry says Enable Debug, otherwise it says Disable Debug.

About

Select the **About** entry in the menu to display a window that describes the current release information for your version of your product.

The about window shows a variety of information including:

- The logged in user ID
- The list of products installed in the application along with the release ID. This information comes from the [installation record](#). Note that in a Cloud installation, only the Cloud product name and release ID are displayed. The details of the products that make up the Cloud installation are not displayed (but are still visible on the installation record).

User Menu

The User menu is available in the application toolbar to provide access to user-specific options. Open the menu by

clicking the User icon

Note: Configurable Menu. Additional menu entries may be visible in your implementation as this menu configuration allows for additional options to be defined.

Preferences

Select the **Preferences** entry in the menu to view or modify your settings in a form that appears in the **Main** tab in the object display area. Alternatively, use the following shortcut key to access preferences directly.

| Keyboard Shortcut |
|-------------------|
| Ctrl+Alt+P |

Refer to [User Preferences](#) for more information.

Switch UI View

Select the **Switch UI View** entry in the menu to change the user experience from the current system default to the prior user experience or from the prior user experience to the current version. This option is only available for users that have access to the **F1UIVIEW** application service.

Logout

Select the **Logout** entry in the menu to complete your current session of the application. Clicking this item logs the current user out and displays the Welcome page so that another user can login. Alternatively, use the following shortcut key to logout.

| Keyboard Shortcut |
|-------------------|
| Ctrl+Alt+L |

Page Title Area

The Page Title Area displays the page title and the page actions toolbar.

For certain pages in the system, the page title may be followed by an information string. It is only applicable to portal-based pages that display a single record. This information is only visible if the portal has been configured to display the primary key's information string. Typically only "stand alone" maintenance portals are configured to show the information string, whereas "all-in-one" portals are not configured this way.

Fastpath: Refer to [Common Base Portals and Zones](#) on page 43 for more information about standard base product portals.

Note: If an information string is long and would interfere with a page actions button, the information string will automatically be truncated and suffixed by an ellipsis, "...", indicating that more information is available. In this situation, the missing text can be viewed if the user hovers their mouse over the string.

The Page Actions Toolbar displays standard control options, such as Save and Duplicate. More detail about the actions that may appear are described in the following section.

Page Actions Toolbar

In the Page Title Area, control functions appear in the Page Actions Toolbar; such as, Clear, Save, Duplicate, Delete and Refresh buttons.

Note:

Buttons in the Page Title Area appear as the function is available to the user; for example, the Delete button will not appear if the user has made any changes to the page's content, or does not have the necessary security rights for this action.

In addition, other functions that are specific to a portal-based page may appear in the toolbar, if configured. For example, the ability to navigate to the Search zone for a specific maintenance object may be visible on the maintenance portal.

This section describes the standard features that are available in the Page Actions Toolbar.

Bookmark Button

Click the Bookmark button on the Page Actions Toolbar to save the current page and context to the bookmarks list.

| Keyboard Shortcut |
|-------------------|
| Ctrl+Alt+B |

Note: Secured. This button is secured using the application service **F1-BOOKMARKS**. Users that do not have security for the application service will not see the Bookmark button (or the corresponding sidebar zone).

After clicking the Bookmark button, you are prompted to provide a name for the bookmark. After saving, it is visible in the [Bookmarks Zone](#), allowing you to return to this page with this context loaded with one click.

Note: Unsaved data will not be included in the bookmark. If you view a record and make changes to data without saving the changes and then bookmark the page, the unsaved changes are not included in the bookmark information.

You may change the name of the bookmark or change the sequence of the bookmarks by navigating to the [User - Bookmarks](#) in the user preferences.

Next/Previous Item Buttons

The **Previous Item** and **Next Item** buttons appear in the Page Actions Toolbar under these conditions:

- You access a fixed page, meaning that it is not portal-based.
- You use a search page to display an item.
- There are multiple items in the search results list *below* or *above* the selected item.

If, for example, you enter search criteria of "Smith" on the User Search page, you might see the following results:

- Smith, Albert
- Smith, Peter
- Smith, Zane

If you select **Smith, Peter**, Peter's user information is displayed on the User page. If you then click the **Next Item** button, **Smith, Zane** will be displayed. In addition, because **Smith, Zane** is the last entry in the search results, the **Next Item** button is no longer needed and will not appear in the Page Actions Toolbar.

If you then click the **Previous Item** button, **Smith, Peter** will be displayed; click again and the **Smith, Albert** record will appear, and, because **Smith, Albert** is the first entry in the search results, the **Previous Item** button is no longer needed and will not appear in the Page Actions Toolbar.

| Keyboard Shortcut | Alternate Shortcut |
|-------------------|--------------------|
| Alt+P | |
| Alt+N | Alt+Shift+N |

Note: Refer to [Shortcut Key Summary](#) for information about the alternate shortcut.

Duplicate Button

Click the **Duplicate** button in the Page Actions Toolbar to create a duplicate of the currently selected object.

Before the new object is added to the database, a dialog appears in which you must enter the unique identifier for the duplicate object. When you click OK, the system creates the record by copying the original record. It may be helpful to think of the duplication function as the equivalent of a "save as" action.

| Keyboard Shortcut |
|-------------------|
| Ctrl+Alt+D |

Note: Copying ancillary information for a record sometimes requires confirmation during a duplication request. If so, you may also be asked if you also want to duplicate ancillary information. If, for example, you duplicate a user group, besides supplying the ID of the new user group, you are asked if all users in the original user group should be linked to the new user group.

This button does not appear in the Page Actions Toolbar when:

- Duplication is not supported for the current object.

- You are on a portal based page. (For these types of pages, if duplication is supported, the actions are defined in a zone on the portal.)
- You have made changes to the object without committing the changes to the database by clicking Save. (After making changes, you must either discard them using the **Refresh** button, or save them.)

Delete Button

Not all transactions have the capability to be deleted. Deletion is related to the business impact of the action. In some transactions, Delete is present for some scenarios and unavailable for others; for example, you may not be able to delete a record at a certain status level.

Note:

If you make a change to an object and do not save the changes to the database, you cannot delete the object until you either save the changes or refresh the object with the contents on the database.

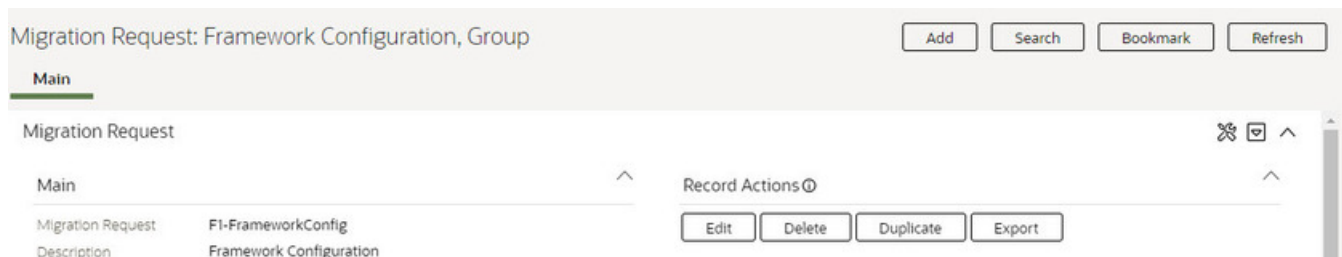

Before you delete an object, the system verifies that the object is not referenced anywhere in the system. If it is, you cannot delete it. If, for example, you attempt to delete a user, the system ensures this user has not been referenced in a user group or on a To Do.

Depending on the type of page that you are using, the option to delete may vary.

- Fixed pages display a Delete button in the page actions toolbar when the option is available.

- Portal-based pages display the Delete button in the object-related map.

- List style fixed pages commonly display the Delete button (garbage can icon) next to the entity in the list.

In all cases, before the object is deleted, a confirmation dialog is displayed.

CAUTION: A timeout situation could occur as the system attempts to verify the use of the deleted object if the object is referenced in many places *and* involves large volumes of production data. If this timeout situation occurs, you must work with your database administration group to delete the offending object.

Clear Button

Click the **Clear** button to remove the values from the currently displayed object's fields. This action is typically used to clear input fields when adding a new object.

| Keyboard Shortcut |
|-------------------|
| Ctrl+Alt+C |

Save Button

Clicking the **Save** button saves any changes you have made in the data on the current object.

| Keyboard Shortcut | Alternate Shortcut |
|-------------------|--------------------|
| Alt+S | Alt+Shift+S |

Note: Refer to [Shortcut Key Summary](#) for information about the alternate shortcut.

The button does not appear unless:

- You enter a page in add mode and default values are loaded.
- You make changes to an object after it is displayed (note that you must tab or click out of the field before the Save button appears).

Refresh Button

Click the Refresh button to reload the values on the page with those from the database.

CAUTION: All unsaved changes are discarded.

| Keyboard Shortcut |
|-------------------|
| Alt+R |

Object Display Area

The Object Display Area contains the details of the object(s) currently being viewed or maintained. For example, if you display a portal, its zones are displayed in this area.

Because many of the page components follow Internet standards of operation, the behavior of these types of components are not explicitly described. This section focuses on special features that are unique to the application framework.

Multiple Tabs

When a page in the application includes a lot of information, the page may be implemented with vertical scrolling to allow the user to view all the information. Or alternatively, the page may be implemented with several tabs, allowing the user to navigate between tabs to view or update information. The following image is a section of the User page showing the multiple tabs.

Figure 1: Multiple Tabs Example

The names of the tabs describe the type of information that will be displayed in the page when the tab is clicked. For example, if you click on the **Favorite Links** tab, the contents of the page show the favorite links configured for the user.

| | Sequence | Navigation Option | Security Access |
|-----------|----------|--------------------------------------|-----------------|
| + [trash] | 10 | * CI0000000841 [search] To Do Role + | Yes |
| + [trash] | 20 | * CI0000000919 [search] User Group + | Yes |

Figure 2: Multiple Tabs Example (After Favorite Links Tab Is Clicked)

Note: Hot key options. Rather than clicking on a tab, you can click $Alt+F2$ or $Alt+Shift+F2$ to scroll through the tabs. $F2$ moves you through the tabs from left to right. $Shift+F2$ moves you through the tabs from right to left.

Note: Hot key options. Use $Alt+$ a number to navigate to the tab page whose relative position corresponds with the number. For example, if you press $Alt+6$ on the above page, the **Favorite Links** tab will be displayed. $Alt+0$ may be used to navigate to the tenth tab. If there are more than 10 tabs on a page, you must use the mouse or $F2$ / $Shift+F2$ to display additional tabs. Note that the numeric keypad on your keyboard cannot be used to implement this function.

Note: Returning to a page that contains multiple tabs. If you return to a page (by clicking the [Back](#) arrow or the [History](#) icon), the page will be positioned on the last tab that was opened.

Note: Page versus Tab nomenclature. The documentation frequently refers to the contents of a given tab as a page. However, the page actually comprises the entire collection of tabs.

Text Box

The following is an example of a basic text box:

If the text box is a large field, the text box may be configured to enable scrolling. In this situation, an expanded edit icon, (a pencil), will appear adjacent to it.

Detailed Description

This BO enter algorithm creates a To Do entry.

The To Do Type is set as follows:

- > If To Do Type Element Name is defined, the value is retrieved from this element in the object's related type.
 - > If no Element Name is defined or no To Do Type is found on the related 'type', the To Do Type parm is used.
- If no To Do Type is found, a log is added for the record with the error.

The To Do Role is set as follows:

- > If To Do Role Element Name is defined, the value is retrieved from this element in the object's related type.
- > If no Element Name is defined or no To Do role is found on the related 'type', the To Do Role parm is used.

Additional capabilities are provided to display and edit data in these text boxes:

- If the field contains more text than is visible, a pop-up that displays the full text appears when you hover your mouse over the text box. The text in the pop-up can be selected and copied.

Detailed Description

This zone type is used to create an info zone. Info zones contain a list of information about a given object. For example, you could set up an info zone to produce a list of all contacts made by the customer in context.

Info zones offer many features that can be used to change how the list looks "on the fly" (by end users). For example, users can add additional columns to the list, change the sort order, ...

For a more detailed description of how these zones look and behave, open the help and navigate to the index entry titled "info zone configuration".

To set up a new zone, fill in the zone's parameters as per each parameter's Comments. For examples, please refer to the "tips" that appear in

Java Class Name

| | | Sequence |
|---|----|----------|
| + | 🗑️ | * 10 |
| + | 🗑️ | * 11 |

* This zone type is used to create an info zone. Info zones contain a list of information about a given object. For example, you could set up an info zone to produce a list of all contacts made by the customer in context.

Info zones offer many features that can be used to change how the list looks "on the fly" (by end users). For example, users can add additional columns to the list, change the sort order, ...

For a more detailed description of how these zones look and behave, open the help and navigate to the index entry titled "info zone configuration".

To set up a new zone, fill in the zone's parameters as per each parameter's Comments. For examples, please refer to the "tips" that appear in the dashboard.

This zone's parameters support a single SQL statement. If you require a zone that is built using multiple SQL statements (e.g., if you need to retrieve rows from disparate sources), please use the Multi-SQL version of this zone type.

- If you click the expanded edit icon, an editable pop-up window appears. If the field is not protected as a result of business rules for the page, you may modify the text in this window.

Note: The following table highlights special characters that are converted to equivalent standard characters when entered in a text box.

| Entered Character Description | Unicode | Converted Character Description |
|------------------------------------|---------|--|
| Curly left double quote. | U+201D | Straight double quote. |
| Curly right double quote. | U+201C | Straight double quote. |
| Curly left single quote. | U+2019 | Straight single quote. |
| Curly right single quote. | U+2018 | Straight single quote. |
| En dash. | U+2013 | Simple hyphen. |
| Em dash. | U+2014 | Simple hyphen. |
| Ellipse | U+2026 | Three dots. |
| Middle dot (bullet / centered dot) | U+00B7 | Asterisk. |
| Fraction 1/4 (using 1 character). | U+00BC | 1/4 (using three separate characters). |
| Fraction 1/2 (using 1 character). | U+00BD | 1/2 (using three separate characters). |

| Entered Character Description | Unicode | Converted Character Description |
|-----------------------------------|---------|--|
| Fraction 3/4 (using 1 character). | U+00BE | 3/4 (using three separate characters). |

Date and Time Fields

When both the date and time are required, the Date and Time fields typically look as follows:

Date / Time  

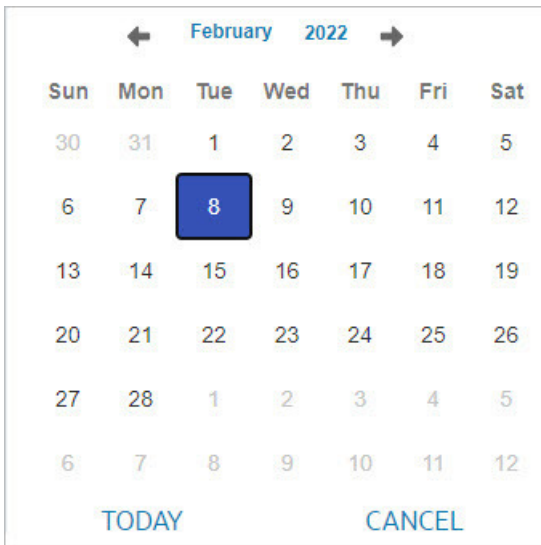

When only the date is required, the Date field looks as follows:

Date 

When only the time is required, the Time field looks as follows:

Time 

If you click on the calendar icon or press the Enter key while the cursor is positioned to the left of the icon in a Date or Date and Time field, the following window appears:

← February 2022 →

| Sun | Mon | Tue | Wed | Thu | Fri | Sat |
|-----|-----|-----|-----|-----|-----|-----|
| 30 | 31 | 1 | 2 | 3 | 4 | 5 |
| 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| 13 | 14 | 15 | 16 | 17 | 18 | 19 |
| 20 | 21 | 22 | 23 | 24 | 25 | 26 |
| 27 | 28 | 1 | 2 | 3 | 4 | 5 |
| 6 | 7 | 8 | 9 | 10 | 11 | 12 |

TODAY CANCEL

Click or press enter to select the date and populate the input field. Use the left and right arrows to scroll back or forward a month. Click on the 'Month' text to bring up a range of months to select from. Click on the year to bring up a range of years to select from.

If you click on the clock icon or press the Enter key while the cursor is positioned to the left of the icon in a Time or Date and Time field, the following window appears:

| | | | | | | | | | | | | |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|----|
| 12 | 01 | 02 | 03 | 04 | 05 | 06 | 07 | 08 | 09 | 10 | 11 | AM |
| 12 | 01 | 02 | 03 | 04 | 05 | 06 | 07 | 08 | 09 | 10 | 11 | PM |
| :00 | :05 | :10 | :15 | :20 | :25 | :30 | :35 | :40 | :45 | :50 | :55 | ↓ |

CANCEL

Select the hour then click or press enter on the minutes to select the time and populate the input field.

Search Button

The search button appears primarily as a magnifying glass.

Algorithm Type F1-BUNIMPAPP

When using a pop-up search window, the search button can appear as a button with its function labeled.

You can have the system search for an item that matches the data you entered using any of the following methods:

- Enter a value in the search field and press **Enter** while the cursor is in the search field. The system assumes you want to search for the value entered and pre-populates it in the search window's search criteria. If a unique match can be found, the system automatically populates the field with details corresponding to the record found. If a unique match cannot be found (either no matches or multiple matches), a search page opens containing selectable items.
- Click the Search button without entering a criteria. This will typically cause a pop-up search window to appear so that you can further refine your search.
- Enter a value and tab out of the search field. The system looks for a value that exactly matches what you entered. If it cannot find such a value, the search dialog will not be presented.

When an item is selected in the search page, the search page closes and the input field is populated with the value selected.

Note: Sorting columns within the search grid. You may click on the column heading of columns in a search grid to cause the contents of the grid to be sorted. Refer to [Sorting Functionality](#) for more information.

Context Menu Button

The Context Menu button is a small arrow that appears adjacent to an object's value or information string. An example is shown below:

Algorithm Type F1-BNDL-INFO

Context menus exist to help you navigate to other pages and populating the page with the current context (by passing the ID of the related object). In addition, the menu items offered in a Context Menu differ depending on the entity that the menu is related to; for example, when you click the Algorithm Type context menu, a pop-up menu similar to this appears:

Different context menus exist for each of the major objects in the system; for example, in Customer Care and Billing, the context menu for Premise contains premise-oriented menu items, whereas the context menu for Account contains account-oriented menu items.

Go To Button

Clicking a Go To button, , opens the page for the related object - it functions like a hyperlink.

| | User Group | Expiration Date | Owner |
|---|---|--|-----------|
| + |  ALL_SERVICES <input type="text"/> Q System User Group | * 12-31-2100  | Framework |

Broadcast Button

Some zones have been configured to "broadcast" unique identifiers to other zones within the portal; if so, you'll see a broadcast icon, , in the first column. Clicking the icon causes specific zones to reload - these zones that have been configured to rebuild when the unique identifier is received. For example, you might have configured a zone to display the image of a bill when a bill ID is broadcast from an info zone.

Embedded Help Icon

The icon containing a small 'i' is an Embedded Help icon.

When an embedded help icon is clicked, a tool tip appears containing additional information.

Work Lists

The work list buttons can appear in a zone's column heading, .

Clicking the icon results in populating the sidebar [Work List Zone](#) with the entire column. The user may use the Work List zone to easily process entries one at a time without returning back to the source query zone.

Note: The Work List zone is populated only upon user request.

Scroll Bars with Dynamic Height

Sometimes the height of a grid isn't sufficient to display a grid's rows. When this occurs, a vertical scroll bar appears and an "expand button" appears above this bar, . For example, the following grid is not high enough to show all of the available sidebar zones:

Sidebar - 10 of 10 zones selected for display.

| Zone | Display | Collapsed | Sequence | Refresh | Security Access |
|-----------------|-------------------------------------|--------------------------|---------------------------------|--------------------------------|-----------------|
| Switch Language | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="20"/> | <input type="text" value="0"/> | Yes |
| Bookmarks | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |
| Collect Entity | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |

If you want to view all of the available zones without using the vertical scroll bar, you can click the expand button. When clicked, the height of the grid expands to show all rows in the grid:

Sidebar - 10 of 10 zones selected for display.

| Zone | Display | Collapsed | Sequence | Refresh | Security Access |
|-------------------|-------------------------------------|--------------------------|---------------------------------|--------------------------------|-----------------|
| Switch Language | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="20"/> | <input type="text" value="0"/> | Yes |
| Bookmarks | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |
| Collect Entity | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |
| Current To Do | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |
| Favorite Links | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |
| Favorite Scripts | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |
| Favorite Searches | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |
| Tags | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |
| To Do Summary | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |
| Work List | <input checked="" type="checkbox"/> | <input type="checkbox"/> | <input type="text" value="0"/> | <input type="text" value="0"/> | Yes |

Notice, after the grid is expanded, the grid's vertical scroll bar disappears and the button in the upper corner becomes a Collapse Button, . If you click the collapse button, the grid will return to its original height.

Note: Search grids. Expand all functionality is not available in search grids.

Sorting Functionality

Grids have a heading row that contains labels for the columns. By clicking a column heading, you cause the rows to be sorted in the order of the selected column. By clicking on a column more than once, you cause the rows to be sorted in reverse order. Clicking the heading a third time removes the sorting function and returns the grid to its default display organization.

The following shows how information look after organizing the grid, clicking the column heading, by algorithm type (notice the icon in the column name).

| | Algorithm | Description  | Algorithm Type  |
|---|--------------|---|--|
| 1 | F1-OVRDT-ALG | Validates date in format YYYY-MM-DD | ADHV-DTD |
| 2 | F1-ACTIVEWS | Web Service - Verify Active Operations | F1-ACTIVEWS |
| 3 | F1-ATCHM-INF | Attachment Information | F1-ATCHM-INF |
| 4 | F1-ATSZCLVL | Attachment Size Class Validation | F1-ATSZCLVL |
| 5 | F1-BAT-LSDEF | Timed Batch - Service Level Based on 1.5 Timer Interval Factor | F1-BAT-LVSVC |
| 6 | F1-BFEMOLOG | Add Business Flag Error MO Log | F1-BFEMOLOG |
| 7 | F1-BFSTDNMVA | Business Flag Standard Name Validation | F1-BFSTDNMVA |

Note: Sorting on dropdown values. If you attempt to sort a column that contains a dropdown value, the information is sorted in the order of the unique identifier associated with the dropdown value, not the description you see on the screen; for example, if you sort on a column containing unit of measure, the information will be sorted in the order of the unit of measure code, not the description that appears in the dropdown. This means that the resultant sort will appear incorrect and therefore we discourage you from doing this.

Get More Functionality

Grids in fixed pages that can potentially contain a large number of rows have special processing that we refer to as Get More functionality. Rather than show every row, the system retrieves the first X records (where X varies from grid to grid, and from release to release) and appends a Get More button to the bottom of the grid:

Get More...

When you click the **Get More** button, the system appends the next X rows to the bottom of the grid.

Note: The absence of a "get more" button. For pages configured to include Get More, if no button appears at the bottom of the grid, this means all of the rows are displayed.

Note: Search grids. The Get More function is not available in search grids.

Adding and Removing Rows Using Arrows

In some editable grids, a new row can be added to another editable grid (the grid on the left) by clicking the Add item button, , of the desired row in the grid on the right:

| | Sequence | Description | | Sequence | Description |
|---|----------|------------------------------|---|----------|----------------|
|  | 10 | Winter kWh charge, first 500 |  | 5 | Service Charge |
|  | 20 | Winter kWh charge, remaining | | | |

When the Remove item button is clicked, , the row is transferred from the grid on the right to the grid on the left. This change will not be committed to the database until you save the object being maintained

Reorganizing Items Using the Up and Down Arrows

Occasionally, rows can be repositioned in an editable grid by clicking up and down arrows. The following is an example of such a grid:

| | | Merge Type | Sequence | SQ Rule |
|--|--|------------|----------|-------------------------------------|
| | | Original | 10 | DA Credits |
| | | Original | 20 | Calc. Number of Days In Bill Period |
| | | Original | 30 | Copy SQs from Master SA to sub SA |

Notice the following about such a grid:

- The up arrow is dim in the first row. This is because it can't be moved further to the top.
- The down arrow is dim in the last row. This is because it can't be moved further down.
- The up and down arrows are usable in all other rows. Each time you click one of these arrows, the respective row is moved up or down one row.

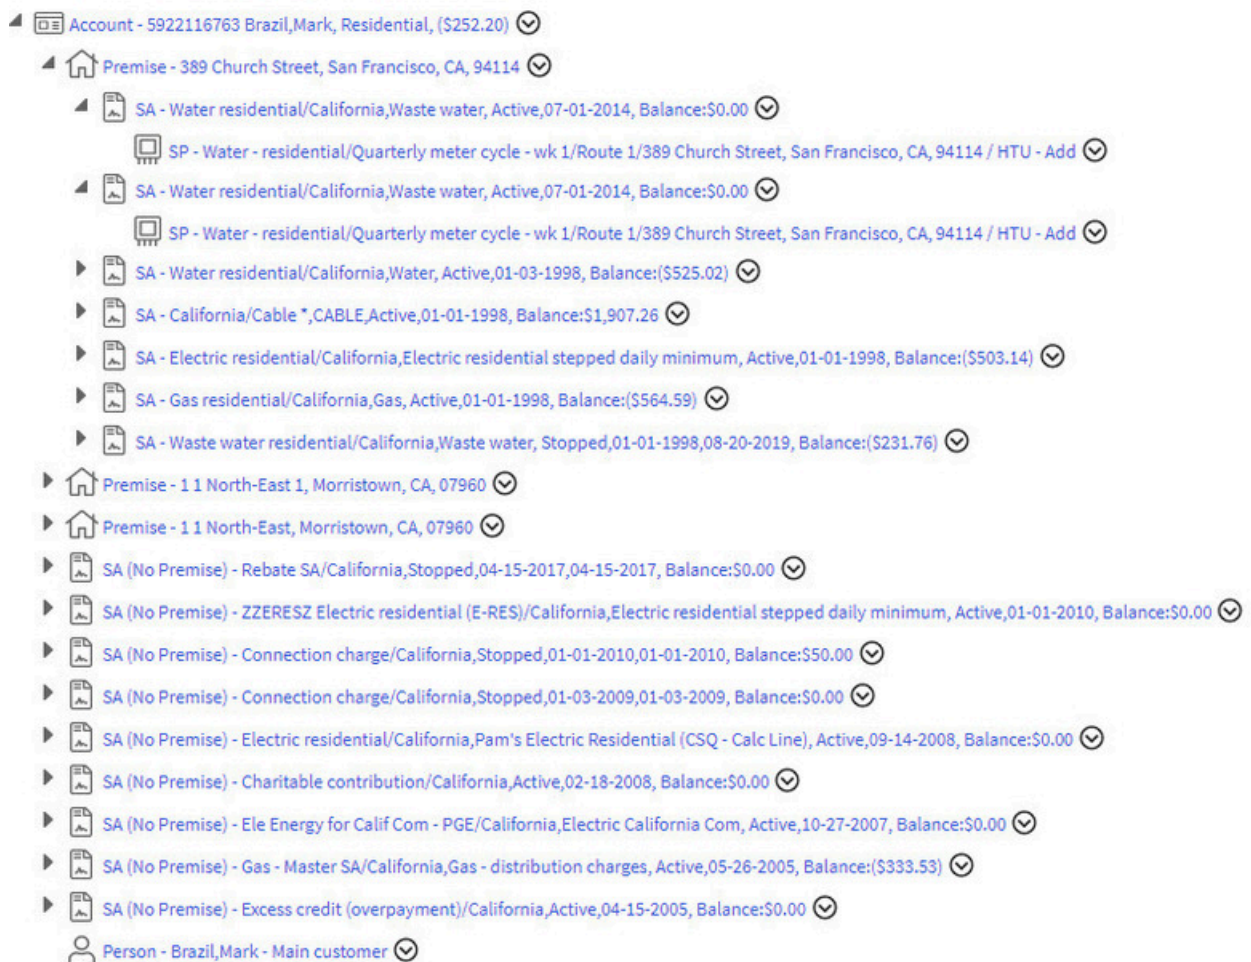

Note: Reminder. When you move rows into a grid, the system does not apply the change to the database until you click the Save button (which commits the entire object to the database).

Trees

Trees are used to illustrate complex relationships between objects. The following is an example from Oracle Utilities Customer Care and Billing of a page with a tree that is expanded:

Account Tree

The following points describe how to use trees:

You can expand and contract the nodes in a tree by clicking on the icon that prefixes the node (you can also click the arrows to expand and contract a node).

Note: Expand all. If you press `Ctrl` while clicking on an icon that prefixes a node, all child nodes (and their children) expand.

You can click the context menu button to cause a context menu to appear. You can navigate to any of the pages that are presented on this menu. Refer to [Context Menu Button](#) for more information.

You can click on the information that appears in an underlined node to drill into the page in which the object is maintained. For example, if you click on the account information, you will be transferred to the Account - Main page.

Note: Important! If you make changes after expanding a tree's nodes (e.g., by drilling down on a Premise and changing the premise's address), the tree will contract to the first node if you return to the page.

Nodes in trees fit into two broad categories:

- **Information nodes.** Information nodes highlight the existence of other data. For example, on the Control Central - Bill Payment Tree, a node exists to highlight the existence of new financial transactions that were created since the last bill was completed.
- **Data nodes.** Data nodes show information about objects in the system. For example, data nodes exist on the Control Central - Bill Payment Tree that show bills and payments.

Required Field Indicator

An asterisk (*) is used to indicate that a field is required. The system determines this based on the field's configuration. When a field becomes required because of an algorithm and not the field's configuration, however, the system will not add an asterisk.

Note:

If a page includes a grid, fields within a row may be marked as required.

Operations 

| | Operation Name | Description | Schema Type |
|---|----------------|-------------|-------------|
| +  | * | * | * |

In this situation, the fields within the grid are **only** required if the row is being populated.

Accordion Windows

Accordion windows are used when the data held in an object's rows does not comfortably fit into a grid.

Each row in an accordion has a header that summarizes a row's details. When you click a header, the row expands to show the details. The following is an example of an accordion where all headers are collapsed (meaning that only summaries of the rows' details are shown):

| Steps | | All 3 displayed | [Expand All] [Collapse All] | Copy | |
|--------------------------|---|-----------------|--|------|--|
| <input type="checkbox"/> | +  | (10) | Edit data - Get the Physical BO for the MO | | |
| <input type="checkbox"/> | +  | (20) | Edit data - Get the prime keys of the BO | | |
| <input type="checkbox"/> | +  | (30) | Edit data - Read the BO | | |

When you expand a header, its details are exposed. For example, the following shows the same accordion after the third row is expanded:

| Steps | | All 3 displayed | [Expand All] [Collapse All] |
|--------------------------|---|-----------------------|---|
| <input type="checkbox"/> | <input type="plus"/> | <input type="trash"/> | (10) Edit data - Get the Physical BO for the MO |
| Step Sequence * | <input type="text" value="10"/> | | |
| Step Type * | <input type="text" value="Edit data"/> | | |
| Text | Get the Physical BO for the MO | | |
| Edit Data Text | <pre>move "parm/mo" to "F1-RetrieveMOOption/input/mo"; move 'FIPB' to "F1-RetrieveMOOption/input/moOptionType"; move 'false' to "F1-RetrieveMOOption/input/isMultiple"; invokeBS 'F1-RetrieveMOOption' using "F1-RetrieveMOOption";</pre> | | |
| <input type="checkbox"/> | <input type="plus"/> | <input type="trash"/> | (20) Edit data - Get the prime keys of the BO |
| <input type="checkbox"/> | <input type="plus"/> | <input type="trash"/> | (30) Edit data - Read the BO |

Note: You must expand to update. In order to update a row in an accordion, you must expand it.

Row Summary and Chunk Management

At the top of an accordion you'll find a summary of its rows. The format of this information differs depending on the number of rows and the size of the accordion:

- If the accordion contains every row, a summary of the total number of rows is displayed.
- If the accordion contains a subset of rows, you are presented with a summary of the rows AND you are provided with options to display different "chunks" of rows.
 - Click **First** to display the first "chunk" of rows (the size of a chunk differs depending on the accordion). This option is dimmed if the first chunk is in the accordion.
 - Click **Previous** to display the previous chunk of rows. This option is dimmed if the first chunk is in the accordion.
 - Click **Next** to display the next chunk of rows. This option is dimmed if the last chunk is in the accordion.
 - Click **Last** to display the last chunk of rows. This option is dimmed if the last chunk is in the accordion.

Sidebar Area

The sidebar is a [portal](#) that contains zones. These zones appear regardless of the object being displayed in the [Object Display Area](#). Refer to [Sidebar Portal](#) on page 31 for a description of these zones. Every user has control over the zones that appear in their sidebar. Refer to [Portal Preferences](#) for more information about how a user can customize the contents of the sidebar.

The sidebar area is displayed before the Object Display area by default. (On the left for a left-to-right language and on the right for a right-to-left language). You have control over its location, width and more as part of your [user preferences](#).

Script Area

CAUTION: Guiding scripts that interact with the user using the script area are limited to surf over fixed pages only and are considered legacy functionality. This technique is not supported on top of portal pages and is planned to be deprecated in a future release.

When a [script is initiated](#), the [object display area](#) shifts down to make room for the script area.

The information in the script area takes you through the steps in the selected business process (provided by your implementation team).

Portal Pages

This section describes using portals and zones to find and display information. This is the preferred technique used by the base product for building user interfaces.

Additionally, portals and zones may be configured by your implementation to supplement the base package provided functionality.

The contents of this section provide background information about portal page behavior.

Portals Are Made Up Of Zones

The term "zone" is used to describe a section on a portal. Each zone has a heading and content.

| Keyboard Shortcuts | Description |
|--------------------|--|
| Alt+]] | Moves the cursor focus to the next zone on the page based on the standard browser keyboard navigation "order". |
| Shift+Alt+]] | Moves the cursor focus to the previous zone on the page based on the standard browser keyboard navigation "order". |

The following is a portal with seven zones:

- Switch Language
- Bookmarks
- Checked Out
- Current Context
- Current To Do
- Favorite Links
- Favorite Scripts

Note: This example may not be available in your application; it is used for illustration purposes only.

The screenshot displays a vertical sidebar with several zones. Each zone has a title and an expansion/collapse icon (upward arrow for expanded, downward arrow for collapsed). The zones are:

- Current Context** (expanded): Contains three items: a person icon for "Brazil,Mark", a calendar icon for "5922116763 4 Brazil,Mark, Residential, (\$252.20)", and a house icon for "1 1 North-East, Morristown, CA, 07960".
- Current To Do** (expanded): Contains a button labeled "Assign me a To Do".
- Customer Contact** (expanded): Contains a "Last" section with "175 days ago - Dandugula,Krishna", a "Type" dropdown menu, a "Comment" text area, and an "Add Contact" button.
- Eligible Scripts** (collapsed): Shown with a downward arrow.
- Favorite Links** (expanded): Contains two links: "User Group +" with a count of [1], and "To Do Role +" with a count of [2].

Users Must Be Granted Security Access To Each Zone

A user must be security granted access rights in order to see a zone on a portal.

Fastpath: Refer to [Granting Access to Zones](#) for information .

Zones May Appear Collapsed When A Page Opens

Zones may be designed to appear collapsed (or minimized) when the portal is initially displayed. To view the

information in a collapsed zone, the user can press the zone's expansion button, , to either expand or collapse the zone:

Favorite Links 

| | |
|----------------|-----|
| Favorite Links | ^ |
| To Do Role + | [1] |
| User Group + | [2] |

A zone's data is only retrieved when it is expanded.

Some Portals Allow User Customization

There are some portals in each base product that are configured to allow user customization. In this case, the portal is visible on the user's portal preferences. For these portals each user has control over the following:

- Which zones appear on their portal
- The order in which the zones appear
- Whether the zones should be "collapsed" (i.e., minimized) when the portal opens.

Users define their preferences by clicking the [User Preferences](#) button. Pressing this button transfers the user to the [User Preferences](#) page on which their [Portal Preferences](#) can be defined.

Portals used for base product query and maintenance pages are typically configured to not allow user customization.

Sidebar Portal

The sidebar is a special portal that always appears on the desktop. Its zones contain tools and data that are useful regardless of the object being displayed.

Note:

Minimize the sidebar. You can minimize the sidebar by clicking on the vertical bar between the sidebar and the object display area. This causes the sidebar portal to disappear and displays a single vertical sidebar bar, allowing more of the page area to display. It also suppresses the refresh of the zones within the sidebar based on updates to the context. Clicking the sidebar bar restores the display of the sidebar portal. Maximizing the sidebar then refreshes the zones with the latest appropriate content.

Minimize the sidebar when launching the system. If desired, a URL parameter may be used to minimize the sidebar when launching the system, using the parameter `minSidebar=true`. Refer to [Creating Application Links in External Applications](#) for more information and examples.

Adjusting the sidebar width. You can adjust the width of the sidebar by moving the slider that separates the sidebar from the object display area. This also updates your user preferences with the new width.

| Keyboard Shortcut |
|-------------------|
| Alt+J |

The contents of this section describe the zones that are provided by the framework product for this portal. Please note the following additional information about the sidebar portal that may impact how it appears.

- **Additional zones may be available in other products.** The zones described below are available in every base product. Please refer to the product-specific documentation for additional sidebar zones available in your product.
- **Context Sensitive Zones may appear.** Some pages may define additional zones that should appear in the sidebar only if that page is displayed. These are referred to as Context Sensitive Zones.
- **Sidebar zones are configurable.** The sidebar portal is configured to allow a user to define preferences for it. Refer to [Portal Preferences](#) for more information.

Note: Security. As a general rule, sidebar zones each refer to a unique application service so that a security administrator may configure which users are allowed to have access to which zones. Note that the user portal preferences indicates which zones a user has security access to.

Bookmarks Zone

After clicking the [Bookmark](#) button and saving a bookmark, it is visible in the **Bookmarks** zone. Clicking one of the links in the zone navigates to the page where the bookmark was saved and loads the information related to the record that was displayed when the bookmark was saved.

Click the trash can icon to delete the bookmark.

Note that a user may change the name of the bookmark or change the sequence of the bookmarks by navigating to the [User - Bookmarks](#) in the user preferences.

Tags Zone

The **Tags** zone provides a quick way to associate the entity currently being displayed with an entity tag or remove any of the tags it currently has. Tagging an entity may be useful to highlight various contexts in which it can be used, for example for testing or reporting purposes. Refer to [Defining Entity Tags](#) for more information.

Note that the zone is visible only when there is an entity in context, i.e. there is an entity to tag, and the user has application security access to this zone.

Collect Entity Zone

The **Collect Entity** zone provides a quick way to add or remove the entity currently being displayed to and from the [migration request](#) in context. This is mainly useful when reviewing data to export and while doing so maintain the export list. The zone automatically appears once an **Entity List** migration request is visited and set in context.

Current To Do Zone

The **Current To Do** zone is designed to streamline the process of working on To Do entries from assignment to completion. It displays key information about the user's current To Do entry and provides functions that help minimize the number of steps it takes to resolve the entry and potentially other entries related to it.

Important: The information here assumes that you have configured the system to use the ability to have a substatus of Assigned, which includes the **In Progress** value. If you are not taking advantage of the substatus, then see below for information about how the functionality described here works differently.

The following sections provide more detail about the zone.

To Do Entry Visible

If you have a To Do Entry that is currently **In Progress**, its information is visible in this zone when you launch the system. As described in [Working On A To Do](#) on page 1089, most of the actions in the system that cause a new To Do Entry to be pushed to this zone cause that To Do Entry to be updated to **Assigned / In Progress**. If you use those actions then the To Do Entry in this zone will always be your current **In Progress**. However, there are use cases that populate the To Do entry without assigning it to you. If you perform those actions, the To Do Entry that is pushed to this zone and remains until you perform a subsequent action that refreshes the information in this zone.

Next To Do Assignment

Users may have the option to click the **Assign me a To Do** button to request the next To Do entry they should work on. This functionality is optional and can be configured to follow your organization's business rules in determining the next task for a user. For example, if your organization practices work distribution "on demand", this feature can be configured to find the highest priority entry a user can work on and assign it to the user. Refer to [work distribution](#) for more information on this business practice.

Note: Next To Do Assignment Rules Are In A Plug-in. Refer to [Installation Options](#) for more information on how to configure the system to take advantage of this function.

If the system is successful in determining the next entry the user should work on, this entry is assigned to the user and moved to In Progress and becomes the user's current To Do. Its information is displayed on the zone.

To Do Information

The user's current To Do may be set using the Next Assignment algorithm, or by actions described in [Working On A To Do](#) on page 1089. Once a current To Do has been set, the zone displays details related to the To Do.

The **Message** describes why the entry exists. The message description allows the user to drill into the page on which the entry's respective object is displayed. For example, if the entry is associated with an asset that needs review, the user is brought to the asset page to view the information and potentially take action. If the **To Do type** has been configured to associate a [script](#) with this To Do entry's message number, then instead of being taken to the respective page, the associated script is launched.

Info displays the standard To Do information. An icon  appears if there are comments on the To Do and a Log

Entry icon  appears if there is a log entry of type **Forwarded**, **Sent Back** or **User Details** on the To Do. Clicking the description drills into the [To Do entry](#) page allowing the user to view more information about the entry or make changes to it as needed.

Depending on the status of the To Do entry and whether you are allowed to perform the actions, the following action buttons may be visible.

- You may use the **Complete** button in the zone to complete the current entry.
- If the current entry is **In Progress** and assigned to you, you may use the **Hold Progress** button to put the entry into the **On Hold** status. This is useful if your implementation wants an accurate picture of how long it takes to work on a To Do entry. You can put the entry on hold if you need to wait for some event to occur before continuing progress on the entry.
- You may see the **Start Progress** button if the current entry is assigned to you and not currently in progress. You may also see this if the current entry is Open and in a role that you are in. (This may happen if you drill into an open To Do from the To Do Search page.) Clicking this button puts the entry into **In Progress**.
- You may see the **Stop Work** button if the current entry is assigned to you and is not currently **In Progress** or **On Hold**. Clicking this button returns the entry to the **Assigned** state (resetting the assigned substatus).

Next / Previous Buttons

The **Previous** and **Next** buttons are enabled on this zone under the following conditions:

- The user selected an entry either on the [To Do List](#) page or the [To Do Search](#) page.
- At least one other entry exists *below* (for Next) or *above* the entry selected (for Previous).

Note: The system recommendation is to use the [To Do Management](#) on page 1093 or [To Do Dashboard / To Do Details](#) portals to manage work lists of To Do entries. Those pages use the worklist zone to manage the list and these Next and Previous buttons are not applicable.

Clicking **Next** or **Previous** will bring the user to the transaction indicated on the To Do Entry's message, where its respective object is displayed. It also makes that To Do the Current To Do displayed in the zone.

| Keyboard Shortcut | Comments | Alternate Shortcut |
|-------------------|----------------|--------------------|
| Alt+Y | Previous To Do | |
| Alt+Z | Next To Do | Alt+Shift+Z |

Note: Refer to [Shortcut Key Summary](#) for information about the alternate shortcut.

Note: When a user drills down on a To Do entry from the To Do List page, the system automatically changes the status of the entry to **Assigned** and **In Progress**. If **Next To Do** or **Previous To Do** is subsequently used to scroll through this list, the system does *not* change the To Do entry's status. You may click the **Start Progress** button in this zone.

Related To Do Entries

If the To Do entry has non-complete [related entries](#) a summary **Related To Do** description appears. The description states the total number of related entries, how many are still in **Open**, how many are assigned to current user and how many assigned to others. This hyperlink navigates to the [To Do Search](#) query allowing you to review the related entries. At this point you may decide to assign entries that can be positively identified as being caused by the same problem as the current To Do also to you.

If at least one related To Do entry is **Open** or also assigned to you, the **Complete All** button is visible. If you determines that the related To Do entries have been resolved with the appropriate action taken, the button may be used to complete in one step the current entry and all related entries that are **Open** or assigned to you.

If the related entries are not resolved with one action, you may opt to use the **Complete** button to complete the current entry alone and work on related entries one at a time. Using the related To Do information hyperlink you may navigate to the To Do search page and drill into the first related To Do to work on using the message hyperlink. This entry now becomes you current To Do and the **Next** and **Previous** action buttons are set to scroll through the related entries list. It's not automatically assigned to you. Use the **Start Progress** button in this zone to assign it to you and start progress.

Implementations Not Using Substatus

If your implementation is not taking advantage of the substatus as described in [The Lifecycle Of A To Do Entry](#), some functionality described above works differently.

When launching the system, no To Do Entry is populated in this zone by default. To Do entries only get populated in this zone when you take an explicit action.

Any action that automatically assigns you a To Do Entry only performs that step and does not update it to **In Progress**.

The buttons **Start Progress**, **Hold Progress** and **Stop Work** are never visible.

If you are using To Do Search and drill in on an entry before assigning it to you, you'd need to go back to To Do Search page or drill into the To Do Entry page to assign it to you. Similarly, if you use the Next / Previous buttons to work through a list from either To Do Search or To Do List where the entries are not already assigned to you, the recommendation is to return to the respective pages to assign them to you.

Favorite Links Zone

Each line in the **Favorite Links Zone** corresponds with one of the user's favorite links (e.g., transactions). Clicking on a line invokes the transaction. The first nine entries can be invoked by pressing an accelerator key (**Ctrl** + the number of the relative position of the link in the list). Note that the numeric keypad on your keyboard cannot be used to implement this function.

Users define their favorite links by clicking the [User Preferences](#) button. Clicking this button transfers the user to the [User Preferences](#) page on which their [Favorite Links](#) can be defined.

Favorite Scripts Zone

The Favorite Scripts zone lists the business process assistant (BPA) scripts that you have defined on your [user preferences](#). You can click on a script to [execute](#) it. You can click the **Search** button in the zone to search for other scripts.

Note: If you do not see the Favorite Scripts zone in the sidebar, navigate to User Menu and click the **Preferences** menu item to display the [User - Portal Preferences](#) page. Under the Sidebar Portal row, select the **Display** option for the Favorite Scripts zone.

Favorite Searches Zone

If you marked a saved search as a favorite using [Saved Searches](#) functionality, the search is visible in the **Favorite Searches** zone. Clicking one of the links in the zone navigates to the page where the search was saved and populates the filter values and executes the search.

Switch Language Zone

The **Switch Language** zone is used to switch the application's language. Only languages that are supported by your implementation will appear.

To switch the application's language, choose the desired language and press the **Refresh** button.

Note: If your implementation uses a single language, you should suppress this zone by [not granting security rights](#) to the zone's application service.

To Do Summary Zone

The **To Do Summary Zone** has several purposes:

- It presents a summary of the [To Do entries](#) that have been assigned to you.
- The colored "age bars" highlight the age of the To Do entries. The colors red, yellow and green are used to highlight the relative number of old, middle-aged and new To Do entries. The age associated with each of these colors is [user-configurable](#). Note, you can hover the cursor over an "age bar" to see the number of To Do entries.
- If you click on the To Do Type description, you'll be transferred to the [To Do Management](#) portal where these To Do entries will be displayed. From this page, you can drill down to the specific entries.

Note: Time saver! Use the worklist button when working on an entry in the [To Do Management](#) portal. All the individual To Do entries will be visible in the Worklist sidebar zone, allowing you to work through additional To Do entries without returning to the To Do Management portal.

Work List Zone

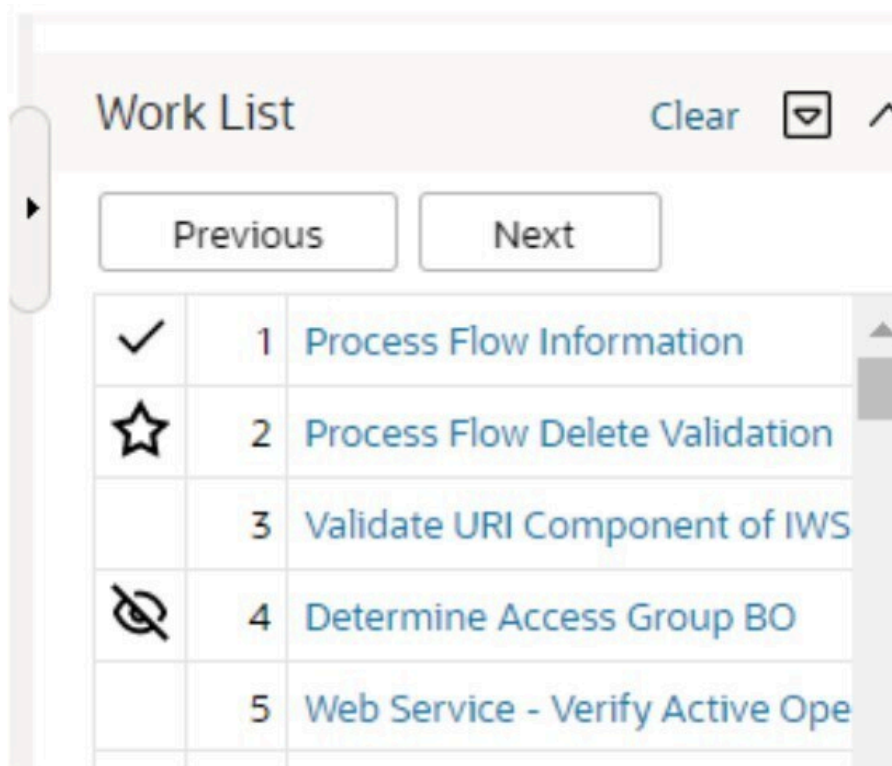

The **Work List** zone is populated when a user click the [Work Lists](#) icon in an info or query zone. When you click the link of the work list entry, the system does whatever it would have done if you had clicked on the hyperlink in the zone. The system marks the current entry with a star. It marks any previously worked entry with a checkmark.

Previous and Next buttons are available in the zone allowing you to go to the next or previous entry without having to locate it yourself and click the link.

You may actively mark an entry to be ignored by the Previous or Next button by clicking the icon column for that entry. An icon of an eye with a slash through it is visible. You can click the icon to re-include that entry in the previous / next action.

The work list stays populated until you either click the Clear link in the zone's header or you overlay the work list by clicking a different column's work list icon.

The image shows a work list zone illustrating that the first entry was "visited", the second entry is the current one being viewed and the fourth entry is marked to skip or ignore.

Zone Types and Characteristics

The topics in this section describe common zone types, function, and common characteristics.

Fastpath: Refer to [The Big Picture of Portals and Zones](#) for a description of general portal and zone functionality.

Common Characteristics of Zones

The following topics describe common characteristics of all zone types supported by the base package.

Zone Visibility

A zone may be configured to dynamically be visible or completely hidden depending on the information being displayed. When hidden, not even the header is displayed.

For configuration information, refer to [Zone Visibility Service Script](#).

Control Zone Headers

A zone may reference a UI Map to define and control its header. This feature provides the means to achieve a uniform look and feel for the application as well as add functionality to the zone header beyond being just a title bar to open and close the zone. Refer to [UI Map](#) and to its context sensitive tips zone for more information on **Fragment** UI Maps and how they are used to construct zone headers.

Explorer Zones

The product provide several zone types that are used to find or display a set of information. These are called explorer zones. There are two types of explorer zones:

- **Info zones.** An info zone displays a list of information about an object. These types of zones often display information without requiring any input from the user.
- **Query zones.** A query zone allows users to find objects matching a given search criteria.

Virtually every aspect of an info or query zone is controlled by its zone [configuration](#). However, most share basic common components described in the subsequent sections.

Search Criteria / Filter Area

For query zones, the Search Criteria Area (also called Filter Area) contains the criteria used to find objects. The design of the zone controls the number and type of filters that appear in this area. After search criteria is entered, clicking the **Search** button causes the system to look for records that match the criteria. The results are shown in the Results Area.

The system automatically collapses the filter area to allow more space for displaying the results. At that time the **Expand Filters** button may be used to open the filter area to enter different criteria. When the filter area is expanded the **Hide Filters** button may be used to collapse the filter area again without performing a new search.

For info zones, the zone's configuration indicates whether or not a Filter area is applicable and if so, whether or not it is open or closed by default. If the filter area is configured, the **Show Filter** icon is visible in the zone header. Click this icon to expose the Filter Area, if it is not visible and click the icon to hide the Filter Area if desired. Use this area to filter the information that appears in the zone by different values. Click the **Search** button to rebuild the Results Area using the specified filters.

For example, the following shows an info zone listing user groups that do not have access to a given Application Service where a filter area has been configured to allow users to show user groups specific to a user by ID or name.

The screenshot shows a web interface for filtering user groups. At the top, it says "User Groups not Linked" with a filter icon. Below that, the filter criteria are listed: "Filters: Application Service CILZRBPP, User ID EUBALDO". A table displays the results:

| | User Group | Description | Grant Access |
|---|------------|-----------------------|--------------|
| 1 | *PORTAL* | Portal System Default | Grant Access |

Below the table is a search form titled "Use to show user groups with specific user". It has three input fields: "User ID" (containing "EUBALDO"), "First Name", and "Last Name". A "Search" button is located at the bottom of the form.

The info zone includes configuration to indicate whether the filter area, when exposed, should be shown at the top of the zone (above the results) or at the bottom of the zone (below the results). For query zones, the search criteria is always displayed at the top.

Note: Press Enter. Rather than clicking the **Search** button, you can press **Enter** to trigger the search / info zone refresh.

Description Bar

The Description Bar describes the search criteria that were used to build the Search Results Area.

Results Area

The Results Area displays the appropriate list of objects. For an info zone, this is the list of appropriate objects with any input filter criteria considered. The following is an example of the results for an info zone. For a query zone, this is the list that matches the search criteria defined in the Filter Area. The following is an example of the results set of an Info Zone.

Business Objects with Status Reason

| | Business Object | Description | Statuses |
|---|-------------------------|---|-----------------------------|
| 1 | FI-BusinessFlagError | Business Flag Error | Discarded |
| 2 | FI-CubeView | Cube View | Active, Inactive |
| 3 | FI-GenericBISyncRequest | Generic BI Sync Request | Discarded, Cancel |
| 4 | FI-MessageFromDevice | Message From Device | Canceled |
| 5 | FI-MessageToDevice | Message To Device | Queued, Canceled, Processed |
| 6 | FI-MigrDataSetExport | Migration Data Set Export | Canceled |
| 7 | FI-MigrDataSetImport | Migration Data Set Import | Canceled, Completed |

For a query zone, the columns that appear may differ depending on the search criteria. For example, if you search for a customer by their driver's license number, the resulting columns may be different than the ones displayed when you search by customer name.

The following points highlight details related to viewing and working with the result set:

- **Broadcast.** If the results set is configured to display a broadcast icon, , it means that at least one other zone on the portal is configured to display data related to the record selected in the results list. Clicking this icon will cause the other zone or zones to be built or refreshed to display related data.
- **Hypertext.** One or more columns in the zone may be configured as hypertext. Clicking the hypertext will result in navigating to another page to display data related to that column based on the configuration for that column.
- **Maximum height.** The maximum height of the report area is controlled by the zone's configuration. A vertical scroll will appear when more rows exist than fit into the height.
- **Maximum rows.** The maximum number of rows that can appear is controlled by the zone's configuration. Excess rows are truncated before display. Please note, you can configure the zone to [export more rows](#) than appear in the Results Area.
- **Control column sorting.** By default zones are designed to allow a user to sort the results list by clicking any column heading. Clicking once sorts ascending. Clicking again sorts descending. However, a zone may be configured to not allow this type of sorting.
- **Work list.** Columns may be configured to enable the [work list](#) icon, . Clicking this pushes all the data into the [Work List zone](#).
- **Rearranging columns.** A zone may be configured to allow a user to rearrange columns and add or remove columns visible in the Result Area. Refer to [Column Configuration](#) for the details.

The type and variety of columns that appear in the Results Area is controlled by the zone's configuration.

Title Bar

The Title Bar contains the zone's description along with other icons and functions described in this section.

In the corner of the Title Bar, you will see an indicator that tells you whether the zone is collapsed or expanded. Each time you click the indicator, the zone toggles between expanded and collapsed. The following image shows a collapsed zone.

Note: Recommendation: For zones that are configured to show on portal preferences, set up [Portal Preferences](#) to collapse zones that aren't needed every time a portal is displayed. Rationale: The system doesn't build collapsed zones when a portal is displayed. Instead, collapsed zones are only built when a user expands them. Thus, indicating a zone is collapsed improves response times.

If the zone is configured with help text, a help icon appears to the right of the zone title. Click this icon to view the help text.

If a [saved search](#) is open for a zone, the name of the saved search is displayed after the zone title.

The following sections describe additional icons and tools visible on the title bar. Note that in addition to the information described in this section, additional actions that are specific to a zone may appear based on configuration. The actions may appear in the form of hypertext, an icon or a button.

Explorer Zone Menu

Click the Explorer Zone Menu icon  to list available tools. The following topics describe each tool.

Clear Filters

Click the **Clear Filters** link in the Explorer Zone menu to clear the filter values and zone data.

Export Data

Click the **Export** link in the Explorer Zone menu to download the zone's data in csv format. This link is hidden if the zone has been configured to not download rows.

Please note the following with respect to this feature:

- Clicking export performs the search because it is possible to configure a number of records for download that differs from the number of records configured to display.
- Because the search is performed, you can request an export even without first searching on the zone. The filters populated (or not populated) at time of exporting are the ones used for the export. If the user did not search at all or did a search and then changed the filters and exported before searching again, the results in the export may not match what is visible on the zone.
- It is possible through zone configuration to mark columns that are visible to the user interface as suppressed in the export. Conversely, it's also possible to mark columns as suppressed on the user interface but included in the export. As such, the columns visible in the export may not always match what is visible in the user interface. This applies when for zones that support [configurable columns](#). Columns removed from view through this technique are still included in the export if not marked to suppress.
- If the column results include any HTML, the HTML is stripped out before exporting.

Print

Click the **Print Zone** link in the Explorer Zone menu to print the zone.

Save Search Options

Query zones and info zones that include filter areas, allow a user to capture and save filter criteria so that the same search can be more quickly executed in the future. Users may save many different search options for the same zone. Users also have the option to nominate one search as the default so that this search is automatically loaded upon entering the zone. In addition, users may choose to set one or more searches as a Favorite, which causes the search to appear in the [Favorite Searches](#) zone in the sidebar. This allows a user to navigate to the portal for that zone and load the saved search in one click.

The Explorer Menu includes various options for supporting Saved Searches that are described below.

Note the following additional points about this functionality:

- **Click Search before Saving.** When a user wants to save a search, the search criteria should be entered and the **Search** button should be clicked prior to saving the search.
- **Criteria is saved, not results.** Although a user must click **Search** prior to saving the search, the system saves the criteria, but not the results. When returning to the query or info zone in the future and opening a given saved search, the results displayed will be the current records in the system that match the saved search criteria.
- **Multi-Query Zones.** When a user is on a multi-query zone, the searches are saved at the multi-query zone level so that all saved searches for the various search dropdowns for a given multi-query zone are visible in the Open Saved Searches menu option.
- **Functionality is Secured.** If for any reason an implementation wishes to restrict which users are allowed to save searches, the functionality is securable. Only users with **Inquire** access to the **F1_USRFAVSCH** application service will see these options in the explorer menu. This is the same application service that is used to provide access to the Favorite Searches sidebar zone.

Save As

The **Save As...** option in the Explorer Zone menu allows a user to save the current entered search criteria. This should be clicked after executing the search.

The user is prompted to provide a name for the search. This search is now available from the Open Saved Searches option. If desired, a user can also choose to make this search the Default or may choose to Add to Favorites.

This option is visible whether or not an existing saved search is loaded. When a saved search is loaded, this option allows a user to make changes to the search criteria and save a new search with that criteria.

Open Saved Search

The **Open Saved Search...** option in the Explorer Zone menu is visible if there are any saved searches for the zone that is currently visible. Select this menu entry to view the current list of saved searches for the zone. For multi-query zones, any saved search for any of the query zones that are part of the multi-query zone are visible. Choose the desired saved search. The criteria is updated with this information and the search is performed.

Save

The **Save** option in the Explorer Zone menu is visible if a Saved Search is already loaded. This option allows a user to save changes to the criteria of an existing saved search (overwriting the previously saved criteria).

Set As Default

The **Set As Default** option in the Explorer Zone menu is only visible if a saved search is loaded and it is not currently the default. Click this option to nominate this search to be the one that is loaded when navigating to this zone from the menu.

Remove As Default

The **Remove As Default** option in the Explorer Zone menu is only visible if a saved search is loaded and it is currently the default. Click this option to no longer load this search automatically when navigating to this zone from the menu.

Add To Favorites

The **Add To Favorites** option in the Explorer Zone menu is only visible if a saved search is loaded and it is not currently included in the favorite searches zone. Click this option to include this search in the [Favorite Searches](#) zone. Once a search is in the Favorite Searches zone, you can use the link to the search in the sidebar to navigate to the portal for this zone and load the saved search in one click.

Note: Not available for dependent zones There are some portals that include a zone that is not the main query or info zone on the portal, but is rather a zone providing additional information for a record that is displayed. If a zone like this has filter options or configurable columns, a user is able to save searches and mark one as a default, but will not be able to add the saved search to favorites because the zone is dependent on other data on the page that is not captured for the individual zone.

Note: Sidebar Zone Preferences. Be sure that your [portal preferences](#) are configured to include the Favorite Searches sidebar zone.

Remove From Favorites

The **Remove From Favorites** option in the Explorer Zone menu is only visible if a saved search is loaded and it is currently included in the [Favorite Searches](#) zone. Click this option when you want to keep the saved search but you no longer want it visible in your Favorite Searches zone. (Deleting a saved search that is also marked as a favorite will automatically remove the search from the favorite searches zone.)

Delete

The **Delete** option in the Explorer Zone menu is only visible if a saved search is loaded. Click this option to remove the currently opened saved search from the list of saved searches.

Note that if the saved search had been configured as favorite, deleting the saved search remove it from the favorite searches zone.

Show Filters

Click the **Show Filters** icon  to show the [Filter Area](#). This button only appears if the zone has been configured to have filters.

Note: If the zone is configured to have filters and the drag and drop (column configuration) area, only one or the other is shown at any given time. It means that a user can either change the filter criteria and refresh the search results or change the column configuration and refresh the results.

Show Column Configuration Area

Click the **Column Configuration** icon  to show the [Column Configuration Area](#). This button only appears if the zone has been configured to allow columns to be dragged and dropped into the Results Area.

Note: If the zone is configured to have filters and the drag and drop (column configuration) area, only one or the other is shown at any given time. It means that a user can either change the filter criteria and refresh the search results or change the column configuration and refresh the results.

The Open Zone Maintenance Icon

Click the **Go To Zone** icon  to switch to the zone's [zone maintenance](#) page. On this page, you can change the parameters that control the zone's behavior.

Note: Debug mode only. This icon only appears when the system operates in [Debug](#) mode.

Configurable Columns

Info zones and query zones may be configured to allow users to rearrange columns and to remove or add columns to the output. This is also referred to as "drag and drop" of columns.

When a zones is configured to support this functionality, the [Show Column Configuration Area](#) icon is visible in the zone title area. Click this icon to expose the Column Configuration Area, if it is not visible and click the icon to hide the Column Configuration Area if desired.

If configurable columns are allowed, a user may rearrange the order of columns currently displayed in the Results Area by clicking the column heading and "dragging" it to the desired location.

In addition, the column configuration area may display columns that are not currently in the Results Area. These are indicated by a color cream background. A user can drag one of these columns to the results area and then click **Refresh** to rebuild the zone.

To remove a column that is currently in the results area, click the trash can icon next to the column name in the column configuration area and then click **Refresh** to rebuild the zone.

The following is an example of how the Column Configuration Area looks:

Multi-Query Zones

This type of zone combines individual Query Zones into a single query zone. A **Search By** dropdown, built from the zone descriptions of the individual Query Zones, allows you to select the desired query to execute. Selecting a specific Query Zone display the filters of that query in the filter area. At this point the zone simply executes the selected Query Zone, as if it was executed on a standalone zone. By default, the first query zone option is selected.

Map Zones

A map zone displays information related to one or more objects. For objects that are maintained using portal-based pages, the standard display of the object is using a map zone. Map zones may be configured to display an explicit map or may dynamically display the map based on the configuration of the record being displayed.

Because the information displayed in a map zone is configured using HTML, virtually any format supported by HTML is possible. The following is an example of a typical map zone used to display information about an object.

Migration Request: Framework Configuration, Group

Add Search Bookmark Refresh

Main

Migration Request

Main

Record Actions

Edit Delete Duplicate Export

Migration Request: F1-FrameworkConfig

Description: Framework Configuration

A [tool tip](#) can be used to display additional help information for the details shown in a map zone. The tool tip may appear adjacent to the section header or adjacent to individual elements on a map.

Note: You can customize the help icon or disable map help using the [Custom Look and Feel](#) feature configuration.

Open Map Maintenance Icon

Click the **Go To Map** icon  to switch to the [UI map](#) maintenance page. On this page, you can view the HTML configuration for the zone. Note that for map zones that display a business object configured without a map, the elements displayed are automatically rendered. In this case, no icon is visible.

Note: Debug mode only. This icon only appears when the system operates in [Debug](#) mode.

Tabbed Display Zones

This type of zone combines individual [map zones](#) into a single zone, allowing for complex of information to be organized and displayed in different tabs.

Tab labels are built from the zone descriptions of the individual zones and become the zone's title. Selecting a specific tab displays the information managed by the underlying zone. By default, the first tab is selected.

Timeline Zone

A timeline zone is used to show events over time for multiple types of data. This type of zone is helpful for providing a consolidated view of separate events occurring in time that may in fact impact each other. For example, in the billing system, a timeline can show bills, payments and collection processes for the same time period.

The topics in this section describe the functionality available in timeline zones.

Timelines Zones Are Configured By Your Implementation Team

The product provides support for creating timeline zones. However, whether timeline zones are configured for your implementation and on which portals they may be visible will depend on your specific configuration. Refer to [Configuring Timeline Zones](#) for general information about configuring timeline zones. Refer to your specific edge application's documentation for details about what type of timeline information is provided out of the box.

You Can Move Through Time

You can click the controls at the top of a timeline zone to change the date-range of the zone's information. To reposition the timeline to a specific date, selected the desired month and year at the top of the zone and click the search arrow.

Controls at the top right of the zone allow you to navigate through time.

- To go back one year, click the double-left arrow.
- To go back one month, click the single-left arrow.
- To go to today, click the middle dot.
- To go forward one month, click the single-right arrow.
- To go forward one year, click the double-right arrow.

Timelines Can Have Many Lines

Depending on how a timeline zone is configured, it will typically have one or more "lines" that show when significant events have occurred. Each line represents a specific type of data. The data may be related to a specific maintenance object, for example, payments may be displayed in one line and bills in another. It may also be possible to create multiple lines for different types of records for the same maintenance object. For example, if your product provides an algorithm to display cases, it may support defining a different entry for each case type.

Each Line Shows Events

Each line on a timeline may contain zero or more events where each event shows the date when the event occurs. For example, the payment line in a timeline has a separate event for every payment received from the customer. Each line's description contains the number of events on the line.

CAUTION:

If a line has more events than can fit onto a timeline, the line will show the first "chunk" of events and a message will appear in the "more info area" explaining that some events have been truncated. If this happens and the truncated events are in a later period, you can reposition the timeline's base period to show the truncated events.

Hovering Over An Event Shows the Event Information

When you hover over an event's date icon, a pop-up widow appears showing details of the event. The following information may appear:

- The event date.
- The event "hover text". Typically the standard information string is shown for each event.
- The event's common "information string" appears. This information is hypertext to allow for easy access to the transaction on which the object is maintained.
- Additional information may appear. This is dependent on the particular timeline algorithm. Refer to each timeline algorithm's description to find out if additional information appears in the pop-up area under any conditions.
- If the algorithm has configured BPA scripts that can be executed to perform business processes on the object, the BPA script description appears prefixed with a "wizard's hat" icon.

Common Base Portals and Zones

The following sections describe common standards followed by the product for base query and maintenance dialogue.

All-In-One Portal

The all-in-one portal is used for low volume objects, where a small number of records are expected.

For example, many control tables use this style of portal. In this portal, rather than separate query and maintenance portals, a single portal allows a user to find a record and maintain the record. A zone listing all existing records is displayed when first entering the portal. A user can perform actions on existing records or add new records from there. More details about the list zone are provided below.

Refer to [Maintenance Portal](#) for information about zones commonly found on maintenance portals.

The all-in-one portal will typically provide the ability to add a new record. This may be a button in the Page Action area or a hyperlink defined directly on the list zone's header area.

List Zone

This info zone appears when first entering the portal and displays a row for each record.

The following functions are commonly available in a list zone:

- A broadcast icon is included in each row. Clicking this icon opens other zones that contain more information about the adjacent record.
- An **Edit** icon may be included in each row. Clicking this icon launches the maintenance BPA script to modify the adjacent record.
- A **Duplicate** icon may be included in each row allowing the user to duplicate the adjacent record without having to first display the record.
- A **Delete** icon may be included in each row allowing the user to delete the adjacent record without having to first display the record.
- If the record has a simple BO lifecycle of **Active** and **Inactive**, the list zone may include a button to **Activate** or **Deactivate** the adjacent record.

Separate Query and Maintenance Portals

For high volume objects where more sophisticated search criteria is needed to find a particular record, separate portals are provided to search for the record and to maintain it.

The query portal contains a zone to search of the object that you wish to maintain. Additional information about the query portal's search zone is provided below. Clicking an appropriate record in the search results navigates to the object's stand-alone maintenance portal.

The query portal will typically provide the ability to add a new record. This may be a button in the Page Action area or a hyperlink defined directly on the list zone's header area.

Query Portal Search Zone

The query portal contains one zone used to search for the object.

The zone may be a standard query zone or may be a multi-query zone providing one or more ways to search for your record.

Once the search results are displayed, click on the hypertext for the desired record's information string to navigate to the stand-alone maintenance portal.

Maintenance Portal

A maintenance portal refers to a page that is used to view and maintain a specific record. These types of records are governed by a business object, which defines the user interface layout for both the display of the record and the add or update of the record.

An all-in-one portal is a type of maintenance portal where the maintenance zone is displayed once a record has been broadcast from the list zone. For the separate query and maintenance portal dialogue, the maintenance portal includes only zones relevant for the specific record selected.

Maintenance portals may have multiple tabs to display information relevant for the object. Often, if the object has a Log, the log is on a separate tab. (However, there may be some maintenance portals that include the log zone on the Main tab.)

The stand-alone maintenance portal is typically configured with the ability to navigate back to the query portal using either a **Search** button in the Page Actions area or using a **Go To Search** hyperlink in the main zone's header area. The stand-alone maintenance portal may also include the ability to add a new record using an Add button in the Page Actions area. (If not, a new record can be added by navigating through the menu or by navigating to the query portal where an Add hyperlink may be found.)

The following sections describe zones that are common to portals used to maintain a record. Note that additional zones may exist for specific all-in-one portals or stand-alone maintenance portals based on the particular functionality. Refer to the documentation for each portal to understand the specific zones that are provided.

Object Display Zone

This is a zone that displays the object being maintained.

An object being displayed may or may not allow for actions or updates to be made. Typically there is a Record Actions section in the display area that presents the valid actions. Depending on the functionality, the actions may prompt the users to input values required for that action.

Log Zone

If the maintenance object for the record includes a status, it typically has a log that records important events in its lifecycle.

This log is shown in an info zone on the portal, either on the Main tab or on a separate Log tab. A link appears in the zone's title bar to allow the user to add a new manual log entry.

Process Flow

This portal is used to guide a user through the steps needed to complete a process flow. If the process flow type is configured to keep a record of a completed process flow then this portal may also be used to display the details of such record.

Refer to [Understanding Process Flows](#) for more information.

Each type of process flow is assumed to be configured with designated custom menu options that allows you to launch a new process flow of that type as well as review saved off and completed records. When reviewing existing process flow records, you are brought to a query portal with options for searching for a specific record. You may **Resume** a saved off but not yet finalized process flow or review a complete one.

The **Process Flow** zone on the portal's **Main** tab page assists the user in completing the process flow as well as displays the information captured on a completed process flow.

Fixed Pages

There are some pages in the system that are built using a fixed page metaphor. All user interfaces implemented in this way function in a similar manner. This section describes functionality to these types of pages.

Note: Not all pages in the application use this metaphor. The preferred metaphor for pages in the system is to use portal-based pages. For more information see [Common Base Portals and Zones](#) on page 43.

Maintenance Pages

Maintenance pages are used to maintain (add, change, etc.) the information in the system using a fixed page metaphor. This section focuses on functionality common to all maintenance pages using this metaphor.

The Unique Identifier Area

Every object in the system must have a unique identifier. For some objects, typically administrative or control table data, the unique identifier is defined by the user creating the record. Other objects, typically master or transaction entities, the unique identifier is assigned by the system after the record is saved.

Where the identifier is displayed depends upon whether the ID is user-defined or system generated.

Pages displaying objects with a user defined identifier (such as To Do Type) typically display the identifier on the left along with a search button. For master and transaction tables, (such as To Do Entry) the unique identifier is typically

found in the upper right corner of the screen along with a search button and is labeled as the entity's ID. In this case, if there is an information string associated with the object, it is displayed on the left.

If the object being maintained has an associated context menu, a [Context Menu Button](#) is displayed appear.

Confirmation & Error Messages

Whenever a database modification action is requested, the system first validates the data to be put on the database.

First, the system validates the information. If there are errors, the first error encountered is displayed in a window. In addition to the error message, the error window also contains the error number and the identities of the programs that detected the error. If you don't understand an error and you have to call product support, please supply them with this information.

If there are no errors, the system is modified.

Warning If Unsaved Changes Exist

If you make any changes to an object and you don't commit these changes to the database, the following warning appears: "You have unsaved changes that will be lost if you continue. Press OK to continue anyway."

If you want to commit the changes, click **Cancel**. You will then return to the page and can make further changes or press Save. If you want to discard your changes and transfer to the new page, click **OK**.

CAUTION: This warning is not displayed if you are working on a *new* object on a fixed page and you navigate to a different page. Information about new objects is preserved in memory in anticipation of your return to the page. For example, if you are in the middle of adding a new user and you want to quickly reference information on a different page, you will not receive the above warning because your information will be saved. If you use the back button to return to the user page, all of the information you were adding will be present and you can enter the rest of the new user's data.

Query Pages

Query pages are used to display record sets in the system. Most query pages function in a similar manner. This section focuses on functionality common to all of the system's query pages.

The Search Area

The upper right corner of the screen is almost always the identifier of the object associated with the search. In Oracle Utilities Customer Care and Billing for example, the unique identifier on the Account Financial History page is the Account ID.

To the right of the unique identifier is a [Search button](#). This button is used to search for a different object than the one whose data is being displayed in the page.

If the object being displayed has an associated context menu, a [Context Menu Button](#) is displayed.

User Preferences

The Preferences (or My Preferences) transaction and the User Maintenance transactions are the same except that with My Preferences, only the following items can be modified:

- Main Tab
 - Language
 - Display Profile
 - Time Zone
 - Email Address
 - Sidebar Width
 - Sidebar Location
 - Sidebar State
 - Home Page
 - To Do Summary Age Bar Parameters

- Bookmarks
 - All information can be modified
- Portal Preferences
 - All information can be modified
- Favorite Links
 - All information can be modified
- Favorite Scripts
 - All information can be modified

User - Main

This page lets you view or define user information and access settings.

To open the page, use one of the following navigation options:

- The **Admin > Security > User > Search** menu item.
- The **Menu > My Preferences** menu item.
- The **User Menu > Preferences** menu item in the application toolbar.

Note that some fields are only modifiable when the page is opened from the from the **Admin** menu.

Description of Page

Basic user identification information is viewed or set in the **First Name**, **Last Name**, **User ID**, and **Login ID** fields, all of which are modifiable only when the page is opened from the **Admin** menu. User and logon IDs must be unique. The Login ID is the ID that the user uses to log in to the system. The User ID is the ID that is used throughout the application when users are assigned to tasks or when the user ID is stamped on records when logging add or update actions.

Language defines the language in which the user's screen prompts and messages appear.

Set **User Enable** to allow the user to access the system.

Note: This field, available only when the page is accessed through the **Admin** menu, provides special field-level security. A user can change the field only if the **Enable/Disable** access mode is set.

Display Profile defines the [display options](#) for the user.

The following fields are related to defining a template user along with some configuration available for using a template user. This fields are modifiable only when the page is accessed through the **Admin** menu. Refer to [template user](#) for more information about these fields.

- Set **User Type** to **Template User** if the user is going to serve as a [template user](#).
- If a user's [portal preferences](#) are to be inherited from a "template user", use the **Portals Profile User** to define the user ID of the template user.
- If a user's [favorite links](#) are to be inherited from a "template user", use the **Favorites Profile User** to define the user ID of the template user.

The **Time Zone** associated with the user may be defined. Implementations may use this information for features and functions where the user's time zone impacts display of data. Refer to [Designing Time Zones](#) for more information about the use of time zones.

Email Address captures the user's email address.

Sidebar Width defines the number of pixels to use for the user's [sidebar](#) area. A setting of 250 is recommended as a minimum. Depending on the width of a user's monitor, a higher setting (such as 250) will display more information without compromising the space on the main area of the application. Setting the value to 0 will suppress the sidebar. The width setting is updated in background to retain the value based on dynamic sizing.

Sidebar Location governs whether the sidebar appears before or after the main page area. If no value is specified, the default position of the sidebar is after the main page area.

Sidebar State indicates whether the sidebar is open or closed. The state is updated in background to retain the value based on dynamic opening or closing of the sidebar.

Home Page defines the page that appears when the user starts a session or clicks the [Home](#) link.

The To Do entry fields control how To Do entries are aged in respect of the "age bars" that appear on [To Do Summary](#), [To Do Supervisor Summary](#) and the [To Do Summary Sidebar Zone](#).

- Use **Lower Age Limit for Yellow Bar** to define the number of days old a To Do entry must be to be considered "yellow" in the age bar. To Do entries below this limit are considered "green" in the age bar.
- Use **Upper Age Limit for Yellow Bar** is the high limit for the "yellow" bar. To Do entries older than this are considered "red" in the age bar.

The **User Group** collection defines the group(s) with which the user is associated and the date (if any) when the user's association expires. This feature is modifiable only when the page is accessed through the **Admin** menu. For more information, see [The Big Picture Of Application Security](#). Assignments of users in a user group can also be established or maintained through the [User Group](#) page.

Note: The ability to maintain the user groups on this page requires special field-level security. A user can change the field only if the **System Administration** access mode is set.

If your implementation has configured [Object Erasure](#) for the User maintenance object, the **Object Erasure Schedule** sidebar zone is visible displaying the erasure status for this user record, if applicable. Refer to [Erasing User Information by Obfuscation](#) for more information on object erasure for User records.

User - To Do Roles

Open the User page and then navigate to the **To Do Roles** tab to define the To Do roles assigned to the user.

The information on this page cannot be modified if accessed through **My Preferences**.

Fastpath: A user's To Do roles control the types of **To Do** entries the user can access. For additional information on To Do roles, see [To Do Entries Reference A Role](#).

Description of Page

The grid contains the user's To Do roles. To modify a To Do role linked to the user, simply move to a field and change its value. To remove a To Do role, click the - (minus) button. To add a new To Do role, click the + (plus) button and enter the role.

Where Used

Every **To Do** entry references a role. A To Do role has one or more users (and a user may belong to many To Do roles). Users who are part of the To Do role assigned to a To Do entry may work on the To Do entry. For more information on this feature, see [The Big Picture Of To Do Lists](#).

User - Access Security

Open the User page and then navigate to the **Access Security** tab to define a user's security rights. You cannot modify this page if you accessed it through **My Preferences**.

Fastpath: Refer to [The Big Picture of Application Security](#) for more information about data access roles and access groups.

Description of Page

Use the **Default Access Group** to define the access group that is defaulted on new records added by this user that are subject to [row security](#).

The scroll area contains the **Data Access Roles** to which this user belongs. A user's data access roles play a part in determining the accounts whose data they can access.

To add additional data access roles to this user, click the + button and specify the following:

Enter the **Data Access Role**. Keep in mind that when you add a **Data Access Role** to a **User**, you are granting this user access to all of the accounts linked to the data access role's access groups.

Use **Expiration Date** to define when the user's membership in this data access role expires.

Note: You can also use [Data Access Role - Main](#) to maintain a data access role's users.

The tree highlights the **Access Groups** to which the above **Data Access Roles** provide access.

User - Bookmarks

This page is used to manage a user's bookmarks that are created when a user clicks the [Bookmark](#) button and saves a bookmark. From this page the user can delete a bookmark, change the name of the bookmark or change the sort sequence.

Open the User page and then navigate to the **Bookmarks** tab to modify or delete a bookmark.

Description of Page

Sequence is the sort sequence associated with the bookmark. Bookmarks with the same sequence are then sorted alphabetically.

Name is the user-defined name assigned to the bookmark. This is the text that is visible in the [Bookmarks](#) sidebar zone.

Note: Favorite Links vs. Bookmarks. Favorite links are configured through the user page and define pages that a user can navigate to. They do not define context (although some pages may use information currently in global context when navigating). Some users may not be allowed to configure their own favorite links and would see the favorite links associated with a profile user. Bookmarks are created using a bookmark button available on each page. The bookmark saves navigation information, context information and also captures some information about the state of a page. Bookmarks are not governed by any user profile configuration.

User - Portal Preferences

The base product contains several [portals](#) that allow users to customize them via portal preferences. Portal preferences allow users to control:

- Which zones appear on the portal
- The order in which the zones appear
- Whether the zones should be "collapsed" (i.e., minimized) when the portal opens.

Note: You may not be able to change your portal preferences. If a note appears immediately before the list of portals, a system administrator has configured your user ID to reference a **Portals Profile User** (this is defined on the **Main** tab). Preferences set in this way cannot be modified. System administrators do this in order to enforce a common look-and-feel throughout the user community.

Open the User page and then navigate to the **Portal Preferences** tab to modify a user's preferences.

Description of Page

The [accordion](#) contains a row for every portal configured to show on user preferences and to which you have access. To change how a portal's zones appear, expand the respective row and change the elements accordingly. The remainder of this section describes how you can configure how a portal's zones appear.

Zone lists all of the [zones](#) in the portal.

Place a check under **Display** if the zone should be displayed on the portal.

Place a check under **Initially Collapsed** if the zone should be minimized when the portal is initially opened. Setting zones as initially collapsed is a good idea to save space and to help pages to load more quickly. Refer to [Zones May Appear Collapsed When A Page Opens](#) for more information.

CAUTION: Recommendation. It is recommended that you set your preferences to collapse zones that you don't use often. This is because the system doesn't perform the processing necessary to build collapsed zones until you ask to expand a zone. Opening a page with zones collapsed accelerates the response times of portal.

Use **Sequence** to control the position of the zone in respect of the other zones. This field is disabled if **Display** is not checked. Duplicate **Sequence** numbers are allowed.

For zones displaying data that is changing often, use **Refresh Seconds** to define in seconds how often the zone is refreshed. The minimum valid value is 15. The maximum valid value is 3600 (1 hour). A value of 0 indicates no automatic refresh.

Security Access indicates whether the user has access rights to a zone. Refer to [Granting Access To Zones](#) for more information.

User - Favorite Links

This page is used to define a user's favorite transactions and URLs. Each such link appears as an entry in the [Favorite Links Zone](#) in the [Sidebar Portal](#) on page 31.

Note: A hot key can be used to execute a favorite link. Rather than clicking a button in the favorite links zone, you can invoke your first nine favorite links by pressing `Ctrl + a number` (where the number corresponds with the relative position of the transaction in your list of favorites). Note that the numeric keypad on your keyboard cannot be used to implement this function.

Open the User page and then navigate to the **Favorite Links** tab to modify a user's favorite links.

Description of Page

Note: You may not be able to change your favorite links. If a **Note** appears beneath your **User ID**, your user id has been setup to reference a specific **Favorites Profile User** as defined on the **Main** tab. If a system administrator has setup your user ID in this way, your preferences may not be changed. System administrators may apply this feature in order to enforce a common look-and-feel throughout the user community.

Each row references a [Navigation Option](#). The navigation options supplied with the base package correspond with the system's menu items. This means you can setup a favorite link to open any transaction in the system (in either **add** or **update** mode).

Note: Favorite links can point to other places. The navigation options supplied with the base package always open a transaction's **Main** tab. If you find yourself continually accessing a different tab page, you can have your implementation team create a new navigation option that references the desired tab page. Once this navigation option is set up, you can reference it as one of your favorite links. In addition, it's also possible for your implementation team to setup navigation options that open a URL outside of the system. For example, your implementation team could setup a navigation option to a credit rating company's website. Once this navigation option is set up, you can reference it as one of your favorite links.

Use a **Sequence** to control the order in which the navigation option appears in the [Favorite Links Zone](#).

Security Access indicates if you have been given security rights to the respective transaction. Refer to [The Big Picture Of Application Security](#) for more information.

Note: Favorite Links vs. Bookmarks. Favorite links are configured through the user page and define pages that a user can navigate to. They do not define context (although some pages may use information currently in global context when navigating). Some users may not be allowed to configure their own favorite links and would see the favorite links associated with a profile user. Bookmarks are created using a bookmark button available on each page. The bookmark saves navigation information, context information and also captures some information about the state of a page. Bookmarks are not governed by any user profile configuration.

User - Favorite Scripts

This page is used to define a user's favorite scripts. Each script is displayed in the **Favorite Scripts** zone on the **Sidebar** where it can be used to [initiate a script](#).

Note: A hot key can be used to execute a favorite script. Rather than selecting a script from the business process assistant search, you can invoke your first nine favorite scripts by pressing `Ctrl + Shift + a number` (where the number corresponds with the relative position of the script in your list of favorites). Note that the numeric keypad on your keyboard cannot be used to implement this function.

Open the User page and then navigate to the **Favorite Scripts** tab to modify a user's Favorite Scripts.

Description of Page

Note: You may not be able to change your favorite scripts. If a **Note** is displayed on top of the grid, your user id has been setup to reference a specific **Favorites Profile User** as defined on the **Main** tab. If a system administrator has setup your user ID in this way, your preferences may not be changed. System administrators may apply this feature in order to enforce a common look-and-feel throughout the user community.

Each row in the grid contains one of your favorite **Scripts**.

Use the **Sort Sequence** to control the order in which the scripts appear in the zone.

Security Access indicates whether you have access to the script's application service. Refer to [The Big Picture Of Application Security](#) for more information.

User - Characteristics

Select **Admin > Security > User > Search** and navigate to the **Characteristics** tab to define characteristic values for the user. You cannot modify this page if you accessed it through My Preferences.

Description of Page

Use the characteristics grid to capture additional information about the user.

You can only choose **Characteristic Types** defined as permissible for the user record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Enter a valid **Characteristic Value** for the selected characteristic type. You may enter more than one characteristic row for the same characteristic type, each associated with a unique **Sequence** number. If not specified, the system defaults it to the next sequence number for the characteristic type.

User - Miscellaneous

Select **Admin > Security > User > Search** and navigate to the **Miscellaneous** tab to view additional information associated with a user.

User Id, First Name and Last Name are displayed. Depending on your implementation, additional zones may appear on the User Portal

If additional zones appear, use the embedded help for information about the fields managed on the zone.

Initiating Scripts

Your implementation team can set up business process assistant (BPA) [scripts](#) to walk you through business processes. Once scripts have been set up, you can initiate a script using any of the following methods:

- You can define a list of your "favorite scripts" on your [user preferences](#). You can then invoke any of the scripts from the Favorite Scripts zone on the sidebar. You can also invoke any of your first 9 favorites by pressing `Ctrl + Shift + a number` (where the number corresponds with the relative position of the script in your list of favorites). For example, if you press `Ctrl+Shift+2` and you've setup your "favorite scripts" to be **Start Autopay** and **Stop sending marketing information**; the **Stop receiving marketing information** script is invoked. Note that the numeric keypad on your keyboard cannot be used to implement this function.
- You can configure a menu item to launch a script by referencing a [navigation option](#) that is a **script** navigation option type.
- The system creates [To Do entries](#) to highlight tasks that require attention (e.g., bills in errors, accounts without bill cycles, etc.). Users can complete many of these tasks without assistance. However, you can set up the system to automatically launch a script when a user selects a To Do entry. For example, consider a To Do entry that highlights a bill that's in error due to an invalid mailing address. You can set up the system to execute a script when this To Do entry is selected. This script might prompt the user to first correct the customer's default mailing address and then re-complete the bill. Refer to [Executing A Script When A To Do Is Launched](#) for more information.
- You can indicate that a script should be [launched upon entering the system](#). This functionality enables an external system to launch the system and immediately launch a script.
- The following [hot keys](#) cause an interactive menu to be displayed:
 - `Ctrl+Alt+Q`

- Ctrl+Shift+S

Description 🔍

Search only Eligible Scripts

| Description | |
|--|----------|
| Account Sync on CS Req Account page | Eligible |
| Accounting Calendar Maintenance | Eligible |
| Activity Asset Completion Action | Eligible |
| Activity Resource Requirement - Add User Log Entry | Eligible |
| Add Crew Type Resources | Eligible |

The menu allows you to search for a script using any word in its description. Note, if you've turned on **Search only Eligible Scripts**, your search is limited to [eligible scripts](#). Note, the system displays an indication if each script in the grid is **Eligible** or **Ineligible** in this section.

You can initiate a script from this area by clicking on it.

When a script is initiated, this menu closes and the [object display area](#) shifts down to make room for the script area.

Note: Securing scripts. Only scripts the user is allowed to execute are displayed. Refer to [Securing Script Execution](#) for more information.

Note: Customize the script area. Using the [Height](#) step type, an individual script may be configured to use more or less of the script area than the standard script area. It is also possible to configure a script to hide the script area altogether.

The information in the script area takes you through the steps in the selected business process (note, your implementation team controls the information that appears in the script area).

The following points highlight useful information common to all scripts:

- **Return focus to script area.** Often during a script the focus moves from the script area to another section of the page. For example, you might be required to fill in data for a new record being added. When you are ready to return to the script area, rather than using the mouse to return to the area, you can press `Ctrl+Shift+F`. The focus returns you to either the first available input field or to a "default" button if no input field is available.
- **The Continue button.** Many steps in a script ask you to click the **Continue** button when you're ready to restart a script. For example, a step may ask you to confirm a customer's automatic payment information and then click **Continue** when you're ready for the script to restart. Rather than using the mouse to click this button, you can press `Ctrl+Shift+C`.
- **Selected button changes color.** When you click a button in the script area, the button selected changes color so that you can easily see which option you selected.

Fastpath: Refer to [The Big Picture Of Scripts](#) for more information about scripts.

Note: You can abort a script at any time by clicking the red X button in the upper right corner of the script area (or by pressing `Ctrl+Shift+X`).

Shortcut Key Summary

The following table summarizes the keyboard shortcuts (hot keys) available in the system:

Note: It is possible that your specific product supports additional shortcut keys. Refer to your product documentation for more information.

Note: It is possible that some of the following system accelerator keys may duplicate shortcuts, or hot keys, that are predefined within your browser. If this is the case, the browser's functionality commonly takes precedence.

Note: It is possible that your implementation uses one of the accelerator keys listed below for a different purpose. For example, in some languages, a shortcut key may be used for a special character in the alphabet not included on all keyboards. It is possible to turn off any of the Alt+letter shortcuts and Ctrl+Alt+letter shortcuts listed below using a properties file entry. The property is `ouaf.shortcut.ignore.altKeys=` where one or more letters may be entered separated by a comma. When setting this property, the system automatically enables a 'potential alternate key' for certain functions (see the table below). Refer to the *Server Administration Guide* for more information about the property.

| Accelerator Key | Potential Alternate Key (see Note above) | Function |
|--------------------------------|--|---|
| Ctrl+Alt+A | | Opens the Admin Menu . |
| Alt+B | | Returns to the previous page on which you were working. This is the equivalent of clicking the Back on page 10 arrow. |
| Ctrl+Alt+B | | Launches the Bookmark dialog. This is the equivalent of clicking the Bookmark button. |
| Alt+C, Ctrl+Alt+C, Alt+Shift+C | | Clears the currently displayed object from the page. This is the equivalent of clicking the Clear button. |
| Ctrl+Shift+C | | If the current step in the Script area has a Continue button, this shortcut is equivalent to clicking Continue . |
| Ctrl+Alt+D, Alt+D | | Creates a duplicate of the object being displayed. Equivalent to clicking the Duplicate button. |
| Ctrl+Alt+F | | Positions the user's cursor to the Search input field. |
| Ctrl+Shift+F | | If the Script area is open and you are working on a different area of the page, this key returns focus to the script area. Focus returns to either the first available input field or to a "default" button if no input field is available. |
| Alt+G | | Returns to the most recent page that was displayed when the Back arrow was clicked. Equivalent to clicking the Forward arrow. |
| Ctrl+Alt+H | | Opens a dropdown list of recently-visited pages, the equivalent of clicking the History icon. |
| Alt+J | | Minimizes the sidebar . It also expands the sidebar, if it was minimized. |
| Alt+K | | Transfers you to To Do Entry - Main for the current item in the To Do list. Pressing Alt+K while on this page takes you to the first To Do entry on the list. |
| Ctrl+Alt+L | | Logs the user out of the system. This is equivalent to clicking the Logout menu item. |
| Ctrl+Alt+M | | Opens the Menu . |
| Alt+N | Alt+Shift+N | Displays the next entry in the search results. Equivalent to clicking Next Item . |
| Alt+O | Alt+Shift+O | Navigates to the user's home page. Equivalent to clicking the Home icon. |
| Ctrl+Alt+P | | Opens your User Preferences page. Equivalent to clicking the Preferences menu item. |

| Accelerator Key | Potential Alternate Key (see Note above) | Function |
|-------------------------------|--|---|
| Alt+P | | Displays the previous entry in the search results. Equivalent to clicking Previous Item . |
| Ctrl+Alt+Q | | Opens the business process assistant , where you can select a script that walks you through a business process. |
| Alt+R Ctrl+Alt+R | | Refreshes the page with the last saved version of the object being displayed in the page. Equivalent to clicking the Refresh button. |
| Alt+S | Alt+Shift+S | Saves any changes that you've made on the database. Equivalent to clicking the Save button. |
| Ctrl+Shift+S | | Opens the business process assistant , where you can select a script that walks you through a business process. |
| Alt+X | Alt+Shift+X | Opens the To Do Summary . |
| Ctrl+Shift+X, Ctrl+Shift+Z | | If the Script area is open, equivalent to clicking the Close button in the script area. If a pop-up window is open, this closes the window. |
| Alt+Y | | Displays the previous item in the To Do list. Equivalent to clicking the Previous button in the Current To Do zone. |
| Alt+Z | Alt+Shift+Z | Displays the next item in the To Do list. Equivalent to clicking the Next button in the Current To Do zone. |
| Alt+Insert | | Inserts a new row into an editable grid if the insertion point is in the grid. Equivalent to clicking the Insert button. |
| Alt+Delete | | Removes a row from an editable grid if the insertion point is in the grid. Equivalent to clicking the Delete button. |
| Alt+[| | Navigates to the next main page component area of the application. Refer to Page Components for the list of the main page components. Using Shift+Alt+[reverses the sequence of navigation. |
| Alt+] | | Navigates to the next zone . When you are on a portal with zones, this key brings you to the next zone in the portal. If you are on the last zone in the portal, the key brings you to the first zone on the sidebar, if visible. Keying through all the zones on the sidebar brings you to the first zone on the portal displayed in the main area. If the page displayed is a fixed page rather than a portal, this key will only navigate within the sidebar. Using Shift+Alt+] brings you to the previous zone. |
| Alt+F1 | | Invokes online Help for the application. Equivalent to clicking the Help entry in the Help menu. |
| Alt+1 ...Alt+9, Alt+0 | | These keys are only applicable when a page / portal with multiple tabs is open. The shortcuts open the tab page whose relative position corresponds with the shortcut number. For example, if you press Alt+3 on a page with multiple tabs, the third tab is displayed. Alt+0 navigates to the 10th tab. If there are more than ten tabs on a page, you must use the mouse or F2/Shift+F2 to display additional tabs. Note that you cannot use the numeric keypad for these shortcuts. |

| Accelerator Key | Potential Alternate Key (see Note above) | Function |
|--|--|--|
| Ctrl+1 ...Ctrl+9 | | Invokes the favorite link whose relative position corresponds with the shortcut number. For example, if you press Ctrl+3, the transaction for your third "favorite link" is invoked. Note that you cannot use the numeric keypad for these shortcuts. |
| Ctrl+Shift+1 ... Ctrl+Shift+9 | | Invokes the favorite script whose relative position corresponds with the shortcut number. For example, pressing Ctrl+Shift+2 selects the second of your "favorite scripts". The numeric keypad cannot be used for these shortcuts. |
| Alt+left arrow | | Populates a scroll area with the previous entry. Equivalent to clicking the scroll control  . |
| Alt+right arrow | | Populates a scroll area with the next entry. Equivalent to clicking the scroll control  . |
| Enter when in a field with an adjacent Search button | | Invokes the search. Equivalent to clicking the Search Button . |
| Enter when a row in a search result grid is highlighted | | Selects the item and closes the search. Note that after selecting an item from the search results, you can press Alt+N or Alt+P to scroll up or down through other items in the result grid without returning to the search results. |
| Enter when a menu item is highlighted | | Selects the menu item. |
| Enter when the insertion point is within a tree node | | Equivalent to clicking on the item in the tree: <ul style="list-style-type: none"> • If the insertion point is on a node image, the node is either expanded or collapsed, dependant on its current state. • If the insertion point is on a context menu, the context menu is opened and normal menu processing applies. • If the insertion point is on a "link" element, normal navigation processing occurs. |
| Tab when a row in a search result is highlighted | | Highlights the next row. |
| Shift + Tab when a row in a search result is highlighted | | Highlights the previous row. |
| Space when the insertion point is on a button | | Equivalent to pressing the button. |
| Space when the insertion point is in a date/time field | | Opens the date/time selection window. |
| Space when the insertion point is in a check box | | Toggles the check box between checked and unchecked. |

| Accelerator Key | Potential Alternate Key (see Note above) | Function |
|---|--|--|
| Page Up while in a list grid | | Scrolls the contents of the list grid up approximately one page. |
| Page Down while in a list grid | | Scrolls the contents of the list grid down approximately one page. |
| Up or Down Arrow when in a dropdown list | | Moves to the next or previous value in the list. You can also press a letter key to locate the next value starting with that letter. |
| Up or Down Arrow keys when in search results | | Highlights the next/previous row in search results. |
| Up, Down, Left or Right Arrow when using a menu | | Highlights other menu items. |
| Esc when using a menu | | Closes the menu. |
| Alt+F2 | | Opens the next tab page when viewing a page / portal with multiple tabs. |
| Shift+Alt+F2 | | Opens the previous tab page when viewing a page / portal with multiple tabs. |

Customer Information

We use the term **customer information** to reference the demographic, geographic, and financial objects that form the core of your CIS system. In this section, we describe how to maintain these objects.

Understanding The V

The "V" is the shape of a diagram we use to illustrate the objects that form the core of the system: **Person, Account, Premise, Service Agreement, and Service Point**. These objects hold demographic, geographic, and financial information about your company's customers and properties. The following diagram illustrates the objects in the "V", as well as important objects related to the "V" objects (**bill, payment, meter, field activity, meter read**).

You must intuitively understand the concepts embodied in the "V" before you can perform the business processes in the system. In this section, we provide an overview of these objects. In later sections, we describe how you maintain this information.

Persons

A person exists for every individual or business with which your company has contact. Besides customers, persons exist for landlords, contractors, accountants at corporate customers, third party guarantors, energy distributors, collection agencies, etc.

On a person is maintained demographic information like Name, Mailing Address, Phone Numbers, Email Address, and Life Support Details.

Most persons are linked to at least one [account](#) because, without an account, the person cannot receive a bill. There are rare examples of persons without accounts; for example, collection agencies that don't receive bills, and parent companies that receive statements (as opposed to bills).

Fastpath:

Refer to [Maintaining Persons](#) for more information about persons.

Accounts

Accounts are the entities for which bills are created. You must create at least one account for every customer. The account contains information that controls when bills are created and how they are formatted.

Every account must reference at least one [person](#) because the person contains the customer's demographic information (e.g., names, phone numbers, forms of ID). We refer to this individual as the "main" person linked to the account. In addition to the "main" person, an account may reference other types of persons, e.g., the billing contact, the third party guarantor of the account's debt, persons who receive copies of bills, etc.

Most accounts are linked to at least one [service agreement](#) because, without a service agreement, there is nothing on which a bill can be based. An account without a service agreement may exist; you just won't be able to do much in the system with such an account.

Fastpath:

Refer to [Maintaining Accounts](#) for more information about accounts.

Service Agreements (SAs)

Think of a service agreement as a contract between your company and a customer. The service agreement contains the terms and conditions controlling how the system calculates charges for the specific service supplied to the customer.

Every [account](#) should have at least one service agreement (otherwise, the account has no financial obligations with your company). There is no limit to the number of service agreements that may be linked to an account. However, most residential customers have X service agreements where X is the number of services sold by your company. For example, if your company sells both electricity and gas, most accounts will have two service agreements.

A separate service agreement is required for every service supplied to every account. Why? Because a variety of fields may differ for each service agreement:

- Obviously, the price of the service is different.
- The credit and collection criteria may be different.
- The general ledger account to which the resultant revenue and/or receivable are linked is different.
- The sales tax could be different for each good / service / location.
- The service point measuring consumption will frequently be different.
- The list goes on...

Service agreements that bill for premise-based services are linked to one or more [premises](#) via their [service points](#). When you link a service point to a service agreement, you are telling the system that the service agreement's account will pay for the service point's service.

Fastpath:

Refer to [Maintaining Service Agreements](#) for more information.

Premises

A premise is created for every location to which your company supplies service. On a premise is maintained geographic information like:

- The address.
- Characteristics that determine tax jurisdictions.
- Descriptions of unusual situations associated with a property.
- The list goes on...

Most premises have at least one [service point](#) because, without a service point, there are no services supplied to the premise. A premise without service points may exist; you just won't be able to do much in the system with such a premise.

Fastpath:

Refer to [Maintaining Premises](#) for more information about premises.

Service Points (SPs)

Think of a service point as a specific location at a premise where your company supplies service. A service point contains information describing the type of service and how it is measured.

A [premise](#) should have at least one service point (otherwise, there are no services supplied to the premise). However, it is permissible for a new premise to exist without service points until you are ready to physically start service at the premise.

A premise may have many service points. However, most residential premises have X service points where X is the number of services sold by your company. For example, if your company sells both electricity and gas, most of your premises will have two service points.

Separate service points are required for every service supplied to a premise. Why? Because a variety of fields may differ for each service point:

- Basic information about the Service Point, including time zone, market, parent Service Point (if applicable), and status.
- Information related to field work performed at the current Service Point, including any applicable warnings or instructions.
- The measurement cycle, route, and route sequence for the Service Point.
- Basic characteristics about the service (e.g., pipe size, take point, amperes, etc.).

When you link a service point to a [service agreement](#), you are telling the system that the service agreement's account will pay for the service point's service.

Fastpath:

Refer to [Service Point - Main Information](#) for information about how to add and update service points.

The following topics describe the relationship between a service point and the physical devices that may be installed at the service point.

Metered versus Item-Based versus Non-Badged Service Points

There are three major categories of service points:

- Those where consumption is measured (e.g., electricity, gas, water) by a meter. We refer to these types of service points as **metered**. A metered service point may have zero or one meter installed at any instant in time. Over time, a metered service point may have many meters installed and removed.
- Those where consumption is not measured, but where there exists some type of badged (i.e., uniquely identified) item that impacts billing and dispatching (e.g., streetlights, a security camera). We refer to these types of service points as **item-based**. An item-based service point may have zero or one badged item installed at any instant in time. Over time, an item-based service point may have many badged items installed and removed.
- Those where one or more non-badged items (i.e., items without a unique identity) that have some impact on billing or dispatching exist. We refer to these types of service points as **unbadged**. At a single instant in time, a non-badged service point may have many unbadged items installed at it. Refer to [Service Points With Multiple Items](#) for an illustration of such a service point.

Note:

Multiple unbadged items can also be defined on metered and item-based service points. Under some billing scenarios, you may define non-badged items on a metered or item-based service point. For example, assume you have an item-based service point that exists to support lamp service. Also assume that the rate for lamp service is based on the type of lamp and the number of feet of electric wire between the pole and the power source. To define the number of feet of wire, you could create a non-badged item type called WIREFEET and indicate the number of feet on the item-based service point. On this service point, you can also keep track of the specific lamp that's installed.

Fastpath:

Refer to [The Big Picture Of Meters, Items and Equipment](#) for more information about meters and items. Refer to [Meters & The "V"](#) for more information about installing meters at a service point. Refer to [Items & The "V"](#) for more information about installing items at a service point.

Service Points With Multiple Items

An example will help explain a single service point with multiple non-badged items. Assume you have a parking lot with 4 lights, none of which are badged.

A Premise With One Service Point Where The Service Point Has Multiple Items

You can set up the above example with one premise with a single non-badged service point. On the service point, you create one item for each type of item in the parking lot:

- 20K lumen lamp
- 10K lumen lamp
- pole

For each type of item, you indicate the quantity that exist in the parking lot:

- 20K lumen lamp - 2
- 10K lumen lamp - 2
- pole - 4

Fastpath:

Refer to [Service Point - Multiple Items](#) for more information about multi-items on service points.

Putting It All Together

To help you understand the significance of the "V", consider a few scenarios:

- When a new residential customer starts service, you create both person and account objects for the new customer. In addition, you also create service agreements and link them to the appropriate service points. You won't have to create a new premise and service points because the customer is probably moving into an existing house.
- If the residential customer moves within your service territory, you don't have to set up new person or account objects. You also don't have to set up new premise and service point objects if the customer is moving into an existing house. You only have to create new service agreements and link them to the appropriate service points (and the system does most of the service agreement set up processes for you).
- A business with a single location uses the same "V" objects as does a residential customer. If the business expands and starts using services at other locations, you simply link new service agreements to the existing account. You don't have to redefine person or account information.

**Note:**

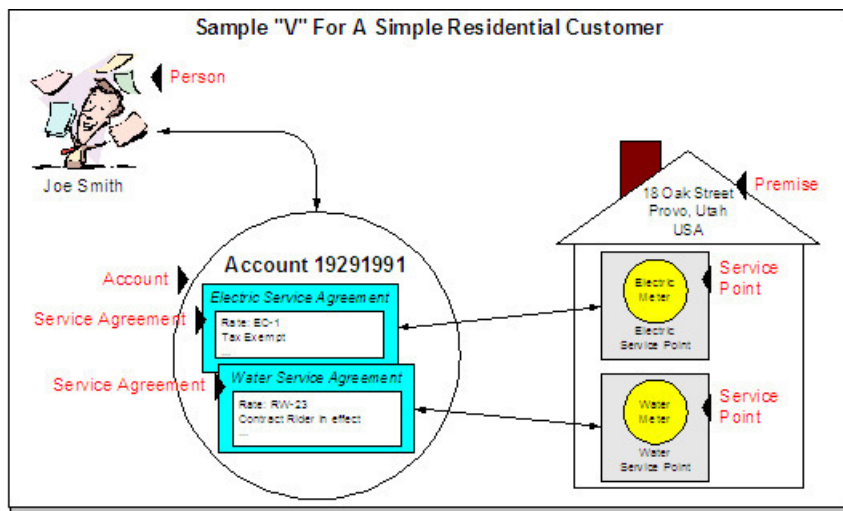

Bottom line. A person and an account are needed for every customer. After these exist, future service requests simply involve stopping existing service agreements and starting new ones. You typically won't have to add or modify premise or service point information unless new locations are built.

**Fastpath:**

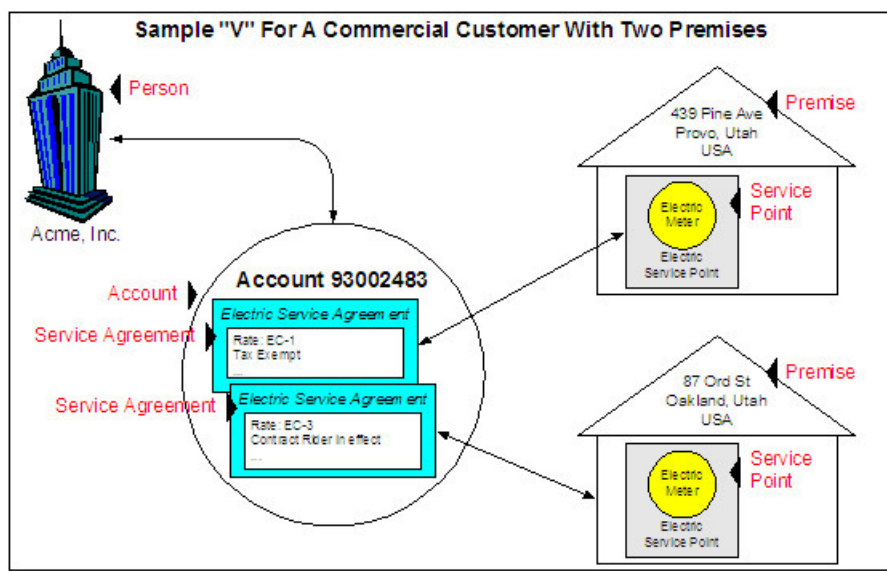

For more information, refer to [Maintaining The "V"](#), [Navigating The "V" Using Control Central](#), [The Big Picture Of Starting Service](#), and [The Big Picture Of Stopping Service](#).

Sample V For A Residential Customer

The following illustration shows a simple residential customer's "V" objects.

**Sample V For A Commercial Customer With Multiple Premises**

The following illustration shows the "V" objects for a commercial customer who pays for service at two premises.

**Note:**

The above example shows a separate service agreement per premise. If your rates allow, you could link both premises to a single service agreement.

How To Set Up Customer Hierarchies

Consider the following customer hierarchy:

The above hierarchy shows a parent company (Michelin Inc) with two subsidiaries. Each subsidiary, in turn, could have their subsidiaries, and these subsidiaries can have their own subsidiaries ...

You must set up a person for every individual and business in a hierarchy. After the basic demographic information is defined, you define each person's children using the [Person to Person](#) page.

Note:

A script can be used to set up a hierarchy. The demonstration database contains a [script](#) that guides users through the process of setting up a hierarchy. Please speak to your implementation staff if you'd like to import this script for use in your implementation.

After a hierarchy is set up, the system displays its members in the [Person Tree Zone](#) (this is a zone on the [Customer Information Portal](#)). In addition, if the persons in a hierarchy have accounts, summary information about these accounts is displayed in the [Account Summary Zone](#).

While hierarchies would typically be set up to define parent companies and subsidiaries, you can use this functionality for many other purposes. For example, a customer relationship manager could set up a hierarchy containing their "important" customers. To do this, they'd need to create a "dummy" person for the parent and then link the "important" customers to it. After this hierarchy is set up, the manager could see a summary of these customers in the [Account Summary Zone](#) whenever they display the "dummy" person.

Navigating The V

The product provides two options for Navigating the V:

- Control Central
- Customer 360

Control Central is the name given to the functionality that helps you:

- Find a person.
- Find an account.
- Find a premise.
- View information about a person / account / premise.
- View alerts and messages about a person / account / premise.
- Navigate to pages that contain information related to a person / account / premise.

Customer 360 is an updated and more configurable alternative to Control Central. The Customer 360 functionality works in conjunction with Unified Search, which provides for a more sophisticated, single-box search for customers

or premises. Once Unified Search has populated a customer and/or premise, you are brought to the Customer 360 portal to see an overview of the customer.

Fastpath:

For more information about the relationships between persons, accounts, and premises, see [Understanding The "V"](#).

Control Central

The following sections describe Control Central features.

Control Central - Search

Open **Menu > Control Central Search** to find a customer and/or a premise.

| Keyboard Shortcut | Alternate Shortcut |
|-------------------|--------------------|
| Alt+L | Alt+Shift+L |

Note: Refer to [Shortcut Key Summary](#) for information about the alternate shortcut.

Note: Automatic transfer to Control Central — Account Information. You are automatically transferred to [Control Central - Account Information](#) when an account / premise is selected on this page.

The contents of this section describe how to use control central search.

Search Facilities

Control Central allows users to search for a person, account and/or premise using a variety of search criteria.

The following search options are provided in the base product:

- **Name and Address:** searches for an accounts, person and / or premise using a person's name and / or a service address.
- **Account ID:** searches for an account using an Account ID.
- **Person Contact:** searches for accounts / persons using a person contact.
- **Phone Number:** searches for accounts / persons using a phone number.
- **Person ID Type/Value:** searches for accounts / persons using a person identifier.
- **Geo Type/Value:** searches for a premise using the geographic identifier of the premise or of one if its service points.

Refer to each search option's zone help for details on the search criteria.

From the search results lists, you can select a record to navigate to [Control Central - Account Information](#), where information about the customer is displayed. You can also navigate to other pages in Control Central to view more information about the account, person and / or premise.

Note:

Automatic transfer to Account Information tab. If your search criteria result in a single customer being retrieved, you are automatically transferred to [Control Central - Account Information](#) with that customer's information displayed.

Meter Search

Control Central does not provide an option to search using a meter ID. If you know the meter ID and want to find who's paying for its service, transfer to [Meter/Item Search](#) and display the meter. All customers who have paid for service measured by the current configuration of the meter will be displayed on this page. You can then use the various context menu buttons to return to Control Central where details about the customer are displayed.

Item Search

Control Central does not provide an option to search using an item ID. If you know the item ID and want to find who's paying for its service, transfer to [Meter/Item Search](#) and display the item. All customers who have paid for the item will be displayed on this page. You can then use the various context menu buttons to return to Control Central where details about the customer are displayed.

Search Options

The **CIS Division** filter can be specified to limit the search to accounts or premises in a particular CIS Division. The matching is done on either the account's CIS Division or the premise's CIS Division depending on whether the search is account-oriented or premise-oriented:

- If searching by only a name, the search results that have an associated account will be matched on the account's CIS Division.
- If searching by a name and any of the address constituents, the search results that have an associated account will be matched on the account's CIS Division.
- If searching by only the address constituents, the search results will be matched on the premise's CIS Division, regardless of whether or not the premise is linked to an account.

The **Show All Premises** search option controls whether you see all of an account's premises in the [search results](#). If turned on, every premise linked to an account is shown in the search results. If turned off, only one premise is shown per account (and this premise is selected at random).

This switch pertains to the following search methods:

- Search by name only (i.e., all address constituents are left blank)
- Search by account ID
- Search by person phone number
- Search by person identifier

This switch does NOT pertain to the following search methods as these are premise-oriented, not account-oriented:

- Search by name when any address constituent is entered
- Search by address constituents only (i.e., name is blank)
- Search by geographic identifier

The benefit of turning this switch off is that an account will be immediately selected when you enter unique account-oriented search criteria. For example, if you specify an **Account ID** and press enter, the system automatically selects the account; you don't have to wait for the search results to be populated with the multitude of premises linked to the account (and then select one of the rows). Please note, an alert highlights if the selected account has other premises.

Note:

Default. The first time you open this page, **CIS Division** and **Show All Premises** are defaulted from your [user preferences](#). When you return to this page, the last values are defaulted.

The **Expand Results** search option is available if your implementation has enabled expanded / fuzzy searching. (Refer to [Advanced Search Options](#) for more information.) This functionality relies on special indexes configured in the database, to attempt to include similar words or alternate spellings of a supplied search value. This expanded searching is applied only to searches by name and / or address constituents.

Wild Cards

The control central searches against **Name**, **Address**, and **City** support wild cards. The wild card character is % and represents any number or character. The system always appends a % for you when you use these search methods. Examples will help clarify this functionality:

- If you enter a B, the system searches for B% (and will find all objects that begin with B).
- If you enter B%N, the system searches for B%N%. It will find anything that

- Starts with a B, and
- has zero or more other characters followed by an N.
- If you enter %B the system searches for %B%. It will find anything with a B in it, no matter what it starts and ends with.

Note:

Certain wildcard searches can result in lengthy response times. If you use the wildcard character to prefix your search criteria (e.g., %San Fran), lengthy response times can result. Why? Because the system will have to look at EVERY customer in the system before it can return the results.

Search Results

The search results at the bottom of the page contain persons, accounts, and premises that match your search criteria. The information displayed in this area differs depending on the type of search you perform. You can perform searches on a customer's name, address, phone number, person contact, person identifier and geographic value.

The information strings that display in the **Person/Account** and **Premise** columns vary depending on what context information is present:

- For a person that is not linked to an account, the Person/Account information string will include the text 'No Account Information' and the Premise column will be blank.
- For an account that does not have a service agreement, the Person/Account information string will include the text 'No Service Agreement' and the Premise column will be blank.
- For an account with a service agreement that is not currently linked to a service point, the Premise column will display 'No Premise Information'.
- For a premise that is not linked to an account, the Person/Account column will display 'No Person Information'.

Note:

The first 300 matches are retrieved and displayed. The base search zones are configured with the *Number of Rows to Display* and *Number of Rows to Retrieve for SQL* parameters set to 300. If you do not find the account / person / premise you are looking for in the set of results, refine your search criteria. A *Control Central Search Factor* feature configuration option (in the *General System Configuration* feature type) controls the maximum number of indexed results that will be evaluated by name and/or address before filtering is done. For instance, if the search factor is set to 3000 and a search is for 'Smith%' on '%Main St', the search will get the first 3000 'Smith%' from the name index and the first 3000 '%Main St' from the address 1 index. Then it will filter out non-matching combinations. Regardless of the resulting set, the search will not return more than the Number of Rows to Retrieve for SQL, which is set to 300. The search factor can be set to any number from 301 to 50000. Note that the higher the factor used, the more possibility of affecting performance. If this option is not specified, the default is 3000.

Automatic selection if only one match. You don't have to select a record if there is one and only one object that matches your search criteria. The system automatically selects it and transfers you to [Control Central - Account Information](#).

Use Tab and Enter to select an account / person / premise. You don't have to use the mouse to select a record when multiple matches are returned. The system highlights the first row in the search results. If this is the account / person / premise you are looking for, press **Enter** to select it. If not, press **Tab** until you've highlighted the desired record and then press **Enter** to select it.

Use the Work List sidebar zone to navigate to any account / person in the search results. When you select a record from the search results, you are automatically transferred to [Control Central - Account Information](#). If you want to look at a different account that appeared in the search results, you do not have to return to the **Main** tab. You can use the **Work List** sidebar zone to load another account without leaving the [Control Central - Account Information](#) page. To build the work list, run the search and click on the Work List button that appears in the **Person /Account** column heading. This will copy over the contents of the **Person/Account** column into the **Work List** zone in the sidebar. Refer to [Work Lists](#) for more information.

Control Central - Account Information

Once [Control Central - Search](#) has populated an account, you are brought to the Account Information page to see an overview of the account.

| Keyboard Shortcut | Alternate Shortcut |
|-------------------|--------------------|
| Alt+I | Alt+Shift+I |

Note: Refer to [Shortcut Key Summary](#) for information about the alternate shortcut.

The following points should be noted about this page:

- Selecting an account on control central causes the [global context](#) information to be refreshed. Various zones available on this page use the value in the global context to display relevant data for the appropriate account, person and premise.
- This portal page may be configured by the user. Refer to [Each User Can Customize Which Zones Appear](#) for information about how to configure which zones appear.
- The Go To Control Central option on the account context menu navigates to this page.

The contents of this section describe the zones that are available on this portal page.

Account Activity History Zone

The **Account Activity History Zone** is a grid that summarizes a variety of account-related events (in reverse chronological order). Clicking on an information hyperlink transfers you to an appropriate page. The following table lists the type of information that may appear in this zone and the portal to which you will be transferred on click of the information hyperlink.

| Activity Label | What Is Displayed | Drill Down Transfers You To |
|--|--|-----------------------------|
| Severance Event. <i>One row is displayed for every Pending and Awaiting Field Activity Completion severance event linked to the account's service agreements.</i> | The severance event's description, status and trigger date (if non-blank). If the event is dependent on earlier events, the earlier events' type and status is appended | Severance Process - Events |
| Severance Process. <i>One row is displayed for every Inactive severance process linked to the account's service agreements. Inactive processes are displayed (as opposed to active) because active severance processes have pending events and pending events are shown separately.</i> | The severance process's SA type description, severance process template description, status and create date/time | Severance Process - Main |
| Collection Event. <i>One row is displayed for every Pending collection event linked to the account.</i> | The collection event's description, status and trigger date | Collection Process - Events |

| | | |
|---|--|-----------------------------------|
| <p>Collection Process. <i>One row is displayed for every Inactive collection process linked to the account. Inactive processes are displayed (as opposed to active) because active collection processes have pending events and pending events are shown separately.</i></p> | <p>The collection process's control, template, status, status reason and create date/time</p> | <p>Collection Process - Main</p> |
| <p>Overdue Event. <i>One row is displayed for every Pending overdue event linked to the account.</i></p> | <p>The overdue event's information based on the overdue event type's Event Information algorithm, if configured. Otherwise, default overdue event information.</p> | <p>Overdue Process - Events</p> |
| <p>Overdue Process. <i>One row is displayed for every Inactive overdue process linked to the account. Inactive processes are displayed (as opposed to active) because active overdue processes have pending events and pending events are shown separately.</i></p> | <p>The overdue process's information based on the overdue process template's Overdue Process Information algorithm, if configured. Otherwise, default overdue process information.</p> | <p>Overdue Process - Main</p> |
| <p>Cut Event. <i>One row is displayed for every Pending cut event linked to the account.</i></p> | <p>The cut event's information based on the cut event type's Event Information algorithm, if configured. Otherwise, default cut event information.</p> | <p>Cut Process - Events</p> |
| <p>Cut Process. <i>One row is displayed for every Inactive cut process linked to the account. Inactive processes are displayed (as opposed to active) because active cut processes have pending events and pending events are shown separately.</i></p> | <p>The cut process's information based on the cut process template's Cut Process Information algorithm, if configured. Otherwise, default cut process information.</p> | <p>Cut Process - Main</p> |
| <p>Write-off Event. <i>One row is displayed for every Pending write-off event linked to the account.</i></p> | <p>The write-off event description, status and trigger date</p> | <p>Write-off Process - Events</p> |
| <p>Write-off Process. <i>One row is displayed for every Inactive write-off process linked to the account. Inactive processes are displayed (as opposed to active) because active write-off processes have pending events and pending events are shown separately.</i></p> | <p>The write-off process template's description, status and create date/time</p> | <p>Write-off Process - Main</p> |
| <p>Customer Contact. <i>One row is displayed for every customer contact associated with the main customer linked to the account.</i></p> | <p>The main name of the person associated with the customer contact, the customer contact's class and type, and the customer contact's date</p> | <p>Customer Contact - Main</p> |

| | | |
|--|--|----------------------------|
| Field Activity. <i>One row is displayed for every unique non-cancelled field activity linked to the account's non-cancelled/non-closed service agreements.</i> | If the field activity not Canceled, the field activity type is orchestrated by Service Order Management (SOM) and the field activity is synchronized: SOM field activity information, Outbound Communication information. Otherwise, premise information and field activity information (from installation options) | Field Activity - Main |
| Pay Plan. <i>One row is displayed for every non-cancelled pay plan linked to the account</i> | The pay plan's type, status, date, and amount | Pay Plan - Main |
| Payment Arrangement. <i>One row is displayed for every non-cancelled payment arrangement (i.e., service agreement with a special role of Payment Arrangement) linked to the account</i> | The service agreement's division, SA type, status, start option (if applicable) and effective period. | Payment Arrangement - Main |
| Credit Rating History. <i>One row is displayed for every credit rating transaction that affects the account's credit rating</i> | The effect on the account's credit rating, the end date, creation date and the process that created the transaction. | Account - C&C |
| Cash-Only History. <i>One row is displayed for every credit rating transaction that affects the account's cash-only score</i> | The effect on the account's cash-only score, the end date, creation date and the process that created the transaction. | Account - C&C |
| Case. <i>One row is displayed for every case associated with the account.</i> | The case's information based on the Case Information algorithm, if configured on installation options. Otherwise, default case information. | Case - Main |
| Rebate Claim. <i>One row is displayed for every rebate claim .</i> | The rebate claim's standard information. | Rebate Claim |
| Business Flag. <i>One row is displayed for every business flag .</i> | The business flag's standard information. | Business Flag |

**Warning:**

The first 25 rows are displayed when this zone is initially built. If more rows exist, a **Next** button appears. If you click this button, the system appends the next set of records.

Account Financial History Zone

The **Account Financial History Zone** lists an account's financial events in reverse chronological order. You can use this grid to both view high-level information about these events and to transfer to the respective page in which an object is maintained.

**Note:**

Approximately a year and half is shown. This zone shows all financial transactions within 20 months of the latest financial transaction. This limitation exists to prevent this zone from becoming unmanageably long.

The following columns are displayed in the grid:

Arrears Date This is the date the event starts aging. This column will be blank if the FT has not started aging yet.

Financial Transaction Type This column indicates the type of financial event: Bill, Payment, Bill Cancellation, Pay Cancellation, Adjustment, and Adjustment (Cancel). If the event is related to an adjustment, the adjustment type's description is displayed instead of "Adjustment".

Current Amount This column shows the financial event's effect on the account's current balance.

Current Balance This column shows the account's current balance after the financial event.

Payoff Amount This column shows the financial event's effect on the account's payoff balance. **Payoff Amount** will be dimmed if it is the same as its **Current Amount**.

Payoff Balance This column shows the account's payoff balance after the financial event. **Payoff Balance** will be dimmed if it is the same as its **Current Balance**.

If you need to see more information about a specific financial transaction, press the go to button to transfer to the respective page in which the information is maintained.

**Fastpath:**

For information about current and payoff balance, refer to [Current Amount versus Payoff Amount](#).

**Warning:**

The first 25 rows are displayed when this zone is initially built. If more rows exist, a **Get All** button appears. If you click this button, the system retrieves a maximum of 750 rows.

Alert Zone

The **Alert Zone** is a grid that contains messages highlighting a variety of situations. Clicking on the hyperlink transfers you to an appropriate page.

Account alerts are implementation-specific. On [Account - Alerts](#), a user can define account-specific alerts that should be displayed whenever the account is selected. The [Alert Types](#) control table contains the possible alert messages.

Alerts are produce from one of two sources.

- Alerts are primarily produced by plugging in alert algorithms on the [installation record](#). The alerts are shown based on the configured sequence on the installation record. Refer to Count Customer Contacts of a Given Type (CC-NBR-VALID) and Count Pay Plans with a Given Status (PP BY STATUS) for examples of such algorithms.
- Alerts can also be created by system-generated alerts, which are also referred to as legacy alerts. To enable the system-generated alerts, set the Use Legacy Alerts **Option Type** on the General System Configuration [Feature Configuration](#) to Y. When this feature is enabled, the system-generated alerts are executed before the plug-in alert algorithms.

**Note:**

A plug-in version for each of the system-generated alerts is provided with the product in addition to many without a system-generated equivalent. If the legacy alert feature is enabled, you would not use the equivalent plug-in alert algorithm, otherwise, these alerts may appear twice on the **Alert Zone**.

You can introduce your own alert algorithms to highlight additional alert conditions based on your business rules.

The table below lists the system-generated alerts that may appear if the use legacy alert feature is enabled and the page to which you will be transferred if you click on the hyperlink. The table below lists alerts in alphabetical order, but it includes a column indicating the order in which the alert will appear.

| Alert Text | Order | Description | Drill Down Transfers You To |
|--|-------|--|--------------------------------|
| Account alerts | 6 | Appears for each user-defined alert associated with an account. | Account - Alert |
| Account has Multiple Premises | 24 | Appears when the account has service agreements whose service points reference multiple premises | Control Central - Account Tree |
| Account SA(s) linked to Umbrella Agreement | 41 | Appears when the account has one or more service agreements linked to a non-canceled terms of service record for an umbrella agreement that is in effect on the current date. | Terms of Service - Main |
| Active Write Off Process | 10 | Appears when an account has an active write off process . Refer to How Are Write off Processes Cancelled for information describing when a write-off process is deactivated. | Write Off Process |
| Appointment Exists | 37 | Appears when a premise has a non-canceled, non-completed field activity that's linked to an appointment . | Appointment |
| Auto-Pay Active: <i>auto pay method description</i> | 25 | Appears when the account has an automatic payment option effective on the current date. The auto pay method description (i.e. Direct Debit or Payment Advice) appears only if payment advice functionality is enabled. Refer to Payment Advices for more information on payment advice functionality. | Account - Auto Pay |

| | | | |
|-----------------------------------|-----|---|----------------------------|
| Cash-Only Account | 11a | Appears when the account's cash-only score exceeds the cash-only threshold on the installation record. Refer to How are credit rating transactions created for information describing how a cash-only score is affected by various system and user events. | Account - C & C |
| Collection Process Active | 8 | Appears when an account has an active collection process . Refer to How Are Collection Processes Cancelled for information describing when a collection process is deactivated. | Collection Process |
| Collection Referral Active | 9 | Appears when the account has active collection agency referrals . | Collection Agency Referral |
| Comment Exists On Account | 5 | Appears when a free-form comment has been entered for the account (on Account - Main) | Account |
| Credit rating: NNNN | 11b | Appears when the account's credit rating falls below the credit rating threshold on the installation record or the account's CIS Division. Refer to How are credit rating transactions created for information describing how a customer's credit rating is affected by various system and user events. | Account - C & C |
| Field Activity Pending | 19 | Appears when any of the premise's service points have a pending field activity | Field Activity |
| Field activity type alert message | 12 | Appears when the premise has a service point with a completed field activity whose type has been marked with an alert message (refer to Field Activity Type) | Field Activity |

| | | | |
|--|-----|--|--------------------------------|
| Held Order Exists | 32 | Appears when the person has a held order . | Order |
| Installation dynamic alerts | 42 | You can install plug-in algorithms on the installation record that will create alerts (if given situations exist). Refer to Count Customer Contacts of a Given Type (CC BY TYPCL) and Count Pay Plans with a Given Status (PP BY STATUS) for examples of such algorithms | Varies by plug-in |
| Landlord Exists | 27 | Appears when a landlord is linked to the premise | Premise |
| Last Contact: <i>days old - user name who added the contact</i> | 3 | Appears when the person and/or premise has a customer contact . The "days old" presents how old the contact is (based on the contact's date). The word Today is shown if the last contact was on the current date. The word Yesterday is shown if the last contact was on the current date - 1 day. If neither is applicable, the number of days old is shown. | Customer Contact |
| Life Support / Sensitive Load on Person | 1 | Appears when any of the account's persons has life support or sensitive load information | Person |
| Life Support / Sensitive Load on Premise | 2 | Appears when the premise has life support or sensitive load information | Premise - Misc. |
| Multiple Financially Resp | 26a | Appears when the account has more than one financially responsible person linked to it | Control Central - Account Tree |
| Non-cash Deposit | 15 | Appears when the account has non-cash deposits effective on the current date | Account - Deposit |

| | | | |
|---|-----|--|--|
| n Open Contact(s) for Person / n Open Contact(s) Premise | 4 | Appears if there are open customer contacts associated with the person and/or premise. Refer to Customer Contacts Can Be Used As Case Files for more information. | Customer Contact |
| Pending Order Exists | 31 | Appears when the person has a pending order . | Order |
| Pending Proposal SA Exists | 36 | Appears when the account has a proposal service agreement in the pending state. Refer to Proposal SA State Transition for more information. | Service Agreement |
| Pending Quote Exists | 34 | Appears when the account has a pending quote. Refer to Quote Lifecycle for more information. | Quote |
| Pending SA Relationships | 16 | Appears when the account has SA relationships that are pending | SA Relationship |
| Pending Start | 17 | Appears when there is a service agreement in the state of pending start linked to the account. Refer to The Lifecycle Of A Pending Start Service Agreement for more information. | Start/Stop |
| Pending Stop | 18 | Appears when there is a service agreement in the state of pending stop linked to the account. Refer to The Lifecycle Of A Pending Stop Service Agreement for more information. | Start/Stop |
| Person is linked to Multiple Accounts | 22 | Appears when the person has multiple accounts. A person's accounts are maintained on the Account - Person page. | Control Central - Customer Information |
| n Persons on Account | 26c | Appears when the account has multiple persons linked to it. An account's persons are maintained on the Account - Person page. | Control Central - Account Tree |

| | | | |
|---|----|--|--------------------------------|
| Premise has Multiple Accounts | 23 | Appears when the premise has service points that are linked to non-closed non-canceled service agreements that are linked to different accounts. | Control Central - Premise Tree |
| Premise has n Child Premise(s) | 40 | Appears when the premise is defined as the parent premise for one or more premises. Refer to Define Premise Hierarchy for more information. | Premise Management |
| Premise is linked to Parent Premise | 39 | Appears when the premise defines a parent premise. Refer to Define Premise Hierarchy for more information. | Premise |
| Quotable Proposal SA Exists | 35 | Appears when the account has a proposal service agreement in the quotable state. Refer to Proposal SA State Transition for more information. | Service Agreement |
| Quote Awaiting Customer Response Exists | 33 | Appears when the account has a complete quote with a quote detail that references a quotable proposal SA. Refer to Quote Lifecycle for more information. | Quote |
| Reactivated SAs Exist | 21 | Appears when any of the account's service agreements exist in the state of reactivated (i.e., a financial transaction has been generated after the service agreement was closed). Refer to The Lifecycle Of A Service Agreement for more information. | Service Agreement |

| | | | |
|---|-----|---|-------------------------------------|
| SA type alert message | 13 | <p>Appears when the customer has a service agreement with an SA type that has been marked with an alert message (refer to SA Type - Details)</p> <p>Note that if the account in control central has more than one service agreement, pressing the drill down button will also launch the service agreement search dialog.</p> | Service Agreement |
| SA type description and status of a non-billed budget service agreement | 14 | <p>Appears for every pending start, pending stop, and active Non-Billed Budget that is linked to the account.</p> | Non-Billed Budget Service Agreement |
| Seasonal Address Exists | 38b | <p>Appears if the person has a seasonal address and there is no seasonal address active on the current date.</p> | Person - Correspondence Info |
| Seasonal Address Currently Effective (MM/DD - MM/DD) | 38a | <p>Appears if the person has an active seasonal address that is effective on the current date. The date range that the seasonal address is effective is included in the alert.</p> | Person - Correspondence Info |
| Severance Process Active | 7 | <p>Appears when any of the account's service agreement has an active severance process</p> <p>Appears when an account has an active severance process. Refer to How Are Severance Processes Cancelled for information describing when a severance process is deactivated.</p> | Severance Process |
| Statement Construct Active | 28 | <p>Appears if the person has an active statement construct</p> | Statement Construct |

| | | | |
|-----------------------|-----|--|--------------------------------|
| Third Party Guarantor | 26b | Appears when the account has a third party guarantor. An account's third party guarantors are maintained on the Account - Person page. | Control Central - Account Tree |
|-----------------------|-----|--|--------------------------------|

Applicable Campaigns Zone

The **Applicable Campaigns Zone** lists the campaigns that may be of interest to the customer. If you press a campaign's Add Order button, you will be transferred to the [Order transaction](#) where you can walk the customer through the campaign's provisions and determine if they are interested in its goods and services.

Fastpath:

Refer to [The Big Picture Of Campaign Eligibility](#) for more information.

Warning:

The first 25 rows are displayed when this zone is initially built. If more rows exist, a **Get All** button appears. If you click this button, the system retrieves a maximum of 750 rows.

Bill Graph Zone

The **Bill Graph Zone** illustrates the ending balance and new charges on each of the customer's historical bills.

Note:

Approximately a year and half is shown. This zone shows all bills within 20 months of the latest bill. This limitation exists to prevent this zone from becoming unmanageably wide.

For [balance-forward accounts](#), both ending balances and current charges are shown in the graph. For [open-item accounts](#), only the current charges are shown in the graph.

The following points describe unique features of this zone:

- If you hover the mouse over a bar in the graph, summary information about the bill will display.
- If you click on a bar in the graph, you will be transferred to the bill page with the respective bill displayed.

Billed Consumption Zone

The **Billed Consumption Zone** illustrates the amount of consumption on each of the customer's historical bills. Up to three units of measure (UOM) are shown for each bill. The system uses the graph UOM's defined on the SA types associated with the customer's active service agreements. If more than three graph UOM's are detected for a customer, the system uses those associated with the service agreement types with the highest bill print priorities.

The following points describe unique features of this zone:

- If you hover the mouse on a bar in the graph, summary information about the bill will display.
- If you click on a bar in the graph, you will be transferred to the bill page with the respective bill displayed.

Note:

Approximately a year and half is shown. This zone shows all bills within 20 months of the latest bill. This limitation exists to prevent this zone from becoming unmanageably wide.

Current Customer Zone

The **Current Customer Zone** contains basic information about the Person / Account / Premise on which you are working.

Person This part of the context area contains the person's standard information. Note, this information is formatted by a plug-in algorithm on the [installation record](#). Refer to the base package's person information algorithm (PERS-INFO) for an example. If you prefer different formatting logic, your system administrator should configure the system appropriately

Account ID This part of the context area contains the unique identifier of the account and the name of its main customer.

Adjacent to the account ID appears a "check digit". This is for information purposes only and is not needed to operate the system. Refer to the Description of Page section under [Account - Main](#) for a description of how "check digit" is calculated.

Premise This part of the context area contains the premise address. The address information is formatted by a plug-in algorithm on the [installation record](#). Refer to the base package's premise format algorithm (PREM-INFO) for an example. If you prefer a different format, your system administrator should configure the system appropriately

Below **Premise**, the account's **Current Balance** and **Payoff Balance** are displayed. **Payoff Balance** will be hidden when it's the same as the **Current Balance**. Refer to [Current Amount versus Payoff Amount](#) for more information.

Aged Debt Bar If the account's **Current Balance** is greater than zero, a colored bar is displayed adjacent. This bar provides information about the age of the account's debt.

The number of segments that appear in this bar is dependent on the elements of the customer's aged balance. The following segments may appear:

- disputed debt (If you handle disputed debt as described in [Disputing Items](#)),
- new charges and debt between 0 and X days old (where X is the account's customer class's bill due days),
- debt between X to 30 days old,
- debt between 31 to 60 days old,
- debt older than 60 days

Note:

If you hover the mouse pointer over a segment of the bar, the respective amount of debt will appear. If you click on the arrears bar you will be taken to the [Account Financial History](#) page. Note that information about debt balances by age is not applicable to [open-item accounts](#).

Start Service Push this button if you want to start service for the account and the service isn't at a premise (e.g., a deposit). Refer to [The Big Picture Of Starting Service](#) for more information.

Stop Service Push this button if you want to stop service for the account at the premise. Refer to [The Big Picture of Stopping Service](#) for more information.

Credit and Collections Info Zone

The **Credit and Collections Info Zone** is a grid that contains a variety of credit & collections-oriented events. Pushing the button adjacent to the information transfers you to an appropriate page. The following table lists the type of information that may appear in this zone and the page to which you will be transferred if you push the adjacent button.

| Activity Label | What Is Displayed | Drill Down Transfers You To |
|---|--|-----------------------------|
| Severance Process. <i>One row is displayed for every Active severance process linked to the account's service agreements.</i> | The severance process's description and create date/time | Severance Process - Main |

| | | |
|--|---|----------------------------|
| Collection Process. <i>One row is displayed for every Active collection process linked to the account.</i> | The collection process's description and create date/time | Collection Process - Main |
| Write-off Process. <i>One row is displayed for every Active write-off process linked to the account.</i> | The write-off process's description and create date/time | Write-off Process - Main |
| Overdue Process. <i>One row is displayed for every Active overdue process linked to the account.</i> | The overdue process's standard information string (this is dynamic as is constructed by an algorithm) | Overdue Process - Main |
| Cut Process. <i>One row is displayed for every Active cut process linked to the account's service agreements.</i> | The cut process's standard information string (this is dynamic as is constructed by an algorithm) | Cut Process - Main |
| Pay Plan. <i>One row is displayed for every Active pay plan linked to the account</i> | The pay plan type's description and create date/time | Pay Plan - Main |
| Payment Arrangement. <i>One row is displayed for every non-cancelled, non-closed payment arrangement (i.e., service agreement with a special role of Payment Arrangement) linked to the account</i> | The service agreement's SA type description, start date and status | Payment Arrangement - Main |

**Warning:**

The first 25 rows are displayed when this zone is initially built. If more rows exist, a **Get All** button appears. If you click this button, the system retrieves a maximum of 750 rows.

Customer Information Zone

The **Customer Information Zone** is a grid that contains information about the current person and account. Pushing the button adjacent to the information transfers you to an appropriate page. The following table lists the type of information that may appear in this zone and the page to which you will be transferred if you push the adjacent button.

**Note:**

Rows are suppressed if the related data is blank for the person / account.

| Label | What Is Displayed | Drill Down Transfers You To |
|------------|---|--|
| Account ID | The account's unique identifier (i.e., account ID) is displayed | An account context menu has been provided (allowing you to drill to a variety of account-oriented pages) |

| | | |
|--|--|---|
| Main Customer | The main customer's name. Note, the person's name is formatted by a plug-in algorithm on the installation record . Refer to the base package's name format algorithm (PERS-INFO) for an example. If you prefer different formatting logic, your system administrator should configure the system appropriately | A person context menu has been provided (allowing you to drill to a variety of person-oriented pages) |
| Set Up Date | The account's setup date | Account - Main |
| CIS Division | The account's CIS division | Account - Main |
| Customer Class | The account's customer class | Account - Main |
| Bill Cycle | The account's bill cycle | Account - Main |
| Current Credit Rating | The account's current credit rating | Account - C&C |
| Next Credit Review Date | The next date on which the account's debt will be reviewed by the account debt monitor . Refer to When Is An Account's Debt Monitored for more information. | Account - C&C |
| <i>A separate row is displayed for each characteristic linked to the account. Each row's label is the characteristic type's description. If the characteristic is future dated, the effective date enclosed in parentheses prefixes the description.</i> | The characteristic's value | Account - Characteristic |
| Auto Pay Source | The account's auto pay source | Account - Auto Pay |
| <i>A separate row is displayed for each miscellaneous person linked to the account. Each row's label is the person relationship type's description.</i> | The main name of the miscellaneous person | A person context menu has been provided (allowing you to drill to a variety of person-oriented pages) |
| Budget Plan | The account's budget plan | Account - Budget |
| <i>A separate row is displayed for each characteristic linked to the person. Each row's label is the characteristic type's description.</i> | The characteristic's value | Person - Characteristic |
| <i>A separate row is displayed for each telephone number linked to the person. Each row's label is the phone type's description.</i> | The telephone number | Person - Main |

A separate row is displayed for each identifier linked to the person. Each row's label is the ID type's description.

The person identifier value

Person - Main

Note: The system supports encryption for Person Identifier. If your implementation has configured the system to encrypt Person Identifier, the data will be displayed with a masked value; such as, *****. Refer to [Encrypting Sensitive Data](#) for more information.

Email Address

The person's email address

Person - Miscellaneous

Service Provider.

The service provider's name and a description of the service provider's billing relationship as of the effective date.

SA Relationship - Main

Warning:

This zone does not support [User Interface Masking](#). If your implementation masks any of the information that appears on this zone, you must disable it and implement a zone that will mask your data appropriately. The demonstration system provides a sample zone that your implementation can import and then customize if necessary; this zone's code is CI_CIMAP. To disable the base package zone simply deny access to its associated application service. You should only grant access to your new Customer Information zone.

Financial Information Zone

The **Financial Information Zone** is a grid that contains financial information related to the account. Clicking the hyperlink transfers you to the appropriate page. The following table lists the type of information that appears in this zone and the page to which you are transferred if you click the adjacent icon.

Note:

Rows are suppressed if the related data is blank for the person / account.

| Label | What Is Displayed | Drill Down Transfers You To |
|-----------------|---|--|
| Current Balance | The account's current balance. If the account's current balance is greater than zero, a colored bar is displayed adjacent. This bar provides information about the age of the account's debt. Refer to Current Customer Zone for more information about this bar. | Clicking on the Arrears Bar or the hyperlink takes you to Account Financial History - Main |
| Payoff Balance | The account's payoff balance. It will only be displayed if the amount differs from the current balance. | Not applicable |

| | | |
|---------------------------|---|------------------------|
| Last Bill | The date and amount of the account's last bill along with its due date. | Bill - Main |
| Last Payment | The date and amount of the account's last payment. | Payment Event - Main |
| Previous Bill | The date and amount of the bill prior to the last bill for the account. | Bill - Main |
| Next Bill Date | The next date on which a bill is scheduled to be produced for the account (based on the account's bill cycle's schedule) | Not applicable |
| Pending Bill Exists | The date of the pending bill. This row only appears if there is a pending bill associated with the account | Bill - Main |
| Freezable Bill Segments | If freezable bill segments exist, this row contains the number of segments and their total amount. | Bill Segment - Main |
| Incomplete Adjustments | If incomplete adjustments exist, this row contains the number of adjustments and their total amount. | Adjustment - Main |
| Freezable Adjustments | If freezable adjustments exist, this row contains the number of adjustments and their total amount. | Adjustment - Main |
| Payment(s) Pending Upload | <p>Appears when the account has a pending payment staging record (i.e., the account has an external payment that has not been uploaded into the system). To prevent payments from being created and frozen before the actual payment is received, external payments are not uploaded into the system until their accounting date is reached.</p> <p>Note that the amount displayed represents the amount tendered for the account, but does not reflect how the payment may be distributed (i.e., the payment may be distributed to other accounts).</p> <p>For information about payment staging records, refer to Interfacing Payments from External Sources.</p> | Payment Upload Staging |

| | | |
|---------------------------------|--|----------------------|
| Incomplete Payment(s) | Appears when the account has payments that are incomplete. This row contains the number of payments and their total amount. Note, incomplete automatic payments that are pending distribution are not included in this alert as they are highlighted on the Auto Pay will be distributed on described below. | Payment - Main |
| Payment(s) with Errors | Appears when the account has payments that are in error. This row contains the number of payments and their total amount. | Payment - Main |
| Freezable Payments) | If freezable payments, this row contains the number of payments and their total amount. | Payment Event - Main |
| Auto Pay will be created on | This row shows the date that the next auto pay will be created. This alert will appear after a bill is completed for an account on auto pay and when your installation option's Auto Pay Creation Option is Create on Extract Date. If the installation option is Create at Bill Completion, then the Autopay will be created immediately at bill completion time and no information is displayed here. Refer to How And When Are Automatic Payments Created? for more information. | Bill - Main |
| Auto Pay will be distributed on | This row shows the date that the next auto pay will be distributed. This alert will appear after a bill is completed for an account on auto pay and when your installation option's Auto Pay Creation Option is Create on Extract Date. If the installation option is Create at Bill Completion, then the payment for the Autopay will be created immediately at bill completion time and no information is displayed here. Refer to How And When Are Automatic Payments Created? for more information. | Payment Event - Main |

Premise Information Zone

The **Premise Information Zone** is a grid that contains information about the current premise. Pushing the button adjacent to the information transfers you to an appropriate page. The following table lists the type of information that may appear in this zone and the page to which you will be transferred if you push the adjacent button.

**Note:**

Rows are suppressed if the related data is blank for the premise.

| Label | What Is Displayed | Drill Down Transfers You To |
|--|--|---|
| Premise Information | The premise's address. Note, the address information is formatted by a plug-in algorithm on the installation record . Refer to the base package's premise format algorithm for an example. If you prefer a different format, your system administrator should configure the system appropriately | A premise context menu has been provided (allowing you to drill to a variety of premise-oriented pages) |
| CIS Division | The premise's CIS division | Premise - Main |
| A separate row is displayed for each characteristic linked to the premise. The label in each row is the respective characteristic type's description. | The characteristic's value | Premise - Characteristic |
| Landlord | The name of the premise's landlord | Landlord Agreement |
| Service Point Information. <i>Note, a separate row is displayed for each service point linked to the premise</i> | The service point's type and service cycle (if specified) | A service point context menu has been provided (allowing you to drill to a variety of service point-oriented pages) |
| Last Meter Read. This row is displayed if a billable meter read exists for the meter configuration that is currently installed at the service point. | The most recent billable meter read's date and time. | Meter Read - Main |
| Meter Configuration. <i>This row is displayed if a meter configuration is currently installed at the service point. If so, this row's label is indented and displayed beneath the related service point</i> | The meter configuration's meter type, badge number, installation date, meter configuration type, number of registers. | A meter configuration context menu has been provided (allowing you to drill to a variety of meter configuration-oriented pages) |
| Next Meter Read. <i>This row is displayed if the service point references a service cycle.</i> | The next scheduled meter read date and an indication of the service point's <i>service cycle</i> | No drill down is available |
| Item Information This row is displayed if an item is currently installed at the service point. If so, this row's label is indented and displayed beneath the related service point. | The item's type, badge number, and state. | An item context menu has been provided (allowing you to drill to a variety of item-oriented pages). |

SA Premise List Zone

The **SA Premise List Zone** contains a row for each non-cancelled, non-closed service agreement linked to the account. The **Premise** (if any), **Current Balance**, **Payoff Balance**, and **SA Information** is displayed for each service agreement.

The service agreements appear in the following order:

- Service agreements linked to the premise on which you're working appear first.
- Next appear service agreements linked to the account that don't have a premise (deposits, charitable contributions, etc.).
- Following this are the remaining service agreements linked to the account.

Note:

Dimmed Payoff Balance. A service agreement's **Payoff Balance** will be dimmed if it is the same as its **Current Balance**. Refer to [Current Amount versus Payoff Amount](#) for more information.

Warning:

The first 25 rows are displayed when this zone is initially built. If more rows exist, a **Get All** button appears. If you click this button, the system retrieves a maximum of 750 rows.

Service Credit Membership Zone

The **Service Credit Membership Zone** contains a row for each pending and active [service credit membership](#) linked to the account. It will also show any inactive membership that contains a balance. The **Service Credit Membership Type**, **Membership Status** and **Balance** (if applicable) are displayed for each membership.

Scheduled Payments Log

This zone displays an account's pending payments. It includes the following

- Pending one time payments initiated from a third party payment processing system.
- Pending one time payments initiated from web self-service
- Pending bill-related automatic payment records

Refer to [Third Party Payment Processing](#) on page 451 for more information on third party payment processing.

Timeline Zone - Account Info

If your implementation team has configured one or more timeline zones, they may be visible on this page. Timeline zones show when significant events have occurred in the past and when significant events will occur in the future. For example, a timeline can show when payments and bills have been received for a customer.

Refer to [Timeline Zone](#) for a detailed explanation of how a timeline zone displays its information and other functionality that it supports.

Refer to [Configuring Timeline Zones](#) for how to add and change timeline zones.

Control Central - Customer Information

Once [Control Central - Search](#) has a person context, you can navigate to this page to view an overview of the related persons, customer contacts, accounts, premises, and service agreements linked to the account.

Note:

User configurable. Refer to [Each User Can Customize Which Zones Appear](#) for information about how to configure which zones appear.

Description of Page

**Note:**

Navigation hint. The Go To Control Central option on the person context menu navigates to this page.

A mouse with a roller is useful. This page can extend vertically past the normal desktop boundary. You will find that a mouse with a "roller" will facilitate navigating through the page.

The contents of this section describe the zones that are available on this portal page.

*Communication History Search***Search Fields**

The following options allow you to search for and find the desired communications:

- **Search By** (dropdown) allows you to specify the type of communication that you want to find. You can search for Customer Contacts, Notifications from Oracle Utilities Notification Center and Lead Event logs, or all communications, which combine the previous two.
- **Start Date** and **End Date** allow you to set a targeted range of communications.
- **Search By Context** (dropdown) allows you to specify whether the communication is associated to the Person, Account, or Premise.
- **Hide Notification Logs** allows you to display the search results with or without the log entries.

Note: The Hide Notification Logs option displays when applicable to the selected Search By option.

Results Grid

The following details are displayed for each communication:

- **Date / Time:**
 - For a customer contact related entry, the Customer Contact Date / Time for the communication
 - For lead / lead event related entries, the Log Date / Time where the Log Type is Notification for the communication
- **Details:**
 - For a customer contact related entry, the Contact Class Description / Contact Type Description is displayed
 - For lead / lead event related entries, the Log Messages for both the lead / lead event for the communication is displayed. There will be one entry for the lead and another for the lead event. If the lead / lead event created a customer contact for a communication, then an entry for the customer contact will also exist.
- **Related Object:**
 - For a customer contact related entry, a hyperlink to the customer contact record
 - For lead / lead event related entries, there will be one entry for the lead and another for the lead event.
 - For the lead related entry, a hyperlink to the lead related to the communication
 - For the lead event related entry, a hyperlink to the lead event related to the communication

Person Tree Zone

The [tree](#) in this zone shows a great deal of information including:

- All accounts linked to the person in context. Refer to [Understanding The V](#) for more information.
- Customer contacts linked to this person.
- The [hierarchy](#) of parents and children linked this person.
- All aliases linked to this person.

You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Active Account Summary Zone

The **Active Account Summary Zone** lists all accounts related to the person in context where they are the main customer on the account. In addition, accounts linked to this person's [children](#) also appear in this zone, and if a child has children, the grandchildren's accounts are included. In fact, the system will look for accounts up to five levels deep (meaning that the great, great grandchildren's accounts will be included in this zone).

Note:

Only accounts linked to child persons with a financial relationship are shown. When you set up a [customer hierarchy](#), you can define both subsidiaries and "key contacts" (i.e., individuals that you contact at a company). As described above, this zone will include accounts related to these subsidiaries and key contacts. However, you might not want to include the personal accounts related to the key contacts in this zone. You can control which accounts appear in this zone when you set up a hierarchy. You do this by turning on the Financial Relationship switch for those [persons](#) whose accounts should be included.

The following columns are displayed in the grid:

Account Info This column contains the standard account information.

Current Balance and **Arrears** This column contains the account's current balance. If the account's current balance is greater than zero, a colored bar is displayed in the **Arrears** column. This bar provides information about the age of the account's debt. Note that information about debt balances by age is not applicable to [open-item accounts](#). Refer to [Current Customer Zone](#) for more information about this bar.

Last Billed Info This column contains information about the last completed bill sent to the account.

Last Contact Info This column contains information about the last customer contact associated with the account's main customer.

Timeline Zone - Customer Info

Your implementation may have configured this page to show one or more timeline zones. Refer [Timeline Zone - Account Info](#) for a description of how to use these zones.

Control Central - Account Tree

Once [Control Central - Search](#) has an account context, you can navigate to the **Account Tree** to see an overview of the persons, premises, and service agreements linked to the account.

Description of Page

This page is dedicated to a [tree](#) that shows the various objects linked to an account. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Control Central - Premise Tree

Once [Control Central - Search](#) has a premise context, you can navigate to the **Premise Tree** to see an overview of the accounts, service points, and service agreements linked to the premise.

Description of Page

This page is dedicated to a [tree](#) that shows the various objects linked to a premise. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Control Central - Bill/Payment Tree

Once [Control Central - Search](#) has an account context, you can navigate to the **Bill/Payment Tree** to see an overview of the financial transactions linked to the account.

Description of Page

This page is dedicated to a [tree](#) that shows the account's bills and payments. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

For [balance-forward accounts](#), bill nodes contain the balance presented on the respective bill, and pay nodes contain the amount of the respective payment. However, for [open-item accounts](#), the tree behaves differently:

- The amount on bill nodes is equal to the sum of the current charges, adjustments and corrections on the bill.
- Each bill or payment will contain an indication if all of its financial transactions are fully matched. If not, the node will become red to highlight that unmatched financial transactions exist.
- If a bill or payment node is expanded, a summary of the match status of its financial transactions is shown.
- Credit and correction notes appear as separate nodes.

Control Central - Payment Agreements

Once [Control Central - Search](#) has an account context, you can navigate to the **Payment Agreements** page to see an overview of the account's payment arrangement requests and/or pay plans.

The contents of this section describe the zones that are available on this portal page.

Payment Arrangement Requests

This zone shows the account's in-progress and finalized (e.g. granted, denied, canceled, etc.) payment arrangement requests.

You can use this zone to: view high-level information about the payment arrangement request, navigate to the **Payment Arrangement Request** or start a payment arrangement request.

The **Broadcast** icon on each row displays the [Payment Arrangement Request Details](#) zone that shows summary information about the payment arrangement request.

The **New Payment Arrangement** action located at the header of this zone is used to start a payment arrangement request.

Refer to this zone's embedded help for information on other available actions.

Payment Arrangement Request Details

This zone is displayed when a Payment Arrangement Request is broadcast from the [Payment Arrangement Requests](#) zone.

It shows key information about the selected payment arrangement request.

Pay Plan Tree

This zone shows the pay plans linked to an account. It displays both current and past (expired) pay plans.

You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

How To Add A New Customer From Control Central

There are three ways to add a new customer from control central:

- You can add a new customer by invoking the [Person](#) and [Account](#) pages from the Menu dropdown. This is not the recommended approach, as it requires several screen interactions; either of the following approaches is preferable.
- If your team has set up sales and marketing campaigns, you can use the [order](#) transaction to add a new customer. Refer to [Order User Interface Flow](#) for more information. Refer to [Sales & Marketing](#) for background information about sales and marketing campaigns.
- Adding a Person from Control Central. You navigate as follows:
 - You start from [Control Central - Search](#). On this page, you determine if the customer already has an account. If so, select it and you're done. If not, proceed to the next step.

- Click the + button adjacent to the Name field to transfer to [Person - Main Information](#) page (with the name you entered already defaulted). Use the Person pages to record all relevant information about the new customer.
- Enter the customer's names, phone numbers, and IDs. Click Save (or press ALT+S) to add the person and account. The value of **Add Account and Start Service** is defaulted to "on" and the **Customer Class** defaults based on the **Person Type**. This means that when you click save the following will happen: a new person is added, a new account is added, the new person is linked to the new account, and you will be automatically transferred to [Start/Stop](#) where you can start service. (**Note:** This is the default behavior of the system. However, an implementation can define different functionality by setting up a [customer information options](#) feature configuration.

Note:

Default. When the system links the person to the account, it defaults the relationship type from the installation options. A different relationship type can be defined for persons versus businesses on the installation record.

If you need to tinker with information on the account, transfer to account maintenance (use the context menu) and make any necessary changes.

Finding Who Pays For A Meter

If you know the customer's meter number but you don't know the customer, you have the following options:

- Go to [Meter - Main](#) and display the meter. The meter's last premise will be displayed on this page. Use the premise's context menu to go to Control Central.
- Go to [Meter/Item Search](#) and display the meter. All customers who have paid for service measured by the current configuration of the meter will be displayed on this page. You can then use the various context menu buttons to toggle to related information.

Finding Who Pays For An Item

If you know the customer's item number but you don't know the customer, you have the following options:

- Go to [Item - Main](#) and display the item. The item's last premise will be displayed on this page. Use the premise's context menu to go to Control Central.
- Go to [Meter/Item Search](#) and display the item. All customers who have paid for the item will be displayed on this page. You can then use the various context menu buttons to toggle to related information.

Customer 360

Use the unified search box to find a customer and/or premise. After selecting a search result, you are brought to the Customer 360 portal to see an overview of the customer.

Refer to [Search](#) for details on how to use the unified search box.

Customer 360 - Unified Search

Use the unified search box to find a customer or premise, in addition to the standard search for menu items. For more complex queries, click the **Advanced Search** to navigate to the advanced search portal.

The contents of this section describe how to use unified search for Customer 360.

Unified Search - Filters and Hints

Depending on the text entered into the toolbar search box, filter rules are dynamically performed to evaluate which filter is applied when searching for a customer.

The following filters and associated filter rules are used:

| Filter | Filter Rule |
|--------|---|
| Name | Minimum of 5 characters excluding whitespaces |

| | |
|---------------|--|
| Address | One or more numeric characters followed by space and an alphanumeric character |
| Account ID | 10 numeric characters |
| ID Number | Social Security Number: 3 numeric characters followed by a dash, 2 numeric characters, a dash and 4 numeric characters |
| Phone Number | Plus character and 1-3 numeric characters (country code, optional) followed by a space, period, dash or open parentheses, 3 numeric characters (area code), followed by a space, period, dash or close parentheses, followed by 3 numeric characters (exchange code), followed by a space, period or dash, followed by 4 numeric characters (subscriber number). |
| Email Address | Non-whitespace characters followed by an @ sign, non-whitespace characters, a period, non-whitespace characters |

To search explicitly using a specific filter, precede the filter value with one of the following predefined hints:

| Filter | Hint | Examples |
|--------------|------|---------------------------------|
| Name | n: | n:brazil |
| Address | ad: | ad:123 main |
| Account ID | ac: | ac:1234567890 |
| ID Number | id: | id:123-45-6789 |
| Contact Info | c: | c:555-2287 c:mbrazil@oracle.com |

For more information on configuring unified search, filters, and hints, refer to [Understanding Unified Search](#).

Unified Search - Search Results

When a search filter is applied, search results matching your search criteria are populated below the toolbar search box. The information displayed in this area can include the person, account, or premise information. Additionally, the search filter and search filter value that was used for determining the matching search criteria is displayed. Select the customer or premise to navigate to the Customer 360 portal.

Note: The first 300 matches are retrieved and displayed. The base search zones are configured with the **Number of Rows to Display** and **Number of Rows to Retrieve for SQL** parameters set to 300. If you do not find the account / person / premise you are looking for in the set of results, refine your search criteria.

Customer 360 - Program Enrollment

The Program Enrollment Zone contains messages highlighting a variety of insights related to the account in context. Insight Types associated to the Insight Class of Program Enrollment are displayed.

The base product provides Insight Types for: Auto Pay Enrollment, E-Bill Enrollment, Budget Billing Enrollment and Customer Web Enrollment. Refer to the Insight Type configuration in the application, for more details.

Note: For more information about Insight Types and Insight Groups, see [Contextual Insights](#).

The following provides high-level steps to define insight types that can be associated to the program enrollment zone:

- Define new Insight Types. For the program enrollment zone, the insight types are intended to be defined with a visual structure of List Insight. Specify an insight algorithm that receives account as input context value.
- Define an Insight Group that references the **Program Enrollment** insight class. Configure the valid visual structure as List Insight.
- Associate the insight types to the insight group.

Customer 360 - Customer Insights

The Customer Insights Zone contains messages highlighting a variety of insights related to the customer (person, account, premise) in context. Insight Types associated to the Insight Class of Customer Insights are displayed.

Note: For more information about Insight Types and Insight Groups, see [Contextual Insights](#).

The following provides high-level steps to define insight types that can be associated to the customer insights zone:

- Define new Insight Types. For the customer insights zone, the insight types are intended to be defined with a visual structure of List or Card. Specify an insight algorithm that receives person, account or premise as input context values. The base package provides algorithm type C1CIALERT (Contextual Insight - Control Central Alert) for exposing control central alerts as contextual insights.
- Define an Insight Group that references the **Customer Insights** insight class. Configure the valid visual structures as List or Card.
- Associate the insight types to the insight group.

In addition to the Customer Insights zone, contextual insights can be configured to potentially render within certain areas of the other Customer 360 zones. The following table lists the available insight classes included in the base package and the associated UI placement within the corresponding customer 360 zone that insights can render. Additionally, the intended valid visual structures are listed as a guideline when defining the associated insight group. Follow the steps as described above to define insight types and insight groups for these zones.

| Insight Class | Zone | UI Placement | Input Context | Valid Visual Structures |
|--------------------------|-------------------------|---|-----------------|-------------------------|
| Customer Context (Upper) | Customer (sidebar zone) | Upper section of the zone, under person name field | PER_ID, ACCT_ID | Badge |
| Customer Context (Lower) | Customer (sidebar zone) | Bottom section of the zone, under person name field | PER_ID, ACCT_ID | Inline |
| Financial History | Financial Activity | Upper section of Financial History tab, above the financial history fields | ACCT_ID | Inline |
| Usage and Billing | Financial Activity | Upper section of Usage and Billing tab, below the filters | ACCT_ID | Inline |
| Payment Agreements | Financial Activity | Upper section of Payment Agreements tab | ACCT_ID | Inline |
| Credit and Collections | Financial Activity | Upper section of Credit and Collections tab, above the credit and collections trees | ACCT_ID | Inline |

Customer 360 - Customer Activity

The Customer Activity History Zone is a grid that summarizes a variety of account-related events (in reverse chronological order). Use the Filter By drop down to select or deselect activity types to display. Clicking on the activity record transfers you to an appropriate page.

This zone displays similar information as the [Account Activity History Zone](#), with a number of additional activity types added. The following table lists the additional types of information that may appear in this zone and the page to which you will be transferred when selecting the activity record:

| Activity Label | What Is Displayed | Drill Down Transfers You To |
|--|---|-----------------------------|
| Bill. One row is displayed for every Completed bill linked to the account. | The bill amount, bill due date, number of days in the bill period, and bill date. | Bill |
| Payment. One row is displayed for every Frozen payment linked to the account. | The payment amount, the payment events tender type(s), payment status, and payment date. | Payment |
| Self Service Task. One row is displayed for every self service task linked to the account. | The self service task type description, self service task status, and creation date time. | Self Service Task |
| Business Flag. One row is displayed for every SP-based business flag linked to the accounts SA/SP's. | The business flag type description, status, and create date/time | Business Flag |
| Device Event. One row is displayed for every device event pertaining to paired device event types (e.g., power outage/restoration) and device event types configured to trigger service issue monitors. | The device event type description, status, and event date/time | Device Event |
| Service Order Field Activity. One row is displayed for every service order field activity that is not linked to a parent orchestrator activity. | The activity type description, service address information, status | Activity |
| Service Order Orchestrator Activity. One row is displayed for every service order orchestrator activity. | The activity type description, service address information, status | Activity |

Customer 360 - Financial Activity

The Financial Activity Zone provides an overview of Usage and Billing, Financial History, and Payment Agreements linked to the account.

The **Usage and Billing** tab provides a graphical view of bills and metered usage. Use the Cost / Usage drop down to toggle between graphs. If the account is associated to multiple premises, use the Premise drop down to view a particular premise.

Note: Usage and Billing settings are configured by adding or changing the Billing and Usage Display Configuration. You can access the portal through **Admin > General > Master Configuration**.

The **Financial History** tab shows financial detail highlights and lists the account's financial events including charges, payments, and adjustments in reverse chronological order. The financial details highlight section contains the following financial information about the account:

- Current Balance
- Last Bill
- Next Bill Date
- Autopay Source
- Deposit Amount
- Payoff Amount

- Payoff Balance
- Current Credit Rating
- Next Credit Review Date

You can use the financial history grid to both view high-level information about these events and transfer to the respective page in which an object is maintained. Additionally, charge and payment events may be expanded for viewing additional details.

The **Payment Agreements** tab lists scheduled payments for the account's active payment arrangements and/or pay plans, and whether the scheduled payment has been received.

The **Credit & Collection** tab appears when the customer in context is active in a collections, severance, overdue, cut, or write-off process. The tab contains a tree showing the respective process and associated events, along with badge insights alongside each node indicating its status.

Note: Refer to the C1-CollectionsSeveranceProcess, C1-OverdueCutProcessTree, and C1-WriteOffProcessTree [tree](#) definitions for more information about the Credit & Collections node definitions and hierarchy.

Maintaining The V

As described in [Understanding The "V"](#), the "V" objects are those that form the core of your business processes. In this section, we describe the pages that maintain these objects.

Note:

Start/Stop Also Maintains The "V". The [Start/Stop Pages](#) also maintain many of the objects in the "V". For example, service agreements are created behind-the-scenes when you start service for a customer. This means you won't have to use most of the pages described in this section as part of your day-to-day activities. Rather, they exist in case you need to override what the system automatically set up for you.

Maintaining Persons

On the person page, you define demographic information about your customers and every other individual or business with which your company has contact. The topics in this section describe the person page.

Fastpath:

For more information about persons and their place in the "V", refer to [Understanding The "V"](#). For more information about how most persons are added, refer to [How To Add A New Customer From Control Central](#). For more information about how a person is required to set up a customer, refer to [Customer Overview](#).

Person - Main Information

The Main page contains core person information like names, telephone numbers, and forms of identification. Open this page using **Menu > Customer Information > Person > Search**.

Description of Page

Person Information contains basic information about the person. These values only appear after the person exists in the database. The **ID** is a system-assigned random number that stays with a person for the life of the system.

Note:

Formatting is performed by a plug-in. The format of **Person Information** is controlled by a plug-in algorithm on the [installation record](#). Refer to the base package's person information algorithm (PERS-INFO) for an example. If you prefer different formatting logic, your system administrator should configure the system appropriately.

The following information may be recorded about a person:

Person/Business indicates if the entity is a person or a business. Valid values are: Person, Business. This value controls how the person's primary name is validated.

Life Support / Sensitive Load indicates if the person has life support or sensitive load equipment. Valid values are: LS/SL (i.e., the person has life support / sensitive load equipment), None. If the customer has LS/SL equipment, make a note of the type of equipment in the **Life Support / Sensitive Load Notes**.

A premise can also have life support / sensitive load information. If the equipment is physically linked to the premise (e.g., a hospital has life support equipment), you should NOT specify the life support information on the person. Rather, transfer to [Premise - Misc](#) and specify life support information on the premise.

Note:

Alert and C&C. If the base package's C1-LSSL-PER algorithm is enabled on the installation record, and life support / sensitive load information is specified, an alert will appear when the person is displayed on control central. In addition, if a person has life support or sensitive load equipment, it is possible for a different credit & collection severance process to be kicked off if the person's account associated has overdue debt. Refer to [Designing Your Severance Procedures](#) for more information.

Person Names are used by [Control Central](#) to look for accounts and persons. In addition, a person's primary name is the addressee on the person's bill unless overridden by the Override Mailing Name (maintained on the **Misc** tab). The following fields display:

- Use **Name Type** to indicate if the name is an Alias, Alternate Representation, Doing Business As, Legal, or Primary name. Note, for new persons, a value of Primary is defaulted. The values for the name type field are customizable using the Lookup table. This field name is NAME_TYPE_FLG
- Use **Person Name** to define the person's name. Note well, the name is case sensitive.

Note:

Alternate representations of a person's name. You would use an Alternate Representation for a person's name when you have an alternate ways to define the person's primary name. Alternate representations are typically used in countries that use multiple character sets (e.g., the Primary name is entered in Chinese, the Alternate Representation is entered in English). When a person has an alternate name, both the main and alternate names can be used to search for a person. The Alternate Representation **Name Type** only appears if you have enabled alternate names on the installation record. Refer to the description of the Alternate Representation field under [Installation - Main](#) for more information.

Validation and formatting are performed by plug-ins. The validation that is applied to **Person Name** (e.g., a comma separating the last and first name - Smith,Patricia) is controlled by a plug-in algorithm on the [installation record](#). More than one algorithm can be plugged into this plug-in spot. Algorithms plugged into this plug-in spot can also perform formatting such as removing special characters that your implementation's business rules do not allow in person names. Other algorithms can be configured to remove or replace text.

- The **Do Not Format** switch can be used to bypass any person name formatting done by the algorithms described above. Validation such as requiring name separator is still applied, but no further formatting is applied. Setting the switch only applies while the record is being saved and is then reset. The switch is reset because the formatting is only applied when the record is subsequently changed. This switch is only shown if the Enable Person Name Format Bypass **Option Type** on the Customer Information Options [Feature Configuration](#) has been enabled

Note: The Person Phone grid appears when the Legacy Person Phone and Email **Option Type** on the Customer Information Options [Feature Configuration](#) has been enabled.

Person Phone numbers are used by [Control Central](#) to look for accounts and persons. The following fields display:

- **Phone Type** indicates the type of phone number, e.g., Home, Mobile, Business, ...
- Use **Phone Number** to define the telephone number. Enter the telephone number in the format described by the **Phone Format**.

Note:

Formatting is performed by a plug-in. The format that is applied to a **Phone Number** is controlled by the algorithm that is plugged in on the respective **Phone Type**. If you prefer a different format, your system administrator should configure this algorithm appropriately.

- Enter the **Extension**, if any, of the telephone number.

Person Contacts provide a central location to capture contact information such as phone numbers and email addresses. Any contact information can be captured. Person Contacts are used on contact preferences for notifications.

While person contacts can be used in lieu of a person phone and all system processes such as start/stop and orders support person contacts, your implementation may still opt to use person phone. Functionality has been provided to create and maintain person contacts from person phone records. When a person contact type is associated with a phone type, the person contact cannot be deleted nor can the fields maintained via person phone be edited. Refer to [Maintaining Person Contact via Person Phone](#) for more information.

Person contacts can also be edited or created from the Account Contact Information Zone. (See [Account - Account Portal on page 111](#) for more information.)

- **Contact Routing** represents a general grouping of person contacts such as email or phone. It is displayed on this page, and is defined on the person contact type.

Note: Contact Routings of type whose Contact Routing type is *Self Service User* can be viewed here and not elsewhere in the system. Furthermore, they can be viewed, but not edited, added, or deleted.

- **Person Contact Type** indicates the type of contact such as, home phone, cell phone, or work email.
- **Contact Information** contains the specific contact information such as, the phone number or email address. Enter the contact information in the format described.

Note:

Formatting is performed by a plug-in. The format that is applied to **Contact Information** is controlled by the algorithm that is plugged in on the respective person contact type (refer to [Setting Up Person Contact Types](#) for more information). If you prefer a different format, your system administrator should configure this algorithm appropriately.

- Enter the **Extension**, if any, of the contact information. (This field is only active when the contact's contact routing is phone or fax.)
- The **Primary** switch must be set for exactly one person contact for each contact routing.
- **Do Not Disturb (From)** and **Do Not Disturb (To)** indicate the times when a person contact should not be used. (**Note:** these fields are active when the Person Contact Type's Allow Do Not Disturb information is set to *Optional*.)
- **Contact Status** indicates the option contact's status. The initial status can be defaulted from the Person Contact Type. The status can be manually maintained, as appropriate. (**Note:** This dropdown is enabled when the Person Contact Type allows Status to be used. It is also disabled when the person contact type's status is configured to be controlled by a process such as an Opt-In process.) See [Person Contact Status Can Be Controlled By A Process](#) for more information.
- **Opt-in** provides functionality to initiate an opt-in process for person contact types configured to support opt-in. This is used to obtain permission to use the person contact type to send notifications. (**Note:** The functionality on this page is not the primary way of initiating an opt-in process.) See [Person Contact Status Can Be Controlled By A Process](#) for more information about Opt-In Processes.
- **Active/Inactive** defaults to Active. Most contact preferences will remain active. When the contact information changes, the information on the existing contact should be updated.

Warning:

It is strongly recommended that existing contacts are updated whenever possible such as when a person's phone number or email address changes. When a person no longer has a contact such as an alternate phone number, the contact should be deleted. Inactive should only be used when the person contact cannot be deleted because it is referenced on another object such as a contact preference.

- **Contact Nickname** (*display only*) if your implementation is using self-service, users can assign nicknames to contacts and they are shown here.

A **Person's ID's** have several uses:

- They are used by **Control Central** when you look for a customer / premise based on their ID.
- They are used to highlight potential duplicate persons.
- **Control Central** displays a person's **primary** identification in the search results area to help a user identify the customer when multiple customers match the search criteria.

Note:

Person ID may be required or optional. The person ID usage flag on the [installation record](#) indicates whether at least one id for a person is required or optional.

Note: The system supports encryption for Person Identifier. If your implementation has configured the system to encrypt Person Identifier, the data will be displayed with a masked value; such as, *****. Refer to [Encrypting Sensitive Data](#) for more information.

The following fields are used to define a person's ID(s).

- Turn on **Primary ID** for the piece of **ID** that is the primary means of identifying the customer.
- Indicate the **ID Type**. The **ID Type** defaults from the [Installation Record](#) based on the **Person Type** (Person versus Business).
- Enter the identification number in the adjacent fields. Please note that if the **ID Number** should be formatted (e.g., dashes in an American social security number), you do not have to enter the dashes. Rather, you can enter the information as a contiguous value and the system will format this for you. The format is shown in the adjacent **Identifier Format** column.

Note:

Formatting is performed by a plug-in. The format that is applied to an **ID Number** (e.g., dashes in an American social security number) is controlled by the algorithm that is plugged in on the respective [ID Type](#). If you prefer a different format, your system administrator should configure this algorithm appropriately.

If you want to add an account for the person when you save the person information, turn on **Add Account and Start Service**. When this switch is on, you must also define the new account's **Customer Class**. If this information is specified, the system creates a new account and links the person to the account using the relationship type from the installation options. In addition, you will be transferred to [Start / Stop](#) where you can start service for the newly added account.

If you have set the Installation Option CIS Division Control flag, you must first define the new account's **CIS Division**. The values are restricted to the user's CIS Division(s). See [Users and CIS Division](#) for more information. The value is defaulted to user's primary CIS Division. The new account's Customer Class must then be defined.

Note:

Default note. The account's customer class defaults from the [Installation Record](#) based on the **Person Type** (Person or Business). If shown, the customer class defaults first from the CIS Division and then from the Installation Record, each based on the **Person Type** (Person or Business)

A message appears in the lower right corner of the page that describes the number of accounts the person has. You can click the adjacent go to button to transfer to [Control Central - Customer Information](#) on which all of a person's accounts appear.

Person - Correspondence Information

This page contains information that may be used to address [bills](#), [letters](#), [quotes](#) and [statements](#). Use **Menu > Customer Information > Person > Search** and navigate to the **Correspondence Info** page.

Description of Page

If the person does not want their primary name (defined on the Main page) used on [bills](#), [letters](#), [quotes](#) and / or [statements](#), specify the desired name in **Override Mailing Name 1, 2, and 3**.

Specify the **Override Mailing Address** fields if the person wants their bills, letters, quotes, and / or statements sent to an address other than their service addresses (for example, a post office box). In addition, if the person's account doesn't already indicate that the person's mailing address should be used, you must update this person's account(s). This information resides in the Address Source field on [Account - Person](#).

Note:

Both the [Start/Stop](#) and [Order](#) transactions allow you to update the person's **Override Mailing Address** and their account's address source using a single transaction.

Address isn't everything. In addition to defining the person's **Override Mailing Address**, there may be additional tasks you must perform in order to route information to this address. Refer to the following links for more information: [where are bills sent](#), [where are letters sent](#), [where are quotes sent](#) and [where are statements sent](#).

If you enter an **Override Mailing Address**:

- The **Country** defaults from your [installation options](#).
- The address constituents may differ depending on the **Country**. Refer to [Defining Countries](#) for more information on the address constituents.
- If you have set up [postal defaults](#), the system will default the address constituents when you tab out of the postal code.
- The Validate button on the person page will only be available if you have set the Allow Address Validation option type to Y on the General System Configuration feature configuration. Once clicked, the Address Validation Script on the General System Configuration feature configuration will be invoked to validate the entered address. Refer to [Implementing Address Validation](#) for more information.

Specify the customer's **Email Address** if you communicate with the customer via Email. In addition to defining the person's **Email Address**, your correspondence routing software must support sending the information via Email. Refer to the following links for more information: [where are bills sent](#), [where are letters sent](#), [where are quotes sent](#) and [where are statements sent](#).

Note: The Email Address field appears when Legacy Person Phone and Email **Option Type** on the Customer Information Options Feature Configuration has been enabled.

Define the **Language** in which the person prefers their bills and correspondence printed.

Note:

Default note. The person's language defaults from [Installation Options - Person](#).

Fastpath:

Refer to [Customer Language](#) for more information on options for supporting multiple languages for your customers.

Define the person's **Time Zone** preference if it is different from the installation's time zone. Refer to [Installation Options – Framework, Main Page](#) for more information. The time zone appears as part of the display anywhere the Do Not Disturb start and end information is displayed; for example, in the Person Portal or Account Portal.

Note: Default Note. The Time Zone defaults to blank, which indicates that the installation's time zone will be used.

The **Seasonal Addresses** scroll is only used if the person wants their correspondence sent to an alternate address during predefined periods. For example, the customer may want their bills sent to their vacation cottage during the summer. Please be aware of the following:

- Seasonal addresses will only be used if the customer's bills, statements, quotes, and / or letters are routed via the postal service. For example, if you route bills to the customer via Email, the seasonal address will never be used to route bills to the customer. Refer to the following links for more information: [where are bills sent](#), [where are letters sent](#), [where are quotes sent](#) and [where are statements sent](#).
- You don't have to specify a seasonal address for every part of the year. For example, if the customer wants their bills sent to their service address except during the summer, you need only enter a seasonal address for the summer.

- You can enter a seasonal address with or without an **Override Mailing Address**. If an **Override Mailing Address** is not specified, the person's correspondence will be addressed as per the instructions on the person's account(s). These instructions reside in the Address Source field on [Account - Person](#).
- You can enter multiple seasonal addresses if the customer so desires.
- The **Seasonal** period is defined in the two adjacent fields. The first field contains the day and month when the season starts; the second field contains the day and month when the season ends. The day and month should be entered in the format defined in your [display profile](#).
- The **Status** of the address must be Active. You can set the status to Inactive if you want a seasonal address ignored (alternately, you can just remove the seasonal address).
- The **Country** defaults from your [installation options](#). The address constituents may differ depending on the **Country**. Refer to [Defining Countries](#) for more information on the address constituents.
- If you have set up [postal defaults](#), the system will default the address constituents when you tab out of the postal code.

Person - Characteristics

The characteristics page contains information that describes miscellaneous information about the person. Use **Menu > Customer Information > Person > Search** and navigate to the **Characteristics** page.

Description of Page

Note:

You can only choose characteristic types defined as permissible on the person record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

The following fields display:

Effective Date Define the date on which the characteristic becomes effective. The effective date defaults from the [Installation Record](#).

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Person - Persons

This page is used to define this person's relationship with other persons. For example, if the person being maintained is a conglomerate, you can define its subsidiaries on this page. Refer to [How To Set Up Customer Hierarchies](#) for more information about hierarchies.

Note:

You're defining "child relationships". It's important to understand that the persons being defined on this page's grid should be thought of as "children" of the person on the top of the page.

Children may have children. It's possible for one of the children to have children itself (for example, if you have a situation where a subsidiary of a conglomerate itself has subsidiaries). To define a child's children, simply display the child person on this page and then define its children.

Equal relationships. It's possible to link persons where no hierarchy is implied by the relationship (e.g., spouses). There are two ways to do this: 1) you can nominate one spouse as the "parent" and the other as the "child" or 2) you can define the spousal relationship for both persons (i.e., you would define Robert Chopin as the husband of Jeanette Chopin, and Jeanette Chopin as the wife of Robert Chopin). If you choose the latter approach, a recursive relationship will exist.

Warning:

If your organization enters multiple levels of person, we want to note that we do not prevent recursive relationships. This means that you could set up a nonsensical situation where person 2 is a child of person 1 and person 1 is a child of person 2.

Use **Menu > Customer Information > Person > Search** and navigate to the Persons page.

Description of Page

The grid contains the "children" associated with the "parent" person who is defined at the top of the page. The following fields display:

Child Person This is the unique identifier of the "child" person. This person's main name appears adjacent.

Child Information An informational message appears to highlight if the child person itself has children. You can click the corresponding go to button to view the child's children.

Relationship Type Indicate the type of relationship between the parent and the child person.

Start Date Indicate the date on which this relationship began. This field defaults from the [Installation Record](#).

End Date If the relationship expires, indicate the date the relationship stops.

Financial Relationship Turn on this switch if the child person has account(s) and information about these account(s) should be displayed when the parent person's hierarchy is displayed in the [Active Account Summary Zone](#).

Person - Person Portal

Select **Menu > Customer Information > Person > Search** and navigate to the **Person Portal** page to view additional information associated with a Person.

Depending on your implementations requirements, you may define additional zones to appear on this Portal.

The contents of this section describe the zones that are available on this portal page.

General Information

Person ID, Person Info are displayed.

Customer Notification Preferences

The Customer Notification Preferences Zone displays notification preferences for the customer in context.

The following table lists the notification types that may appear in this zone and the page to which you will be transferred to if you click on a hyperlink (if applicable).

| Type | What Is Displayed |
|--|---|
| <p>Bill Routing for each account the person receives a copy of the bill.</p> <p>Type hyperlink navigates you to the Account – Persons tab</p> | <p>Customer Information: Customer Information hyperlink navigates you to the Account</p> <p>Contact Method: Bill Route Type specified on the account</p> <p>Contact Information: Contact details for the Bill Route Type defined for the account</p> |
| <p>PPB New Charge if the person has an active prepaid biller.</p> <p>Type hyperlink navigates you to the Prepaid Biller Task</p> | <p>Customer Information: Customer Information hyperlink navigates you to Prepaid Biller Task</p> <p>Contact Method: Notification Preference for how the customer will be notified each time a new charge is calculated (specified on the Prepaid Biller Task)</p> <p>Contact Information: Contact details for the new charge Notification Preference</p> |
| <p>PPB Payment Request if the person has an active prepaid biller.</p> <p>Type hyperlink navigates you to the Prepaid Biller Task</p> | <p>Customer Information: Customer Information hyperlink navigates you to Prepaid Biller Task</p> <p>Contact Method: Notification Preference for how the customer will be notified when their prepaid balance is</p> |

| Type | What Is Displayed |
|--|--|
| | less than the required minimum balance (specified on the Prepaid Biller Task) Contact Information: Contact details for the payment request Notification Preference |
| Quote Routing for each account where the person receives a copy of quotes. Type hyperlink navigates you to the Account – Persons tab | Customer Information: Customer Information hyperlink navigates you to the Account Contact Method: Quote Route Type specified on the account Contact Information: Contact details for the Quote Route Type defined for the account |
| Statement Routing for each statement the person will receive. Type hyperlink navigates you to the Statement Construct – Main tab | Customer Information: Customer Information hyperlink navigates you to Person Contact Method: Statement Route Type specified on the statement construct Contact Information: Contact details for the Statement Route Type defined for the statement construct for each statement |

Self-Service Notification Preferences

This zone displays active notification preferences for the customer in context and is only applicable if your implementation integrates with [Oracle Utilities Customer Self Service](#).

The applicable notification types (self-service task types) are defined on the [Self-Service Integration master configuration](#).

The following details are displayed for each active notification task (self service task) and the page to which you will be transferred if you click on a hyperlink (if applicable):

- Notification Task Information – Summary information for each of the customer’s active notification tasks. The hyperlink navigates you to the notification task (self-service task).
- Account Info – Details of the account linked to the notification task (self-service task). The hyperlink navigates you to the account.
- CSS Web User – End customer’s User ID supplied by Oracle Utilities Customer Self Service when the customer registers for the notification task (self-service task).
- Delivery Types – List of customer’s preferred communication channels specified on the notification task (self-service task).

Self Service Payment Options

This zone provides the ability to add, edit, and delete payment options used in customer self-service. This information is only applicable if your implementation integrates with [Oracle Utilities Customer Self Service](#).

Refer to the zone help for more details.

Maintaining Accounts

The account record contains information that controls billing and collection processes. You should only need to use this page if you need to fine-tune the information that the system has set up by default because:

- Most accounts are created when you [add a new person](#) or when you [complete an order](#) for a new customer.
- Many fields are populated behind-the-scenes as part of the [service activation process](#).

The topics in this section describe the pages on which account related information is maintained.

Fastpath:

For more information about accounts and their place in the "V", refer to [Understanding The "V"](#).

Account - Main Information

The Main page contains core account information. Open this page using **Menu > Customer Information > Account > Search**.

Description of Page

The primary name of the **Account's** main customer and the **Account ID** are displayed on every tab in this page. These values only appear after the account exists on the database. The **Account ID** is a system-assigned random number that stays with an account for life.

Note:

Formatting may be performed by a plug-in. The basic information about an account that appears at the top of this page (and on many other pages in the system) may be formatted by a plug-in algorithm on the [installations record](#). Refer to the base package's account information algorithm (C1-AC-INFO) for an example. If you prefer different formatting logic, your system administrator should configure the system appropriately.

A "check digit" is displayed adjacent to the account ID. This is for information purposes only, and is not needed to operate the system. The following points describe how the check digit is calculated for an Account ID equal to 0011883422

- Calculate the sum of the first and every alternate digit in the account id. $A = 14 = 0+1+8+3+2$
- Calculate the sum of the second and every alternate digit in the Account ID and multiply by 2. For example, $B = 30 = (0 + 1 + 8 + 4 + 2) * 2$
- Add A and B. For example, $C = 44 = 14 + 30$
- Count the number of digits used to calculate B that are greater than 4. For example, $D = 1$ since only 8 is greater than 4.
- Multiply D by 9. For example, $E = 9 = 1 \times 9$
- Subtract E from C. For example, $F = 35 = 44 - 9$
- Subtract the units position of F from 10 to find the check digit. For example, check digit = $5 = 10 - 5$ (5 is subtracted from 10 because $F = 35$ and there the units position is 5).

Note:

Technical note. The above is calculated in the common routine called CIPCACDN .

Set Up Date is the date the account was initially set up. This is purely informational.

Currency Code defines the currency in which the account's financial transactions are expressed. All rates and payments associated with this account must be denominated in this currency.

Note:

Default note. The currency defaults from the [Installation Record](#) and may be overridden here.

Customer Class plays a part in:

- If and when a customer is subject to late payment charges.
- The account's default collection class and when the account debt monitor reviews an account. Refer to [The Big Picture of Credit & Collections](#) for more information about how and when an account's debt is reviewed.
- And several other functions. Refer to and [Setting Up Customer Classes](#) for more information.

Note:

Default note. The customer class defaults from [Installation Options - Account](#) (Person Customer Class) and may be overridden at will. If you have set the Installation Option CIS Division Control flag, the customer

class defaults first from the CIS Division and then from the Installation Record. When this option is set, the CIS Division is shown on the page before customer class. You may only select Customer Classes with the account's CIS Division.

CIS Division defines the jurisdiction that governs this account. You may only select **CIS Divisions** associated with the account's *Customer Class*. If you have set the Installation Option CIS Division Control flag, you need to choose the CIS Division before choosing the Customer Class. The values are restricted to the user's CIS Division(s). See [Users and CIS Division](#) for more information. The value is defaulted to user's primary CIS Division. This field is updated behind the scenes every time a service agreement is activated (the system uses the **CIS Division** associated with the service agreement's SA type). If you have assigned a **CIS Division** and do not want the system to change it when a service agreement is activated, turn on **Protect CIS Division**. If the CIS Division's **Restrict to Account CIS Division** flag is set to *Restricted*, the Protect CIS Division is turned on and cannot be turned off.

Note:

CIS Division governs many functions. An account's CIS Division impacts its subsequent bill due dates, late payment charge dates, credit & collections review dates, its default budget plan, the roles assigned to To Do entries, and the calendar of workdays. Refer to [Setting Up CIS Divisions](#) and [Setting Up Customer Classes](#) for more information.

Access Group controls which users are allowed to view and update this account's information (including bills, service agreements, payments, and premises). The system defaults this value from one of three sources, stopping after an access group is determined. The first is the Customer Class Control – Determine Access Group system event. The next is the access group defined directly on Customer Class Control. Lastly, it is defaulted from the user's *default access group*. Refer to [The Big Picture of Row Security](#) for a complete description of how account security is implemented in the system.

The optional Account **Management Group** controls the roles assigned to [To Do entries](#) associated with an account. Refer to [Setting Up Account Management Groups](#) for more information.

Enter a **Comment** to define unusual information about the account. If this field is populated, an alert will highlight such in the [Alert Zone](#).

Bill Cycle controls when a bill is produced for an account. This field is updated behind the scenes every time a service agreement with a service point is activated. The route the system takes to do this update is as follows:

- It looks for all service points linked to the service agreement.
- It extracts the *service cycle* from one of the service points.
- Finally, it takes the bill cycle from the *service cycle*.

Note:

The list of bill cycles is restricted to those without a CIS Division and those with a CIS Division that matches the account's CIS Division. When the account does not have a CIS Division, the list is not restricted.

While this is a little complicated, it makes sense because it keeps the bill cycle in sync with the *service cycle*.

If you have assigned a bill cycle and do not want the system to change the bill cycle when a service agreement is activated, turn on **Protect Bill Cycle**.

If you want to stall billing until after some future date, enter the date in **Bill After**. Note that the bill's cutoff date should be after this date, for the account to bill.

Mailing Premise ID defines the address on bills for persons who have their bill sent to the account's mailing premise. This field may be updated behind the scenes when a service agreement is activated. The word "may" is used because the system will only update an account's mailing premise if there are no active service agreements currently linked to the account. Refer to [Account - Person Information](#) for more information about how to define where a person has their correspondence and bills sent.

If you do not want the mailing premise to change when a service agreement is activated, turn on **Protect Mailing Premise**.

If a user should review the account's printed bills before they are sent to the customer in an on-going basis, enter this user's ID in **Bill Print Intercept**. This User ID will then be copied to future [Bill - Bill Routing](#) pages when they are created. If the user no longer desires to intercept future bills, their User ID can be removed from this field.

The balances shown in the scroll are the total amounts of debt belonging to every debt class linked to the account's service agreements. The following information is displayed:

- **Debt Class** is the debt class associated with the account's service agreement(s).
- **Current Balance** is the amount of debt the customer currently owes.
- **Payoff Balance** is the amount the customer would owe if they wanted to pay off their debt.

To see summary information about the service agreements that contribute to the financial totals click the go to button adjacent to the respective amount.

Warning:

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

Account - Auto Pay

The Auto Pay page is used when an account pays their bills automatically (e.g., by direct debit or credit card).

Fastpath:

Refer to [How And When Are Automatic Payments Created](#) for more information.

Open **Menu** > **Customer Information** > **Account** > **Search** and navigate to the **Auto Pay** page to maintain this information.

Description of Page

The **Account Auto Pay** scroll defines the bank account / credit card from which the customer's automatic payments are debited. Multiple auto-pay options may exist if the customer changes auto-pay options over time. The following fields display:

- **Start Date** is the date on which the automatic payment information comes into effect. The system creates an automatic payment for any bill produced for this account with a due date on/after this date and on/before the **End Date**. If **End Date** is not specified, this means the automatic payment option applies indefinitely. You need only specify an **End Date** if the customer wants to stop paying automatically.
- **Auto Pay ID** is the unique, system-assigned identifier of the auto-pay record. This value is assigned after the information is saved on the database and may not be modified.
- Use **Auto Pay Source** to define the source of the funds used to satisfy the automatic payment request. For example, if a customer indicates that they want to use their checking account to pay their bill, you would specify the **Auto Pay Source Code** associated with their bank. The source's description and external source ID (e.g., bank routing number) are displayed adjacent.
- Use **Auto Pay Method** to specify whether you want the system to process automatic payments as Direct Debit or Payment Advice. This field is visible only if feature configuration is set up to support payment advice functionality. Refer to [Payment Advices](#) for more information on the payment advice functionality.
- Use **External Account ID** to define the customer's bank account / credit card number.

Note:

The system supports encryption for the External Account ID. If your implementation has configured the system to encrypt the External Account ID, the data will be displayed with a masked value; such as, *****. Refer to [Encrypting Sensitive Data](#) for more information

- You will be required to define an **Expires On** date if the **Auto Pay Source Code** references a tender type that requires an expiration date (e.g., if the Auto Pay Source is a credit card company).
- Enter the **Name** of the customer as it appears in the financial institution's system. This name is routed to the financial institution.

**Note:**

Default note. The **Name** will default to the primary name of the main customer linked to the account after you enter a **Start Date**. This defaulting is only possible for accounts that exist on the database.

- In some locales, customers can define a **Maximum Withdrawal Amount** to limit the amount of money that is automatically debited from their account. Refer to [How To Implement Maximum Withdrawal Amounts](#) for more information.
- Use **Comments** to describe anything interesting / unusual about the automatic payment request.

Account - Person Information

The Account Persons page contains information about the person(s) linked to the account.

**Note:**

Both customers and non-customers (e.g. the accounting service that handles the bills of a commercial customer) can be linked to an account.

When you add an account from [Person - Main](#) or from [Order - Main](#) the system automatically links the person to the account, so you typically won't have to open this page. However, if you need to link multiple persons to an account (e.g., because you need to send a duplicate of the account's bill to someone other than the main customer) or change information about a person on an account, open **Menu > Customer Information > Account > Search** and navigate to the **Persons** page.

Customer Self Service and Account - Person Information:

It is possible that an implementation may have configured the system to integrate with Customer Self-Service. Account - Persons can be created through the self-service application and will use a reserved relationship type that is defined on the self-service master configuration.

Records with this relationship type can be thought of as “owned by the self-service application.” Changes to fields on the page are disabled because the record can be deleted by the self-service application.

You can change the relationship type to another value, which will indicate that the record is no longer owned by self-service. Self-service can no longer delete this record and changes are allowed to the fields on the page. Please note that the relationship cannot be changed back to the self-service designation

Description of Page

The **Account Persons** scroll contains one entry for every person linked to the account. The following fields display:

Person ID The unique identifier of the person linked to the account. The person's name is displayed adjacent.

Main Customer Turn on this switch if the person is the main customer on the account. Only one person on an account may be designated as the main customer.

The significance of the main customer is that its name will appear adjacent to the account ID throughout the system.

Financially Responsible Turn on this switch if the person is financially responsible for the account's debt.

This switch is on and gray if the person is the **Main Customer** because the main customer is always financially responsible. If multiple persons are linked to the account, you use this switch to indicate which ones are financially responsible versus those that are linked for other purposes.

Third Party Guarantor Turn on this switch if the person is a third party guarantor of the account's debt. This switch is off and gray if the person is the **Main Customer**.

Relationship Type Define the relationship between the person and the account. Refer to [Setting Up Account Relationship Codes](#) for information about setting up relationship types.

**Note:**

Default note. When the system links the person to the account when you add an account from [Person - Main](#), it defaults the relationship type from the [Installation Record](#).

Self-Service Role indicates that the Account - Person record has a corresponding entry in the self service application and contains the value for the access in self-service. If there is no corresponding entry in self-service, this field will not display. If configured in the Self-Service Master Configuration, a hyperlink appears allowing direct access to self-service.

Prefix/Suffix and **Pfx/Sfx Name** Use these fields if you need to append additional information to a customer's name when correspondence or bills are sent to this person. For example, if the account has declared bankruptcy you might attach "Debtor In Possession" to the person's name. Use **Prefix/Suffix** to indicate if the **Pfx/Sfx Name** should be appended to the front or the back of the customer's name.

Receives Copy of Bill Turn on this switch if the person receives a copy of the account's bills. Turning off this switch grays the remaining fields. This switch is on and gray if the person is the **Main Customer** because the main customer always receives a copy of the bill.

Fastpath:

Refer to [The Source Of Bill Routing Information](#) for more information about how the remaining information is used to format the address of a bill.

Bill Route Type Indicate how the bill is sent to the customer. This field's value defaults from the [Installation Record](#).

- If the **bill route type** you select indicates that bills are routed via Fax, the person's fax number is displayed adjacent. The fax number displayed is from a fax person contact associated with an active contact preference, the person's primary fax person contact identified by the contact routing, or a person's fax phone type identified by a flag on the phone type. Which is shown is dependent on how your system is configured.
- If the **bill route type** you select indicates that bills are routed via Email, the person's [Email address](#) is displayed adjacent. The email address displayed is from an email person contact associated with an active contact preference, the person's primary email person contact identified by the contact routing, or a person's email. Which is shown is dependent on how your system is configured.
- If the **Bill Route Type** you select indicates that bills are routed via the Postal service, you must choose an appropriate **Address Source** to define which address should be used.

Refer to [Setting Up Bill Route Types](#) for more information about bill route types.

Bill Format Indicate if the customer should receive a Detailed or a Summary bill.

Note:

The values for this field are customizable using the Lookup table. The values need to match the formats supported by your bill print software. This field name is BILL_FORMAT_FLG.

Number of Bill Copies Indicate how many copies of the bill the person receives.

Customer PO ID Indicate the purchase order ID the customer wants printed on their copy of the bill.

Note:

Receives Copy of Quote and **Quote Route Type** only appear if the quotation Contract Management module is not [turned off](#).

Receives Copy of Quote Turn on this switch if the person receives a copy of the account's quotes. Turning off this switch grays the remaining fields. This switch is on and gray if the person is the **Main Customer** because the main customer always receives a copy of the account's quotes.

Fastpath:

Refer to [Printing Quotes](#) for more information about how the remaining information is used to format the address of a quote.

Quote Route Type Indicate how the quote is sent to the customer. This field's value defaults from the [Installation Record](#).

- If the **quote route type** you select indicates that quotes are routed via Fax, the person's fax number is displayed adjacent. The fax number displayed is from a fax person contact associated with an active contact preference, the

person's primary fax person contact identified by the contact routing, or a person's fax phone type identified by a flag on the phone type. Which is shown is dependent on how your system is configured.

- If the **quote route type** you select indicates that quotes are routed via Email, the email address displayed adjacent. The email address displayed is from an email person contact associated with an active contact preference, the person's primary email person contact identified by the contact routing, or a person's email. Which is shown is dependent on how your system is configured.
- If the **quote route type** you select indicates that quotes are routed via the Postal service, you must choose an appropriate **Address Source** to define which address should be used.

Refer to [Setting Up Quote Route Types](#) for more information about quote route types.

Receives Collection and Overdue Notices Turn on this switch if the person receives letters (i.e., notifications) initiated by collection, severance, write-off, overdue and cut events. These events will send letters to the main customer and any other person linked to the account that **Receives Notifications**. This switch is on and gray if the person is the **Main Customer** because the main customer always receives notifications. Refer to [Printing Letters](#) for more information about how letters are produced by the system.

Address Source If the **Bill Route Type** or the **Quote Route Type** you selected indicates that bills / quotes are routed via the postal service, you must choose the appropriate **Address Source**.

Choose Mailing Premise on Account if bills / quotes should be sent to the address associated with the Mailing Premise on the first page. This address is displayed adjacent.

Choose Person if bills / quotes should be sent to the [person's mailing address](#). This address is displayed adjacent.

Choose Account Override if bills / quotes should be sent to an override address specified below. Typically, you would only choose this option if the person has multiple accounts and each account's bills / quotes should be sent to a different address. If you choose this option, the bottom of this page will become populated with fields that should be used to specify this override address.

Override address constituents If you selected an **Address Source** of Account Override, you must enter the address to which bills / quotes will be sent in the address constituents. The number and type of address constituents is based on the [Country](#). These fields will be invisible for other **Address Sources**.

Note, the **Country** defaults from [Installation Options - System](#). The City, County and State default based on the **Country** and **Postal** if a [Postal Default](#) exists for the postal code.

The Validate button on the account page will only be available if you have set the Allow Address Validation option type to Y on the General System Configuration feature configuration. Once clicked, the Address Validation Script on the General System Configuration feature configuration will be invoked to validate the entered address. Refer to [Implementing Address Validation](#) for more information.

Allow Communication Preference: Turn on this switch if person contacts can be used on communication preferences for this account. The switch is on and disabled when the person is the **Main Customer** because their contact information can always be used on contact preferences for notifications.

Account - Financial Balances

The financial balances page is an information-only page that subdivides an account's debt by debt class. The balances shown on this page are the total amounts of debt belonging to every debt class linked to the account's service agreements.

Note:

The source of debt class. An account's debt comes from its service agreement(s). Every service agreement has an SA type. Every SA type references a debt class.

Open **Menu** > **Customer Information** > **Account** > **Search** and navigate to the **Financial Balances** page.

Description of Page

The account's **Current Balance** displays at the top of the page.

The **Debt Class Balances** scroll contains one entry for every debt class linked to the accounts non-closed / non-cancelled service agreements. The following information is displayed for each debt class.

- **Debt Class** is the debt class associated with the account's service agreement(s). To see summary information about the service agreements that contribute to the debt class totals click the adjacent Go To button.
- **Current Balance** is the amount of debt the customer currently owes.
- **Payoff Balance** is the amount the customer would owe if they wanted to pay off their debt. Payoff balance is only displayed if it differs from current balance.

Warning:

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

- The **Debt Class Arrears** shows the age of all amounts that make up the current balance.
- The **Days Old** and **Amount** information shows the age of the debt class's debt.

Note:

Information about debt balances by age is not applicable to [open-item accounts](#).

Account - Bill Messages

The Account Message page contains information about the message(s) to appear on an account's bills. Both one-time and permanent messages may be defined. This information is used when the system assembles messages to appear on an account's bill. Refer to [The Source of Bill Messages](#) for more information about bill messages.

Open **Menu** > **Customer Information** > **Account** > **Search** and navigate to the **Bill Messages** page.

Description of Page

The following fields are displayed:

Bill Message The message code and description of the message that appears on the customer's bill.

Bill Message Type Use Temporary to indicate the message should only be linked to the next bill produced for the account. Use Permanent if the message should appear on every bill. Note, a value of Temporary defaults.

Account - C&C

The Credit Rating page contains the credit rating transactions that impact an account's credit rating and cash-only score. To view or modify these transactions, open **Menu** > **Customer Information** > **Account** > **Search** and navigate to the C&C page.

Description of Page

Collection Class controls how the account's debt is compared against collection criteria to determine if a collection process should be started. Refer to [The Big Picture of Credit & Collections](#) for more information about how and when an account's debt is reviewed.

Note:

Default note. The **Collection Class** defaults from the account's customer class when the account is first added. It may be overridden at will.

If you need to prevent an account from being reviewed by credit and collections processes (i.e., the [account debt monitor](#) and the [write-off monitor](#)), use **Postpone Credit Review Until** to define the future date when these processes can again review the account's debt.

Last Credit Review Date is the date when the account's debt was last reviewed by the [account debt monitor](#) (ADM).

Note:

Forced ADM review. If you want the account debt monitor to review an account's debt the next time it runs, simply change the **Credit Review Date** to a date in the distant past (e.g., 1/1/1900). The next time the ADM background process runs with the Include Minimum Days Review (Y/N) set to Y, it'll see that a great deal of time has passed since the last time it reviewed the account's debt and review it (and then set the **Credit Review Date** accordingly).

The account's **Current Credit Rating** is displayed. For an explanation of how this number is derived, see [How is an account's credit rating calculated?](#)

The account's **Current Cash-Only Score** is displayed. For an explanation of how this number is derived, see [How is an account's cash-only score calculated?](#)

The **Credit Rating History** scroll contains one entry for each credit rating history record associated with the account. The following fields display:

Start Date This is the first date the credit rating transaction affects the account's credit rating and cash-only score.

End Date This is the last date the credit rating transaction affects the account's credit rating and cash-only score.

The Created On message is formatted using an algorithm on the [Installation Options](#).

Affect Credit Rating By This is the effect of the credit rating transaction on the account's credit score. This should be a *negative* number because the *lower* the score the worse the credit rating.

An account's credit rating is equal to the start credit rating amount defined on the [installation record](#) plus the sum of credit rating demerits that are currently in effect. When an account's credit rating is less than the credit rating threshold defined on the [installation record](#), the account's credit rating is displayed as an alert in the [Alert Zone](#).

Affect Cash-Only Score By This is the effect of the credit rating transaction on the account's cash-only score. The *higher* the score, the greater the chance this account will be marked as cash-only. Therefore, a *positive* number should be used to make the score go up.

An account's cash-only score is equal to the start cash-only score defined on the [installation record](#) plus the sum of cash-only points that are currently in effect. When an account's cash-only score exceeds the cash-only threshold score defined on the [installation record](#), the account is flagged as cash-only in the [Alert Zone](#) and on the payment event page.

Comments Enter comments to clarify the reason(s) for the creation of the transaction.

How are credit rating transactions created?

Credit rating transactions may be created as follows:

- Certain types of severance events add credit rating transactions. The number of credit rating and cash-only points is defined on the [severance event type](#).
- Certain types of severance events add credit rating transactions. The number of credit rating and cash-only points is defined on the severance event type.
- Certain types of write-off events add credit rating transactions. The number of credit rating and cash-only points is defined on the [write-off event type](#).
- If a payment tender is canceled with a cancellation reason that indicates the cancellation was due to non-sufficient funds, a credit rating transaction is created. The number of credit rating and cash-only points is defined on the [payment cancellation reason code](#).
- You may configure your system to create a credit rating transaction when a pay plan is broken. To do this, you must plug in an appropriate Broken Algorithm on the [pay plan type](#).
- A user may create credit rating transactions at their discretion.
- Algorithms may add credit rating transactions. The system provides sample overdue event and cut event activation algorithms that add credit rating transactions. Refer to C1-OE-CR-RT and C1-CE-CR-RT for more information. Some examples of algorithms your implementation may decide to introduce: the creation of a late payment charge. To do this you could introduce a new adjustment freeze algorithm.

**Note:**

Created By Flag. The credit rating transaction includes a **Created By** flag that is customizable using the Lookup table. This field name is CR_RAT_CRE_BY_FLG. If your implementation uses algorithms to create credit rating history transactions, you may consider adding appropriate values to the Created By flag. Also note that the Created By flag includes the value Other , which may be used by your implementation specific algorithms if you do not want to add a new custom value.

How is credit rating calculated?

An account's credit rating is calculated by summing the Affect on Credit Rating from credit rating transactions effective on the current date. This value is added to the beginning credit rating defined on the installation record. The result is the customer's current credit rating.

Note: CIS Division can override the beginning credit rating. The system processes first check the account's CIS Division to see if the beginning credit rating has been specified on the CIS Division.

What impact does credit rating have in the system?

The following points describe the impact of an account's credit rating:

- An account's current credit rating is displayed in the Control Central Alert area when it's less than the threshold credit rating defined on the installation record.
- An account's credit rating may affect how the account's debt is collected. We used the word "may" because an account's credit rating will only affect collection criteria if you set up your collection processes to do this.

**Fastpath:**

For more information, refer to [Designing Your Collection Class Control Overrides](#).

How is cash-only score calculated?

An account's cash-only score is calculated by summing the Affect on Cash-Only Score from credit rating transactions effective on the current date. This value is added to the beginning cash-only score defined on the installation record. The result is the customer's current cash-only score.

Note: CIS Division can override the beginning cash-only score. The system processes first check the account's CIS Division to see if the beginning cash-only score has been specified on the CIS Division.

What impact does cash-only score have in the system?

If an account's current cash-only score exceeds the cash-only threshold on the installation record, and the base package's C1-CASH-ACCT algorithm is enabled on the installation record:

- The customer is flagged as cash-only in the Control Central Alert area.
- If a user attempts to add a payment whose tender type is a cash-equivalent, a warning is issued.

Account - Budget

The Budget page contains information about all service agreements linked to an account that are eligible to participate in a budget billing plan. Refer to [Budget Billing](#) for more information about how this information affects the account's bills.

**Note:**

You are actually changing service agreements. When you change a service agreement's budget amount on this page, you are actually changing the service agreement's recurring charge amount. Refer to [Service Agreement - Recurring Charge](#) for more information.

Eligible service agreements. It's important to be aware that some service agreements linked to an account may not be eligible for budget plans. For example, assume you have a customer with a deposit service agreement and one or more utility service agreements. This customer will be billed for their deposit regardless of the utility service agreements' budget amounts. You define whether a service agreement may participate in a budget plan on the service agreement's SA type.

Open **Menu** > **Customer Information** > **Account** > **Search** and navigate to the **Budget** page to view this information.

Description of Page

The appearance and dialogue of this page differs slightly for an account with a small number of service agreements (100 or less) versus a large number of service agreements (more than 100).

- For an account with a small number of service agreements, the user may click the **Recommend Budget** button to generate a **New Budget** for each service agreement. At that point the service agreement's budget amount has not been updated. The user may review the calculated amounts; make desired changes and then click Save to update the budget amount for the service agreements.

Warning:

You must save the page in order for the budget changes to take effect.

- For an account with a large number of service agreements, the user may click the **Calculate and Apply New Budget** button. At that point the system will calculate the recommended budget and update the **Budget Amount** on all the eligible service agreements. To change the budget amount for one or more of the service agreements, the user navigates to the service agreement page using the drill down button adjacent to the service agreement in question.

Click **Cancel Budget** to have the system set the **New Budget** amount to zero for all the account's service agreements on budget.

Note:

Budget Recommendation. Though this page lists all SAs eligible for a budget, the budget recommendation only calculates a budget amount for SAs whose start and end date (if any) includes the budget date.

Budget Plan controls how the account's debt is managed for budget-related purposes. Specifically, it controls how the recommended budget amount is calculated and how / when the customer's budget is periodically changed.

Note:

Default note. Budget plan defaults based on the account's customer class / division combination.

The list of budget plans is restricted to those without a CIS Division and those with a CIS Division that matches the account's CIS Division. When the account does not have a CIS Division, the list is not restricted

Use **New Budget Date** to define the effective date of any changes to the customer's budget amount (this date is the effective date on the respective service agreements' recurring charge history).

The system displays the sum of the service agreements' current budget amounts in **Current Account Budget**.

For accounts with a small number of service agreements, the system displays the sum of the service agreements' new budget amounts in **Recommended Account Budget**.

The grid that follows contains a row for each service agreement linked to the account that is eligible to participate in a budget billing plan:

SA Information This is a concatenation of basic information about the service agreement.

Last Changed Date This is the date when the service agreement's budget amount (i.e., recurring charge amount) was last changed.

Current Budget This is the existing budget amount (i.e., recurring charge amount) for the service agreement.

Recommended Budget For accounts with a small number of service agreements, the service agreement's budget amount (i.e., recurring charge amount) will be changed to reflect this value when the page is changed. The effective date of the change is defined in **New Budget Date**.

Account - Deposits

The Deposits page contains information about all cash and non-cash deposits linked to an account.

Note:

Cash versus Non-cash Deposits. Non-cash deposits (e.g., letters of credit, surety bonds, 3rd party deposits) can be added and maintained on this page. Cash deposits are maintained using service agreements. Refer to [Cash Deposits](#) for information about how to add and maintain cash deposits.

Open **Menu** > **Customer Information** > **Account** > **Search** and navigate to the **Deposits** page to view this information.

Description of Page

The following fields appear in the **Deposit Summary**:

Cash Deposits On Hand The total amount of cash deposits currently held for the account. This value is equal to the sum of the payoff balances from all service agreements whose SA type has a special role of Cash Deposit. Refer to [Cash Deposits](#) for information about how to add and maintain cash deposits.

Cash Deposits Requested This value is equal to the sum of Total Amount to Bill from all service agreements whose SA type has a special role of Cash Deposit. Refer to [Cash Deposits](#) for information about how to add and maintain cash deposits.

Non-Cash Deposits The total amount of active non-cash deposits currently held for the account. This value is equal to the sum of non-cash deposits displayed in the scroll below (note, non-cash deposits can be maintained in the same scroll).

Total Deposits on Hand This is the sum of cash and non-cash deposits held for the account.

Turn on **Do Not Review or Refund** if this account should not be considered by the Deposit Review background process (this process highlights customers who require an additional deposit) or by the Deposit Refund background process. Refer to [The Big Picture Of Deposits](#) for more information about these processes.

The **Non-Cash Deposit** scroll contains an entry for every non-cash deposit linked to the account. Refer to [Non Cash Deposits](#) for more information.

To modify a non-cash deposit, simply move to a field and change its value. To add a new non-cash deposit, click the + button and then fill in the information for each field.

Start Date This is the date the non-cash deposit is effective.

End Date This is the expiration date of the non-cash deposit.

Non Cash Deposit Type Select the appropriate non-cash deposit type. The value selected is important as it controls whether the system requires a **Third Party Deposit** and whether the system will create a To Do entry near the expiration date of the deposit. Refer to [Setting Up Non-Cash Deposit Types](#) for more information.

Deposit Class Select the deposit class in which this non-cash deposit should be included. This value is used when the system amalgamates an account's total deposits when checking if the account holds an adequate deposit (amalgamation and recommendation happens within a deposit class). Refer to [Deposit Class Controls Everything](#) for more information about the significance of deposit class.

Deposit Amount Indicate the amount of the non-cash deposit.

Document Number Enter the document number, if any, associated with the non-cash deposit (e.g., the letter of credit number, the surety bond number, etc.).

Third Party Deposit SA If a 3rd party has paid the cash deposit for the account, reference the deposit SA associated with the 3rd party. Refer to [3rd Party Deposits](#) for more information about how 3rd party deposits are maintained in the system.

Comments Enter any free-form comments about the non-cash deposit.

Account - Characteristics

The characteristics page contains information that describes miscellaneous information about the account. Use **Menu > Customer Information > Account > Search** and navigate to the **Characteristics** page.

Description of Page

Note:

You can only choose characteristic types defined as permissible on the account record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

The following fields display:

Effective Date Indicate the date on which the characteristic value becomes effective. Note, the effective date defaults to the account's setup date (defined on the **Main** page).

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Account - Alerts

The alerts page contains information that describes various alerts assigned to the account. Use **Menu > Customer Information > Account > Search** and navigate to the **Alerts** page.

Alerts assigned to an account appear in the [Alert Zone](#). They are used to bring important information to the attention of any customer service representative who looks at the account.

Description of Page

The following fields display:

Alert Type Indicate the type of alert to show on Control Central.

Start Date Indicate the date on which the alert starts showing in Control Central. The current date defaults.

End Date Indicate the date on which the alert stops showing in Control Central. The alert is shown through the end date. You can leave this field blank if the alert should be effective indefinitely. The date defaults to the **Start Date** plus the **Alert Type's** alert period.

Account - Account Portal

Select **Menu > Customer Information > Account > Search** and navigate to the **Account Portal** page to view additional information associated with an Account.

Depending on your implementations requirements, you may define additional zones to appear on this Portal.

The contents of this section describe the zones that are available on this portal page.

General Information displays Account ID and Account Info

Account Contact Information Displays person contacts that are associated with the account in context. Only records for persons that allow communication preferences are shown.

- This zone provides the ability to add or edit existing person contacts. The edit functionality is limited. This provides a convenient way to edit basic information for person contacts. When adding a person contact, person contact types associated with phone types are not available.
- Full maintenance of person contacts can be performed on the *Person – Person Contacts* page.

Push Communication Preferences Displays contact preferences and opt-out preferences for push-based notification types; meaning, those notifications that customers do not need to subscribe in order to receive. You can maintain the customer's preferred method(s) of contact (the preferences) for receiving these notifications, or process a customer's request to opt out of receiving them.

Note:

Push notifications have parent and individual notification types. Communication preferences are established for parent notification types. The individual notification types reference a parent notification type and define the message to be sent using the preferences established for the parent. As mentioned, for push notifications a subscription is not needed; a default contact can be determined in the absence of contact or opt-out preferences.

Not all notification types are relevant to all customers. Notification types can be configured with a suppression criteria algorithm that can prevent some notification types from appearing. It is possible that a notification type was suppressed after active contact preferences were set up. These notification types and their contact preferences are also shown when the filter is set to show inactive preferences.

- Refer to [Push vs. Subscription Notification Types](#) and [Parent vs. Individual Push Notification Types](#) for more information.
- Please see the zone's help text for information about this zone's fields.

Subscription Communication Preferences Zone displays contact preferences for subscription-based notification types - meaning those notifications to which customers need to subscribe in order to receive them. You can maintain the customer's preferred method(s) of contact (the preferences) for receiving these notifications. A notification for subscription-based notification cannot be sent without an active contact preference. Opting out is not applicable to subscription-based notification types.

Note:

Unlike push notifications, communication preferences are established for the subscription notification types, which also defines the message to be sent.

Not all notification types are relevant to all customers. Notification types can be configured with a suppression criteria algorithm that can prevent some notification types from appearing. It is possible that a notification type was suppressed after active contact preferences were set up. These notification types and their contact preferences are also shown when the filter is set to show inactive preferences.

- Refer to [Push vs. Subscription Notification Types](#)
- Please see the zone's help text for information about this zone's fields.

Account Management Portal

The Account Management portal is used to maintain multiple accounts linked to a particular customer.

Open this page using **Menu > Customer Information > Account Management**

Some examples of customers with large numbers of accounts include:

- Public school districts with many school locations
- Corporate entities with many franchise locations
- Large apartment complexes with many open units
- Service providers billed for many end customers
- Cities, counties, or townships (for street lights, sewer service, etc.)

You can select one or more accounts to update, or you can broadcast an account's service agreements for group SA maintenance. Update actions can be performed on either accounts or SAs. The following items are examples of the account information that can be updated:

- Mailing address
- Characteristics
- Autopay information
- Bill cycle

- Account management group

The following items are examples of the service agreement information that can be updated:

- Rate schedules
- Contract riders and contract values
- Tax exemptions
- Characteristics

When you update information, you can select an account or SA to use as a template, and use this as a basis for updating multiple accounts. The system will copy information from the template to the selected accounts or service agreements. Refer to the embedded help on the Update Details page for more information about using a template to update accounts.

Description of Page

Use the Account Search zone to search for a person. The **Person ID** is required. **Include Hierarchy** determines whether you wish to search for accounts directly linked to the person id specified, or if you want to find all accounts in the hierarchy using person to person relationships. You can also enter one or more of the following values to further restrict the list of accounts returned: **Customer Class, Account Management Group, Bill Cycle** or **Characteristic Type/Value**.

Once a person is selected, you can view and maintain the accounts and the service agreements associate with the person. Click the broadcast icon next to an account to view SAs for the account. The Service Agreement List zone includes a summary listing of the non-closed, non-canceled service agreements of the broadcast account.

Select one or more accounts and click **Update Accounts** to modify account information. Select one or more service agreements and click **Update Service Agreements** to modify service agreement information. Refer to the embedded help on the Update Details page for descriptions of the values that can be updated.

The Person Tree zone, similar to that of Control Central, shows the hierarchy of child persons for the person that has been broadcast.

Account - SAs For A Debt Class

This is an information-only page that shows an account's service agreements grouped by debt class.

Note:

The source of debt class. An account's debt comes from its service agreement(s). Every service agreement has an SA type. Every SA type references a debt class.

To access this page, drill down on a debt class shown on **Menu > Customer Information > Account > Search**.

Description of Page

The **Account ID** and the primary name of the account's main customer are displayed.

Debt Class is the debt class associated with the account's service agreement(s).

Note:

An account may have service agreements that belong to other debt classes. Navigate to [Account - Main Information](#) to see a list of all debt classes associated with an account.

The **Service Agreement** scroll contains one entry for each service agreement that belongs to the **Debt Class**. The following information is displayed for each service agreement.

- **SA (service agreement) Info** is a concatenation of important details about the service agreement.
- **Premise** defines the service agreement's main premise.
- **Current Balance** is the amount of debt the customer currently owes.
- **Payoff Balance** is the amount the customer would owe if they wanted to pay off their debt. Payoff balance is only displayed if it differs from current balance.

**Warning:**

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

- **SA Arrears** displays the age of the amounts that make up the current balance.
- The **Days Old** and **Arrears Amount** information shows the age of the service agreement's debt.

**Note:**

Information about debt balances by age is not applicable to [open-item accounts](#).

Using The Account/Person Replicator

There are two different ways to use this transaction:

- You can make many copies of a given Person / Account combination. This may be required if your company works with third party agencies who enroll customers on its behalf. In this situation, the third party agency may receive blocks of pre-allocated account numbers to be used when they enroll a customer. When a customer signs up, the person information can be updated with information about the newly enrolled customer.
- Perform the following steps if you need to create many copies of a given person and account:
 - [Add a new person and account](#) if you don't already have a customer to serve as your "template".
 - Use the Account/Person Replicator to create copies of the person and the account as described below (and make sure to use the Replicate Acct and Person option).
- You can create many Accounts for a single Person. This may be required if you have a customer who wants many separate accounts rather than a single consolidated account.
- Perform the following steps if you need to create many copies of a given account for a specific person:
 - Select the account that serves as the template account for the person. Note, this account must be linked to the person who wants the many accounts.
 - Use the Account/Person Replicator to create copies of the account as described below (and make sure to use the Replicate Account Only option).

Use **Menu > Customer Information > Account/Person Replicator** to open this page.

Description of Page

Choose the **Account** that serves as the template account.

**Note:**

Recommendation. Carefully verify that the template account you have chosen is correct before you save the replicated accounts. After you save the replicated accounts, any corrections could prove time consuming.

At the top of the page, indicate the **Number** of accounts and persons **to Replicate**.

Indicate the **Main Person Name Base**, which will be used as the main person name for all the new persons to be created. This field will be protected if you choose a **Replicate Type** of Replicate Account Only (as no persons are created).

Use **Replicate Type** to define if you want to create multiple copies of an account for a given person or if you want to create many new person / account combinations. See the description that appears above for more information about this field.

After entering the above, click the **Replicate** button to generate your new accounts and persons. The grid displays informational messages describing what will happen when you click save. For example, it will verify how many accounts will be created, the person whose record will be copied, the name that will be used on all the new persons, etc..

If everything looks clean, click **save**.

Information Replicated for New Persons

Except for the main name, which you indicate in the **Main Person Name** field, all information for the main person linked to the account will be copied to the new persons.

Warning:

This copy includes the person's identification number. This will result in multiple persons with the same identification number. You should ensure that the identification number for your template person is a temporary number. When you sign up your actual customer, be sure to update the identification number to a valid number for the person.

Information Replicated for New Accounts

Although most information for an account will be copied, not all information will be. The following points describe the information that is NOT copied on newly replicated accounts:

- Mailing premise will be set to blank
- Setup Date is set to the current date
- Credit Review Date and Postpone Credit Review Until Date will be set to blank
- Auto Pay information will not be copied
- Credit Rating History will not be copied
- Non-cash deposit information will not be copied

Note:

that all miscellaneous persons linked to the account (i.e., those who are not flagged as Main Customers) will be linked to the new accounts. With this functionality, for example, you can create a person for a third party enroller and link this enroller to the template account. This enroller will then be linked to all the new accounts.

Maintaining Service Agreements

A service agreement contains the terms and conditions controlling how the system calculates charges for a specific service supplied to a customer. The topics in this section describe the pages on which service agreement related information is maintained.

Note:

The system creates most service agreements behind the scenes. Most service agreements are created "behind the scenes" by the system as part of the Start Service and Order completion processes. You should only have to access the service agreement pages if you need to fine-tune what the system defaults. Refer to [Start/Stop](#) and [Maintaining Orders](#) for the details.

Service Agreement and Usage Subscription. A Usage Subscription will exist for each 'usage-oriented' service agreement.

Fastpath:

For more information about service agreements and their place in the "V", refer to [Understanding The "V"](#). For more information about the source of information defaulted onto service agreements, refer to [Setting Up Start Options](#).

Warning:

Take special care when adding a new service agreement to specify the appropriate Division and SA Type as it will affect how the customer is billed, what rate can be specified, how overdue debt is collected, and much more. After the service agreement is activated, you may not change its SA type.

The Lifecycle Of A Service Agreement

The following diagram shows the possible lifecycle of a service agreement.

Pending Start When you initiate a request to start service, the system initiates a service agreement in the state of Pending Start. A pending start service agreement remains in this state until everything necessary to start service is defined in the system.

Active The system automatically changes the state of Pending Start service agreements to Active when everything necessary to start service exists in the system. Refer to [Activating Pending Starts](#) for more information. While in this state, the system bills the service agreement's account for the service.

Pending Stop When you initiate a request to stop service, the system progresses the service agreement to the Pending Stop state. A pending stop service agreement remains in this state until everything necessary to stop service is defined in the system.

Stopped The system automatically changes the state of Pending Stop service agreements to Stopped when everything necessary to stop service exists in the system. Refer to [Finalizing Pending Stops](#) for more information. The service agreement remains in this state until it is paid in full.

A service agreement can be automatically stopped depending on the SA Type configuration of the **Stop Option Flag**. Service agreements configured to automatically stop will be stopped when all SP related SAs of the account are stopped. For example, if an account has a cable service and a charitable contribution service agreement then the charitable contribution service agreement can be configured to automatically stop when the cable service agreement is stopped. The stop date of the charitable contribution will be set equal to the stop date of the electric SA.

Closed The system moves a service agreement to the Closed state when it no longer has a financial balance.

Reactivated The system moves a service agreement to the Reactivated state if a financial transaction is created after a service agreement is Closed (e.g., when a payment is canceled after the service agreement is closed). Please be aware that Reactivated service agreements are processed by the [Write Off Monitor](#).

When the service agreement once again has a zero balance (e.g., because the customer pays or the debt is written off), the service agreement returns to the Closed state.

Cancelled You may Cancel a service agreement if it shouldn't exist (because the customer doesn't want service). While cancellation doesn't physically remove a service agreement from the database, most queries and trees suppress information about canceled service agreements. This means cancellation is a nice way to logically delete undesired service agreements.

You'll notice in the above diagram that you can cancel an Active, Pending Stop or Stopped service agreement. You may only do this if the service agreement's financial transactions and non-billed billable charges are all cancelled.

You should rarely have to change a service agreement's status. Why? Because the system changes the status behind-the-scenes when various events take place. For example,

- When you request a service start using the Start/Stop page, the system creates a service agreement in the pending start state.
- If you cancel a pending start before service is activated, the system automatically changes the state of the service agreement to cancelled.
- When everything necessary to start service exists, the system automatically changes the state of the service agreement to active.
- When you request a service stop using the Start/Stop page, the system changes the state of the stopped service agreement to pending stop state.
- When everything necessary to stop service exists, the system automatically changes the state of the service agreement to stopped.
- When a final payment is received and the stopped service agreement's balance becomes zero, the system automatically changes the state of the service agreement to closed. The system can also close a service agreement as part of the write-off processing.
- If the payment bounces, the system automatically changes the state of the service agreement to reactivated. And the system will change it back to closed when the account's balance returns to zero.
- If a billable charge is interfaced into the system, the system automatically changes the state of the service agreement to reactivated.

You may need to manually change a service agreement's state for the following reasons:

- If a service agreement was activated inadvertently, you may cancel it (and therefore logically remove it from the system) after canceling all of its financial transactions. You do this by clicking the cancel button on the service agreement page. You may also cancel an incorrect service agreement if the status transitions to pending stop or stopped before you have a chance to correct the mistake.
- If you don't want to wait for the system to automatically activate a pending start service agreement, you may push the activate button on the service agreement page. You might do this in order to create a bill for an impatient customer.
- If you don't want to wait for the system to automatically finalize a pending stop service agreement, you may push the stop button on the service agreement page. You might do this in order to create a real time final bill for a customer.
- If you don't want to wait for the system to automatically close a stopped service agreement, you may push the close button on the service agreement page.
- Sometimes a service agreement is closed or stopped by mistake. You can activate a stopped, closed, or reactivated service agreement using the **Reinstate SA** button on the service agreement page. Using the **Reinstate SA** button retains the current service's billing history.

Note:

One time invoices (i.e., one-time billable charges) are interesting. One-time invoice service agreements follow the above lifecycle; it's just that they do it quickly. You see, when a one-time invoice service agreement is created, both its start and stop dates are known (they are the invoice date). If you followed the above state transition discussion, you'll understand that the system progresses these invoices from pending start to stopped when the service agreement is activated.

Renewing Service Agreements

Some service agreement types (e.g., non-billed budgets) may allow or require renewal. If renewal is optional, a renewal date may be specified when the service agreement is created. If renewal is required, you must specify a renewal date.

The *SA renewal background process* initiates the renewal for all active service agreements when the renewal date is reached (i.e., the renewal date is on or before the process date). When a service agreement is renewed:

- The SA renewal algorithm (specified on the SA type) is executed. The SA renewal algorithm can be used to customize the processing required to renew an SA.
- If the SA renewal algorithm is successful, the renewal and expiration date (if calculated by the renewal algorithm) on the service agreement are updated with the values returned from the renewal algorithm.
- If the renewal process is not successful, a To Do list entry (of type TD-SARN) is created for the account and service agreement.

Expiring Service Agreements

Service agreements may specify an expiration date. Some service agreement types (e.g., Non-Billed Budgets) require an expiration date. The [SA expiration background process](#) initiates the request to stop service for all active SAs when the expiration date is reached (i.e. the expiration date is on or before the process date).

Service Agreement - Main Information

The Main page contains basic service agreement information. Open **Menu** > **Customer Information** > **Service Agreement** > **Search** to maintain this information.

Description of Page

SA (service agreement) **Info** and **SA ID** are displayed on every page. These values only appear after the service agreement exists on the database. The **ID** is a system assigned random number that stays with a service agreement for life. The **SA Info** is a concatenation of important details about the service agreement and its account.

Note:

Formatting may be performed by a plug-in. The contents of **SA Info** may be formatted by a plug-in algorithm on **SA Type**. Refer to the base package's C1-SAT-INFO for an example. If such an algorithm is not plugged-in on the SA Type, the system looks for a corresponding algorithm on the [installation record](#). Refer to the base package's C1-SAI-INFO for an example. If you prefer different formatting logic, your system administrator should configure the system appropriately.

SA Status defines the state of the service agreement. The system typically changes the state of a service agreement behind-the-scenes. If you can't wait for the system, use one of the adjacent buttons:

- Click the **Activate SA** button to activate a Pending Start service agreement.
- Click the **Cancel SA** button to cancel a Pending Start or Active, Pending Stop or Stopped service agreement.
- Click the **Initiate Stop** button to populate the **End Date** and change the state of the service agreement to Pending Stop.
- Click the **Stop SA** button to stop a Pending Stop service agreement.
- Click the **Close SA** button to close a Stopped or Reactivated service agreement.
- Click the **Reinstate SA** button to reinstate a Closed, Reactivated, or Stopped service agreement to an Active service agreement.

Fastpath:

Refer to [The Lifecycle of a Service Agreement](#) for more information about **SA Status**.

If the [quotation](#) module is not **turned off**, a "real" service agreement can be created when a [proposal service agreement](#) is **accepted**. If the service agreement you've displayed was created in such a way, information about the **Proposal SA** will appear beneath **SA Status**.

Enter the **Account ID** that is financially responsible for the service agreement. If you change a service agreement's **Account ID**, you are effectively transferring this service agreement (and its debt) to the new account.

Indicate the **CIS Division** and **SA Type**. These fields are very important as they control numerous aspects of the service agreement's behavior. These fields are gray when the status is not Pending Start.

Note: If the service agreement's account's CIS Division's **Restrict to Account CIS Division** flag is set to *Restricted*, the CIS Division is set to the account's CIS Division and cannot be changed.

**Fastpath:**

For more information about what the SA type controls, refer to [Setting Up SA Types](#).

The **Start Date** defines when the financial relationship begins. The **End Date** defines when the financial relationship terminates. If the end date is blank, the service agreement has not yet been terminated.

Use **Maximum Bill Threshold** if you want the system to generate a bill error when a bill segment is produced in batch that exceeds a given value. These bill errors will appear on the standard billing queries and To Do lists. If, after reviewing the high value bill segment, a user truly intends to send the bill out, they should regenerate the bill. Refer to [How To Correct A Bill Segment That's In Error](#) for more information.

**Note:**

Default note. The value of **Maximum Bill Threshold** defaults from the service agreement's SA type.

If the **SA Type** has a special role of Interval, you must enter the **Cutoff Time** and **Start Day Option** that is used by interval pricing and derivation algorithms to determine the start and end intervals to process. Similarly, if the **SA Type** has a special role of Bill Determinants Required, you must enter the **Cutoff Time** and **Start Day Option** that is used on a bill determinants usage request. Refer to [Start and End Times for Billing](#) for more information about how these fields are used.

- The **Cutoff Time** is entered in "legal time". This value defaults from either the start option or the [installation record](#). Refer to [Bill Period and Seasonal Time Shifts](#) for information describing how this field is used.
- For **Start Day Option**, you may choose Current Day or Previous Day. This value defaults from either the start option or the [installation record](#).

Use **Customer Read** to define if the customer reads their own meter. Valid values are: Yes, No.

Turn on **Allow Estimates** if it's OK for the billing process to estimate this service agreement's consumption if a real meter read is missing at billing time. If the SA type does not allow estimates, this field will be gray.

**Note:**

Consumption estimation. Consumption is only estimated by billing if all of the following points are true:

- a) A real read cannot be found;
- b) The service agreement allows estimation;
- c) The bill cycle schedule allows estimation (if the bill is produced by the billing background process);
- d) The operator allows estimation (if the bill is produced as a result of an ad hoc request);
- e) The rate schedule allows estimation;

If you've set up the system to use [start options](#), you can have the system default many fields by copying the terms from a start option when service is started using either **Start / Stop** or the **Order** transaction. The **Start Option** field contains the last start option whose field values were copied to the service agreement. If you need to change a service agreement's terms by applying a different start option, you can. Refer to [Changing A Start Option](#) for a description of how to do this.

If the service agreement's rate uses premise-based characteristics for taxation and other purposes, **Characteristic Premise ID** defines the premise that supplies these characteristics. This field also defines the premise under which the service agreement's bill segments are classified and is used to identify where the service agreement's service is located on various windows. This field is gray if the service agreement's SA type doesn't require a characteristic premise. For more information about rates and their use of characteristics, refer to [Setting Up Bill Factors](#) .

**Note:**

Selecting a characteristic premise. If the service agreement has service points, only premises associated with these service points may be selected as a **Char Premise**. If the service agreement doesn't have service points, any premise may be selected.

Your conversion process will fill in **Old Account ID** for service agreements that were converted from your legacy CIS system. The [payment upload process](#) uses this field to locate the accounts for payments that reference a legacy account number.

If the service agreement requires a total amount to bill, the amount is displayed. This field is typically only used on loan or cash deposit service agreements. It holds either the loan amount or the desired cash deposit. If you increase this field's value, the customer will be billed for any difference between the new amount and the total amount billed (and paid for) to date. The label that appears for this field is defined on the SA type (on the Billing tab). We recommend that the system be set up so that this label is very specific, for example:

- It should be called **Cash Deposit Amount** if the total amount to bill is for a deposit.
- It should be called **Loan Amount** if the total amount to bill is for a loan.

Number of Payment Periods only appears for loan SA types. It displays the number of periods specified when the loan was first activated. (The number of payment periods may have been subsequently changed on [Loan maintenance](#).)

If the service agreement uses a recurring charge, the current recurring charge amount is displayed. Transfer to the [Service Agreement - Recurring Charge](#) to update this value. This field is not visible if the service agreement's SA type doesn't allow recurring charges. The label that appears for this field is defined on the SA type (on the Billing tab). We recommend that the system be set up so that this label is very specific, for example:

- It should contain **Budget Amount** if the recurring charge is for a budget.
- It should contain **Installment Amount** if the recurring charge is used for a deposit being paid in installments.
- It should contain **Payment Amount** if the recurring charge is used for a loan.

SA Relationship ID contains the ID of the SA Relationship that is associated with a sub service agreement. This field is only visible on sub service agreements. Refer to [Sub Service Agreements](#) for more information.

CIAC Review Date displays the last date that the Contributions In Aid of Construction (CIAC) review process ran for this service agreement. This field is only visible if the SA type indicates this is a CIAC service agreement. Refer to [CIAC Segmentation](#) for more information on CIAC.

Deposit Interest Calculated contains the last date the system applied interest. This field is only visible if the SA type has a special role of Cash Deposit.

The **Scheduled Payment Autopay** flag determines if the Non-Billed Budget scheduled payments are excluded from automatic payment or included by automatic payment. If the account is not set up for automatic payment for the period that covers the Non-Billed Budget, this flag cannot be set. This field is only visible if the SA has a special role of Non-Billed Budget.

The **NBB Recommendation Rule** displays the description of the non-billed budget recommendation rule used for this SA. This field is only visible if the SA has a special role of Non-Billed Budget.

Expiration Date contains the date at which the service agreement is set to expire.

Renewal Date contains the date at which the service agreement is to be renewed. Renewal date is disabled if renewal is not allowed on the SA type.

Debt Class indicates the debt class into which the service agreement's current balance is categorized by credit and collections. A service agreement's debt class is defined on its SA type. Refer to [Different Collection Criteria For Different Customers And Different Debt](#) for more information about debt class.

Current Balance indicates the amount the customer currently owes for the service.

Payoff Balance indicates the amount the customer would owe if they wanted to close the service agreement. This value is only displayed when it differs from current balance.

Fastpath:

Refer to [Current Amount versus Payoff Amount](#) for more information.

The **Days Old** and **Arrears Amount** information shows how old the current balance is. This information will be blank if the current balance is a credit.

**Note:**

Information about debt balances by age is not applicable to [open-item accounts](#).

This bottom of this page contains a [tree](#) that shows the various objects linked to the service agreement. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

The topics that follow describe miscellaneous features on this page.

Changing A Start Option

If the service agreement is in the pending start state, you can use the [Start/Stop - Pending SAs](#) page to change the service agreement's SA type and/or start option.

If the service agreement is in the active or pending stop states and if the SA type uses [start options](#), a button appears on Service Agreement - Main called **Apply New Start Option**. When clicked, the **Apply New Start Option** dialog box opens.

The fields in this dialog box allow you to define a **Start Option** whose terms should be copied to the service agreement as of a given effective date (**Apply Start Option on**). Because most terms on a service agreement are effective-dated, it's important that you understand the following ramifications of applying a start option (note, we use the word "terms" to generically reference any of the fields that can be defaulted from a start option):

- Terms are reused if **Start Option** contains the same value as defined in the service agreement. For example,
 - If the **Start Option** references the same rate as defined in the service agreement, a new rate record will NOT be created.
 - If the **Start Option** references a contract rider that's currently defined in the service agreement, a new rider will NOT be created.
- Terms that support explicit expiration (i.e., those with an end date) are expired if they are not referenced on the new **start option**. For example, if the service agreement has a rider that is not referenced on the new **start option**, it will be expired.

**Note:**

Interval profiles and TOU maps are expired using the Start Day Option and Cutoff Time in the new start option and not the existing values for the SA.

- Terms that support implicit expiration (i.e., those without an end date) are left unchanged if they are not referenced on the new **start option**. For example, a service agreement characteristic that isn't referenced on the new **start option** will NOT be modified when a new start option is applied.

**Note:**

Only start options related to the service agreement's SA type can be used. It should be noted that only start options related to the service agreement's SA type can be specified. If the service agreement is in the pending start state, you can change the service agreement's SA type on the **Main** tab or via [Start/Stop - Pending SAs](#). If the service agreement is active, you may not change its SA type.

When you click **OK** a warning window will appear that summarizes the changes that will be made to the service agreement. After confirming what will be changed, click **OK** to change the service agreement's terms. The **Start Option** that is shown on the **Main** tab will now reflect the start option whose terms were just applied.

The Impact of Proposal Service Agreements

If the [quotation](#) module is not [turned off](#), you may display a [proposal service agreement](#) on Service Agreement - Main. This section describes how Service Agreement - Main differs when a proposal service agreement is displayed.

The **SA Status** section is replaced with a section that shows the status of the proposal service agreement (proposal SA).

Proposal SA Status defines the state of the proposal service agreement. The [Quote Maintenance](#) transaction typically changes the status of a proposal SA when users accept, decline and cancel quote details. If you wish to change the status of a proposal SA independent of this transaction, you can press one of the adjacent buttons

- Click the **Activate** button to change the status from Pending to Quotable. Note, you can set up the system to automatically make newly created proposal SAs quotable by plugging in the appropriate Proposal SA Creation algorithm on the SA's SA type.
- Click the **Accept** button to change the status from Quotable to Accepted. When you accept a proposal SA, you will be asked to supply the **Start Date** of the real service agreement that will be created.
- Click the **Decline** button to change the status from Quotable to Declined. When you decline a proposal SA, you will be asked to supply a **Decline Reason**.
- Click the **Cancel** button to change the status from Quotable to Canceled.
- Click the **Reactivate** button to return a Canceled or Declined proposal SA to the Quotable state.

Fastpath:

Refer to [Proposal SA State Transition](#) for more information about **Proposal SA Status**.

If the proposal SA has been declined, the **Decline Reason** appears beneath **Proposal SA Status**. Refer to [Accepting / Declining Quote Details](#) for more information.

If the proposal SA was changed after a quote detail was generated using the proposal SA's terms, a **Remark** appears beneath **Proposal SA Status** highlighting such.

Note:

Changing A Start Option. You can [Apply A New Start Option](#) on pending and quotable proposal SAs.

If a real service agreement was created when the proposal SA was accepted, **Real SA ID** appears and contains the ID of the real service agreement. Refer to [Accepting / Declining Quote Details](#) for more information.

Service Agreement - Rate Info

The rate info page contains the service agreement's rate and information needed by the rate to calculate the service agreement's bill segments. This information is only displayed if the service agreement's SA type allows a rate.

Open **Menu > Customer Information > Service Agreement > Search** and navigate to the **Rate Info** page.

Description of Page

The **Rate** grid controls the rate used to calculate the service agreement's bill segments. Multiple rows will only exist if the service agreement's **Rate** changes over time.

A service agreement's **Rate** is populated by the system when service is started. The method used to populate the initial **Rate** depends on how service is started and whether you use start options:

- If the service agreement's SA type uses [start options](#):
 - If the [Order](#) transaction is used to start service, the rate is populated using the [start option](#) associated with the package that was selected by the user when the order was completed.
 - If [Start/Stop](#) is used to start service, the rate is populated using the start option selected by the user when service was initiated.
- If the service agreement's SA type does not use [start options](#), the [SA type's default rate](#) is populated on the service agreement.

Billing selects a single rate from the **Rate** grid when it calculates a bill segment for the service agreement. If multiple rates are defined in this grid, the rate is selected based on the service agreement's SA type's [Rate Selection Date](#). The following fields display:

- **Effective Date** is the date the rate becomes effective. The service agreement's start date defaults.
- **Rate Schedule** defines the rate used to calculate the service agreement's bill segments. Note, you can only choose rates defined as permissible on the service agreement's SA type; the permissible rates are shown in the adjacent tree.

**Note:**

Possible override. If your service agreement is linked to a terms of service record, it is possible that the rate used by the system could get [overridden by one referenced on the terms of service](#). If the rate is overridden by the TOS, the tree on this page indicates the rate source.

The **Contract Rider** grid contains the contract riders that are in effect for the service agreement. This information is defaulted when service is started using a start option (using the contract rider information defined on the [start option](#)). You should only have to access this section if you need to fine-tune what the system defaults.

Billing uses this information when it calculates a bill segment for the service agreement if:

- The rate used to calculate the bill segment contains a calculation rule that references a bill factor.
- The referenced bill factor requires a contract rider to levy the associated charge.

If a **Contract Rider** does not exist or is not effective, the charge associated with the calculation rule is not applied to the customer's bill.

To modify a contract rider linked to the service agreement, simply move to a field and change its value. To remove a contract rider, click the - button. To add a new contract rider, click the + button and fill in the information for each field. The following fields display:

- Use **Start Date** to define the date on which the contract rider becomes effective. The service agreement's start date defaults.
- Use **End Date** to define the date on which the contract rider expires. This field need only be specified if the contract rider expires on an explicit date.
- Use **Bill Factor** to define the type of rider. You may only reference **Bill Factors** designated as being applicable for contract riders. Note, the **Bill Factors** linked to the rate that are marked with contract rider applicability are shown in the adjacent tree under the Contract Rider node.

**Fastpath:**

For more information about contract riders, refer to [Defining General Bill Factor Information](#).

The **Contract Values** grid contains the contract values that are in effect for the service agreement. This information is defaulted when service is started using the contract value information defined on the [start option](#) used to start service (if any). You should only have to access this page if you need to fine-tune what the system defaults.

Billing uses this information when it calculates a bill segment for the service agreement if:

- The rate used to calculate the bill segment contains a calculation rule that references a bill factor.
- The referenced bill factor uses a contract value to define the amount charged.

The following fields display:

- Use **Start Date** to define the date on which the contract value becomes effective. The service agreement's start date defaults.
- Use **End Date** to define the date on which the contract value expires. This field need only be specified if the value rider expires on an explicit date.
- Use **Bill Factor** to define the type of value. You may only reference **Bill Factors** designated as allowing values in contract terms. Note, the **Bill Factors** linked to the rate that are marked as allowing values in contract terms are shown in the adjacent tree under the Contract Value node.
- Use **Value** to define contract value.

**Fastpath:**

For more information about contract values, refer to [Defining General Bill Factor Information](#).

The **Tax Exemptions** section contains the taxes from which the service agreement is all or partially exempt.

Billing uses this information when it calculates a bill segment for the service agreement if:

- The rate used to calculate the bill segment contains a calculation rule that references a bill factor.
- The referenced bill factor can have tax exemptions that limit the amount of the charge.

If the bill factor doesn't have a tax exemption or there are none that are effective during the bill period, the tax is levied in full. If the service agreement is exempt, the appropriate charge associated with the tax is calculated. We strongly recommend using the "%T" substitution character in the [Description on Bill](#) on tax-exemptible calculation rules so that an appropriate tax exemption message appears on the customer's bill.

Fastpath:

For more information about tax exemptions, refer to [Defining General Bill Factor Information](#).

The following fields display:

- Use **Start Date** to define the date on which the tax exemption becomes effective.
- Use **End Date** to define the date on which the tax exemption expires.
- Use **Bill Factor** to define the tax from which the service agreement is exempt. You may only reference bill factors designated as being tax exemptible. Note, the **Bill Factors** linked to the rate that are marked as tax exemptible are shown in the adjacent tree under the Tax Exemption node.
- Use **Percent Exempt** to define the customer tax exemption percent (e.g., 90 means the customer is 90% exempt and will only pay 10% of the normal tax rate).
- Use **Tax Exempt Type** to specify the type of exemption.
- Use **Tax Certification** if the customer has a tax exemption certificate.

Rate Information Tree

The [tree](#) shows the service agreement's permissible rates and the related types of contract riders, contract values and tax exemptions that are possible given these rates.

- The Permissible Rates node displays all the rate schedules associated with the service agreement's SA Type.
- The Effective Rate Schedule node indicates the rate schedule currently effective.
- The Contract Rider node displays the bill factors linked to the service agreement's rate(s) that may have contract riders defined for them. If you expand a node, you can see the individual calculation rule(s) on which the bill factor is specified. If the service agreement has a value defined for the contract rider that is currently in effect, it is also shown.
- The Contract Value node displays all the bill factors linked to the service agreement's rate(s) that may have contract values defined for them. If you expand a node, you can see the individual calculation rule(s) on which the bill factor is specified. If the service agreement has a contract value defined that is currently in effect, it is also shown.
- The Tax Exemption node displays all the bill factors linked to the service agreement's rate(s) that may have tax exemptions defined for them. If you expand a node, you can see the individual calculation rule(s) on which the bill factor is specified. If the service agreement has a tax exemption defined for the bill factor that is currently in effect, it is also shown.

If the service agreement is currently linked to a terms of service record for an effective umbrella agreement, additional information is displayed in the tree.

- The Permissible Rates node displays the rate source value associated with the service agreement's SA Type.
- If the terms of service record linked to the service agreement has a template SA and the rate source is Check TOS First, then SA , the Effective Rate Schedule node displays the rate schedule for the template SA. An additional node indicating whether the rate source is the template SA or the current SA is displayed below.
- The Contract Rider, Contract Value and Tax Exemption nodes include the terms of service usage value from the bill factor.

Fastpath:

Refer to [Rate Terms Overridden By Terms Of Service](#) for more information.

Service Agreement - SA / SP

The SA / SP page contains the service points that are linked to the service agreement. This information is only displayed if the service agreement's SA type allows service points.

This information is updated by the system when service is started. You should only have to access this page if you need to fine-tune what the system defaults.

Warning:

You must understand the "V" very well before attempting to maintain this information. Refer to [Understanding The "V" for more information](#).

Use **Menu > Customer Information > Service Agreement > Search** and navigate to the SA/SP page

Description of Page

Billing uses SA / SP information to amalgamate consumption when it calculates a bill segment for the service agreement. The following fields are displayed:

Service Point ID The identity of the service point. The type and location of the service point is displayed adjacent. This field is gray after the service point is committed to the database.

Meter/Item Info The meter / item that is currently installed at the service point is displayed. Refer to [Installing and Removing A Meter](#) and [Installing and Removing An Item](#) for more information.

How to Use (SP) Indicates how billing uses the consumption associated with the service point. This field is gray for item-type service points. Valid values are: Add, Check, Subtract. Add service points have their consumption added to the total amount of consumption billed under a service agreement. Subtract service points have their consumption subtracted from the total amount of consumption billed under a service agreement. Check service points are ignored by billing.

Use Percent Indicates the percentage of this service point's consumption that is billed under the service agreement. This field is gray for item-type service points.

Start Date/Time The date and time the service point's consumption starts being billed under the service agreement. This is defaulted from the service agreement's start date.

Note:

For SAs whose type has a special role of Bill Determinants Required, the time component of the start date/time does not necessarily reflect the SA's cutoff time.

Start Meter Read The meter read that records the register values, as they appeared when the service point was linked to the service agreement. The meter reading's date and time are displayed adjacent. This field is disabled for item-type service points.

Note:

Only meter reads that have been marked as "Use on Bill" may be specified.

Stop Date/Time The date and time the service point's consumption stops being billed under the service agreement. This is defaulted from the service agreement's end date.

Note:

For SAs whose type has a special role of Bill Determinants Required, the time component of the stop date/time does not necessarily reflect the SA's cutoff time.

Stop Meter Read The meter read that records the register values as they appeared when the service point was unlinked from the service agreement. The meter reading's date and time are displayed adjacent. This field is disabled for item-type service points.

Note:

Only meter reads that have been marked as "Use on Bill" may be specified.

The **Field Activity** grid contains the list of field activities that have been generated in respect of this SA / SP. Refer to [Field Activities to Start Service](#), [Field Activities to Stop Service](#) and [The Big Picture Of Severance Events](#) for more information.

Field Activity The unique ID of any field activity associated with starting, stopping, investigating, or severing the service at the service point.

Field Activity Type Indicates why the field activity is linked to the SA/SP. Valid values are Start Activity, Stop Activity, Severance Activity, Cut Process, or Service Activity.

The **Characteristics** grid contains characteristics that are only applicable for a given SA / SP combination. These are typically only used for obscure SA/SP relationships for which unusual pricing terms or interval billing options have been set up.

Note:

You can only choose characteristic types defined as permissible on the SA/SP record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

The following fields display:

Effective Date Indicate the date on which the characteristic value becomes effective. The service agreement's start date defaults.

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Service Agreement - Characteristics, Quantities, & Recurring Charges

This page contains the Characteristics, Contract Quantities, and Recurring Charges that are in effect for the service agreement.

Use **Menu > Customer Information > Service Agreement > Search** and navigate to the **Chars, Qty & Rec. Charges** page.

Description of Page

The **Characteristics** grid contains information that describes miscellaneous information about the service agreement. This information is defaulted when service is started using the characteristics defined on the [start option](#) used to start service (if any). You should only have to access this section if you need to fine-tune what the system defaults.

Note:

You can only choose characteristic types defined as permissible on the service agreement record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

The following fields display:

Effective Date Indicate the date on which the characteristic value becomes effective. The service agreement's start date defaults.

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

The **Contract Quantity** grid contains the contract quantities that are in effect for the service agreement. This information is defaulted when service is started using the contract quantities defined on the [start option](#) used to start service (if any). You should only have to access this section if you need to fine-tune what the system defaults.

Billing may use this information when it calculates a bill segment for the service agreement if the rate has pre-processing calculation groups. Refer to [All Calculation Rule-Based Rates Share a Common Structure](#) for more information about pre-processing calculation groups.

The following fields display:

Effective Date The date this quantity becomes effective. The service agreement's start date defaults.

Contract Quantity Type The type of contract quantity.

Contract Quantity The contract quantity.

The **Recurring Charge** section contains effective-dated information that defines the recurring charge amount used to calculate the service agreement's bill segments. This information is only displayed if the service agreement's SA type allows a recurring charge amount.

A service agreement's recurring charge amount history is updated by the system behind-the-scenes as part of the Start Service process. The budget recalculation process can also update this information. You should only have to access this section if you need to change a service agreement's recurring charge amount on some future date.

Billing uses recurring charge information to select the appropriate recurring charge when it calculates a bill segment for the service agreement. To modify a recurring charge, simply move to a field and change its value. To change the recurring charge amount effective on a given date, click the + button to insert a row, then fill in the information for each field. The following fields display:

Effective Date The date the charge becomes effective. The service agreement's start date defaults.

Note:

Recurring charge changes during a bill period. Only one recurring charge will be used on any bill segment. The system selects the recurring charge value effective on the end date of the bill segment.

Recurring Charge Amount The recurring charge amount.

Service Agreement - Miscellaneous

The miscellaneous page contains information that describes miscellaneous information about the service agreement. Use **Menu > Customer Information > Service Agreement > Search** and navigate to the **Misc** page.

Description of Page

Start Requested By displays the information entered in the Requested By field on the Start Stop page when this SA was started.

Stop Requested By displays the information entered in the Requested By field on the Start Stop page when this SA was stopped.

Select the **SIC** associated with the customer. This is typically only used for commercial and industrial customers.

Enter a **Business Activity** associated with the customer. This can be used to further define what types of activities are served by this contract.

The bill message grid contains information about the message(s) to appear on a service agreement's bill segments. Both one-time and permanent messages may be defined. This information is used when the system assembles messages to appear on an account's bill (as part of bill completion). Refer to [The Source Of Bill Messages](#) for more information. The following fields are displayed:

- For **Bill Message**, select a message code to appear on the customer's bill.
- For **Bill Message Type**, use Temporary to indicate the message should only be linked to the next bill produced for the account. Use Permanent if the message should appear on every bill. Note, a value of Temporary defaults.

The terms and conditions (T&C) grid contains the service agreement's T&C's. This information is defaulted when service is started using a start option (using the T&C information defined on the [start option](#)). You should only need to change this information if you need to fine-tune the defaults. Refer to [Legal Terms and Conditions May Be Specified on Service Agreements](#) for more information. The following fields display:

- Use **Start Date** to define the date on which the T&C becomes effective. The service agreement's start date defaults.
- Use **End Date** to define the date on which the T&C expires. This field need only be specified if the T&C expires on an explicit date.
- Use **Terms and Conditions** to define the type of T&C.

Service Agreement - Contract Options

The contract options page contains the contract options and contract option events for interval billing service agreements. Refer to [Contract Option Background Topics](#) for more information.

Open this page using **Menu > Customer Information > Service Agreement > Search** and then navigate to the **Contract Options** page.

Description of Page

The **Contract Option** collection contains effective-dated information that defines the contract options linked to the service agreement. The following information may be defined for each contract option:

Contract Option Id This is the id of the [contract option](#) to link to the service agreement. The **SA Contract Option ID** is displayed adjacent. This is the unique identifier of the SA / contract option record.

Effective Date/Time This is the date and time that the contract option is in effect for the service agreement.

Expiration Date/Time This is the date and time that the contract option is no longer in effect for the service agreement.

The **Override Events Collection** contains information about the override events for a shared contract option. Refer to [SA May Override a Shared Event](#) for more information.

If a contract option event for a shared contract option should not be applicable to this service agreement, enter the **Contract Option Event ID**, the **Override Date/Time** that the override is effective and the **Status**. The status value of Active means that the override is in effect. The status value of Inactive 'cancels' the override, meaning that the event is applicable to this service agreement.

If seasonal time shift records are linked to both the base time zone and to the time zone on the service agreement's characteristic premise, the **Seasonal Time Shift** associated with the time zone on the characteristic premise is displayed. Refer to [Time Zone and Time Changes](#) for more information.

The **Seasonal Time Shift Remark** indicates whether the data is displayed and should be entered in legal time or standard time. Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time.

Note:

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is [turned off](#). **Contract Option and Dynamic Option.** A Dynamic Option will exist for each Contract Option.

Fastpath: For more information about Dynamic Option, refer to Dynamic Option.

Service Agreement - Interval Info

Note:

The transactions described in this section are only available if the interval billing module is turned on. This Customer Care and Billing functionality has essentially been deprecated and should be performed within a meter data management system. This functional area remains within Customer Care and Billing exclusively for upgrading customers who currently use Interval Billing within an earlier version of this system.

The interval info page contains various collections needed by an interval service agreement. This information may be used by validation and derivation algorithms or may be used by interval and time of use pricing algorithms. Refer to [Interval Billing](#) for more information.

Note:

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is [turned off](#).

Open this page using **Menu > Customer Information > Service Agreement > Search** and then navigate to the **Interval Info** page.

Description of Page

The [tree](#) at the bottom of this page shows information about interval profiles and TOU maps that are referenced in the calculation rules linked to one of the service agreement's rates.

- A node will display for each Interval Profile Relationship Type, which is priced directly, i.e., it is referenced on a calculation rule of type Interval Pricing. When this node is expanded, information about every Interval Pricing calculation rule, which references this relationship type is displayed.
- A node will display for each TOU Map Relationship Type and Interval Profile Relationship Type, which are referenced on a calculation rule of type TOU Pricing. When this node is expanded, information about every TOU Pricing calculation rule which references these relationship type is displayed.
- A node will display for each Interval Profile Relationship Type, which is referenced on a calculation rule of type Calculation Algorithm. When this node is expanded, information about every Calculation Algorithm calculation rule, which references this relationship type is displayed.
- A node will display for each TOU Map Relationship Type, which is referenced on a calculation rule of type Calculation Algorithm. When this node is expanded, information about every Calculation Algorithm calculation rule, which references this relationship type is displayed.

The **Interval Profile** collection contains effective-dated information that defines the interval profiles linked to the service agreement. Refer to [Interval Pricing Background Topics](#) for more information.

To link an interval profile to a service agreement, enter the Interval Profile Relationship Type that defines the role that this interval profile will serve for the service agreement. Choose the Interval Profile Id for the profile that you wish to link to this service agreement. This profile may be Common or SA Owned.

Fastpath:

If the profile does not exist yet, then you must create it. Refer to [How to Link Common Profiles to a Service Agreement](#) and [How to Link SA Owned Profiles to a Service Agreement](#) for more information.

The **Start Date/Time** indicates the date and time that this profile is linked to the service agreement for this profile relationship type.

The **End Date/Time** indicates the date and time that this profile is no longer linked to the service agreement for this profile relationship type.

The **Status** values are Active and Inactive. By default, all records are active. The system will use the start date/time and end date/time to ensure that it processes the correct profile for the SA and Profile Relationship Type for the correct time period. No two profiles may be active for the same SA, Profile Relationship Type and overlapping time period. A user may change the status of a record to Inactive. The system will not change this status.

If data for this profile is derived using a creation algorithm on the interval profile's profile type, then the **Derivation Algorithm** and the **Creation Priority** for the interval profile type are displayed.

Fastpath:

Refer to [Setting Up Interval Profile Types](#) for more information about linking data creation algorithms to an interval profile type.

The **Derive Interval Data** button will be enabled when the service agreement is in a billable status. Use this button to [create profile data through data derivation](#). Clicking this button opens the **Derive Interval Data** dialog box.

In the resulting dialog box, turn on **Force Derivation** and enter a **Force Derivation Start Date** if you wish the system to re-derive data for a period that may have already been derived.

Note:

Not all algorithms will necessarily support [force derivation](#). It depends on whether or not the algorithm can detect changes in the source data.

Enter the **Cutoff Date** to indicate to the system until what date to generate data for.

After clicking **Process**, the system will execute any "Interval Data Creation" derivation algorithm linked to the [profile type](#) of an SA Owned profile where this SA is the owner. The algorithms are executed in creation priority order.

**Note:**

You can design your control tables so that the appropriate common and SA-owned profiles are linked to the service agreement at start time. Refer to [Designing Your Interval Billing Start Options](#) for more information about designing and setting up these start options.

The **TOU Map** collection contains effective-dated information that defines the TOU maps linked to the service agreement. Refer to [Time of Use Mapping Background Topics](#) for more information.

To link a TOU map to a service agreement, enter the **TOU Relationship Type** that defines the role that this TOU map will serve for the service agreement. Choose the **TOU Map ID** for the map that you wish to link to the service agreement. This map may be Common or SA Owned.

The **Start Date/Time** indicates the date and time that this TOU map is linked to the service agreement for this TOU map relationship type.

The **End Date/Time** indicates the date and time that this TOU map is no longer linked to the service agreement for this TOU map relationship type.

The **Status** values are Active and Inactive. By default, all records are active. The system will use the start date/time and end date/time to ensure that it processes the correct map for the SA and Map Relationship Type for the correct time period. No two maps may be active for the same SA, Map Relationship Type and overlapping time period. A user may change the status of a record to Inactive. The system will not change this status.

If data for this map may be created using a creation algorithm on the TOU map's map type, then the **Derivation Algorithm** and the **Creation Priority** for the [TOU map type](#) are displayed.

The **Derive TOU Data** button will be enabled when the service agreement is in a billable status. Use this button to [automatically create TOU map data](#). Clicking this button opens the **Derive Interval Data** dialog box.

In the resulting dialog box, turn on **Force Derivation** and enter a **Force Derivation Start Date** if you wish the system to re-derive data for a period that may have already been derived.

**Note:**

Not all algorithms will necessarily support [force derivation](#). It depends on whether or not the algorithm can detect changes in the source data.

Enter the **Cutoff Date** to indicate to the system until what date to generate data for.

After clicking **Process**, the system will execute any "TOU Data Creation" algorithm linked to the [TOU map type](#) of an SA Owned profile where this SA is the owner. The algorithms are executed in creation priority order.

**Note:**

You can design your control tables so that the appropriate common and SA owned TOU maps are linked to the service agreement at start time. Refer to [Designing Your Interval Billing Start Options](#) for more information about designing and setting up these start options.

If seasonal time shift records are linked to both the base time zone and to the time zone on the service agreement's characteristic premise, the **Seasonal Time Shift** associated with the time zone on the characteristic premise is displayed. Refer to [Time Zone and Time Changes](#) for more information.

The **Seasonal Time Shift Remark** indicates whether the data is displayed and should be entered in legal time or standard time. Refer to [Interval Time Display](#) for more information. If the data is displayed in legal time use the **Show in Standard** button to toggle to standard time. If the data is displayed in standard time use the **Show in Legal** button to toggle to legal time.

Service Agreement - TOU Contract Values

This page enables you to define customer specific time of use values. Refer to [Customer Specific TOU Values](#) for more information.

Open this page using **Menu > Customer Information > Service Agreement**, then navigate to the **TOU Contract Values** page.

Description of Page

The service agreement may contain a collection of TOU contract values, which change over time.

Choose the **Bill Factor** that defines the type of value. You may only reference bill factors designated as "TOU" bill factor types and where the value may be in contract terms.

Indicate the **TOU Group** that corresponds with the TOU group on the service agreement's TOU Map. Once entered, the collection of TOU codes linked to this TOU group will display.

For a given TOU contract value entry, the **Start Date** and **End Date** indicate when these TOU values are effective.

For each **Time of Use** code, enter the appropriate **Value**.

TOU Contract Values Tree

The [tree](#) shows bill factors linked to the service agreement's rate that may have TOU contract values defined for them.

Service Agreement - Billing Scenario

Note:

This tab may not appear. This tab is suppressed if the quotation Contract Management module is [turned off](#).

This page allows you to define a [proposal service agreement's](#) billing scenario. Refer to [Proposal SAs Contain Billing Scenarios](#) for more information.

Open this page using **Menu > Customer Information > Service Agreement > Search**, then navigate to the **Billing Scenario** page.

Description of Page

This page is protected if the service agreement being displayed is not a [proposal service agreement](#).

When a quote is generated for a proposal SA, the system creates a simulated bill segment for each billing scenario linked to the proposal SA. Each simulated bill segment shows the prospect how much their bill would be if the pricing terms on the proposal SA were applied to the billing scenario's consumption in the related time period.

Note:

You should not have to enter this information from scratch. You can set up the system to automatically generate billing scenarios when a proposal SA is created. Refer to [Proposal SAs Contain Billing Scenarios](#) for the details.

The following information is defined for each billing scenario:

- **Start Date** and **End Date** define the simulated bill segment's period.
- The grid contains the consumption that will be priced during this period:
 - **Unit of Measure** is the unit of measure of the service quantity.
 - **TOU** is the time-of-use code of the service quantity.
 - **SQI** is the service quantity identifier of the service quantity.
 - **Initial Service Quantity** is the initial quantity passed to the rate (and massaged by the rate's pre-processing calculation group(s), if any exist).
 - **Service Point ID** is used if your rate uses pre-processing calculation groups that require characteristic values from the service point or premise. For example, the calculation rule that converts CCF to therms uses a bill factor to store the conversion factor. This bill factor may have been configured to use characteristics on the service point / premise (e.g., the conversion factor may differ based on the storage location associated with the service point).

Note:

Interval service agreements and template consumption. Refer to [Proposal SAs And Interval Consumption](#) for a description of how interval consumption is defined on a proposal SA.

Service Agreement - SA Portal

Select **Menu > Customer Information > Service Agreement > Search** and navigate to the **SA Portal** page to view additional information associated with an SA.

Depending on your implementation's requirements, you may define additional zones to appear on this Portal.

The contents of this section describe the zones that are available on this portal page.

General Information displays **SA ID** and **SA Info**.

Consumer Contract Products displays the service agreement's consumer contract products. **Add, Edit** and **Delete** actions are provided.

Maintaining SA Relationships

The SA Relationship page contains information about a specific relationship between a service provider and a customer.

Warning:

The following page looks deceptively simple. It's not. Refer to [The Big Picture of SA Relationships and Service Providers for more information](#).

Open **Customer Information, SA Relationship** to maintain this information.

Description of Page

The **SA Relationship Info** is a concatenation of important information about the SA relationship record. The **SA Rel ID** is a system-assigned random number that stays with a SA relationship record for life. This value is assigned when the record is added to the database.

SA Relationship Status defines the state of the SA relationship. The buttons are used to change the state:

- Click the **Activate SA Rel** button to activate a **Pending** SA relationship. This button is only enabled when the status of the SA relationship is **Pending**.
- Click the **Cancel SA Rel** button to cancel an **Active** or **Pending** SA relationship. This button is only enabled when the status of the SA relationship is **Active** or **Pending**.

Note:

Automatic SA Relationship creation and activation. The system automatically creates and activates required SA Relationships when the Activate SA background process sees that there are required SA relationships for the master SA Type.

Account ID is the account associated with the **Service Agreement ID**. This field is protected after the SA relationship has been added to the database.

Use **Service Agreement** to define the "master" service agreement ID that has a relationship. This field is protected after the SA relationship has been added to the database.

Premise is a display-only field that shows the **Service Agreement's** characteristic premise (i.e., the primary premise associated with the service agreement).

Use **SA Relationship Type** to define the type of relationship. This field is only enabled if:

- A **Service Agreement ID** is specified, and
- The status of the SA Relationship is not **Canceled**, and
- All sub SAs in the grid at the bottom of the page (if any) are **Canceled**.

Enter the **Effective Date** of the relationship. This field is only enabled if:

- A **SA Relationship Type** is specified, and

- The status of the SA Relationship is not **Canceled**.

Usage defines how this relationship is used. The following options are available:

- **Relationship With SP**. Use this option if this relationship is used to define a relationship between a customer and a service provider.
- **Expire SA Relationship**. Use this option if this relationship expires any prior relationship between a customer and a service provider and there is no relationship with a service provider going forward.

If the **SA Relationship Type**'s Service Provider Model is **Market Service Provider**, the following fields are enabled:

- **Market** identifies the market in which the service provider participates. Selecting a value will enable **Provider Configuration Option**.
- **Provider Configuration Option** specifies a service provider's billing/payment relationship within the specific market. Selecting a value will enable the **Market Relationship Service Provider**.
- **Market Relationship Service Provider** specifies the 'It's Us' service provider, meaning the utility company who is implementing this system. This is either a distributor or a retailer, depending on the utility's role in the market. The selection list consists of service providers with the selected billing/payment relationship for the selected market.

Note: Refer to [Setting Up Market SA Relationship Options](#) for more details on Service Provider Market Options.

The **Service Provider** associated with this relationship is the one who provides the related service, if any. You can only choose service providers who are linked to the "master" service agreement's SA type and the above **SA Relationship Type**. In addition, if the **SA Relationship Type**'s Service Provider Model is **Market Service Provider**, the service provider must also be valid for the selected **Market**, **Provider Configuration Option** and **Market Relationship Service Provider**. The **Service Provider** field is only enabled if:

- **Usage** is **Relationship with SP**, and
- A **SA Relationship Type** is specified, and
- The **SA Relationship Type**'s Service Provider Model is **Market Service Provider** and **Market**, **Provider Configuration** and **Market Relationship Service Provider** are specified, and
- The status of the SA Relationship is not **Canceled**, and
- All sub SAs in the grid at the bottom of the page (if any) are **Canceled**.

If the **Service Provider** reads the customer's meter (as defined on the service provider's record), the customer's override **Read Cycle** should be defined. This field is only enabled if:

- A **Service Provider** is specified, and
- The **Service Provider** has the ability to override the service point's *service cycle*, and
- The status of the SA Relationship is not **Canceled**

The **Account Number in Provider's CIS** is the customer's ID in the service provider's system. This field is only enabled if:

- A **SA Relationship Type** is specified, and
- The status of the SA Relationship is not **Canceled**.

The **Create Sub SA** button is used to create [Sub Service Agreements](#) for a service provider for which your organization provides billing services. This button will be gray if:

- You do not provide billing services for the service provider (i.e., the service provider doesn't have a billing relationship of **It's Us** or **We Bill For Them**), or
- If the SA relationship's **Status** is not **Active**, or
- If the status of the master **Service Agreement** is not **Active**, **Pending Start**, or **Pending Stop**.

The grid at the bottom contains the sub service agreements (if any) that exist when your organization provides billing service for the **Service Provider**. You can click the Go To button on a row to transfer to the sub service agreement. Refer to [Sub Service Agreements](#) for more information. Note: you can click the **Create Sub SA** button to create sub service agreements for a service provider.

**Note:**

Automatic sub SA creation. The system will automatically create sub service agreements for you. It does this when the Analyze SA Relationships background process (known by the batch control ANLYZSAR) sees that a new SA relationship has been activated.

Service Provider SA Relationship

Use this page to manage a service provider's SA relationships and customers. You can view a given service provider's SA relationships of a given type that is in effect on a specified date. You can expire existing relationships or add new relationships. This page is particularly useful for managing [negotiated terms](#).

Open **Menu > Customer Information > Service Provider SA Relationship** to view this information.

Description of Page

Select the **SA Relationship Type**.

If the **SA Relationship Type's** Service Provider Model is **Market Service Provider**, the following additional inputs are required:

- **Market** identifies the market in which the service provider participates. Selecting a value will enable **Provider Configuration Option**.
- **Provider Configuration Option** specifies the service provider's billing/payment relationship within the specific market. Selecting a value will enable the **Market Relationship Service Provider**.
- **Market Relationship Service Provider** specifies the 'It's Us' service provider, meaning the utility company who is implementing this system. This is either a distributor or a retailer, depending on the utility's role in the market. The selection list consists of service providers with the selected billing/payment relationship for the selected market.

Note: Refer to [Setting Up Market SA Relationship Options](#) for more details on Service Provider Market Options.

Select the **Service Provider**. If the SA Relationship Type's Service Provider Model is **Market Service Provider**, the service providers to choose from are those that are valid for the selected **Market, Provider Configuration Option, SA Relationship Type** and **Market Relationship Service Provider**.

Enter an **Effective Date**. This date filters the results so that only those SA relationships that are in effect on this date are shown.

Use **SA Filter** to restrict the SA relationships that are shown in the grid based on criteria of the related master service agreement. The following options are available:

- **Address.** Use this option to restrict SA relationships to those whose service agreements are linked to service points associated with a given **Address, City** and/or **Postal** code. Note, you can specify any combination of these fields.
- **All.** Use this option if you do not wish to restrict SA relationships based on service agreement attributes.
- **Geographic Type.** Use this option to restrict SA relationships to those whose service agreements are linked to premises or service points associated with a given **Geo Type** and **Value**.
- **SA Type.** Use this option to restrict SA relationships to those whose service agreements are linked to a given **CIS Division** and **SA Type**.

Don't forget to click the search button after changing the filters.

The **Select All / Clear All** buttons are used to select / unselect the SA relationships in the results grid. These buttons are enabled if there is at least one SA relationship in the results grid.

The grid that follows contains a line for each SA relationship that has a status of pending or active that meets the search criteria. Canceled SA relationships are not shown. If an SA relationship has more than one sub-SA, additional lines are used to show the additional sub-SA information. The following information appears in the grid:

- **Select box.** Use this checkbox to select SA relationships that you want to expire using the **Expire SA Relationship(s)** button.

- Click the go to button to transfer to the [Account - Main page](#) where you can perform maintenance functions on the account listed under Account Information.
- The **Account ID** column shows the account of the master SA linked to the SA relationship.
- The **Account Information** column shows information about the account identified by the account ID.
- Click the go to button to transfer to the [Premise - Main page](#) where you can perform maintenance functions on the premise listed under Premise Information.
- The **Premise Information** column shows information about the premise of the service point linked to the master SA of the SA relationship. If the master SA is linked to multiple service points, one is selected at random.
- The **Premise ID** column shows the ID of the premise whose premise information is shown.
- Click the go to button to transfer to the [Service Agreement - Main page](#) where you can perform maintenance on the service agreement listed under SA Information.
- The **SA Information** column shows information about the master SA that the SA relationship is linked to.
- The **SA ID** column shows the ID of the master SA that the SA relationship is linked to.
- Click the go to button to transfer to the [Service Agreement - Main page](#) where you can perform maintenance on the service agreement listed under Sub SA Information.
- The **Sub SA Information** column shows information about the sub SA linked to the SA relationship.
- The **Sub SA ID** column shows the ID of the sub SA linked to the SA relationship.
- Click the go to button to transfer to the [SA relationship page](#) where you can perform maintenance functions on the SA relationship listed under SA Relationship Information.
- The **SA Relationship Information** column shows information about the SA relationship meeting the search criteria.
- The **SA Relationship ID** column shows the ID of the SA relationship meeting the search criteria.

Following the grid is a section with action buttons that allow you to add or expire relationships for the given service provider:

- Press the **Expire SA Relationship(s)** button to expire the SA relationships that you have selected with the checkbox. You will be asked to confirm the date that you want the selected SA relationships to expire. Each selected SA relationship is expired by creating a new SA relationship without a service provider, i.e., its **Usage** is **Expire SA Relationship**. This new SA relationship will be effective the day after the expiration date you specify. This is because an SA relationship that expires on a given day is deemed to be effective until the end of that day.
- Note that you can only expire SA relationships where the SA type and SA relationship type allow gaps in the relationship.
- Press the **Add SA Relationship** button to add a new SA relationship for the service provider and SA relationship type entered above. Enter the effective date for the new SA relationship and the service agreement that the new SA relationship is for. After confirmation, a new SA relationship is added in a pending status. Note that if there is an existing SA relationship with the same effective date whose **Usage** is **Expire SA Relationship**, this relationship is replaced by a new SA relationship with the given service provider.

Maintaining Premises

The premise record contains geographic information about your service addresses.

The following methods list the various ways in which premises can be created:

- A premise can be added via the [premise replicator](#).
- A premise can be added when an [order](#) is completed.
- A premise can be added using this transaction.

The topics in this section describe the premise maintenance transaction.

Fastpath:

For more information about premises and their place in the "V", refer to [Understanding The "V"](#). For more information about the relationships between premises, service points, meters and items, refer to [An Illustration Of A Premise](#).

Premise - Main Information

The Premise page contains basic premise information. Open **Menu > Customer Information > Premise > Search** to maintain this information.

Description of Page

Basic information about the **Premise** and the premise's unique identifier (i.e., the **Premise ID**) are displayed on every page. These values only appear after the premise exists on the database. The ID is a system assigned random number that stays with a premise for life.

Note:

Formatting is performed by a plug-in. The basic information about a premise that appears at the top of this page (and on many other pages in the system) is controlled by a plug-in algorithm on the [installation record](#). Refer to the base package's premise format algorithm (PREM-INFO) for an example. If you prefer a different format, your system administrator should configure the system appropriately.

Indicate the **Premise Type** to categorize the type of premise.

The address's constituent fields vary based on the **Country**. Please refer to the [Country](#) page for more information.

Note:

Default note. A premise's **state, city, county, division, characteristics, trend area** and **geographic data** default from your postal default information. Refer to [Setting Up Premise & Service Point Postal Defaults](#) for more information. If you change the premise's postal code, the system will default geographic values based on the new postal code.

Use **CIS Division** to define the jurisdiction in which the premise is located if the premise type allows CIS Division. This defaults based on the **Country** and the **Postal**, but can be overridden here. If your implementation has set the Installation Option Control By CIS Division flag, the values are restricted to the user's CIS Division(s). See Users and CIS Division for more information. The value is defaulted to user's primary CIS Division, but that can be overridden by the postal defaults

The Validate button on the premise page will only be available if you have set the Allow Address Validation option type to Y on the General System Configuration feature configuration. Once clicked, the Address Validation Script on the General System Configuration feature configuration will be invoked to validate the entered address. Refer to [Implementing Address Validation](#) for more information.

Indicate whether the address is a valid **Mailing Address**. Premises that are valid mailing addresses may be specified as the mailing premise on an account. Refer to [Account - Person Information](#) for more information.

Use **Landlord Agreement** to define the landlord agreement that covers the premise, if any.

Note:

Landlord reversion. When you specify a landlord agreement on a premise, you are telling the system that service associated with the premise's service points should be reverted to the landlord's account when a tenant stops service. The system uses this information during the stop service process to automatically create pending start service agreement(s) for the landlord.

Managing a large number of premises for the same landlord If the [premise management](#) module is not **turned off**, the [premise management](#) page helps you to [manage the premises linked to the landlord](#).

If the [premise management](#) module is not **turned off**, you may reference a **Parent Premise** to include this premise in a [premise hierarchy](#).

At the bottom of this page is a [tree](#) that shows the various objects linked to the premise. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Premise - Characteristics

The Characteristics page contains information that controls taxation and other rate options that differ based on geography. Use **Menu > Customer Information > Premise > Search** and navigate to the **Characteristics** page.

Description of Page

Many charges that appear on bills associated with consumption at this premise are controlled by the premise's characteristic values (e.g., the taxing city defines the city tax percent applied to the premise's consumption). Refer to [An Illustration Of A Bill Factor And Its Characteristics](#) for more information.

Characteristics also matter if your rates were set up to convert measured consumption into some other unit of measure before charges can be calculated (e.g., converting a cubic foot of gas to its therm value). Refer to [All Calculation Rule-Based Rates Share a Common Structure](#) for more information about pre-processing calculation groups.

Note:

You can only choose characteristic types defined as permissible on the premise record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

The following fields display:

Effective Date Indicate the effective date of the characteristic type and value. The effective date defaults from the [Installation Record](#) when you are adding a new premise. The effective date defaults to the current date when you are changing an existing premise.

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Note:

Default note. A premise's characteristics default from your postal default information. Refer to [Setting Up Premise & Service Point Postal Defaults](#) for more information. If you change the premise's postal code, the system will default characteristic values based on the new postal code.

Premise - Miscellaneous

The Miscellaneous page contains information meter read controls and life support information related to the premise. Use **Menu > Customer Information > Premise > Search** and navigate to the **Misc** page.

Description of Page

Turn on **OK to Enter** if the meter is located in the interior of the premise and your company has permission to enter.

Indicate a **MR Warning** if a specific warning should be downloaded to the person who reads the meter.

Indicate a **MR Instruction** if specific instructions should be downloaded to the person who reads the meter. Meter read instructions and warnings are downloaded as part of the meter read download.

Use **Instruction Details** to provide more detailed instructions to the individual who reads meters at this premise.

Turn on **Key at Premise** if the meter is secured in a locked area and your company has the key. If this field is turned on, you may also specify the **Key ID**.

Specify the **Trend Area** in which the premise is located.

Note:

Default note. A premise's trend area defaults from your postal default information. Refer to [Setting Up Premise & Service Point Postal Defaults](#) for more information.

Indicate if the premise has life support or sensitive load equipment. Valid values are: LS/SL (i.e., the premise has life support / sensitive load equipment), None. If a value of LS/SL has been selected, define the type of equipment in **Life Support / Sensitive Load Notes**.

Note:

A person can also have life support / sensitive load information. If the equipment is personal (i.e., it travels with the person as they move from premise to premise), you should NOT specify the life support information on the premise. Rather, transfer to [Person - Main](#) and specify life support information on the person.

Alert and C&C. If the base package's C1-LSSL-PREM algorithm is enabled on the installation record, and life support / sensitive load information is specified, an alert will appear when the premise is displayed on control central. In addition, if a premise has life support or sensitive load equipment, it is possible for a different credit & collection severance process to be kicked off if the account associated with the premise has overdue debt. Refer to [Designing Your Severance Procedures](#) for more information.

Premise - Geographic Data

The Geographic Data page contains information that defines where the premise is located. Use **Menu > Customer Information > Premise > Search** and navigate to the **Geographic Data** page.

Description of Page

Enter the **Time Zone** in which the premise is located. This value defaults from your [postal defaults](#). Please note that **Time Zone** is only relevant for interval billing customers. Refer to [Time Zone and Time Changes](#) for more information.

The geographic information is used by [Control Central](#) to look for premises. The following fields display:

Geographic Type Indicate the type of geographic data.

Geographic Value Specify the coordinate value. If the entered value must be in a specific format, a description of the required format is displayed adjacent. For example, if you see the format 99A 99A 99 9, you must enter 2 numbers, followed by a letter, followed by a space, followed by 2 numbers, followed by a letter, followed by a space, followed by 2 numbers, followed by a space, followed by a single number.

Note:

Formatting is performed by a plug-in. The format that is applied to a **Geographic Value** is controlled by the algorithm that is plugged in on the respective [Geographic Type](#). If you prefer a different format, your system administrator should configure this algorithm appropriately. Note, algorithms of this type will NOT convert the input value into the relevant format (i.e., you must enter the information in the exact format dictated by the algorithm).

Default note. A premise's geographic data defaults from your postal default information. Refer to [Setting Up Premise & Service Point Postal Defaults](#) for more information. If you change the premise's postal code, the system will default geographic values based on the new postal code.

Premise - Alternate Address

Warning:

This tab only appears if you have enabled alternate addresses on the installation record. Refer to the description of the Alternate Representation field under [Installation - Main](#) for more information.

This page is used when you have an alternate way to define a premise's address. This is typically used in countries that use multiple character sets (e.g., the **Main** address is entered in Chinese, the **Alternate Address** is entered in English). When a premise has an alternate address, both the main and alternate addresses can be used to search for a premise.

Open **Menu > Customer Information > Premise > Search** and navigate to the **Alternate Address** page to maintain this information.

Description of Page

The remaining fields on the page are used to define the premise's alternate address.

The address's constituent fields vary based on the **Country**. **Country** is always protected on this page because a premise's alternate address must be located in the same country as its main address. Please refer to the [Country](#) page for more information about address constituents.

Note:

Default note. An alternate address's **state**, **city** and **county** default from your postal default information. Refer to [Setting Up Premise & Service Point Postal Defaults](#) for more information.

The **Swap Main / Alt Address** button becomes enabled when you've entered an **Alternate Address**. When clicked, the contents of the address on the **Main** tab are swapped with the **Alternate Address**.

Premise - Premise Portal

Select **Menu > Customer Information > Premise** and navigate to the **Premise Portal** page to view additional information associated with a Premise.

Depending on your implementations requirements, you may define additional zones to appear on this Portal.

The contents of this section describe the zones that are available on this portal page.

General Information

Premise ID, **Premise Info** are displayed.

Maintaining Service Points

Service point records contain information describing the services supplied to a premise.

The following methods list the various ways in which service points can be created:

- A service point can be added when a premise is created using the [premise replicator](#).
- A service point can be added when an [order](#) is completed.
- A service point can be added using this transaction.

Fastpath:

For more information about service points and their place in the "V", refer to [Understanding The "V"](#). For more information about the relationships between premises, service points, meters and items, refer to [An Illustration Of A Premise](#).

Service Point - Main Information

This page contains basic service point information. Use **Menu > Customer Information > Service Point > Search** to open this page.

Description of Page

Service Point information and **SP ID** are displayed on every page. These values only appear after the service point exists on the database. The **ID** is a system assigned random number that stays with a service point for life. The **Service Point** information is a concatenation of important details about the service point and its premise.

Enter the **Premise ID** of the premise at which the service point is located.

Indicate the **SP Type**. A service point's SP type controls the following:

- It defines the type of service delivered at the SP.
- It defines the service point as metered or item-based.
- It plays a part in how consumption at the service point is estimated for high / low and missing read purposes.
- It defines characteristics that are the same for all of its service points.
- It defines the type of field activities that may be performed at its service points.
- It defines the type of meters that may be installed at its service points.
- It defines the type of service agreements that may pay for service at its service points.

- It defines the types of equipment that may be linked to its service points.

Fastpath:

Refer to [Setting Up Service Point Types](#) for more information about SP types.

Use the **Service Point Status** to indicate if the service point is In Service or Abolished. SP status controls whether the service point can be linked to new service agreements.

Note:

The values for the SP status field are customizable using the Lookup table. This field name is SP_STATUS_FLG.

If the **Service Point Status** is In Service, the **Abolished Date** is gray; otherwise, it contains the date the service point was abolished.

Specify the **Install Date**. This is the date of the installation of the service point at the premise. It is not the date of installation of any meters or other physical device(s) at the service point.

The following service point information will not be displayed for all SP Types. If the SP Type allows external service requests, portions of this information will be hidden for adding service points. All of these fields will be hidden for maintaining an existing service point that allows external service requests:

- Use the **Service Point Source Status** to define whether the service point is connected to the source of power. Valid values are: Connected and Disconnected. If the source status is disconnected, use **Disconnect Location** to specify where service was severed. Source status impacts the type of field activity created for the service point under various circumstances. For example, if a customer wants to start service at a service point that is disconnected, a field activity that reconnects the service point would be generated. Refer to [Setting Up Field Activity Type Profiles](#) for more information about automated field activity generation.
- Use **Location** to define where the service point is located on the premise. If needed, **Location Details** may be used to clarify the location at the premise.
- If the **SP Type** uses a service route, specify the **Service Cycle**, **Service Route**, and **Service Cycle / Route Sequence** to define the logical position of the service point in the meter reader's route.
- At the bottom of this page is a [tree](#) that shows the various objects linked to a service point. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Service Point - Facilities

This page contains miscellaneous information about a service point. Use **Menu > Customer Information > Service Point > Search** and navigate to the **Facilities** page.

Description of Page

Designate the facility hierarchy that supplies service to the service point using the **Facility Levels**. The prompts that appear in front of the facility levels differ depending on the type of service (the type of service is defined on the service point's SP type).

Use the **Description** to specify anything special about the service point.

Service Point - Characteristics

The characteristics page contains information that describes miscellaneous information about the service point. Use **Menu > Customer Information > Service Point > Search** and navigate to the **Characteristics** page.

Description of Page

Service point characteristics are purely informational. The following fields are displayed:

Effective Date Indicate the effective date of the characteristic type and value. The service point's install date defaults.

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Note:

Default note. A service point's characteristics default from your postal default information. Refer to [Setting Up Premise & Service Point Postal Defaults](#) for more information.

Service Point - SP Type Info

The SP type info page is an information only page that shows the characteristics the service point inherits from its SP type. Use **Menu > Customer Information > Service Point** and navigate to the **SP Type Info** page.

Description of Page

This page shows the characteristics the service point inherits from its SP type. No fields on this page may be modified.

Service Point - Geographic Information

The Geo page contains geographic information that defines where the service point is located. Use **Menu > Customer Information > Service Point > Search** and navigate to the **Geo** page.

Description of Page

The following fields are displayed:

Geographic Type Indicate the type of geographic data.

Geographic Value Specify the coordinate value. If the entered value must be in a specific format, a description of the required format is displayed adjacent. For example, if you see the format 99A 99A 99 9, you must enter 2 numbers, followed by a letter, followed by a space, followed by 2 numbers, followed by a letter, followed by a space, followed by 2 numbers, followed by a space, followed by a single number.

If the geographic type has a required format, you must enter the geographic value in the respective format; the system will NOT convert the input value into the relevant format.

Note:

Default note. A service point's geographic data defaults from your postal default information. Refer to [Setting Up Premise & Service Point Postal Defaults](#) for more information.

Service Point - Multiple Items

The multi-item page is used to define the non-badged items that exist at the service point. Refer to [Service Points With Multiple Items](#) for more information about when to set up this information for a service point.

Use **Menu > Customer Information > Service Point > Search** and navigate to the **Multi-Item** tab to open this page.

Description of Page

Billing accumulates all unbadged items linked to a service point and levies a charge for each type of item based on information in the service agreement's rate.

The collection of items at a service point is effective dated and therefore when you modify this information, you must differentiate between:

- Correcting how the collection of items looked historically by changing existing data.
- Adding another collection of items to reflect how the items look after field work has taken place.

Note:

Removing Multi-items from a Service Point. If you want to remove all multi-items from a service point, add a multi-item collection that doesn't include any items. The effective date should be the date the multi-items were removed from the service point (i.e. no longer applicable to the rate).

Define the **Effective Date** of the collection of items.

The following fields display:

Item Type Indicate the type of item, its description is displayed adjacent.

Item Count Indicate how many of the given type of item exist at the service point.

Service Point - Device History

The device history page is an information only page that shows the meters or items that have been installed at the service point. Use **Menu > Customer Information > Service Point > Search** and navigate to the **Device History** page.

Description of Page

This page shows the history of meters / items that have been installed at this service point. No fields on this page may be modified. Refer to [Installing and Removing A Meter](#) and [Installing and Removing An Item](#) for more information.

Service Point - Equipment

The equipment page contains the equipment that is linked to the service point. Use **Menu > Customer Information > Service Point > Search** and navigate to the **Equipment** page. Refer to [Equipment May Be Associated With Service Points](#) for more information.

Description of Page

The following fields display:

Equipment ID Indicate the unique equipment identifier. When a piece of equipment is entered, its **Badge Number** and **Equipment Type** description are displayed adjacent.

Note:

This is actually the ID of an item as an item must be set up for each piece of equipment that can be linked to a service point. Only items with an item type defined on the service point's SP type's equipment collection may be defined (in other words, the valid types of equipment are defined on the service point's SP type).

Equipment Count This field should be 1 except when you are using an item to define a generic piece of equipment. If you use an item to define a generic piece of equipment, you can indicate the number of such generic pieces of equipment that are associated with this service point.

Install Date Define the date that the equipment was installed at the service point.

Removal Date Define the date that the equipment was removed from the service point.

Comment Use comments to explain anything unusual about the piece of equipment.

Service Point - Operations Area

The Op Area page is used to define the operation area that is assigned to field activities associated with this premise. A different operation area can be associated with different categories of field activities (identified by a field activity's field activity type's field service classification). Use **Menu > Customer Information > Service Point > Search** and navigate to the **Op Areas** page.

Description of Page

The following fields display:

Field Service Class Indicate the field service classification.

Operation Area Specify the operation area that manages field activities associated with the field service classification.

Note:

Default note. A service point's operations areas default from your postal default information. Refer to [Setting Up Premise & Service Point Postal Defaults](#) for more information.

Service Point - SP/SA

The SP / SA page contains the service agreements that are linked to the service point.

This information is updated by the system when service is started. You should only have to access this page if you need to fine-tune what the system defaults.

Warning:

You must understand the "V" very well before attempting to maintain this information. Refer to [Understanding The "V" for more information](#).

Use **Menu > Customer Information > Service Point > Search** and navigate to the **SP/SA** page.

Description of Page

Billing uses **SP / SA** information to amalgamate consumption when it calculates a bill segment for a service agreement. To modify information for a service agreement linked to the service point, simply move to a field and change its value. To add a new service agreement, click +, then fill in the information for each field.

This page works exactly the same as the [Service Agreement - SA / SP](#) page except for the field described below:

Service Agreement The identity of the service agreement. The division and type of the service agreement is displayed adjacent. This field is gray after the service agreement is committed to the database.

Fastpath:

For a detailed description of the remaining fields on this page, refer to [Service Agreement - SA / SP](#).

Service Point - Field Info

The Field Info page allows the user to override premise field information on a specific service point. It also shows the corresponding premise field information.

Use **Menu > Customer Information > Service Point > Search** and navigate to the **Field Info** page

Description of Page

To override premise field information on a specific service point, set **Override Premise Field Information** to Yes. If the value is set to No, the premise information may not be overridden.

Turn on **OK to Enter** if the meter is located in the interior of the premise and your company has permission to enter.

Indicate a **MR Warning** if a specific warning should be downloaded to the person who reads the meter.

Indicate a **MR Instruction** if specific instructions should be downloaded to the person who reads the meter. Meter read instructions and warnings are downloaded as part of the meter read download.

Use **Instruction Details** to provide more detailed instructions to the individual who reads meters at this premise.

Turn on **Key at Premise** if the meter is secured in a locked area and your company has the key. If this field is turned on, you may also specify the **Key ID**.

Service Point - SP Route Configuration

The SP Route Configuration page contains the effective dated route configurations for the Service Point.

**Note:**

This tab may not appear. This page only appears if the service point's SP Type allows multiple route usage.

Description of Page

Define the **Effective Date** of the collection of Service Routes.

Use **Comments** to explain anything unusual about the service point.

The Service Routes grid contains a row for each unique **Service Cycle/Route** :

Specify the Service Cycle in which the service point resides.

Use **External Route Reference** to indicate how this service point is referenced in an external system, if applicable.

Enter the Service Cycle/Route Sequence to define service point's relative position within the route.

**Fastpath:**

Refer to [Designing Cycles for Metered Services](#) and [Designing Cycles for Waste Collection Services](#) for information on designing service cycles.

Service Point - SP Portal

Select **Menu > Customer Information > Service Point > Search** and navigate to the **SP Portal** page to view additional information associated with a Service Point.

Depending on your implementations requirements, you may define additional zones to appear on this Portal

The contents of this section describe the zones that are available on this portal page.

General Information

SP ID, SP Info are displayed.

Device Information

This zone provides an overview of device that is currently installed on the service point as well as an overview of the device's configuration.

- Clicking Device Information navigates to Meter Data Management application's Device Maintenance Portal.
- Clicking Service Point Information to Meter Data Management application's Service Point Maintenance Portal.

Installed Assets

This zone shows the assets and components that are currently installed on the service point.

- Clicking Asset Information navigates to Asset Management application's Asset Maintenance Portal.

Sidebar Portal

The [Sidebar](#) is a portal that always appears on the Oracle Utilities Customer application desktop. Its zones contain tools and data that are useful regardless of the object being displayed.

**Note:**

User configurable. Refer to [Each User Can Customize Which Zones Appear](#) for information about a user can configure which zones appear.

Global context. The system automatically refreshes the values saved in [global context](#) with information about the object that appears in [Object Display Area](#). Various zones available in the sidebar portal have been designed to display data related to a person id, account id or premise id, which are populated by the base global context algorithm C1-GLBL-CTXT.

The contents of this section describe the zones that are available on this portal.

**Note:**

Other zones exist. The zones described below are unique to Oracle Utilities Customer applications. Please see [Core Sidebar Zones](#) for a description of other zones that can appear on the sidebar.

Current Context Zone

The **Current Context Zone** contains basic information about the customer on which you are working.

A maximum of three rows may appear:

- The first row contains a person [context menu](#) and the person's name. You can click on the person's name to transfer to the [Person - Main](#) page. Note, the person's name is formatted by a plug-in algorithm on the [installation record](#). Refer to the base package's name format algorithm for an example. If you prefer different formatting logic, your system administrator should configure the system appropriately.
- The second row contains an account [context menu](#) and the account's:
 - ID and check digit
 - The primary name of the main customer
 - Customer class
- The last row contains a premise [context menu](#) and the premise's address and premise type. Note, the address information is formatted by a plug-in algorithm on the [installation record](#). Refer to the base package's premise format algorithm for an example. If you prefer a different format, your system administrator should configure the system appropriately.

Customer Contact Zone

The **Customer Contact Zone** has three purposes:

- It shows the age of the **Last** customer contact associated with the person displayed in the Current Context zone. The word Today is shown if the last contact was on the current date. The word Yesterday is shown if the last contact was on the current date - 1 day. If neither is applicable, the number of days old is shown.
- It shows the name of the person who added this contact.
- It greatly simplifies the addition of a new customer contact. To add a new contact, simply select the **Type** of customer contact, enter a brief **Comment**, and press the **Add Contact** button.
- After the contact is added, you can click the hyperlink in the **Last** area to go to the newly added contact where you can set up [reminders](#) or indicate the contact should [remain open until future resolution](#).

Financial Information Sidebar Zone

The **Financial Zone** that appears on the sidebar contains the same information that is described in the [Financial Information Zone](#) on the account information portal.

Alert Sidebar Zone

The **Alert Zone** that appears on the sidebar contains the same information that is described in the [Alert Zone](#) on the account information portal.

Customer Context Zone

Along with the [Premise Context Zone](#), the Customer Context Zone is an alternative to the Current Context Zone. It contains basic information about the customer on which you are working. When a person or account is in context, the following information appears:

- Customer Name
- Primary Person Identifier
- Account ID. When the person in context is the main customer on multiple accounts, this will appear as a drop down, allowing for selection and switching between these accounts in context.

- Current Balance
- Aged Debt Bar. If the account's Current Balance is greater than zero, a colored bar is displayed adjacent. This bar provides information about the age of the account's debt.
- CIS Division. This appears only when multiple divisions exist.
- Customer Class
- Related Financially Responsible Persons

Note: The base package delivers this zone configured on the Sidebar Portal but with the **Display** turned off by default. To enable the Customer Context zone, navigate to your [User - Portal Preferences](#), open the Sidebar portal settings and turn on the **Display** option for the Customer Context zone.

Premise Context Zone

Along with the [Customer Context Zone](#), the Premise Context Zone is an alternative to the [Current Context Zone](#).

The zone contains a tree that shows the various objects linked to the premise in context as well as any additional premise(s) associated to the account in context. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Note: Refer to the C1-PremiseTree [tree](#) definition for more information about the premise tree node definitions and hierarchy.

Moving Service options are used to initiate start, stop, or transfer service requests.

Note: The base package delivers this zone configured on the Sidebar Portal but with the **Display** turned off by default. To enable the Premise Context zone, navigate to your [User - Portal Preferences](#), open the Sidebar portal settings and turn on the **Display** option for the Premise Context zone.

Setting Up Bill Print Groups

Bill print groups allow you to categorize an account's service agreements into groups for bill print purposes.

Note:

Bill print groups are optional. Typically, only accounts with many SAs will use bill print groups because the standard bill print priority is sufficient for accounts with a limited number of SAs. Refer to [SA Type - Billing](#) for more information about the standard bill print priority.

Let's use an example to clarify the bill print group concept. Consider a local government's account. This account would have many service agreements (some for the police department, others for the court system, others for the department of public works, etc.).

If you don't create a bill print group for this customer, their bill segments will be printed in the order dictated by each segment's service agreement's SA type's bill print priority. If you create a bill print group for this customer, you can define the customer's desired categories (e.g., police, courts, DPW, etc.) and then link each of the account's SAs to the appropriate category.

Note:

Nomenclature. We refer to the categories under a bill print group as "subgroups". A bill print group can have an unlimited number of subgroups. When you create a subgroup, you define its relative bill print priority and the associated verbiage to print on the bill (assuming you print information about the subgroup on the bill).

We'd like to highlight the following characteristics of bill print groups:

- A bill print group is associated with a specific account. If multiple customers have the exact categorization preferences, you will have to set up multiple bill print groups.
- Over time, a customer could have many bill print groups. This would happen if a customer's bill categorization preferences change over time. We'd like to stress that while an account can have multiple bill print groups, only one will be used by the bill print process (the one effective on the bill date).

- Bill print groups only affect printed bills. Bill print groups do not affect the order in which service agreements appear on the bill maintenance transaction.
- If new service agreements are added after a bill print group is set up for an account, they will not be linked to a subgroup. If you neglect to link the new service agreements to one of the bill print group's subgroups they will be printed under the "default" subgroup (every bill print group must have one default subgroup to cater for this situation).

Warning:

While the system supports the definition of bill print groups and the categorization of an account's service agreements into the various subgroups, the base package's bill print extract does NOT take advantage of this information.

The topics in this section describe how to set up a bill print group and how to link an account's service agreements to its subgroups.

Bill Print Group - Main

Open **Menu > Customer Information > Bill Print Group > Search** to maintain an account's bill print group and subgroups. After defining this information, transfer to the **SA Sub Group** page to link the account's service agreements to the subgroups.

Description of Page

The **Bill Print Group ID** is displayed on every page. This value only appears after the bill print group exists on the database. The ID is a system-assigned random number that stays with a bill print group for life.

Enter the **Account ID** associated with the bill print group.

Use **Effective Date** to define when the bill print group is effective for the account. This date is important as it allows a customer to change their preferences over time. For example, if the customer wants to change the number of subgroups on a given date, you would simply add a new bill print group effective on this date and then define the new subgroups (and link each service agreement to one of the subgroups).

Use **Status** to define if the bill print group is Active or Inactive. You would only use the Inactive value if the bill print group is no longer needed (as there is no delete action on this transaction).

Enter a brief **Description** of the bill print group.

Use **Comments** to describe anything special about the bill print group.

The grid contains the bill print group's subgroups. The following information should be defined for each subgroup:

- **Bill Print Sub Group.** This is the unique identifier of the bill print subgroup.
- **Sub Group Bill Print Priority.** This is the relative print priority of the subgroup in respect of the other subgroups.
- **Use as Default.** Turn on this switch for the default sub group. A bill print group must have one and only one default subgroup. The default group is used by the bill print process if it detects a service agreement that is not linked to a subgroup (it links this service agreement to the default subgroup).
- **Sub Group Description.** This is a brief description of the subgroup.
- **Description on Bill.** This is the verbiage that will print on the bill (assuming you print something on your bills for the subgroup).

After defining the bill print group's subgroups, navigate to the **SA Sub Group** tab to link the account's service agreements to the subgroups.

Bill Print Group - SA Sub Group

This page is used to link the account's service agreements to one of the bill print group's subgroups.

Open **Menu** > **Customer Information** > **Bill Print Group** > **Search** and navigate to the **SA Sub Group** page to maintain this information.

Description of Page

The **Bill Print Group's ID**, **Account ID** and **Effective Date** are displayed at the top of the page.

The filters control the service agreements that appear in the **SAs in Bill Print Group** grid. The following points describe the various options:

- Use the **SA Filter** to define the types of service agreements that appear in the grid. The following options are available:
 - **Address**. Use this option to restrict service agreements to those linked to service points associated with a given **Address**, **City** and/or **Postal** code. Note, you can specify any combination of these fields.
 - **All**. Use this option if you do not wish to restrict service agreements based on service agreement attributes.
 - **Bill Print Sub Group**. Use this option to restrict service agreements to those that are linked to a given **Bill Print Sub Group**.
 - **Geographic Type**. Use this option to restrict service agreements to those linked to service points associated with a given **Geo Type** and **Value**.
 - **SA Type**. Use this option to restrict service agreements to those linked to a given **CIS Division** and **SA Type**.
- Use **Status Filter** to restrict the service agreements based on their status. The following options are available:
 - **All**. This option shows all service agreements regardless of status.
 - Refer to [Service Agreement Lifecycle](#) for the various status values.

Don't forget to click the search button after changing the filters.

The **SAs in Bill Print Group** contains an entry for every non-cancelled service agreement linked to the account that is linked to one of the bill print group's subgroups. The following information appears in the grid:

- Use **Bill Print Sub Group** to define the subgroup associated with the service agreement.
- Use **Sequence** when there is more than one service agreement in the subgroup. The sequence controls the order in which the service agreement's financial information appears on the bill.
- The **SA Information** column provides a brief description of the service agreement.
- The **Service Agreement** column contains the unique identifier of the service agreement.
- The **Premise Information** column contains the characteristic premise associated with the bill segment's service agreement.

The next set of filters control the service agreements that appear in the **SAs Not in Bill Print Group** grid. The following points describe the various options:

- Use the **SA Filter** to define the types of service agreements that appear in the grid. The following options are available:
 - **Address**. Use this option to restrict service agreements to those linked to service points associated with a given **Address**, **City** and/or **Postal** code. Note, you can specify any combination of these fields.
 - **All**. Use this option if you do not wish to restrict service agreements based on service agreement attributes.
 - **Geographic Type**. Use this option to restrict service agreements to those linked to service points associated with a given **Geo Type** and **Value**.
 - **SA Type**. Use this option to restrict service agreements to those linked to a given **CIS Division** and **SA Type**.
- Use **Status Filter** to restrict the service agreements based on their status. The following options are available:
 - **All**. This option shows all service agreements regardless of status.
 - Refer to [Service Agreement Lifecycle](#) for the various status values.

Don't forget to click the search button after changing the filters.

The **SAs Not in Bill Print Group** contains an entry for every non-cancelled service agreement linked to the account that is NOT linked to one of the bill print group's subgroups. The following information appears in the grid:

- Use **Bill Print Sub Group** to define the subgroup associated with the service agreement.

- Use **Sequence** when there is more than one service agreement in the subgroup. The sequence controls the order in which the service agreement's financial information appears on the bill.
- The **SA Information** column provides a brief description of the service agreement.
- The **Service Agreement** column contains the unique identifier of the service agreement.
- The **Premise Information** column contains the characteristic premise associated with the bill segment's service agreement.

Landlord Reversion

Landlord reversion occurs when a landlord would like to have service reverted to their name when a tenant moves out. The landlord defines their reversion preferences using a [landlord agreement](#).

- A landlord's preferences can differ for each type of service. For example, you can indicate that a specific landlord always wants electric and gas service reverted to their account when a tenant stops service. However, they do not want water service to revert.
- A landlord's preferences can also be seasonal. For example, you can indicate water service should only revert to the landlord's account during the winter.

The account to use for the reversion of service is defined on the landlord agreement.

Assuming that you have plugged-in a landlord reversion algorithm on [SA type](#), the system uses the information defined on landlord agreement to create a pending start service agreement(s) for the landlord when service for the existing tenant is stopped.

The following examples illustrate how your organization's landlord reversion algorithm might handle various scenarios for a premise that defines a landlord agreement that indicates service should be reverted:

- When the existing customer calls to stop service and no new customer is scheduled to move in, a pending start service agreement is created for the landlord.
- When a new customer calls in to start service
 - If the start date matches the outgoing customer's start date, the pending start service agreement for the landlord is canceled
 - If the start date is earlier than the outgoing customer's stop date, the pending start service agreement for the landlord is canceled and the stop date of the outgoing customer is changed to match the new date
 - If the start date is later than the outgoing customer's stop date, the pending start service agreement for the landlord is updated with a stop date that matches the new customer's start date
- If changes are made to start or stop dates for the tenants' service agreements, a service agreement for the landlord may need to be created or canceled
 - If the change in dates causes a gap in service that did not exist before, a landlord service agreement is created to cover the gap
 - If the change in dates means that the tenants are now starting and stopping on the same date (and there used to be a gap), a landlord service agreement is canceled
- If the new customer cancels their pending stop, a landlord service agreement is created (if one did not exist) or the landlord SA's stop date is removed (if the new customer's start date resulted in a gap that was being covered by the landlord).

Setting Up Landlord Agreements

The landlord agreement page is used to maintain a landlord's service reversion preferences.

Note:

A landlord could have many landlord agreements. A landlord will have at least one landlord agreement. However, if the landlord has different service reversion preferences for different properties, you can create

multiple landlord agreements - one for each set of preferences. After a landlord's reversion preferences have been defined, link the landlord agreement record to the respective premises.

Use **Menu > Customer Information > Landlord Agreement > Search** to maintain a Landlord Agreement.

Description of Page

Landlord and **Landlord ID** only appear after the landlord is added to the database. **Landlord ID** is a system-assigned random number that stays with the landlord agreement for life. **Landlord** is the description of the landlord agreement.

If the [premise management](#) module is not **turned off**, a message is displayed indicating the number of premises linked to this landlord. Clicking the hyperlink message text transfers you to the [premise management](#) page, which helps you to [manage the premises linked to the landlord](#).

Enter a **Description** of the landlord agreement.

Use **Account ID** to define the account to use when service is reverted to the landlord. This should be one of the landlord's accounts.

The grid that follows contains one row for each type of service to be reverted to the landlord's account. Any service point whose service type is not referenced in this scroll will NOT revert to the landlord's account when a tenant stops service. For each row define the following:

- **Service Type** defines the type of service point that will revert to the landlord's account when a tenant stops service. Note, a service point inherits its service type from its SP Type.
- Turn on **Seasonal** if the service should only revert to the landlords account during a specific season of the year. When turned on, you must define the **Start Month/Day** and the **End Month/Day** of the effective season.

Note:

The month and day must be entered in the format MM/DD. For example, if a season starts on March 1, you must enter the value as 03/01.

Using The Premise Replicator

You use the premise replicator to create many copies of a premise and its service points.

Perform the following steps to replicate a premise:

- Add a [premise](#).
- Add one or more [service points](#) to the premise.
- Use the [premise replicator](#) to create copies of the premise and its service points.

The topics in this section describe how to use the premise replicator.

Premise Replicator - Main Information

You use this page to create many copies of a given premise and its service points.

Warning:

The system warns you if you attempt to create. However, this is just a warning as you may want to generate similar premises and then update them with, for example, a unique apartment number on [Premise - Main Information](#).

Use **Menu > Customer Information > Premise Replicator** to open this page.

Description of Page

Choose the **Premise** that serves as the template premise.

**Note:**

Recommendation. Carefully verify the template premise using the other pages in this page before you save the replicated premises. After you save the replicated premises, any corrections could prove time consuming.

The two sections at the top of the page determine the number of replica premises to be created and the address information that will be set up for each premise. The left section is used to define how the system will create the part of the address that is *different* for each replica premise. The right section defines the parts of the address that will be the *same* for each replica premise.

In the left section:

Use the **Replicate** option to control how the position of the replicated number in the first address line:

- Choose Street Number if the replicated number should prefix the **Base** value in the first address line of the premise. For example, if you have a **Start #** of 1020 and a **Base** value of Main St and you choose the Street Number option, the first replicated premise will be 1020 Main St.
- Choose Apartment Number if the replicated number should suffix the **Base** value in the first address line of the premise. For example, if you have a **Start #** of 1020 and a **Base** value of 101 Main St, Apt. and you choose the Apartment Number option, the first replicated premise will be 101 Main St, Apt. 1020 .

Indicate the **Number Of Premises** you wish to create.

Use **Base** to define the information that will appear at the end of the first address line on each of the replicated premises. Use **Start #** to define the number assigned to the first copy of the premise. Use **Increment** to define the value to increment successive numbers by. The first and last address lines to be created by the replicator are displayed below.

For example, if the first address you want to create is 101 Derby St, and the last address is 199 Derby and you want to do the odd numbered side of the street, you'd enter the following parameters:

Number of Premises would be 50

Address Suffix would be Derby St

Start From would be 101

Increment by would be 2

The right section displays the rest of the address information that will be copied onto each replicated premise. This information is defaulted from the template premise that you selected. The Address 1 field is not shown because you define the information to be entered there in the previous section, as explained above. The remaining fields, however, may be edited if so desired.

After entering the parameters, click the **Replicate** button to generate your new premises. You can use the sections at the bottom of the page to view the premises that will be created when you click save. The left section will show how Address Line 1 will look on the first 10 premises. If you are creating more than 10 premises, the right section will show how Address Line 1 will look on the last 10 premises. If everything looks clean, click save.

Premise Replicator - Premise

The Premise page is a display only page provided to let you confirm that the premise you selected on the add dialog is the one to be used as the template by the replicator. Use **Menu > Customer Information > Premise Replicator** and navigate to the **Premise** page.

Description of Page

This is a display only page that displays key information about the premise being replicated.

Premise Replicator - Premise SPs

This is a display only page provided to let you confirm that the premise you selected on the add dialog is the one to be used as the template by the replicator. Use **Menu > Customer Information > Premise Replicator** and navigate to the **Premise SPs** page.

Description of Page

This is a display only page that displays the details about the template premise's service points.

Start/Stop

The topics in this section describe how to start and stop service.

Warning:

Please see [Order versus Start/Stop](#) for a discussion of the pros and cons of using the order transaction versus the start/stop transaction to start service.

The Big Picture Of Starting Service

Almost all requests to start service involve a conversation between a customer and a customer service representative (CSR). During this conversation, the following is defined:

- WHO will pay for the service (i.e., the account).
- WHERE the service is consumed (i.e., the premise). Note, this is only required for premise-oriented services.
- WHEN the service is requested (i.e., the start date).
- WHAT TYPE of service is desired (i.e., the service agreement and service points).
- HOW MUCH will be paid for the service (i.e., the rate and contract riders).

After the conversation is complete, one or more service agreements in the state of pending start will exist. If the service agreement uses service points, field activities may also be created.

In this section, we provide background information about the start process. For information about the page used to start service, refer to [Start Stop Maintenance](#).

The Lifecycle Of A Pending Start Service Agreement

When you request a new service for a customer, a pending start service agreement is created. The following diagram illustrates the lifecycle of a typical pending start service agreement:

The above diagram is referenced in the topics that follow.

Starting Service and Field Activities

When you initiate a request to start service, the system creates a service agreement in the state of pending start. If the service agreement is service point-oriented, pending field activities necessary to start will be created at some point prior to the service agreement being activated. The question is when? The contents of this section provide information about when they are created and what types of activities are created.

Fastpath:

When you enable the Control Central alert algorithm, C1-PEND-STRT, an alert displays when there is a pending start service agreement linked to the account. This algorithm is plugged-in on the [installation record](#).

What Type Of Start Field Activities Are Created

The type of the service point (e.g., electric residential, gas industrial) and the state of service (e.g., disconnected / no meter, connected / meter installed) at the service point dictate the type of field activity. For example, if the service point doesn't currently have a meter, the new field activity should request a meter installation. Whereas if there's already a meter installed, but it's turned off, the type of field activity should be to turn on the meter.

If you've set up your system properly, the system creates the appropriate field activity given the type and state of the service point; you shouldn't have to be aware of field activities.

In addition to being linked to the service points, these field activities are also linked to the service agreement / service point relationship so that the system can automatically activate the service agreement when the field activities are complete.

Note:

Back-to-Back. We use the term **back-to-back** to describe the situation when a single field activity supports both the stop and start service requests. The fieldwork algorithm delivered with the base package sets up a back-to-back situation by default when it is aware of both the start AND stop customers at a premise.

Fastpath:

For more information about the field activities associated with your SP types, refer to [Setting Up Field Activity Type Profiles](#). Refer to [The System Activates Most Service Agreements Behind-The-Scenes](#) for information about how the system monitors field activities linked to a service agreement. Refer to [The Lifecycle Of Field Activities And Field Orders](#) for information about how field activities are dispatched and completed.

When Start Field Activities Are Created

Field activities will be created when the pending start service agreement is created if the following conditions are true:

- The Create Field Activity Start Stop switch is enabled on the installation record. Refer to [Installation Options - Main](#) for more information.
- The appropriate create fieldwork creation algorithm is defined on the service agreement's SA type. Refer to [SA Type - Algorithms](#) for more information.

If the Create Field Activity Start Stop switch is NOT enabled on the installation record, field activities will NOT be created when the pending start is saved. Rather, a background process (PSASPM) creates the field activities shortly before the start date. The number of days before the start date on which field activities will be created is defined on the service agreement's SA type's fieldwork creation algorithm.

Note:

A fail safe. If any person or process attempts to activate a pending start service agreement and neither of the above events has taken place, field activities will be created when the user attempts to activate the pending start. The creation of the field activities will prevent the service agreement from being activated as described under [The System Activates Most Service Agreements Behind The Scenes](#).

Warning:

Field activities will only be created if you have defined the appropriate field work creation algorithm on the service agreement's SA type. The algorithm that is supplied with the base package checks if the service agreement / service point already has a start read or a start field activity , if so, field activities will not be created (the field work has already been initiated).

How To Start Service Using A Scheduled Meter Read

Another option exists for starting service when all that is required is a meter reading. If the requested start date is close to a scheduled meter read date, you can forego a special trip into the field to get the reading. The system can use the scheduled meter read as long as it is close enough to the start date (you can determine how "close enough" is defined using a parameter on the batch process described below).

If the start date does not exactly match the date that the meter was read, it will prorate the reading, store it as a meter read of type system prorated, and will link it to the SA/SP so that the service agreement can be started. A special batch process (called FANRMRCO) exists to perform the analysis of whether or not a reading is available and if its date is close enough (the number of days is an input parameter to the process). It performs the proration as well and creates the special meter reads.

To use scheduled reads to start service, you need to set up and use a special field activity type: "Meter Read Near Cycle" - it will not be eligible for dispatch and its only step type is "read meter". The base package supplied field activity creation algorithm accepts this field activity type as an input parameter. Start (and stop) events are then created with field activities that use this field activity type. The batch process mentioned above looks for field activities of this type and tries to use a scheduled meter read to complete them.

Note:

If **FANRMRCO** cannot find a reading in the specified time period, it will cancel the special field activity and create a normal activity according to the field activity profile. If it finds a peak demand type reading or a consumption type reading, it posts a To Do entry. The type of To Do entry is defined as a parameter of the batch process.

Activating Pending Starts

When you initiate a request to start service, the system initiates a service agreement in the state of pending start. A pending start service agreement remains in this state until everything necessary to start service is defined in the system. At that time, the service agreement can be activated.

What Is Necessary To Start Service?

The service agreement's SA type defines what is necessary to start service:

- For SA types that have service points, all field activities linked to the service point must be complete before the service agreement can be activated. If field activities are linked to the service agreement, the system automatically links the appropriate billable read to the service point as its start read when the field activity is complete. (The completed field activity should have a read linked to it. If it is billable, it is used as the start read.)
- For SA types that don't have service points (e.g., charitable donations, deposits, one-time charges), everything necessary to activate the service agreement is defined when you initiate the request to start service. These types of service agreements can be activated immediately.

Warning:

If the completed field activity linked to the SA / SP doesn't have an associated read (for whatever reason), the system still activates the service agreement but leaves the SA/SP without a starting read. It does this because it relies on billing to create a bill segment error the first time it attempts to bill the service agreement.

If a service agreement has required SA relationship types (e.g., if an energy supply service agreement must have a SA relationship defining the distribution company), the system activates the service agreement even when these required relationships are not defined. It does this because it counts on billing to create a bill segment error the first time it attempts to bill the service agreement (billing creates an error bill segment for a service agreement if it does not have its required SA relationships defined).

The System Activates Most Service Agreements Behind-The-Scenes

Service agreements are activated by one of the following methods:

- The SA activation background process (**SAACT** or **C1-ACTSA**) automatically activates pending start service agreements once it detects that everything necessary to start service is defined in the system. This is the most common method for activating service agreements. This process runs as often as your organization desires (but it should run at least daily).

Note:

Sub SAs are not handled by the SA activation background process. If your organization uses the **SA relationship** functionality and you have service providers that necessitate **sub service agreements**, you should be aware that the SA activation background process only activates normal and master SAs; sub SAs are activated by the **analyze SA relationships** background process (described in the next bullet point).

- If your organization uses the **SA relationship** functionality and you have service providers that necessitate **sub service agreements**, the analyze SA relationships background process (**ANLYZSAR**) automatically activates pending start sub SAs if their master SA is active.
- You can automatically activate a service agreement when it's created if you plug-in an SA creation algorithm of type SACR-AT on the SA type. Because everything necessary to start service must be defined in the system before a service agreement can be activated, this method only works for SA types that don't have service points (e.g.,

charitable donations, deposits, one-time charges, etc.). If this algorithm is not plugged in on an SA type, service agreements of that type are activated by the SA activation background process or manually.

- You can activate a service agreement manually (assuming everything that's necessary to activate service is in place). Simply open [Service Agreement - Main](#) and click the **Activate SA** button. This is only necessary if you do not want to wait until the SA activation background process next runs.

What Happens At Activation Time?

When a service agreement is activated, the following takes place:

- If the service agreement has start-oriented field activities linked to its service points, billable read(s) from the field activity(s) are linked to the service agreement's service points as their start reads. If there are no associated billable reads, the system still starts the service agreement knowing that billing will generate an error when the service agreement is billed.
- The service agreement's state is changed from pending start to active.
- If the account's bill cycle is not protected and the service agreement has a metered service point, the bill cycle will be changed to reflect the service point's *service cycle's* bill cycle.
- If the account's mailing premise is not protected and the service agreement has a service point whose premise is a mailing premise, the mailing premise is changed to reflect the service point's premise.
- If the account's division is not protected, the division is changed to reflect the service agreement's SA type's division.
- If there is a start adjustment defined on the service agreement's start option, an adjustment is levied.
- The main customer's billing address is changed to reflect the value specified on the Start/Stop page (and this may involve changing the main customer's override mailing address on their person record).

What Happens After A SA Is Started?

Fastpath:

Refer to [The Lifecycle Of A Service Agreement](#) for more information about a service agreement's lifecycle.

The Big Picture Of Stopping Service

To stop service you must define:

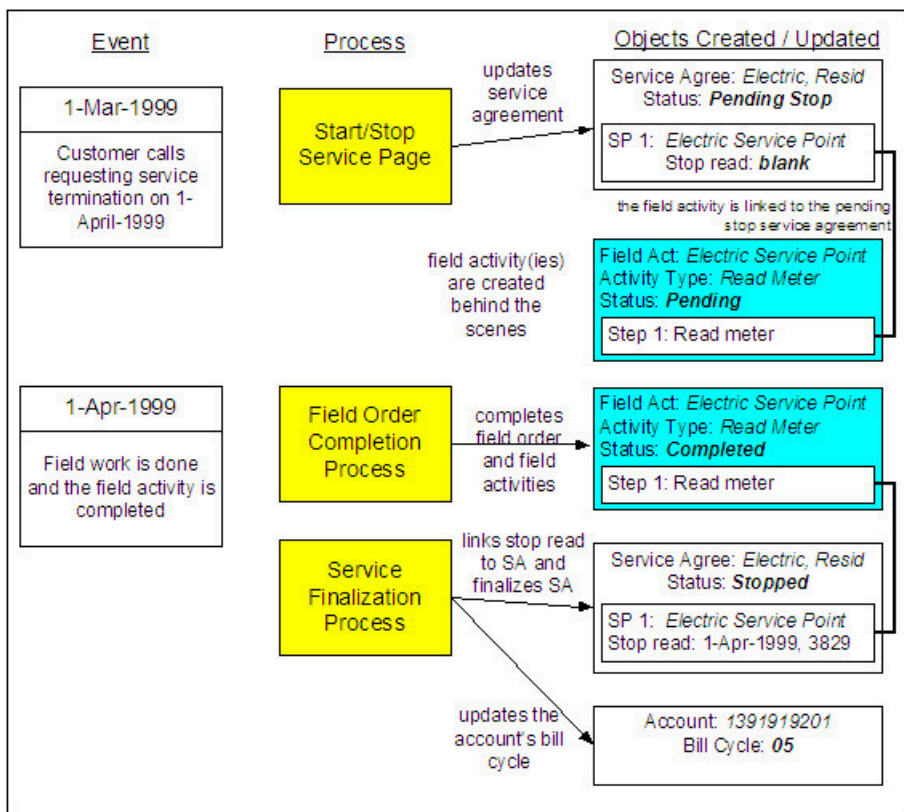

- WHO pays for the service (i.e., the account).
- WHEN service should stop (i.e., the stop start date).
- WHAT services to stop (i.e., the premise or specific service agreements).

After the above is defined in the system, the state of one or more service agreements will be changed to pending stop. If the service agreement uses service points, field activities may also be created.

In this section, we provide background information about the stop process. For information about the page used to stop service, refer to [Start Stop Maintenance](#).

The Lifecycle Of A Pending Stop Service Agreement

When you request to stop service for a customer, the status of an existing service agreement becomes pending stop. The following diagram illustrates the lifecycle of a typical pending stop service agreement:

The above diagram is referenced in the topics that follow.

Stopping Service and Field Activities

When you initiate a request to stop service, the system changes the service agreement to the state of pending stop. If the service agreement is service point-oriented, pending field activities necessary to stop will be created at some point prior to the service agreement being stopped. The question is when? The contents of this section provide information about when they are created and what types of activities are created.

What Type Of Stop Field Activities Are Created

The type of the service point (e.g., electric residential, gas industrial) and the state of service (e.g., disconnected / no meter, connected / meter installed) at the service point dictate the type of field activity. For example, an industrial electric meter may require a different type of field activity to stop service than does a residential gas meter.

If you've set up your system properly, the system creates the appropriate field activity given the type and state of the service point; you shouldn't have to be aware of field activities.

In addition to being linked to the service points, these field activities are also linked to the service agreement / service point relationship so that the system can automatically stop the service agreement when the field activities are complete.

Note:

Back-to-Back. We use the term **back-to-back** to describe the situation when a single field activity supports both the stop and start service requests. The fieldwork algorithm delivered with the base package sets up a back-to-back situation by default when it is aware of both the start and stop customers at a premise.

Fastpath:

For more information about the field activities associated with your SP types, refer to [Setting Up Field Activity Type Profiles](#). Refer to [The System Finalizes Most Service Agreements Behind-The-Scenes](#) for

information about how the system monitors field activities linked to a service agreement. Refer to [The Lifecycle Of Field Activities And Field Orders](#) for information about how field activities are dispatched and completed.

When Stop Field Activities Are Created

Field activities will be created when the pending stop service agreement is recorded when the following conditions are true:

- The Create Field Activity Start Stop switch is enabled on the installation record. Refer to [Installation Options - System](#) for more information.
- The appropriate create fieldwork creation algorithm is defined on the service agreement's SA type. Refer to [SA Type - Algorithms](#) for more information.

If the Create Field Activity Start Stop switch is NOT enabled on the installation record, field activities will NOT be created when the pending stop is saved. Rather, a background process (PSASPM) creates the field activities shortly before the stop date. The number of days before the stop date on which field activities will be created is defined on the service agreement's SA type's fieldwork creation algorithm.

Note:

More information about the Create Field Activity Start Stop switch on the installation record. When this switch is on (and the user doesn't override it), pending field activities will be created when a start or stop is recorded (as opposed to shortly before the start/stop date). You might want to turn this switch off if it's possible for the state of the service point (or its meter / item) to change between the time service is requested and the actual service date. Why? Because the state of the SP and its meter / item affects the type of field activity that is created. For example, if a customer wants to start service and there is no meter at the metered service point, an "install meter" field activity is created. However, if by the time the install date comes around, a meter has been installed by some other means; this field activity is inappropriate. This is why if you might want to set up the system to wait until shortly before the service date to create the field activity (i.e., it reduces the likelihood that an inappropriate field activity is created).

A fail safe. If any person or process attempts to finalize a pending stop service agreement and neither of the above events has taken place, field activities will be created when the user attempts to finalize the pending stop. The creation of the field activities will prevent the service agreement from being stopped as described under [The System Finalizes Most Service Agreements Behind The Scenes](#).

Warning:

Field activities will only be created if you have defined the appropriate field work creation algorithm on the service agreement's SA type. The algorithm that is supplied with the base package checks if the service agreement / service point already has a stop read or a stop field activity, if so, field activities will not be created (the field work has already been initiated).

How To Stop Service Using A Scheduled Meter Read

Another option exists for stopping service when all that is required is a meter reading. If the requested stop date is close to a scheduled meter read date, you can forego a special trip into the field to get the reading. Refer to [How To Start Service Using A Scheduled Meter Read](#) for more information; the stop service option works in the same way and uses the same field activity type.

Finalizing Pending Stops

When you initiate a request to stop service, the system changes the service agreement's state to pending stop. A pending stop service agreement remains in this state until everything necessary to stop service is defined in the system. At that time, the system automatically changes the state of the service agreement to stopped, and at that time the service agreement can be final billed.

So, how does the system know that "everything necessary" is in the system? In this section we provide the answer and explain the many other things that may take place at pending stop finalization.

The System Finalizes Most Service Agreements Behind-The-Scenes

The SA activation background process ([SAACT or C1-STPSA](#)) finalizes a pending stop service agreement when everything necessary is in place. The service agreement's SA Type defines what's necessary:

- For SA Types that don't have service points (e.g., charitable donations, deposits, third party billing), everything necessary to finalize the service agreement is defined when you initiate the request to stop service. These types of service agreements can be finalized immediately.
- For SA Types that have service points, all field activities linked to the service point must be complete. If field activities are linked to the service agreement, the system will automatically link the appropriate billable read to the service point as its stop read when the field activity is complete.

Warning:

If the completed field activity linked to the SA / SP doesn't have an associated read (for whatever reason), the system still stops the service agreement but leaves the SA/SP without a stop read. It does this because it counts on billing to create a bill segment error when it attempts to final bill the service agreement.

When the SA activation background process detects that everything necessary to stop service is in place, it automatically stops the service agreement. This process runs as often as your organization desires (but it should run at least daily).

Note:

Sub SAs are not handled by the SA activation background process. If your organization uses the [SA relationship](#) functionality and you have service providers that necessitate [sub service agreements](#), you should be aware that the SA activation background process only stops normal and master SAs; sub SAs are stopped by the [analyze SA relationships](#) background process.

You can stop a service agreement real-time (assuming everything that's necessary to stop service is in place). Simply open [Service Agreement - Main](#) and click the **Stop** button.

What Happens At Finalization Time?

When a service agreement is finalized, the following takes place:

- If the service agreement has stop-oriented field activities linked to its service points, billable read(s) from the field activity(s) are linked to the service agreement's service points as their stop reads. If there are no associated billable reads, the system still stops the service agreement knowing that billing will generate an error when the service agreement is billed. Note, you can see the field activities that are linked to a service agreement using [Service Agreement - Service Point](#).
- If the service agreement's SA type has a [SA Stop algorithm](#), the algorithm is executed.
- If the service agreement is for a [non-billed budget](#) (i.e., the SA type has a special role of Non-billed Budget), the system removes all covered SAs from the Non-Billed Budget. Refer to [Stopping Non-Billed Budgets](#) for more information.
- If the service agreement is covered by a [non-billed budget](#), the SA is removed from the Non-Billed Budget. Refer to [Stopping a Covered SA](#) for more information.
- When the last active service agreement covered by a non-billed budget is stopped, the Non-Billed Budget will be [stopped](#) (i.e., its state will be changed from active to pending stop).
- The service agreement's state will be changed from pending stop to stopped.
- If the service agreement has an active severance process, the process and its severance events will be canceled.
- If the service agreement is linked to an active collection process, the service agreement is "removed" from the collection process. If the collection process has no other active service agreements, it is canceled.
- When the last service agreement linked to an account is stopped, the account's bill cycle will be changed so that the account will be final billed when billing next executes. The system selects the latest open bill cycle where the

Freeze and Complete switch value matches the value of the Freeze and Complete switch of the account's current bill cycle. In addition, the account's protect bill cycle flag is set to No so that the next time this account starts service, its bill cycle will be set based on the new service point's service cycle.

- The main customer's billing address will be changed to reflect the value specified on the Start/Stop page (and this may involve changing the main customer's override mailing address on their person record).
- If the service agreement is for a deposit (i.e., the SA type has a special role of Cash Deposit), the system calculates interest through the stop date. In addition, the SA's current balance is synchronized with its payoff balance (using the sync adjustment code defined on the service agreement's SA type).
- When the last active service agreement governed by a deposit class is stopped, all active deposit service agreements governed by the same deposit class will be stopped (i.e., their state will be changed from active to pending stop). These pending stop deposit service agreement will then be stopped (as per the above points).
- When a service agreement is stopped, the system automatically cancels the budget. Refer to [Canceling A Budget](#) for more information.

What Happens After A Service Agreement Is Stopped?

Fastpath:

Refer to [The Lifecycle Of A Service Agreement](#) for more information about a service agreement's lifecycle.

Start/Stop Maintenance

You use the start/stop page to both start and stop service.

This page handles a variety of scenarios, including:

- Starting some or all services at a premise. Note, the system will automatically stop the existing customer when you indicate a new customer is starting.
- Stopping some or all services at a premise. Note, the system will automatically revert service to a landlord's account when you indicate a tenant is stopping.
- Starting non-premise-oriented services.
- Stopping non-premise-oriented services.
- Changing the mailing address associated with the account's main customer.

Fastpath:

Refer to [The Big Picture Of Starting Service](#) for more information about starting service. Refer to [The Big Picture Of Stopping Service](#) for more information about stopping service.

The topics in this section describe the start/stop page in detail.

Start/Stop - Main

Fastpath:

The **Description of Page** section that appears below simply describes the fields on this page. Refer to [How To](#) for a description of how to perform common start/stop functions.

Use **Menu > Customer Information > Start/Stop** to open this page.

Description of Page

The **Account ID** and the primary name of the **Account's** main customer are displayed at the top of the page.

If the total number of pending start/stops for the account does not exceed the start stop details threshold defined in [Installation Options](#), the grid contains an entry for every Pending Start and Pending Stop service agreement linked to the **Account ID**.

If information appears on the right portion of the grid, that means that "reciprocal relationships" exist. The following points describe potential reciprocal relationships:

- A reciprocal will be shown for a Pending Start service agreement if the Pending Start service agreement has at least one service point and if another service agreement is found that satisfies the following criteria:
 - The status of the service agreement is not Canceled or Active ,
 - The service agreement is linked to all of the Pending Start service agreement's service points (and all SA/SP records have the same stop date as defined on the qualifying service agreement).
 - The service agreement's stop date is on/before the start date.
 - The service agreement's SA type has a service type that is the same as the Pending Start service agreement's service type.
- Note: if multiple service agreements meet the above criteria, the latest qualifying service agreement is shown as the reciprocal.
- A reciprocal will be shown for a Pending Stop service agreement if the Pending Stop service agreement has at least one service point and if another service agreement is found that satisfies the following criteria:
 - The status of the service agreement is not Canceled
 - The service agreement is linked to all of the Pending Stop service agreement's service points (and they all have the same start date as defined on the qualifying service agreement).
 - The service agreement's start date is on/after the stop date.
 - The service agreement's SA type has a service type that is the same as the Pending Stop service agreement's service type.
- Note: if multiple service agreements meet the above criteria, the earliest qualifying service agreement is shown as the reciprocal.

Note:

If multiple reciprocals exist for a given SA, none of the reciprocals will be shown. In this situation, an appropriate message is displayed highlighting this situation. The existence of multiple reciprocals is rare, but it could happen, for example, if multiple customers are paying for a service point's service (where one customer pays for 60% of the metered consumption and the other pays for the remaining 40%).

The following columns appear in the grid:

Drill Down (button) Click this button to drill down into details of the pending start/stop SA. This button transfers you to the **Pending SA** tab.

Action An icon will be displayed to highlight if the associated SA is a pending start or a pending stop. The start icon (green octagon) appears if the SA is a pending start. The stop icon (red octagon) appears if the SA is a pending stop. If there is a reciprocal SA for the pending **start**, the stop icon appears adjacent; clicking it will cause the SA grid to scroll to the left (so that you can see the pending stop). If there is a reciprocal SA for the pending **stop**, the start icon appears adjacent; clicking it will cause the SA grid to scroll to the left (so that you can see the pending start).

Date This is the start date for pending start service agreements and the stop date for pending stop service agreements.

Cancel Turn on this switch if you wish to cancel the pending start/stop.

Note:

Field activities will be cancelled too. If you cancel a pending start/stop that has field activities , the field activities will also be cancelled. Refer to [Starting Service and Field Activities](#) for the details about how the system automatically creates the field activities to support start service requests. Also, refer to [Stopping Service and Field Activities](#) for the details about how the system creates the field activities to support stop service requests.

System-generated reciprocals will be cancelled too. If you cancel a pending start/stop that has a SYSTEM-GENERATED reciprocal SA, the reciprocal will also be cancelled.

Premise Information If a characteristic premise is linked to the service agreement, summary information about the pending start/stop SA's characteristic premise is displayed.

SA Information Summary information about the pending start/stop SA is displayed.

Action If this column is blank, then there is no reciprocal start/stop for the service agreement whose details appear to the left. If this column is not blank, then the information that appears to the right describes the reciprocal SA of the SA to the left. If a reciprocal SA exists, two icons will always appear: if a start and stop combination appears, the SA to the left is a pending stop (and clicking the stop icon will cause the pending stop to appear); if a stop and start combination appears, the SA to the left is a pending start (and clicking the start icon will cause the pending start to appear).

Date This is the start date for pending start service agreements and the stop date for pending stop service agreements.

Cancel Turn on this switch if you wish to cancel the pending start/stop.

Note:

Field activities will be cancelled too. If you cancel a pending start/stop that has field activities, the field activities will also be cancelled. Refer to [Starting Service and Field Activities](#) for the details about how the system automatically creates the field activities to support start service requests. Refer to [Stopping Service and Field Activities](#) for the details about how the system creates the field activities to support stop service requests.

System-generated reciprocals will be cancelled too. If you cancel a pending start/stop that has a SYSTEM-GENERATED reciprocal SA, the reciprocal will also be cancelled.

Account Info The name of the main customer associated with the reciprocal's service agreement's account is displayed.

Premise Information Summary information about the pending start/stop premise is displayed.

SA Information Summary information about the pending start/stop SA is displayed.

If the total number of pending start/stops for the account exceeds the start stop details threshold defined in [Installation Options](#), the **Total** number of **Pending Starts** and **Total** number of **Pending Stops** is displayed together with a grid containing a summary of the pending start and pending stops.

The grid contains an entry for every group of Pending Start / Pending Stop service agreement linked to the **Account ID** with the same pending start / pending stop date, action, premise, and CIS division/SA Type.

The following columns appear in the grid:

Date This is the start date for pending start service agreements and the stop date for pending stop service agreements.

Action An icon will be displayed to highlight if the associated SA(s) are pending start or pending stop. The start icon (green octagon) appears if the SA(s) are a pending start. The stop icon (red octagon) appears if the SA(s) are a pending stop. Click the icon to navigate to the [Start Stop - Pending SA](#) tab where the associated pending start / pending stop service agreements will be displayed.

Premise Information Summary information about the pending start/stop premise is displayed.

CIS Division / SA Type This is the CIS division and service agreement type of the pending start / pending stop service agreements.

Total This is the total number of service agreements with the same **Date**, **Action**, **Premise**, and **CIS Division / SA Type**.

Following the Pending Start / Pending Stop grid are two sections; one is used to start service, the other is used to stop service.

The following points describe the fields in the start service section (refer to [How To](#) for a description of how to perform common start functions).

- Use **Start Date** to define the date on which you want service to commence.
- Use **Start Method** to define what you want to start. Valid values are:

- Start Premise SPs. Use this method if you want to start selected services at a premise. This method allows you to control the display of the service agreements to be started, providing a manageable view when there are many service agreements to be started at a premise.
- Start a Premise. Use this method if you want to start services at a premise.
- Start a SA. Use this method if you want to start a non-premise-oriented service (e.g., a deposit, a charitable contribution, a one-time charge).
- If you have selected the Start Premise SPs or Start a Premise option, use **Address** and **City** to select the premise. Refer to [Control Central - Search](#) for suggestions in respect of how to use these fields. The selected address and premise ID appear below the selection.

Note: If the service agreement's account's CIS Division's **Restrict to Account CIS Division** flag is set to *Restricted*, the premise search is restricted to the premises without a CIS Division and those whose CIS Division matches the account's CIS Division,

- If you have selected the Start a SA option, use **CIS Division** and **SA Type** to define the type of service agreement you wish to start.

Note: If the service agreement's account's CIS Division's **Restrict to Account CIS Division** flag is set to *Restricted*, the CIS Division is set to the account's CIS Division and cannot be changed.

Warning:

Take special care when adding a new service agreement to specify the appropriate CIS Division / SA Type as it will affect how the customer is billed, what rate can be specified, how overdue debt is collected, and much more. After the service agreement is activated, you may not change its SA type.

- Use **Requested by** to define who requested the stop (e.g., Customer, Jane Smith).
- Click the **Start** button to start service. When you click this button, the [Start Confirmation](#) page appears.

The following points describe the fields in the stop service section (refer to [How To](#) for a description of how to perform common stop functions).

- Use **Stop Date** to define the date on which you want service to stop.
- Use **Stop Method** to define what you want to stop. Valid values are:
 - Stop Selected SAs. Use this method if you want to stop selected service agreements linked to the account.
 - Stop a Premise. Use this method if you want to stop ALL services at a premise.
 - Stop a SA. Use this method if you want to stop a specific SA.
 - Stop all Active SAs. Use this method if you want to stop ALL service agreements linked to the account.
- If you have selected the Stop a Premise option, choose the **Premise ID**. You can optionally choose a specific premise if you selected the Stop Selected SAs option.
- If you have selected the Stop a SA option, choose the **SA ID**.
- Use **Requested by** to define who requested the stop (e.g., Customer, Jane Smith).
- Click the **Stop** button to stop service.

Note: Manual date entry is disabled on the start and stop dates and the date picker must be used when the **Disable Manual Date Entry Option Type** on the Customer Information Options [Feature Configuration](#) has been enabled.

Start/Stop - Start Confirmation

The Start SA Confirmation page appears after a user clicks the **Start** button on [Start/Stop - Main](#). This page presents a summary of the service agreement(s) that will be created if the **Start** button on this page is clicked. Refer to [How To](#) for a description of how to perform common start functions.

Description of Page

The **Account ID** and the primary name of the account's main customer are displayed at the top of the page.

The **Start Date** is the date on which the service is scheduled to start.

Start Requested By contains the name of the person who requested the start.

The **SAs to Start** scroll contains an entry for every service agreement that will be created if you click the **Start** button. If you do not want a service agreement to be created, click the - button (or turn off **Start this SA**). If you'd like to start a non-premise oriented service agreement, click the + button. The following fields appear on this page:

Start this SA Turn this switch on if you want this type of service agreement to be created. Turn this switch off if you do not want this type of service agreement to be created.

If you used a **Start Method** of Start a SA on the Start/Stop page, this switch will be turned on by default.

If you used a **Start Method** of Start a Premise (or Start Premise SPs) and this is the first customer at a premise, this switch will be turned on for all service agreements that appear in the scroll. However, if there was a previous customer at the premise, this switch is only turned on for those types of service agreements used by the previous customer (we assume the new customer only wants the services used by the previous customer). Service agreements that are possible, but were not used by the previous customer, will appear in the scroll with this switch turned off.

CIS Division / SA Type These fields define the type of service agreement that will be created. If you change the CIS Division, you must change the SA Type to reflect one of the services that the division manages.

Note: If the service agreement's account's CIS Division's **Restrict to Account CIS Division** flag is set to *Restricted*, the CIS Division is set to the account's CIS Division and cannot be changed.

If the SA is linked to a service point, the SA types are restricted based on the type(s) of service points (SP) the system has associated with the service agreement (as indicated in the message box). If there are no SPs, only SA types that don't use SPs are displayed. If there is a single SP, only SA types valid for the related SP Type are displayed. If there are multiple SPs, only SA types valid for all related SP Types are displayed.

Note:

Default Note. If the service is linked to a service point, the SA Type defaults based on the SP Type. Refer to [SP Type - SA Type](#) for more information.

Start Option Some SA Types have [start options](#). A start option defines the rate and contract terms defaulted on the service agreement. This field will be gray if the SA type does not use start options.

Total Amount to Bill Use this field if the service agreement is supposed to bill a given amount over its lifetime. This is typically used for deposit service agreements to define the amount of the deposit that should be billed. If the deposit is billed in installments, the installment amount is specified in the next field. This field is gray if the respective SA type doesn't use the Total Amount to Bill option.

This button is only appears if the SA type has a "special role" of Cash Deposit and references a deposit class. When clicked, the system attempts to calculate a recommended deposit amount by calling the recommended deposit amount algorithm that is plugged in on the SA type's deposit class.

Customer Read Use this value to define if the customer reads their own meter. Valid values are Yes and No. This field does not appear for some SA types.

Allow Estimates Turn on this switch if it's OK for the system to estimate this service agreement's consumption if a real meter read is missing at billing time. If the SA type does not allow estimates, this does not appear.

Recurring Charge Amount This field's label is dynamic based on the content of the Recurring Charge Amount Label on the respective SA Type. This field is gray if the respective SA type doesn't use the Recurring Charge option. This field is typically used only for the following types of service agreements:

- Service agreements on a levelized payment plan. This field contains the amount charged each month for the service regardless of the actual amount owed.
- Merchandise service agreements on an installment plan. This field contains the installment amount.
- Deposit service agreements on an installment plan. This field contains the installment amount.
- Charitable contribution service agreement. This field contains the contribution amount.

Note:

Default note. The recurring charge amount defaults based on the **Start Option**.

SIC Select the SIC code associated with the customer. This is typically used only for commercial and industrial customers.

Business Activity Enter a description of the business activity at the location where this service is being started.

SA Information This is a display-only area that provides information about the specific pending start SA. For example, information about the service points linked to the SA will be displayed for SP-oriented service agreements.

Messages This is a display-only area that provides information about the account's start/stop situation in general. For example, if there are multiple accounts paying for service at the premise an appropriate message will be displayed.

When you click the **Start** button, the system performs the following for every service:

- A service agreement is created effective on the start date.
- If a start option is specified, the service agreement's rate and contract terms are populated using information on the option. If a start option is not specified, the service agreement's rate is populated with the SA type's default rate.
- Service points are linked to the service agreement (if the service agreement is service point-oriented). The SA/SP start date for each service point is the same as the SA's start date.

If you use a **Start Method** of Start Premise SPs on [Start/Stop - Main](#), the **SAs to Start** are displayed in a grid; you can control the service agreements that appear using filter options. You may want to use the filter if you have a premise with a large number of service agreements to start.

Premise Info displays summary information about the premise at which services are to be started.

The section beneath **Premise Info** provides you with options that control which service agreements appear in the grid. The following points describe the various options:

- Use the **SP Type Filter** to restrict the service agreements that appear in the grid based on the SP type of the service points that will be linked to the service agreement. The following options are available:
 - All. Use this option if you do not wish to restrict service agreements based on service point type.
 - Specific SP Type. Use this option to restrict service agreements to those that will be linked to service points of a specific **SP Type**.
- Use the **Geographic Type Filter** to restrict the service agreements that appear in the grid based on a geographic type and value of the service points that will be linked to the service agreement. The following options are available:
 - All. Use this option if you do not wish to restrict service agreements based on a geographic type and value.
 - <Geographic Type>. Use this option to restrict service agreements to those that will be linked to service points associated with the selected geographic type and **Geographic Value**.
- Select whether to Include or Exclude service agreements that are linked to service points where **Service Exists Already**. These service agreements are those that would be not be started by default. Refer to the description of the **Start this SA** checkbox for more information on service agreements that would be not be started by default.

Don't forget to click the search button after changing the filters.

The **Select All / Clear All** buttons are used to select service agreements to start. These buttons are enabled if at least one service agreement is displayed in the grid.

Note:

30 service agreements at a time. Clicking **Select All** selects the first 30 service agreements in the grid. If more than 30 service agreements exist, you must select and start them in batches.

The grid that displays contains the **SAs to Start** that match your filter criteria. Click the drill down button to open the **Start SA Confirmation Details** page.

The fields in the grid on the Start SA Confirmation page and on the Start SA Confirmation Details page are as described above for the **SAs to Start** scroll. Differences are highlighted here:

SP Info This is summary information about the service point at which service is to be started.

SP Identifier The service point's SP type's identifying geographic type and value. Refer to [Setting Up Service Point Types](#) . Up to three geo types and values are displayed in the SAs to Start grid.

Click the **Start** button on the Start SA Confirmation page to start the selected SAs. Click on the **Close** button to return to the main page - any changes made on this page since the last time you clicked **Start** are discarded.

Start/Stop - Stop Confirmation

If you choose the stop method of Stop Selected SAs, the Stop SA Confirmation page appears after a user clicks the **Stop** button on [Start/Stop - Main](#). This page presents a summary of the service agreement(s) that will be stopped if the **Stop** button on this page is clicked. Refer to [How To](#) for a description of how to perform common start stop functions.

Description of Page

The **Account ID** and the primary name of the account's main customer are displayed at the top of the page.

The **Stop Date** is the date on which the service is scheduled to stop.

Requested By contains the name of the person who requested the stop.

The section beneath **Requested By** provides you with options that control which service agreements appear in the grid. The following points describe the various options:

- Use the **Premise Filter** to restrict the service agreements to those that are linked to a specific characteristic premise. The following options are available:
 - All. Use this option if you do not wish to restrict service agreements based on premise.
 - No Premise. Use this option to restrict service agreements to those that do not have a characteristic premise.
 - Specific Premise. Use this option to restrict service agreements to those with a characteristic premise of **Premise ID**.
- Use the **SA Type Filter** to restrict service agreements to those of a given SA Type.
 - All. Use this option if you do not wish to restrict service agreements based on SA Type.
 - Specific SA Type. Use this option to restrict service agreements to those of a given **CIS Division** and **SA Type**.
- Use the **Geographic Type Filter** to restrict the service agreements that appear in the grid based on the geographic type and value of the service points that are linked to the service agreement. The following options are available:
 - All. Use this option if you do not wish to restrict service agreements based on a geographic type and value.
 - <Geographic Type>. Use this option to restrict service agreements to those that will be linked to service points / premises associated with the selected geographic type and **Geographic Value**.

Don't forget to click the search button after changing the filters.

The **Select All / Clear All** buttons are used to select service agreements to stop. These buttons are enabled if at least one service agreement is displayed in the grid.

Note:

30 service agreements at a time. Clicking **Select All** selects the first 30 service agreements in the grid. If more than 30 service agreements exist, you must select and stop them in batches.

The grid that follows contains the service agreements to stop that match your filter criteria. The following information appears in the grid:

Select Box Use this checkbox to select service agreements that you want to stop.

Premise Information Summary information about the pending stop premise is displayed.

SA Information Summary information about the pending stop SA is displayed.

SP Identifier The service point's SP type's identifying geographic type and value. Refer to [Setting Up Service Point Types](#). Up to three geo types and values are displayed.

Click the **Stop** button on the Stop SA Confirmation page to stop the selected SAs. Click on the **Close** button to return to the main page - any changes made on this page since the last time you clicked **Stop** are discarded.

Start/Stop - Address/Phone

Open **Menu** > **Customer Information** > **Start/Stop** and navigate to the **Address/Phone** page to change basic information about a customer while you are starting or stopping service.

Note:

A subset of person and account information. This page features a subset of person and account fields that typically change when a customer moves. You can always use the [Person](#) or [Account](#) transactions to change this information.

This information is held in limbo. The information on this page will only be updated on the respective person / account when the first service agreement linked to the account is activated or stopped (i.e., this information is held in limbo until the pending start / pending stop is activated / stopped).

Main customer information. The information on this page is associated with the account's main customer (as defined on [Account - Person Information](#)). If you need to change information about any other person linked to the account, you must transfer to [Account - Person Information](#) and make the changes there.

Use **Bill Route Type** to indicate how the bill is sent to the customer. If the **Bill Route Type** you select indicates that bills are routed via fax, make sure you specify a fax number in the **Telephone Numbers** below (note, the system knows which of a [person's phone numbers](#) is a fax number by the phone type). If the **Bill Route Type** you select indicates that bills are routed via Email, make sure to specify the person's **Email Address** below. If the **Bill Route Type** you selected indicates that bills are routed via the postal service, select the appropriate **Address Source**. You have the following options:

- Choose Mailing Premise on Account if bills should be sent to the [account's mailing premise](#). This address is displayed below.
- Choose Person if bills should be sent to the [person's mailing address](#) . This address is displayed below.
- Choose Account Override if bills should be sent to the [account person's override address](#). This address is displayed below. Typically, you would only choose this option if the person has multiple accounts and each account's bills should be sent to a different address.

If the **Address Source** is Person or Account Override , the respective address fields are displayed and may be changed. If the **Address Source** is Mailing Premise on Account, the account's mailing premise is displayed and cannot be modified. Refer to [Premise - Main Information](#) for information about these fields.

Note:

Default note. If you switch the **Bill Route Type** from a non-postal to postal routed, the **Address Source** defaults to the bill address source defined on the account (if one exists) or Mailing Premise on Account if bill address source is not specified for the main customer.

Note:

By default, the **Address Source** field is protected on Start/Stop– Address/Phone page if the **Bill Route Type** is set to a value other than Postal. To enable the **Address Source** field for all **Bill Route Types** in most circumstances, set the Always Enable Address Source option type on the General System Configuration feature configuration to Y.

Regardless of the **Always Enable Address Source** option value, **Address Source** and **Address Information** are displayed but both are disabled when **Bill Routing Method** is *Not Postal* and **Quote Routing Method** (on Account – Persons page) is *Postal* . A message “*The Main Person receives Quotes at this address. To edit it, go to the 'Persons' tab on the Account.*” is displayed next to the **Address Source**.

Fastpath:

Refer to [Setting Up Bill Route Types](#) for more information about bill route types.

The person contacts, from the [Person - Main](#) page are displayed so that you can review and update them as necessary.

Note: The Email Address field appears when the Legacy Person Phone and Email Option Type on the Customer Information Options [Feature Configuration](#) has been enabled.

Specify the customer's **Email Address**. This can be used to route bills to the customer via email (if your bill routing software supports this function).

Telephone Numbers are used by [Control Central](#) to look for accounts and persons. If the person has more than 20 phone numbers, the first 20 will be shown as display only with a message indicating that more phone numbers exist until you save your start or stop. Once the start or stop has been saved, you are able to modify the phone number collection.

Note: The Person Phone grid appears when the Legacy Person Phone and Email **Option Type** on the Customer Information Options [Feature Configuration](#) has been enabled.

The following fields display:

- **Phone Type** indicates the type of phone number, e.g., Home, Mobile, Business, ...
- Use **Phone Number** to define the telephone number. Enter the telephone number in the format described by the **Phone Format**.

Note:

Formatting is performed by a plug-in. The format that is applied to a **Phone Number** is controlled by the algorithm that is plugged in on the respective [Phone Type](#). If you prefer a different format, your system administrator should configure this algorithm appropriately.

- Enter the **Extension**, if any, of the telephone number.

Start/Stop - Pending SA

If you need to change additional information about the pending start or stop SAs, navigate to the **Pending SA** tab. Alternatively, you can click the Drill Down button on the SA grid of the **Main** tab.

Description of Page

If the total number of pending start/stops for the account does not exceed the start stop details threshold defined in [Installation Options](#), an entry appears in the scroll for each entry in the SA grid on the main page. Use the **Pending Start/Stop SA** navigation arrow buttons to select the pending SA you want to review or modify. This page is split between the primary SA on the top, and the reciprocal SA on the bottom. The following fields are available.

Primary SA:

SA Info Summary information about the pending start/stop SA is displayed.

Cancel Turn on this switch if you wish to cancel the pending start/stop.

Date This is the start date for pending start service agreements and the stop date for pending stop service agreements.

Reason This column indicates if the pending start/stop is System Generated or Customer Requested. System-generated starts are created when a tenant stops service at a premise covered by a landlord agreement. System-generated stops are created when a customer requests a start at a premise where the existing customer hadn't already requested a stop.

CIS Division / SA Type These fields define the type of service agreement that will be created. These fields will be gray if the service agreement is pending stop.

If you change the CIS Division, you must change the SA Type to reflect one of the services that the division manages.

If the SA is linked to a service point, the SA types are restricted based on the type(s) of service points (SP) the system has associated with the service agreement (as indicated in the message box). If there are no SPs, only SA types that don't use SPs are displayed. If there is a single SP, only SA types valid for the related SP Type are displayed. If there are multiple SPs, only SA types valid for all related SP Types are displayed.

Start Option Some SA Types have [start options](#). A start option defines the rate and contract terms defaulted on the service agreement. This field will be gray if the SA type does not use start options or if the service agreement is pending stop.

Premise Summary information about the pending start / stop premise is displayed.

Reciprocal SA:

SA Info Summary information about the pending start/stop SA is displayed.

Cancel Turn on this switch if you wish to cancel the pending start/stop.

Date This is the start date for pending start service agreements and the stop date for pending stop service agreements.

Reason This column indicates if the pending start/stop is System Generated or Customer Requested. System-generated starts are created when a tenant stops service at a premise covered by a landlord agreement. System-generated stops are created when a customer requests a start at a premise where the existing customer hadn't already requested a stop.

CIS Division / SA Type These fields define the type of service agreement that will be created or stopped. This field will be gray if the service agreement is pending stop.

If you change the CIS Division, you must change the SA Type to reflect one of the services that the division manages.

If the SA is linked to a service point, the SA types are restricted based on the type(s) of service points (SP) the system has associated with the service agreement (as indicated in the message box). If there are no SPs, only SA types that don't use SP's are displayed. If there is a single SP, only SA types valid for the related SP Type are displayed. If there are multiple SPs, only SA types valid for all related SP Types are displayed.

Start Option Some SA Types have [start options](#). A start option defines the rate and contract terms defaulted on the service agreement. This field will be gray if the SA type does not use start options or if the service agreement is pending stop.

Premise Summary information about the pending start / stop premise is displayed.

Account The name of the main customer associated with the reciprocal's service agreement's account is displayed.

If the total number of pending start/stops for the account exceeds the start stop details threshold defined in [Installation Options](#), the pending start/stop SAs and their reciprocal SAs are displayed in a grid; you can control the service agreements that appear using filter options.

The section beneath **Account** provides you with options that control which service agreements appear in the grid. The following points describe the various options:

- Use the **SA Action Filter** to restrict the service agreements that appear in the grid to pending starts or pending stops. The following options are available:
 - All. Use this option if you do not wish to restrict service agreements based on SA Action.
 - Start. Use this option to restrict service agreements to pending starts.
 - Stop. Use this option to restrict service agreements to pending stops.
- Use the date filter to restrict service agreements to those that will start or stop between the **From Date** and the **To Date**.
- Use the **Premise Filter** to restrict the service agreements to those that are linked to a specific characteristic premise. The following options are available:
 - All. Use this option if you do not wish to restrict service agreements based on premise.
 - No Premise. Use this option to restrict service agreements to those that do not have a characteristic premise.
 - Specific Premise. Use this option to restrict service agreements to those with a characteristic premise of **Premise ID**.
- Use the **SA Type Filter** to restrict service agreements to those of a given SA Type.
 - All. Use this option if you do not wish to restrict service agreements based on SA Type.
 - Specific SA Type. Use this option to restrict service agreements to those of a given **CIS Division** and **SA Type**.

- Use the **Geographic Type Filter** to restrict the service agreements that appear in the grid based on the geographic type and value of the service points that are linked to the service agreement. The following options are available:
 - All. Use this option if you do not wish to restrict service agreements based on a geographic type and value.
 - <Geographic Type>. Use this option to restrict service agreements to those that will be linked to service points / premises associated with the selected geographic type and **Geographic Value**.

Don't forget to click the search button after changing the filters.

The **Select All / Clear All** buttons are used to select service agreements if you plan on issuing any of the mass update actions at the bottom of the page. These buttons are enabled if at least one service agreement is displayed in the grid.

Note:

30 service agreements at a time. Clicking **Select All** selects the first 30 service agreements in the grid. If more than 30 service agreements exist, you must select and start them in batches.

The grid that displays contains the service agreements that match your search criteria. Click on the drill down button to open the **Pending SA Details** page.

Please refer to the **Pending Start/Stop SA** scroll for a description of the fields in the pending start/stop SA grid on the Pending SA tab and on the Pending SA Details page. Additional fields are described here:

Pending SAs Grid:

- **Select box.** Use this checkbox to select service agreements for mass update.
- The **Action** icons highlight if the associated SA is a pending start or a pending stop and if there are reciprocal SAs. Refer to the action icon on [Start Stop - Main](#).

Mass Update Buttons:

Use the **Cancel Selected** button to cancel the selected pending start/stops together with any associated reciprocal pending start/stops. This button is enabled if you have selected one or more pending SAs.

Use the **Change Start/Stop Date** button to change the start/stop date for the selected pending start/stop service agreements. If a selected start/stop has a reciprocal SA, its start/stop date is also changed. This button is enabled if you have selected one or more pending SAs.

Start/Stop - Pending Field Activity

When you start/stop service point-oriented service, field activities are typically created. You can view every non-cancelled, non-complete field activity linked to the account's service agreements on the **Pending Field Activity** page.

Note:

The field activities are NOT limited to those associated with starting / stopping service. So, if a customer has a pending "cut for non payment" field activity , it would also appear on this page.

Description of Page

An entry appears in the scroll for every Pending and Held field activity linked to the account's service agreements. The information in the **Field Activity** column contains a summary of the field activity and its service point. The information in the **How Used** column describes the purpose of the field activity (such as, Start Activity, Stop Activity, and Severance Activity).

If the total number of pending start/stops for the account exceeds the start stop details threshold defined in [Installation Options](#), you can control the field activities that appear using filter options.

The section beneath **Account** provides you with options that control which field activities appear in the grid. The following points describe the various options:

- Use the **Schedule Date** filter to restrict the field activities that appear in the grid to those that are scheduled between. The following options are available:
 - All. Use this option if you do not wish to restrict field activities to a specific schedule date.

- **Specific Date.** Use this option to restrict the field activities to those with a schedule date between the **From Date** and the **To Date**.
- Use the **Premise Filter** to restrict the field activities to those that are linked to service points at a specific premise. The following options are available:
 - **All.** Use this option if you do not wish to restrict field activities based on premise.
 - **Specific Premise.** Use this option to restrict field activities to those linked to a service point at the given **Premise ID**.
- Use the **SP Type Filter** to restrict field activities to those that are linked to service points of a given SP Type.
 - **All.** Use this option if you do not wish to restrict field activities based on SP Type.
 - **Specific SA Type.** Use this option to restrict field activities to those of a given **SP Type**.
- Use the **Geographic Type Filter** to restrict the field activities that appear in the grid based on the geographic type and value of the service points that are linked to the service agreement. The following options are available:
 - **All.** Use this option if you do not wish to restrict field activities based on a geographic type and value.
 - **<Geographic Type>.** Use this option to restrict field activities to those that are linked to service points / premises associated with the selected geographic type and **Geographic Value**.

Don't forget to click the search button after changing the filters.

How To

The topics in this section describe how to perform common start/stop functions.

How To Start Service At A Premise

The following instructions specifically reference the *Start a Premise* Start Method. You can also use the *Start a Premise's SPs* Start Method and its corresponding user interface.

You navigate through the pages as follows:

- Use [Control Central - Search](#) to look for the customer. If the customer exists, click the Start Service button to transfer to Start/Stop. If the customer doesn't exist, add a new person/account by following the instructions under [How To Add A New Customer From Control Central](#).
- Specify the **Start Date**, **Start Method** (Start a Premise), and select a premise (by entering the premise **Address** and clicking the search button).
- Click the **Start** button to review the various service agreements that will be created.

Note:

Service agreements are created. Each row in the scroll is associated with a service agreement. When you close the page, the system creates new service agreements in the state of pending start.

- If you're starting service at a premise, the system automatically populates the Start Confirmation page with information about every service agreement to be created. To do this, we make a basic assumption - the customer wants every service at the premise. If this assumption is incorrect, simply remove the service agreement from the scroll (by turning off the **Start this SA** switch) before closing the page.

Note:

Automatically stop the existing customer. If there's a customer currently paying for service at the premise, the system automatically sets up the stop information for the existing customer. The stop date of the existing customer is the start date of the new customer. If you don't want to stop the existing customer, simply indicate such in the scroll.

Warning:

Take special care when adding a new service agreement to specify the appropriate CIS Division and SA Type as it will affect how the customer is billed, what rate can be specified, how overdue debt is collected, and much more. After the service agreement is activated, you may not change its CIS Division / SA type.

Fastpath:

Refer to [Starting Service and Field Activities](#) for the details about how the system automatically creates the field activities to support start service requests.

How To Stop Service At A Premise

The following instructions specifically reference the *Stop a Premise* Stop Method. You can also use the *Start Selected SAs* Stop Method and its corresponding user interface.

You navigate through the pages as follows:

- Use [Control Central - Search](#) to find the customer. Click the Stop Service button to transfer to Start/Stop.
- Specify the **Stop Date**, **Stop Method** (Stop a Premise), and select a **Premise** (the premise will have been pre-selected for you if you drilled down from Control Central).
- Click the **Stop** button to stop service at the premise.
- When you click the stop button, the system changes the status of each service agreement to pending stop and sets the stop date accordingly. If we stopped a service agreement that we shouldn't have, simply cancel the stop by checking the **Cancel** column in the grid (and save the page)

Note:

Landlord reversion. If you stop service at a premise that references a landlord agreement, the system will automatically create pending start service agreements for the landlord for those service types covered by the landlord agreement.

Fastpath:

Refer to [Stopping Service and Field Activities](#) for the details about how the system creates the field activities to support stop service requests.

How To Start A Deposit

Charging a customer for a deposit involves creating a service agreement. Deposit service agreements are just like other service agreements in many ways:

- The system bills the customer for the deposit using information on the service agreement.
- The customer pays for the billed amount.
- If the customer doesn't pay, credit & collections starts a collection process to encourage the customer to pay.

Deposit service agreements differ from regular service agreements in the following ways:

- Deposit service agreements typically don't cause a receivable account to be affected when the deposit is billed. It is only when the deposit is paid that a financial transaction occurs (debit cash, credit deposit payable).
- Deposit service agreements have a credit balance when the billed amount is paid (the deposit paid by the customer is a liability of your company - it owes the customer this money).
- Deposit service agreements may be billed in installments or in a lump sum.

Creating a deposit service agreement involves the following steps:

- Select the account on Control Central and open Start/Stop.
- Enter a **Start Date** and **Start Method** of Start a Premise.
- Indicate the premise that the deposit service agreement will cover using the Address and click the **Start** button.
- After you click the **Start** button, the Start Confirmation page will appear:
 - Choose an appropriate **CIS Division / SA Type** for the deposit service agreement.

- If **Start Options** have been created for the CIS Division / SA Type, you need only select the appropriate option and close the page. The system will use the information on the start option to populate the service agreement's billing parameters (e.g., the total deposit due, the installment amount, etc.).
- If **Start Options** have not been created for the CIS Division / SA Type, you must define the total amount of the deposit and the installment amount, if any. You define the total amount of the deposit in **Total Amount To Bill**. You can have the system recommend a deposit amount by pushing the  that appears adjacent to this field.
- If you allow the customer to pay the deposit in installments, define the Installment Amount (the prompt for this field is defined on the SA type and therefore will differ depending on how you've set up the system). After defining this information, close the page. The system will use the information you entered to create a deposit service agreement.

Note:

The above information related to starting a deposit assumes that the deposit SA Type is set up as a premise-based service. If your company does not associate a deposit with a specific premise, you will need to set up your SA Type for the deposit accordingly. Then, you will need to use a Start Method of Start a SA.

How To Start A Charitable Contribution

If a customer elects to contribute money to a charitable organization, you must create a service agreement. Charitable contribution service agreements are just like other service agreements in many ways:

- The system bills the customer for the elected contribution amount using information on the service agreement.
- The customer pays the billed amount.
- If the customer doesn't pay, credit & collections may start a collection process to encourage the customer to pay (depending upon how the charitable contributions debt class has been set up on your system).

Charitable contribution service agreements differ from regular service agreements in the following ways:

- Charitable contribution service agreements typically don't cause a receivable account to be affected when the charitable contribution is billed. It is only when the charitable contribution is paid that a financial transaction occurs (debit cash, credit charitable contribution payable).
- Charitable contribution service agreements have no balance when the billed amount is paid because the money is being forwarded to a charity.

Creating a charitable contribution service agreement involves the following steps:

- Select the account on Control Central and open Start/Stop.
- Enter a **Start Date** and **Start Method** of Start a SA.
- Indicate the **CIS Division / SA Type** of the charitable contribution agreement and click the **Start** button.
- After you click the **Start** button, the Start Confirmation page will appear:
 - If **Start Options** have been created for the CIS Division / SA Type, you need only select the appropriate option and close the page. The system will use the information on the start option to populate the service agreement's billing parameters (i.e., the charitable contribution amount to be periodically billed).
 - If **Start Options** have not been created for the CIS Division / SA Type, you must define the charitable contribution amount (the prompt for this field is defined on the SA type and therefore will differ depending on how you've set up the system). After defining this information, close the page. The system will use the information you entered to create a charitable contribution service agreement.

How To Start A One-Time Charge Service Agreement

You create a one-time charge (i.e., billable charge) whenever a customer should be charged for a service that occurs outside the normal course of business. For example, you would create a billable charge to charge a contractor for the repair of a ruptured gas line.

A billable charge must reference a service agreement. This service agreement behaves just like any other service agreement:

- **Bill segments are created for the service agreement.** Whenever billing is performed for an account with billable charge service agreements, the system creates a bill segment for each unbilled billable charges.
- **Payments are distributed to the service agreement.** Payments made by an account are distributed to its billable charge service agreements just like any other service agreement.
- **Overdue debt is monitored.** The credit and collections process monitors billable charge service agreements for overdue debt and responds accordingly when overdue debt is detected.

Therefore, in order to levy a one-time charge, the customer must have a billable charge service agreement. If one already exists (because of a previous billable charge), you don't have to create a new service agreement. Rather, transfer to the Billable Charge page and add a billable charge for the service agreement. If the customer doesn't already have billable charge service agreement, create one by performing the following steps:

- Select the account on Control Central and open Start/Stop.
- Enter a **Start Date** and **Start Method** of Start a SA.
- Indicate the **CIS Division / SA Type** of the billable charge service agreement and click the **Start** button.
- After you click the **Start** button, the Start Confirmation page will appear. Simply close the confirmation page to save the agreement.
- After the billable charge service agreement has been created, add a billable charge to it (the easiest way is to use the SA context menu). Refer to [Maintaining Billable Charges](#) for more information.

How To Start Service When Multiple Service Points Measure Consumption

When you start service at a premise, the system automatically links service points to service agreements in the same manner as existed for the previous customer. So, if the previous customer amalgamated consumption of three service points and billed this under a single service agreement, the system will create the same configuration for the new customer.

This works fine when the unusual service point configurations have already been set up for the previous customer. However, it doesn't work when the premise is new. So, if you have a new premise that has multiple service points whose consumption needs to be amalgamated under a single service agreement, do the following:

- Start service for only one of the service points to be linked to the service agreement. When you start service, the system creates a service agreement, links the service point to it, and links a field activity to the service point.
- For every service point that wasn't linked to the service agreement:
 - Create a [field activity](#) to start service at the service point.
 - Link the service point to the pending service agreement and link the field activity to the service point on the service agreement. Both of these tasks are done on [Service Agreement - SA / SP](#).

field activities

Note:

That's it. The activation process will automatically activate the service agreement when the fieldwork is complete on all of its service points.

Customer Contacts

Customer contacts are used to record when and why a customer contacted your company. They can also be associated with person, accounts, and premises. This information can be used for both audit and statistical purposes. The topics in this section provide details about how customer contacts are created and used in the system.

Person-Based Versus Premise-Based Customer Contacts

Customer Contacts can be linked to the person, account, and premise.

- If a person is associated with the customer contact, it is considered to be a person-based contact regardless of whether an account and/or premise are also associated with the contact.
- If only a premise is associated with the customer contact, the system will designate the contact as premise-based.
- Contacts that have an account associated with them must also have a person associated and the contact will become person-based. There are no account-based customer contacts.

Customer Contacts that are associated with a person, account, and/or premise can be accessed through each entity's context menu.

How Customer Contacts Are Created

You can add a Customer Contact at any time using either of the following methods:

- Use the [customer contact maintenance](#) page.
- Use the [Customer Contact Zone](#) on the sidebar.

When customer contacts are created through the Customer Contact sidebar zone, the system populates person, account, and/or premise based on context.

In addition to manually adding customer contacts, your implementation team can set up plug-in algorithms that create customer contacts when certain events transpire. For example, you can plug-in an algorithm on the [customer class](#) object that creates a customer contact whenever an order is completed. Because the number and type of plug-ins can be customized for your implementation, we cannot provide a concise list of all such algorithms.

In addition to the above, a variety of events can trigger the creation of a customer contact. Refer to [Customer Contacts Are Used To Trigger Letters](#) for the details.

Customer Contacts Are Used To Trigger Letters

In order to send a letter to a customer, a customer contact must be created for the customer. These types of customer contacts reference a customer contact type that, in turn, references a [letter template](#). The letter template controls the type of information that is merged into the "form letter" and how the letter is physically produced. Refer to [Printing Letters](#) for more information about letter templates and how letters are physically produced.

Because these letters are being sent to a customer, the customer contact that triggers a letter must be person-based. See [Person-Based Versus Premise-Based Customer Contacts](#) for more information.

Customer contacts that trigger letters can be produced by any of the method described under [How Customer Contacts Are Created](#). While a user can create this type of customer contact (e.g., if a customer requests a form to sign-up for automatic payment), the primary sources of customer contacts that trigger letters are via system events and algorithms. Besides algorithms, the following system events may generate customer contacts automatically:

- **Collection events.** When a customer falls in arrears, the system creates a collection process. A collection process is a series of events meant to encourage the customer to pay their outstanding debt. A classic collection event is one that creates a customer contact that, in turn, causes a letter to be sent to the customer requesting payment. These customer contacts are created with person and account populated. Refer to [The Big Picture Of Collection Events](#) for more information.
- **Severance events.** The last event in a collection process typically creates a severance process for each service agreement that's in arrears. A severance process is a series of events that leads to service being severed. A classic severance event is one that creates a customer contact that, in turn, causes a letter to be sent to the customer warning of impending cutoff (or telling them they've been cutoff and the terms necessary to reinstate service). These customer contacts are created with person and account populated. Premise is also populated if the service agreement being severed is associated with a premise. Refer to [The Big Picture Of Severance Events](#) for more information.
- **Write-off events.** After a customer has been final billed, a write-off process will be created. A write-off process is a series of events that leads to the debt being written off. A classic write-off event is one that creates a customer contact that, in turn, causes a letter to be sent to the customer informing them of that their debt has been referred

to a collection agency. These customer contacts are created with person and account populated. Refer to [The Big Picture Of Write Off Events](#) for more information.

- **Overdue events.** Overdue processes can be used to collection on past due debt. An overdue process is a series of events that are used to collect on debt. Some overdue events may create a customer contact that, in turn, causes a letter to be sent to the customer. These customer contacts are created with person and account populated. Refer to [The Big Picture Of Overdue Events](#) for more information.

Your implementation team can introduce plug-in algorithms to create a customer contact when certain events take place. If the created customer contact references a letter template, a letter will be triggered. Because the number and type of plug-ins can be customized for your implementation, we cannot provide a concise list of all such algorithms.

Algorithms that are delivered with the product populate person, account, and/or premise based on the information available when the customer contact is created. For example, the field activity remark algorithm populates the premise and also the person and account if the field activity's service point is linked to a service agreement. From the service agreement the account and account's main person are obtained and used on the customer contact.

A Customer Contact May Trigger Reminders

If you want the system to remind you (via a [To Do entry](#)) about a customer-related issue, you can set up a "reminder" on a customer contact. To do this, follow these steps:

- Determine if you need a new customer contact or if you can reuse one that already exists. If you need a new customer contact, use any of the "online methods" described under [How Customer Contacts Are Created](#).
- Refer to the embedded help on the Customer Contact Reminders zone on the Customer Contact portal for more information about using reminders.

Customer Contacts Are Used To Record Notifications

Notification types may reference a customer contact type that is used to create a record of notifications of that type. This is supported for both message-based and template-based notifications. Refer to [Template-Based vs. Message-Based Notification Types](#) for more information.

Customer contacts create from template-based notifications contain more notification details and support an integration that updates the customer contact with information from an integration system such as *Oracle Integration Cloud* and also from the system responsible for delivering the notification. Customer contacts may also be added and updated by an integration system to record notifications initiated from an external system such as outage notifications that originate from a network management system.

Customer Contacts Can Be Used As Case Files

If a customer calls with a complaint (e.g., they suspect their bill is too high), you can start a "case file" for the complaint by creating a customer contact. This customer contact should be marked as "open".

Note:

Alerts. Customer contacts that are marked as being open cause an alert to appear when the customer is displayed on control central.

Over time, as you work on the case, you can add entries to the customer contact's log to describe your progress.

You can use the customer contact's [reminder](#) functionality to remind you to check out the case on a future date (or dates).

When the case is resolved, you simply turn off the customer contact's open indicator and add an appropriate entry to the log describing the resolution.

Maintaining Customer Contacts

Customer contacts are used to record when and why a customer contacted your company. This information is used for both audit and statistical purposes. The topics in this section describe how to maintain customer contacts. Refer to [The Big Picture Of Customer Contacts](#) for background information about customer contacts.

To view and maintain customer service requests, open **Menu > Customer Information > Customer Contact > Search**. You are brought to a query portal with options for searching for customer contacts.

Once a customer contact has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones are displayed:

- **Customer Contact**
- **Customer Contact Reminders**

Refer to the zones' embedded help for more information.

Printing Letters

As described under [Customer Contacts Are Used To Trigger Letters](#), you must create a customer contact whenever you want to send a letter to a customer. The contents of this section describe the technical implementation of letter production.

The Letter Extract Processes

Customer contacts that trigger letters reference a [customer contact type](#) that, in turn, references a [letter template](#). Two background processes are provided with system that control the information extracted into a file.

C1-LTPEX – Letter Extract

This process produces a letter extract file based on letter extract records that are configured with each letter template. Each letter template can be configured with a different set of record type. Some record types have configuration options such as which characteristic types to extract or how to identify the object to extract. This is a highly configurable extract that should reduce the need for a custom solution.

The record layouts can be viewed in the application on the Letter Template Extract Record List zone on the letter template portal.

Note:

This batch does not utilize the extract algorithm plug-in spot on letter template. The sample Online Letter Image algorithm provided with the system calls the letter template extract algorithm plug-in spot and is not compatible with this solution.

LTRPRT – Letter Extract

This process uses the extract algorithm on the letter template and is responsible for extracting the information merged onto your letters. These algorithms create the "flat file records" that are passed to your letter print software.

Additionally, the extract algorithm can be called if your letter print software has the ability to construct a real-time image of a letter (in a PDF). You can plug-in an Online Letter Image algorithm on the [Installation Record](#). This type of algorithm calls the letter template's extract algorithm to extract the information that is merged onto the letter. Refer to [Technical Implementation of Online Letter Production](#) for the details.

Note:

Alternate print / routing methods. If you require different print formats, you must create new letter extract algorithms and plug them in on your [letter template](#).

**Note:**

This process is not intended for new implementations. For information related to the record layouts produced by the sample algorithms provide for use with this process, please refer to the documentation supplied with CC&B 2.7.0.1 and earlier.

BI Publisher Versus Document Composition Applications

Using BI Publisher as your external reporting tool to display an online letter image differs from using document composition applications as follows:

- An extract file is not required when using BI Publisher. The sample reports provided to use with these external report tools do not have to extract information from another object to merge into a letter.
- Generating letters in batch is not supported yet.

**Fastpath:**

Refer to [Letter Print - BI Publisher Sample Welcome Letters - CI_LTRGN_ENG REPORT](#) for more information.

Where Does The Address Come From?

The following points describes the source of a letter's address:

- For letters generated as a result of collection events, severance events, write-off events and overdue events, the address is extracted as follows:
 - The respective [Account - Person](#) record is retrieved for the letter recipient (note, the account ID is retrieved from the related collection / severance / write-off / overdue process).
 - If the person has a [seasonal address](#) effective on the business date, the letter's address is the respective seasonal address.
 - If the address source is Mailing Premise on Account, the letter's address is the [account's mailing premise](#).
 - If the address source is Account Override, the letter's address is the override address on the respective [Account - Person](#) record.
 - If the address source is Person, the letter's address is the [person's mailing address](#) .
 - If the address source is not defined, the [person's mailing address](#) is used.
 - If an address was not populated as a result of the above, the letter is not produced and a warning is issued by the background process responsible for creating the letter extract file.
- For all other types of letters, the address is extracted as follows:
 - If the letter's person has a [seasonal address](#) effective on the business date, the letter's address is the respective seasonal address.
 - If the letter's person has a [mailing address](#) , it is used.
 - Otherwise, the system checks if the letter's person has at least one account where the person is the main customer and the account has at least one active service agreement. If so, the logic described above is executed for the first such account found.
 - If an address was not populated as a result of the above, the letter is not produced and a warning is issued by the background process responsible for creating the letter extract file.

Technical Implementation Of Online Letter Display

Users can view an image of any letter that is sent to a customer if you plug plug-in an Online Letter Display algorithm on the [Installation Record](#)

Note: Some display algorithms rely on the extract algorithm on each [letter template](#). Algorithms of this type format the records that contain the customer information that is passed to your printing software.

The system can make a call to an external system to retrieve a letter image. Many letter print vendors support this functionality.

The system provides an Installation – Online Letter Display algorithm type (C1GENLTTRURL) that can generate a dynamic URL.

- The algorithm of this algorithm type supports dynamic variables such as the customer contact ID and static variable such a vendor or implementation supplied security key.
- The algorithm constructs a URL including generating HASH or security keys.
- The system displays the retrieved image in a separate browser session.
- Refer to the algorithm type description for information about this algorithm type.

The system can interact with either document composition applications, or a reporting engine (such as BI Publisher).

The system provides an Installation – Online Letter Display algorithm type (C1-LT-DISP) that interacts with Documaker to render an online image of your letter. The following points describe what takes place when clicking **Display Letter**.

- The algorithm based on this algorithm type calls the letter extract algorithm on each [letter template](#).
- The letter extract algorithm will construct the information that appears on the letter
- The constructed information is passed to document composition software that will reconstruct the letter's image in a PDF format.
- The system displays the PDF in a separate browser session. Note that the client must have Adobe Acrobat Reader installed to view PDF files.

The system provides an algorithm that interacts with BI Publisher to render an online image of a letter. The following points describe what takes place when clicking Display Letter when these sample algorithms are used.

- The sample Online Letter Display algorithm C1-ONLTR-RPT is executed.
- This algorithm calls the letter extract algorithm. The sample letter extract algorithm C1-LTREX-RPT is supplied for displaying letters via BI Publisher. This is not actually extracting data because when you use BI Publisher, the report itself is responsible for extracting and formatting the data. The base product algorithm supplied returns the appropriate report code to the Online Letter Display algorithm, which in turn returns the report code to the customer contact page.
- A user exit on the customer contact page invokes BI Publisher and displays the letter in a separate browser session.

Fastpath: Refer to [Letter Print - BI Publisher Sample Welcome Letters - CI_LTRGN_ENG REPORT](#) for more information.

Reproducing The Letter Print Flat File

You can reproduce the flat file containing the information sent to your printing software at any time. Simply request the respective extract batch process and specify the run number associated with the historic run.

How To Reprint A Specific Letter

If you need to reprint a specific letter, navigate to [Customer Contact - Main](#) and turn on the **Reprint** switch (and save the customer contact). Alternatively, if your implementation has [enabled the online creation of letter images](#), you can also click the **Display Letter** button on this page and then print the resultant PDF on your local printer.

Letter Data Area Organization

The following refers to logic supported by letter extract process C1-LTPEX – Letter Extract. Refer to [The Letter Extract Processes](#) for more information.

The letter extract records are defined using data areas. There is an organizing data area that includes a detail data area and optionally a characteristic data area. The detail data area contains the individual elements. Using the account

record as an example, the organizing data area is “Account Letter Extract Record” and includes two other data areas, “Account Details Letter Extract” and “Account Characteristics Letter Extract”. This was done to:

- Ensure that characteristic records are extracted directly after their associated record.
- Properly sequence parent records followed by their characteristic then followed by a child record and its characteristic.
- Allow custom extensions to the detail record. See [Extending Letter Record Types](#) for more information.

The characteristic data area is only included on objects with a characteristic collection. For consistency, objects without a characteristic record still follow same pattern with an organizing and detail data area. There are two special records, the end of letter record and the summary record that do not follow this pattern.

Letter Extract File Structure

The following refers to logic supported by letter extract process C1-LTPEX – Letter Extract. Refer to [The Letter Extract Processes](#) for more information.

The letter extract file structure is impacted by the extract format. The extract batch, contains a File Format parameter that supports XML, CSV, and fixed position extract formats.

When the format is set to XML, the organizing data area as described in [Letter Data Area Organization](#), is treated as a single schema. The included data areas are nested within the organizing data area. For example, an account record configured with two characteristics to extract will be nested in a single schema with a detail group and two occurrences of the characteristic list group.

When the format is set to CSV or fixed position, the included data areas are treated as an individual schema so that each record is extracted on a separate row. For example, an account record configured with two characteristics to extract will produce three rows in the extract file.

Extending Letter Record Types

The following refers to logic supported by letter extract process C1-LTPEX – Letter Extract. Refer to [The Letter Extract Processes](#) for more information.

Each record type has a business object that defines the format and the logic to extract records of that type. The BO Extract Record plug-in spot contains the logic to populate the record's data area. This plug-in spot supports multiple algorithms. Each business object is delivered with one algorithm configured for this plug-in spot that contains the logic to populate the record type's elements.

As described in [Letter Data Area Organization](#), there is a detail data area that contains the individual elements for a record type. If your implementation wants to extend a delivered record type, define a custom data area that extends the detail data area. The organizing data area should not be extended. To populate the custom data area, create an additional algorithm for the Extract Record plug-in spot. The record's schema is passed into the plug-in spot so subsequent algorithms have access to values defined by previous algorithms.

Maintaining Declarations

The declaration page allows you to define a declaration percentage for a combination of account, premise, service type, declaration type and date range. The declaration may be used by algorithms to adjust certain calculations in the system. For example you may give certain customers a reduced VAT rate. The declaration is used to indicate the reduced rate for the qualifying customer.

Open **Menu > Customer Information > Declaration > Add** to create a new declaration.

Note:

Applicable for UK market. This page is intended for the United Kingdom market. Other markets may disregard this transaction.

Description of Page

The **Declaration Info** is a concatenation of important information about the declaration record. The **Declaration ID** is a system-assigned random number that uniquely identifies this record.

Use **Account ID** to indicate the account for this declaration.

Use **Premise ID** to indicate the premise for this declaration.

The **Service Type** controls the service agreements covered by this declaration. All service agreements for this account and premise whose service point is for this service type are covered.

Use the **Declaration Type** to indicate the type of declaration. The system includes the declaration types CCL Relief and Reduced Rate VAT.

Note:

The values for this field are able to be customized using the Lookup table. This field name is DCL_TYPE_FLG.

Enter the **Start Date** and **End Date** to indicate the effective period of this declaration. The start date defaults to the current date.

Enter the **Declaration Percentage**.

If this declaration is related to an external document, indicate the **Document Reference**.

This bottom of this page contains a [tree](#) that shows information about all the declarations linked to this account. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Service Tasks

The topics in this section describes service tasks.

The Big Picture of Service Tasks

Service tasks are records that can be used to perform a variety of tasks. Examples include:

- Task-related records performed by users of other Oracle Utilities applications, such as Oracle Utilities Customer Self Service.
- Task-related records performed by Oracle Utilities Customer Care and Billing to manage specific processing, such as net energy metering true-ups, or prepaid billing to create bill segments for smart meter prepaid service agreements.

For additional information about Service Tasks, see [Defining Service Tasks Options](#)

Searching and Viewing Service Tasks

Use this procedure to search for and view service tasks using the Service Task Query portal.

1. Select **Menu** , then **Service Task**.
2. Enter your search criteria.

Base package search options include customer name, external ID and service task ID.

Self-service task search criteria include service task type.

3. Click **Refresh**.
4. In the search results list, click the link for the service task you want to view or edit. The selected service task opens in the Service Task portal.

Registration Points

Understanding Registration Points

Deregulated markets operate by passing transactions between market participants to manage market processes. Markets use a unique market identifier for market participants to identify the customer or premise that the transaction applies to.

Some markets will identify a customer at a premise and the unique identifier will change with each new customer at the same premise. Other markets will identify the premise as the unique identifier and all customers at that premise will use the same identifier.

A registration point can manage a unique identifier at the premise level, service point level or the service agreement level. Therefore, providing the ability to operate in all markets.

Registration points can be associated directly with market transactions and/or market processes. Transactions can be implemented to trigger from changes to a registration point, or any object associated with the registration point. Transactions from Market Participants are received and validated against the registration point and can update the registration point directory or associated objects.

A registration point search portal provides a central location for all transactions associated with a customer and/or premise to be viewed in a single location.

For implementations operating in deregulated markets, refer to your implementation documentation for further details relating to registration point(s) constructed for your market(s).

Refer to [Understanding Market](#) for more details on markets.

Maintaining Registration Points

This portal is used to display and maintain a Registration Point.

Refer to [Understanding Registration Points](#) on page 182 for more details.

To view and maintain registration points, open **Menu > Customer Information > Registration Point > Search**. You are brought to a query portal with options for searching for registration points.

Once a registration point record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones are displayed:

- **Registration Point**
- **Registration Point Attributes**
- **Registration Point Characteristics**
- **Market Messages and Market Processes**
- **Registration Point Relationships**

Refer to the zones' embedded help for more information.

Consumer Contracts

Maintaining Consumer Contracts

This portal is used to display and maintain a Consumer Contract.

Refer to [Understanding Consumer Contracts](#) for more details.

To view and maintain consumer contracts, open **Menu > Customer Information > Consumer Contract > Search**. You are brought to a query portal with options for searching for consumer contracts.

Once a consumer contract record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones are displayed:

- **Consumer Contract** shows the details of the consumer contract.
- **Consumer Contract Milestone** shows the significant dates on which specific actions will take place for the consumer contract.
- **Consumer Contract Product** shows the related contract product versions
- **Consumer Contract Change Request** shows the related consumer contract change request(s) that created and/or updated the consumer contract.

Refer the zones' embedded help for more information.

Customer Service Requests

Understanding Customer Service Requests

Customer service requests can be used to orchestrate complex customer related processes that can create or update multiple objects.

- Customer service request person
- Customer service request account
- Customer service request premise
- Customer service request service agreement
- Customer service request consumer contracts
- Customer service request contract product
- Customer service request service location

An implementation can add custom components to use the customer service request objects to add or update persons, accounts, premises and contracts.

To see the available customer service request types in your implementation, refer to the Customer Service Request business objects in the application.

About Starting, Stopping and Transferring Service Using Customer Service Requests

The system is delivered with step-by-step processes to facilitate start, stopping and transferring service. A few different objects are used to comprise these processes. These objects are designed to work with each other – like a matched set.

A **Process Flow Type** controls the user experience by combining a series of panels that create the steps of the flow. The process flow guides the user to gather information based on configured business rule. It also orchestrates performing business logic contained in plug-in spots to progress the process flow. For example, it uses a chosen premise to then show the user the available services to start at that premise. Along the way, the process flow creates and interacts with an underlying transaction.

A **Customer Service Request** is a lifecycle-based transaction that is created by the process flow. The customer service request is comprised of a parent request and child objects to record, update, and provide processing for persons, accounts, service agreements, and premises. The customer service request lifecycle continues after the process flow is complete and until all associated services are activated, stopped, or canceled.

A **Customer Service Request Type** contains the business rules that the process flow and customer service request jointly interpret, apply, and enforce. The customer service request type's business rules settings are called controls. They along with the plug-in spots, define the type's behavior. Some configuration is used by the process flow and some by the customer service request. For example, the customer service request type has controls that impact the fields used to search for a person and a plug-in spot used to create pending start service agreements.

The Start Service Process and Request

When starting service, the system creates a start service process flow and assigns it a customer service request type. The process flow type (start service process) and customer service request type (start service request type or request type) are determined from the action method with Action Method Role of **Start Service**. See [Action Method](#) for more information about setting up action methods. The customer service (start service) request parent and child business objects are defined on the request type.

The system is delivered with the following objects that are used to start service

- Process Flow Type **C1-STARTSERVICEREQUEST**.
- Customer Service Request Type business object **C1-StartServiceRequestType**
- Customer Service Request business object **C1-StartServiceRequest**
- Customer Service Request Person business object **C1-CustSvcRequestPerson**
- Customer Service Request Account business object **C1-CustSvcRequestAccount**
- Customer Service Request Premise business object **C1-CustSvcRequestPremise**
- Customer Service Request Start SA business object **C1-StartServiceRequestSA**

The start service process can be initiated via BPA script (refer to script C1StaActMtdR).

Start Service Process

The start service process contains five steps or panels. The logic that is enabled is defined in the request type. The following overview of the four panels assumes the request type has enabled the described functionality. This is meant to illustrate the full features provided with the start service process. The request type can be configured to accommodate your business rules.

If your organization operates in multiple jurisdictions, it is likely that the **Control By CIS Division** flag is set on the [Installation Record](#). When set, the premise search is presented before the process flow is started. This is done to get the CIS Division from the premise and pass it to the action method. This is useful when action method is used to associate customer service request types and/or process flow types to specific CIS Divisions.

Move-to Premise. This panel is used to search for the starting premise. This is the first step to ensure that the new or existing customer's Move-to Premise exists and is in your service territory. In some instances, such as when **Control By CIS Division** flag is set on the [Installation Record](#), the Move-to Premise is known and is passed into the process flow. In this case, premise is already selected and can't be changed.

Customer Identification. This panel is used to create a new person and/or account or ensure a person's existing account is eligible for service. If the start service process began without an existing person in context, a person search is provided to ensure the person is in fact not in your system to help prevent creating duplicate person records. If no person is found, the information used to search for the person such as their name, phone number, or ID is used to create a new person. If an existing person is found, the start process then continues as if the person was provided when the process began.

Regardless if an existing person is being used or a new person is being added, the start process determines if a credit or ID check needs to be performed and if it does, performs it. It then checks to see if the person has accounts that are eligible for service. For example, accounts used for bankruptcy or accounts that have been dormant for too long might not be eligible for service. A control determines if a new account can be created even if an existing account is eligible for service. This is useful to prevent duplicate accounts for the same person, unless your business rules allow it. The start process then uses the previous information to determine if a deposit is required. For more information, please see [Verifying Identity, Checking Credit and Requiring Deposits when Starting Service](#).

Note:

When specifying **First Name** and **Last Name**, the person's name is formatted as Last Name + <Person Name Separator Character> + First Name, if name separator is being used. Otherwise, person's name is formatted as First Name + <space> + Last Name.

Customer Class must be defined for a new account. The values are restricted to the customer classes defined on the customer service request type. If the **Control By CIS Division** flag is set on the [Installation Record](#), **CIS Division**

must also be specified. The values are restricted to the user's CIS Division(s). See [Users and CIS Division](#) for more information

Note:

Default note. **CIS Division** is defaulted from the premise. If there is no CIS Division defined on the premise, the CIS Division on the customer service request type is used, if it has one. Otherwise, **CIS Division** is not defaulted. If the CIS Division is configured to ensure the same CIS Division is used on related accounts, premises and service agreements, it can't be changed. **Customer Class** is defaulted from the [Installation Record](#) based on the **Person Type** (Person or Business). If **CIS Division** is specified, the **Customer Class** defaults first from the CIS Division and then from the [Installation Record](#), each based on the **Person Type** (Person or Business).

Before transitioning to the next panel, this panel interacts with the start service request to create person and account records. When a new person or account is added, their record will exist in the system after this point, even if this process is not completed.

Services to Start. On this panel the services to start are selected. After inputting a start date, the panel displays services to start in three different groupings.

If a deposit is required, the first sections is shown. The start process defaults the deposit service agreement request type, calls the deposit calculation plug-in spot on deposit class, and defaults installments information amounts if configured on the request type. The start process enforces rules pertaining to installment amounts. While not common, additional deposit SAs can be added.

The next section shows the eligible services to start at the premise. This is based on the premise's SPs. This section is built by calling the algorithm in configured in the **Determine Services to Start** plug-in spot defined on the request type. It returns the default SA Type(s) for each service point based on the existing or prior service or the initial services defined on the SP Type if this is the first service at this SP. The start SA box is usually checked by default and can be unchecked to start only some of the eligible services at the premise. In rare cases, the start SA box is unchecked by default if some services are on and some services are off at the premise. This is done to replicate the current service at the premise by default. Entries cannot be removed or added to this collection of eligible services to start. Field service notes can be entered for the premise or service point.

The third service section is where additional services such as charity can be started. Additional services can default from the request type or be added. The search is designed to exclude deposit and SP-based services shown in the prior sections.

Note:

If the CIS Division is configured to ensure the same CIS Division is used on related accounts, premises and service agreements, only service agreement types for the current CIS Division are defaulted to the panel. Additionally, when manually adding service agreement types, the CIS Division is set to the current CIS Division and can't be changed. The current CIS Division is determined based on the following hierarchy:

- Account
- Premise
- Customer Service Request Type

At the end of the panel, premise attributes such as indicating if life support equipment is at the premise or if there are specific field warnings relevant to the premise.

Person and Account Details. This panel is where all other person and account information is gathered. This includes all person contact information, other names, other person identifies, alternate mailing address, paperless billing enrollment, autopay enrollment and updates, adding other persons on the account, and more.

Review and Submit. This panel provides an opportunity to review the information before submission.

When the start process is finished, a **Summary** is shown. The start service information is copied to the start service parent and child requests. The start service process is completed, and the start service request takes over.

Start Service Request

The start service request lifecycle is comprised of this logic:

- The start service request first checks to see if there are pre-requisites to starting service. See [Introducing Your Business Rule Before Starting or Transferring Service](#).
- Once any prerequisites have been completed, the request applies any person and account updates gathered during the start service flow. It then creates the pending start SAs by calling the algorithm plugged into the **Process Services to Start** plug-in spot on the request type.
- The request then monitors the pending SAs for activation.
- Once all services are active, premise updates are applied.
- The start request is then complete.

Note: For more details, see the start service request business object detailed description.

The Stop Service Process and Request

When stopping service, the system creates a stop service process flow and assigns it a customer service request type. The process flow type (stop service process) and customer service request type (stop service request type or request type) are determined from the action method with Action Method Role of **Stop Service**. See [Action Method](#) for more information about setting up action methods. The customer service (stop service) request parent and child business objects are defined on the request type..

The system is delivered with the following objects that are used to stop service

- Process Flow Type **C1-STOPSERVICEREQUEST**.
- Customer Service Request Type business object **C1-StopServiceRequestType**
- Customer Service Request business object **C1-StopServiceRequest**
- Customer Service Request Person business object **C1-CustSvcRequestPerson**
- Customer Service Request Account business object **C1-CustSvcRequestAccount**
- Customer Service Request Premise business object **C1-CustSvcRequestPremise**
- Customer Service Request Start SA business object **C1-StopServiceRequestSA**

The stop service process can be initiated via BPA script (refer to script C1StpActMtdR).

Stop Service Process

The stop service process contains three steps or panels. The logic that is enabled is defined in the request type. The following overview of the two panels assumes the request type has enabled the described functionality. This is meant to illustrate the full features provided with the stop service process. The request type can be configured to accommodate your business rules.

Services to Stop. This panel is used to choose the services to stop for the account. After entering a stop date, the algorithm in configured in the **Determine Services to Stop** plug-in spot defined on the request type is called. It returns the stoppable services for the account. The services at the premise in context are selected to stop by default. Other premises and non-premise-based service can also be selected to stopped but are not selected by default. Non-premise-based services with a characteristic premise matching the premise in context are defaulted to stop.

Field service notes can be entered for the premise or service point where service is being stopped.

Additionally, as customers stop service at a premise, some premise attributes such as indicating if life support equipment is at the premise or if there are specific field warnings relevant to the premise may need to be updated. Premise updates can be made for any premise where service is being stopped.

Person and Account Details. This panel has the same features as the same panel in the Start Service Process. The options presented are controlled by the stop request type

Review and Submit. This panel provides an opportunity to review the information before submission.

When the stop service process is finished, a **Summary** is shown. The stop service information is copied to the stop service parent and child requests. The stop service process is completed, and the stop service request takes over.

Stop Service Request

The stop service request lifecycle is comprised of this logic:

- The stop service request applies any person and account updates gathered during the stop service flow. Services that are chosen to stop are transitioned to pending stop by the algorithm plugged into the **Process Services to Stop** plug-in spot on the request type.
- The request then monitors the pending stop SAs to check when they have stopped.
- Once all services are stopped, the request applies any premise updates.
- The stop request is then complete.

Note: For more details, see the stop service request business object detailed description.

The Transfer Service Process and Request

When transferring service (starting and stopping service for the same customer), the system creates a transfer service process flow and assigns it a customer service request type. The process flow type (transfer service process) and customer service request type (transfer service request type or request type) are determined from the action method with Action Method Role of **Transfer Service**. See [Action Method](#) for more information about setting up action methods. The customer service (transfer service) request parent and child business objects are defined on the request type.

The system is delivered with the following objects that are used to transfer service:

- Process Flow Type **C1-TRANSFERSERVICEREQUEST**.
- Customer Service Request Type business object **C1-TransferServiceRequestType**
- Customer Service Request business object **C1-TransferServiceRequest**
- Customer Service Request Person business object **C1-CustSvcRequestPerson**
- Customer Service Request Account business object **C1-CustSvcRequestAccount**
- Customer Service Request Premise business object **C1-CustSvcRequestPremise**
- Customer Service Request Start SA business object **C1-StartServiceRequestSA**
- Customer Service Request Stop SA business object **C1-StopServiceRequestSA**

The transfer service process can be initiated via BPA script (refer to script C1TrnActMtdR).

Transfer Service Process

The transfer service process contains five steps or panels. The logic that is enabled is defined in the request type. The transfer process combines panels from the start and stop processes into one process.

Move-to Premise. This panel is similar to the Move-To Premise panel used in the Start Service Process. Since an account is known at the start of the transfer service process, the search result is limited to the account's CIS Division if the CIS Division is configured to ensure the same CIS Division is used on related accounts, premises and service agreements.

Services to Start. This panel is the same as the same panel used in the Start Service Process. The options presented are controlled by the transfer request type.

Services to Stop. This panel is the same as the same panel used in the Stop Service Process. The options presented are controlled by the transfer request type.

Person and Account Details. This panel is similar to the same panel in the Start and Stop Service Processes. The only notable difference is that this panel allows for the creation of a customer contact for the starting and stopping service. The options presented are controlled by the transfer request type.

Review and Submit. This panel provides an opportunity to review the information before submission.

When the transfer service process is finished, a **Summary** is shown. The transfer service information is copied to the transfer service parent and child requests. The transfer service process is completed, and the transfer service request takes over.

Transfer Service Request

The transfer service request lifecycle is comprised of this logic:

- The transfer service request first checks to see if there are pre-requisites to starting service. See [Introducing Your Business Rule Before Starting or Transferring Service](#).
- Once any prerequisites have been completed, the request applies any person and account updates gathered during the transfer service flow. It then creates the pending start SAs by calling the algorithm plugged into the **Process Services to Start** plug-in spot on the request type. Next it creates the pending stop SAs by calling the algorithm plugged into the **Process Services to Stop** plug-in spot on the request type.
- The request then monitors the pending start SAs for activation and the pending stop SAs for stopping.
- The move-to premise is updated as soon as one of its SAs are Active. Each move-from premise is updated as soon as one of its SAs are Stopped.
- The transfer request is completed when all of the following are true:
 - All premises are updated
 - All SAs to start are Active
 - All SAs to stop are Stopped.

Note: For more details, see the transfer service request business object detailed description.

Additional Information About the Start, Stop, and Transfer Processes

The following explains some of the more intricate details performed during the start, stop, and transfer processes.

Override Mailing Address

By default, the main person on an account's mailing address source is the mailing premise on the account. Other person's on the account do not default the address source and one must be chosen. Aside from the mailing premise on the account, the system stores a mailing address information on the person and directly on the account person record, which is called Account Override. The account/person record indicates the address source for that account/person.

Your business rules may define where alternate mailing addresses are stored or when each is used. The request type defines which alternate location is used or if both are used. When adding an alternate mailing address, the address is stored in the preferred location or if both are enabled, Person or Account Override must be selected.

Existing data might not reflect your current business rules. For example, the request type is set to Account Override, but the address source is already set to Person. In this case, the process behaves as if both sources are enabled and a message is shown to indicate that the current address is stored in the source not supported by the request type. The process does not require the source to be changed.

Default Bill Route Type

When a new person and account are added or when a new person is linked to an account as an other person, the bill route type is defaulted from the installation record.

Paperless Billing

The processes allow customers to enroll in paperless billing if not already enrolled. If the current bill route type's routing method is email or fax, the customer is considered already enrolled. When enrolling, the bill route type defined on the request type is used.

Autopay Enrollment

The processes allow customers to enroll, check, or stop automatic payments. If enrolled, the details of the current record are shown. Changing the enrollment expires the currently effective and creates a new record effective the following day. To stop automatic payments, uncheck the box next to the enrollment details and the current record is expired.

Displaying Insights on Start and Transfer Service Processes

The Start and Transfer Service Processes can display insights about the premise, account and the services at the premise.

The insights are shown when a premise is selected from the search results for the Move-to Premise and on the header of subsequent panels – i.e. Customer Identification, Services To Start and Account Details.

The base product provides Insight Classes for each category of insights (premise-based, account-based and service-based), as well as Insight Types that can be linked to the Insight Groups for these Insight Classes.

The following are the steps to enable insights on Start and Transfer Service processes:

- Add an Insight Group for the **Start/Stop/Transfer Insights - Account-Based** Insight Class. Link the Highlight Account Info - Inline (C1-ACCTINFO-INLINE) Insight Type to the Insight Group.
- Add an Insight Group for the **Start/Stop/Transfer Insights - Premise-Based** Insight Class. Link one or more of the following insight types:
 - Highlight Unique Accounts Had Service At Premise - Inline (C1-UNACCTSP-INLINE)
 - Highlight Life Support/Sensitive Load on Premise - Inline (C1-PREMLSSL-INLINE)
 - Highlight Open Cases - Inline (C1-CASEOPEN-INLINE)
 - Highlight Open Business Flags - Inline (C1-OPBUSFLG-INLINE)
 - Highlight Field Activity Type - Inline (C1-FLDACTTY-INLINE)
 - Highlight Pending Field Activity - Inline (C1-PENDFA-INLINE)
 - Highlight Premise Link To Parent Premise - Inline (C1-PRMPNT-INLINE)
 - Highlight Child Premises - Inline (C1-PRMCHILD-INLINE)
 - Highlight Premise Linked to Multiple Accounts - Inline (C1-PRMACCTS-INLINE)
 - Highlight Landlord - Inline (C1-LANDLORD-INLINE)
- Add an Insight Group for the **Start/Stop/Transfer Insights - Service-Based** Insight Class. Link the Highlight Premise Service Info - Inline (C1-PREMSVC-INLINE)

Maintaining Customer Service Requests

This portal is used to display and maintain a Customer Service Request.

Refer to [Understanding Customer Service Requests](#) on page 183 for more details.

To view and maintain customer service requests, open **Menu > Customer Information > Customer Service Request > Search**. You are brought to a query portal with options for searching for customer service requests.

Once a customer service request record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones are displayed:

- **Customer Service Request** zone shows the details of the customer service request.
- **Customer Service Request Person** shows the related person(s). Select a record to go to the specific portal where the details can be viewed and maintained.
- **Customer Service Request Account** shows the related account(s). Select a record to go to the specific portal where the details can be viewed and maintained.
- **Customer Service Request Premise** shows the related premise(s). Select a record to go to the specific portal where the details can be viewed and maintained.
- **Customer Service Request SA** shows the related service agreement(s). Select a record to go to the specific portal where the details can be viewed and maintained.
- **Customer Service Request Contract** shows the related contract(s). Select a record to go to the specific portal where the details can be viewed and maintained.
- **Customer Service Request Contract Product** shows the related contract product(s). Select a record to go to the specific portal where the details can be viewed and maintained.

- **Customer Service Request Service Location** shows the related service location(s). Select a record to go to the specific portal where the details can be viewed and maintained.
- **Customer Service Request Related Object** shows other related entities.

Refer to the zones' embedded help for more information.

Maintaining Customer Service Request Person

This portal is used to display and maintain a Customer Service Request Person.

This portal is displayed when a record is selected from the **Customer Service Request Person** zone on the Customer Service Request portal. Refer to [Maintaining Customer Service Requests](#) on page 189 for more details.

The **Customer Service Request Person** zone shows the details of the related person. Refer to the zone's embedded help for more information.

Maintaining Customer Service Request Account

This portal is used to display and maintain a Customer Service Request Account.

This portal is displayed when a record is selected from the **Customer Service Request Account** zone on the Customer Service Request portal. Refer to [Maintaining Customer Service Requests](#) on page 189 for more details.

The **Customer Service Request Account** zone shows the details of the related account. Refer to the zone's embedded help for more information.

Maintaining Customer Service Request Premise

This portal is used to display and maintain a Customer Service Request Premise.

This portal is displayed when a record is selected from the **Customer Service Request Premise** zone on the Customer Service Request portal. Refer to [Maintaining Customer Service Requests](#) on page 189 for more details.

The **Customer Service Request Premise** zone shows the details of the related premise. Refer to the zone's embedded help for more information.

Maintaining Customer Service Request SA

This portal is used to display and maintain a Customer Service Request SA.

This portal is displayed when a record is selected from the **Customer Service Request SA** zone on the Customer Service Request portal. Refer to [Maintaining Customer Service Requests](#) on page 189 for more details.

The **Customer Service Request SA** zone shows the details of the related SA. Refer to the zone's embedded help for more information.

Maintaining Customer Service Request Contract

This portal is used to display and maintain a Customer Service Request Contract.

This portal is displayed when a record is selected from the **Customer Service Request Contract** zone on the Customer Service Request portal. Refer to [Maintaining Customer Service Requests](#) on page 189 for more details.

The **Customer Service Request Contract** zone shows the details of the related contract. Refer to the zone's embedded help for more information.

Maintaining Customer Service Request Contract Product

This portal is used to display and maintain a Customer Service Request Contract Product.

This portal is displayed when a record is selected from the **Customer Service Request Contract Product** zone on the Customer Service Request portal. Refer to [Maintaining Customer Service Requests](#) on page 189 for more details.

The **Customer Service Request Contract Product** zone shows the details of the related contract product. Refer to the zone's embedded help for more information.

Maintaining Customer Service Request Service Location

This portal is used to display and maintain a Customer Service Request Service Location.

This portal is displayed when a record is selected from the **Customer Service Request Service Location** zone on the Customer Service Request portal. Refer to [Maintaining Customer Service Requests](#) on page 189 for more details.

The **Customer Service Request Service Location** zone shows the details of the related service location. Refer to the zone's embedded help for more information.

Meter Management

In addition to **meters**, the system also supports the definition and installation of non-metered devices. We use the term **item** to reference these non-metered devices. In this section, we describe how you set up and install both types of devices at service points.

Background Topics

The topics in this section provide background information about a variety of meter and item related issues.

Meters versus Items versus Equipment

Fastpath:

Refer to [The Big Picture of Meters, Items and Equipment](#) for the details.

Meters & The V

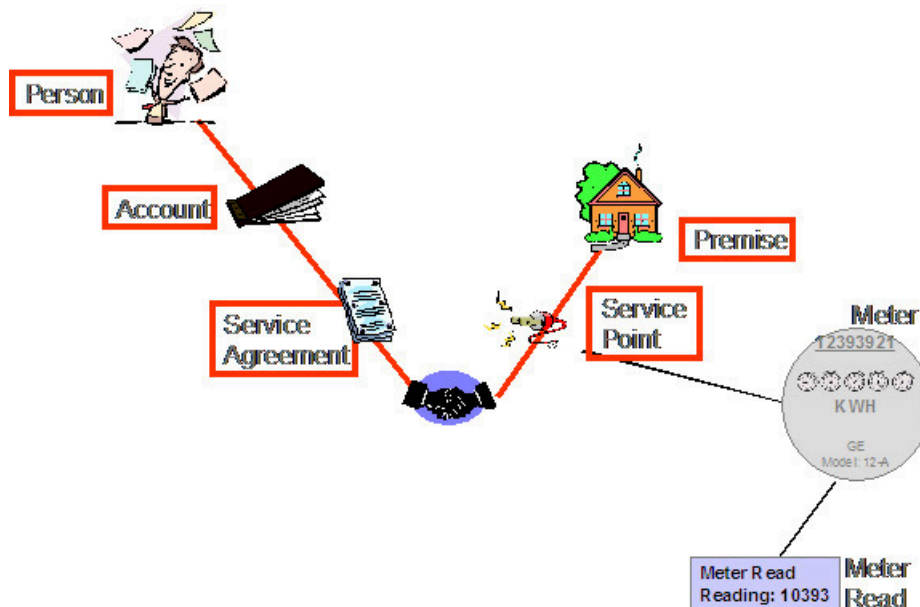

Note:

The "V". The "V" is the nickname given to the demographic and geographic information that forms the heart of your CIS system. This section assumes you are familiar with the "V". If you aren't, refer to [Understanding The "V"](#).

Over time, a meter may be installed at many service points and a service point may have many meters installed at it (but at any instant in time, only one meter may be installed at a service point).

The meter installed at a service point measures the consumption used at a service point. It's quite possible for a single meter's consumption to be billed on multiple service agreements because its service point may be linked to multiple service agreements. This is necessary, for example, when water consumption is used to bill both water and sewage service agreements. Another example might be when electric consumption is used to bill both transportation and energy service agreements.

The following illustration will help you visualize the relationship between a meter and the "V".

Items & The V

Note:

The "V". The "V" is the nickname given to the demographic and geographic information that forms the heart of your CIS system. This section assumes you are familiar with the "V". If you aren't, refer to [Understanding The "V"](#).

If there are charges in your rates based on the number and type of items installed at a service point (e.g., lamp charges), you must use either of the following techniques:

- If the item is badged (i.e., uniquely identified), you would set up an item and link it to an **item - based** service point. An item-based service point may have zero or one item installed at any instant in time. Over time, an item-based service point may have many badged items installed and removed. Refer to [Installing / Removing An Item](#) for more information.
- If the item does not have a unique identifier, you do NOT have to set up phony items for it. Rather, you can use the system's multi-item functionality and simply define the number of each TYPE of item that is installed at a service point. Refer to [Service Points With Multiple Items](#) for an illustration of such a service point.

Note:

Another way to think of an item is something that does NOT measure consumption, but impacts billing in some way. Examples include streetlights, light poles, and security cameras.

Warning:

The above example illustrated a service point that has a single item installed at it at any one point in time. We use the term "**badged item**" to reference the thing that can be installed at such a service point (because it has a unique ID that appears on a badge). In addition to badged items, you can install an unlimited number of **non-badged** items at any type of service point. Refer to [Service Points \(SPs\)](#) for more information.

Gaining Access To The V Using Meter/Item Search

The topics in this section describe the Meter/Item Search page.

Meter/Item Search - Main

Note:

Definition of a "device". In the following discussion, we refer to meters and items interchangeably using the term "device".

This page contains functionality that helps you:

- Find where a device is installed and who pays for the device.
- Find the devices associated with a person, account, premise or service point.
- Navigate to pages that contain information related to a device, its service point, its account(s) and its service agreement(s). For example,
 - After finding the meters related to account 1929210192, you could navigate to the page where a meter read is added for one of the meters.
 - After finding the account that pays for lamp BY10291, you could navigate to Control Central to view summary information about the customer.
 - Etc.

Fastpath:

For more information about the relationships between devices and your customers and premises, refer to [Understanding The "V"](#), [Meters and The V](#), and [Items and The V](#).

To look for a device or the customer associated with a device, open **Menu > Meter > Meter / Item Search**.

Description of Page

The top half of the page is where you enter criteria used to search for a device.

In **Search Type**, you define the type of devices that you want to search for. You have the following options:

All This value means that you want to search for meters AND items. You'd use this, for example, if you wanted to search for all meters and items linked to a given customer. This is the default value.

Meter This value means that you want to search for meters (and exclude items).

Item This value means that you want to search for items (and exclude meters).

After defining the appropriate **Search Type**, you then define how to search for the device. The following search methods are available:

Note:

Closed service agreements are ignored. When the system displays a device's **Account** and **Service Agreement Information**, it ignores closed service agreements. This means that if a device is installed at a service point that is only linked to closed service agreements, no **Account** or **Service Agreement Information** will be displayed for the device.

| Search Method | Description |
|---------------|---|
| Person Name | <p>Use this field to search for the devices associated with an account using a person's name. The person may be the main customer on the account or a third party related to the account.</p> <p>You can enter all or part of the person's name. If the person is a business, enter all or part of the business name. If the person is a human, you must enter the name in the format Last,First (e.g., Walton,Richard).</p> <p>The name search is not case sensitive.</p> <p>This search method cannot be combined with other search methods.</p> <p>Please be aware that only persons whose accounts have devices installed will appear in the search results at the bottom of the page.</p> <p>Also note, ALL devices that were ever installed at a person's account(s) are displayed, even if the device has been subsequently replaced.</p> |

Account ID

Use this field to search for the devices associated with a given account ID.

You can enter all or part of the account ID.

This search method cannot be combined with other search methods.

Please be aware that only accounts that have devices installed will appear in the search results at the bottom of the page.

Also note, ALL devices that were ever installed at an account are displayed, even if the device has been subsequently replaced.

SA ID

Use this field to search for the devices associated with a given service agreement ID.

You can enter all or part of the SA ID.

This search method cannot be combined with other search methods.

Please be aware that only service agreements that have devices installed will appear in the search results at the bottom of the page.

Also note, ALL devices that were ever installed a service agreement are displayed, even if the device has been subsequently replaced.

SP ID

Use this field to search for the devices associated with a given service point ID.

You can enter all or part of the SP ID.

This search method cannot be combined with other search methods.

Please be aware that only service points that have devices installed will appear in the search results at the bottom of the page.

Also note, ALL devices that were ever installed a service point are displayed, even if the device has been subsequently replaced.

Premise ID

Use this field to search for the devices associated with a given premise ID.

You can enter all or part of the premise ID.

This search method cannot be combined with other search methods.

Please be aware that only premises that have devices installed will appear in the search results at the bottom of the page.

Also note, ALL devices that were ever installed at a premise are displayed, even if the device has been subsequently replaced.

Address

Use this field to search for the devices installed at a premise using the first line of a service address.

You can enter all or part of the first line of the address. For example, if you're looking for 324 Hawthorne Lane, you can enter 324 Haw rather than the entire address.

The address search is not case sensitive.

Address may be combined with the **City** and **Postal** search methods. Otherwise, this search method cannot be combined with other search methods.

Please be aware that only premises that have devices installed will appear in the search results at the bottom of the page.

Also note, ALL devices that were ever installed at the premise are displayed, even if the device has been subsequently replaced.

City

Use this field to search for the devices installed at a premise using a city name associated with a service address.

You can enter all or part of the city name. For example, if you're looking for someone in San Francisco; you can enter San Fra, San F, San Francisco, etc.

The city search is not case sensitive.

We strongly recommend qualifying a **City** search with and **Address** or **Postal** code, otherwise the resultant list can be too large to deal with. Otherwise, this search method cannot be combined with other search methods.

Please be aware that only premises that have devices installed will appear in the search results at the bottom of the page.

Also note, ALL devices that were ever installed at the premise are displayed, even if the device has been subsequently replaced.

Postal

Use this field to search for the devices installed at a premise using a postal code associated with a service address.

You can enter all or part of the postal code.

The postal code search is case sensitive.

We strongly recommend qualifying a **Postal** search with and **Address** or **City**, otherwise the resultant list can be too large to deal with. Otherwise, this search method cannot be combined with other search methods.

Please be aware that only premises that have devices installed will appear in the search results at the bottom of the page.

Also note, ALL devices that were ever installed at the premise are displayed, even if the device has been subsequently replaced.

Badge Number

Use this field to find where a device is installed and who pays for the device by entering the device's badge number.

You can enter all or part of the device's badge number.

This search option is case sensitive.

This search method cannot be combined with other search methods.

Also note,

- For meters, only customers associated with the latest configuration of the meter are displayed.

- For items, all customers associated with the item are displayed.

SP Geo Type and SP Geo Value

Use this field to search for the devices installed at a service point by using one of the service point's Geo Types / Values. Refer to [Service Point - Geographic Information](#) for more information about Geo Types / Values.

If you use this method, you must select an **SP Geo Type** and enter all or part of the **SP Geo Value**.

This search option is case sensitive.

This search method cannot be combined with other search methods.

Please be aware that only service points that have devices installed will appear in the search results at the bottom of the page.

Also note, ALL devices that were ever installed at the service point are displayed, even if the device has been subsequently replaced.

Meter ID Type and Meter ID Number Use these fields to find where a meter is installed and who pays for the meter by entering one of the meter's alternate ID's. Refer to [Meter - Meter ID](#) for more information about Meter ID Types / Numbers.

If you use this method, you must select a **Meter ID Type** and enter all or part of the **Meter ID Number**.

This search option is case sensitive.

This search method cannot be combined with other search methods.

Also note, only customers associated with the latest configuration of the meter are displayed.

The system shows the results of your search request in the grid at the bottom of the page. The following information appears in the grid:

Note:

Use the context menus to navigate elsewhere. Please be aware that the context menus that prefix each cell provide a simple means to navigate to pages related to the meters / service points / accounts / service agreements.

Meter / Item Information This contains a concatenation of important information about the device. This information includes (but is not necessarily limited to) the device's type, badge number, serial number, and status.

SP Information This contains a concatenation of important information about the service point at which the device is installed. This information includes (but is not necessarily limited to) the service point's type, service cycle, premise address, and premise type. If the meter has never been installed at a service point, this column will be blank.

Account Information This contains a concatenation of important information about the account who pays for the device. This information includes (but is not necessarily limited to) the name of the main customer linked to the account, the customer class, and account ID. If the meter has never been installed at a service point or the service point is not linked to a service agreement, this column will be blank.

SA Information This contains a concatenation of important information about the service agreement that is linked to the device. This information includes (but is not necessarily limited to) the division / SA type, start option, status, and effective period. If the meter has never been installed at a service point or the service point is not linked to a service agreement, this column will be blank.

Blank column This column contains a "go to" button that will transfer you to the [SA / SP page](#) where you can see details about this service point's relationship to the service agreement.

Geographic Value This column only appears if you have used the SP Geo Type/Value search option. It will contain the geographic value associated with the service point.

Meter ID Number This column only appears if you have used the Meter ID Type / Number search option. It will contain the meter ID number associated with the meter.

Maintaining Meters

Meter records contain information about your meters. The topics in this section describe the pages on which meter-related information is maintained.

After you have set up the core meter information, navigate to [Maintaining Meter Configurations](#) to define how the meter's registers are configured.

If you need to create several copies of a given meter and its configuration, navigate to [Meter Replicator - Main Information](#).

Meter - Main Information

The Main page contains core meter information. Open this page using **Menu > Meter > Meter > Search**.

Description of Page

The following meter information is displayed at the top of the page:

Meter Info The description of the meter type concatenated with the meter's badge number and status.

Meter ID This is a system-assigned random number that stays with a meter for life. This value only appears after the meter exists on the database.

Premise ID The unique identifier of the premise at which the meter is installed (or was last installed).

Note:

Who pays for service? Use the Premise Context Menu to navigate to Control Central to see information about the customer linked to the current/last service point at which the meter is/was installed.

Service Point Information about the service point at which the meter is installed (or was last installed).

Install Date The date the meter was installed at its last location.

Removal Date The date the meter was removed from its last location.

The remaining fields are maintained on the remainder of this page.

The **Badge Number** is the identifier stamped on the meter. This is NOT the manufacturer's serial number. Rather, it's the number on the badge that typically appears on the face of the meter. This number is what most operators use to identify the meter.

Note:

Duplicate Badge Numbers. If the meter's meter type allows duplicate badge numbers, multiple meters of a given meter type may have the same badge number. Otherwise, duplicate badge numbers are not allowed for a given meter type.

Indicate the **Meter Type**. This field is very important as it defines the type of service associated with this meter. It also defines characteristics common to all meters of a given type and the type of equipment that can be linked to the meter.

Use the **Meter Status** to indicate if the meter is Active, Ordered, or Retired.

Note:

The values for the meter status field are customizable using the Lookup table. This field name is MTR_STATUS_FLG.

Define the meter's **Manufacturer** and **Model**.

Enter the manufacturer's **Serial Number**.

Use **Date Received** to define the date on which the meter was received from the manufacturer.

Use **Date Retired** to define the date when the meter is retired from service. This field is gray when the meter status is Active or Ordered.

Use **Retire Reason** to define why the meter was retired from service. This field is gray when the meter status is Active or Ordered.

Use **Comments** to describe unusual characteristics of the meter.

The **Meter Configuration** scroll/grid combination contains an overview of the meter's configurations and each configuration's registers. This information is not modifiable on this page. To modify this information, use the **Meter Configuration** context menu to transfer to the **Meter Configuration** page. Refer to [Meter Configuration Maintenance](#) for a description of the fields in the scroll and grid.

Meter - Meter ID

A meter may have alternate ID's other than its badge number. If it does, each alternate form of ID is defined using the **Menu > Meter > Meter > Search** and navigate to the **Meter ID** page.

Description of Page

To modify a meter ID, simply move to a field and change its value. To add a new alternate form of identity, click + to insert a row, then fill in the information for each field. The following fields display:

Meter ID Type Indicate the type of meter ID.

Meter ID Number Indicate the alternate meter id.

Where Used

The data on this page is used by the meter read upload process to identify the meter configuration that is being read. Refer to [Uploading Meter Reads](#) for more information.

Meter - Characteristics

The characteristics page contains information that describes miscellaneous information about the meter. Use **Menu > Meter > Meter > Search** and navigate to the **Characteristics** page.

Description of Page

Meter Info is a concatenation of the meter's meter type and badge number.

Meter ID is the system-assigned random number that stays with a meter for life. This value only appears after the item exists on the database.

To modify a characteristic, simply move to a field and change its value. To add a new characteristic, click the + button to insert a row, then fill in the information for each field. The following fields display:

Effective Date Indicate the date on which the characteristic value becomes effective. The meter's date received defaults.

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Note:

Default note. If the meter's meter type has required characteristics, the respective characteristic types will default in the above grid.

Meter - SP Installation History

The SP Installation History is an information-only page that shows the history of service points at which the meter has been installed. Use **Menu > Meter > Meter > Search** and navigate to the **SP Installation History** page.

This page shows the history of the service points at which the meter has been installed. No fields on this page may be modified.

Meter - Equipment

The equipment page contains the equipment that is linked to the meter. Use **Menu > Meter > Meter > Search** and navigate to the **Equipment** page. Refer to [Equipment May Be Associated With Meters](#) for more information.

Description of Page

To modify a piece of equipment, simply move to a field and change its value. To add a new piece of equipment, press + to insert a row, then fill in the information for each field. The following fields display:

Equipment ID Indicate the unique identifier of the equipment.

Note:

This is actually the unique ID of an item as an item must be set up for each piece of equipment that can be linked to a meter. Only items with an item type defined on the meter's meter type's equipment collection may be defined (in other words, the valid types of equipment are defined on the meter's meter type).

Badge Number This is a display-only field that contains the equipment's badge number.

Equipment Type This is a display-only field that contains a description of the equipment's item type.

Equipment Count This field should be 1 except when you are using an item to define a generic piece of equipment. If you use an item to define a generic piece of equipment, you can indicate the number of such generic pieces of equipment that are associated with this meter.

Install Date Define the date that the equipment was installed at the meter.

Removal Date Define the date that the equipment was removed from the meter.

Comment Enter a comment to explain anything unusual about the piece of equipment.

Meter - Location History

The meter location history page has two purposes:

- You can view the history of the service points and stock locations at which a meter has been located.
- You can change a meter's current stock location if it is not installed at a service point.

It's important to be aware that location history is only recorded when the meter's meter type indicates that its location is tracked. Refer to [The Big Picture of Asset Inventory](#) for further information.

Use **Menu > Meter > Meter > Search** and navigate to the **Location History** page.

Description of Page

The rows in the grid show where the meter has been located over its lifetime. The following types of rows may be displayed:

- When a meter is installed at a service point, a stock location history record is created with a **Location History Type** of SP Install.
 - **Location Date/Time** is the time of installation. This may not be modified.
 - **Location** is the service point at which the meter is installed. This may not be modified.
- When a meter is removed from a service point, a stock location history record is created with a **Location History Type** of SP Removal.
 - **Location Date/Time** is the time of removal. This may not be modified.
 - **Location** is a stock location. This value is defaulted based on the [service point's postal defaults](#). You may change this **Location** if the defaulted value is incorrect.
- When a new meter is added, you must create a location history record to define the stock location at which the meter is stored.
 - Enter the **Date/ Time** the meter was received.
 - The **Location History Type** is defaulted to Stock.
 - Use **Location** to define the stock location where the item is being stored.

- If a meter is transferred from one stock location to another, you must create a location history record as described above.

To create a new location history record, click the + button to insert a row, then fill in the information for each field.

Note:

Location history may have gaps. A meter's [Stock Location History Is Created Behind the Scenes](#) and is only created if stock location is being tracked.

Meter - Meter Tree

The meter tree page contains high-level information about various objects linked to the meter. Use **Menu > Meter > Meter > Search** and navigate to the **Meter Tree** page.

Description of Page

This page is dedicated to a **tree** that shows the various objects linked to the meter. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Meter – Meter Portal

Select **Menu > Meter > Meter > Search** and navigate to the **Meter Portal** page to view additional information associated with a Meter.

Depending on your implementations requirements, you may define additional zones to appear on this Portal.

The contents of this section describe the zones that are available on this portal page.

General Information

Meter ID, **Meter Info** are displayed.

Maintaining Meter Configurations

A meter's registers are defined in respect of an effective-dated meter configuration. When you reconfigure a meter's registers, you add a new configuration with an effective date equal to the reconfiguration date. Whenever you add a configuration, you must specify how *all* of the registers look on the configuration date; you don't just specify those registers that have changed.

Every meter must have at least one configuration, otherwise the system doesn't know what it measures and meter reads cannot be specified for the meter. A meter without meter reads cannot be billed (or linked to a service agreement!).

A meter configuration has one or more registers. The number is dependent on how many things are measured. For example, if you have a meter that measures kilowatt-hours and kilovolt-amperes, its configuration will have two registers.

Fastpath:

For more information about meter configurations, refer to [The Structure of a Meter](#).

Changing A Configuration

Because meter configurations are effective-dated, you have to deal with the difference between correcting an incorrect configuration and introducing a new configuration.

- You *correct* a configuration if you entered some part of the information about the configuration in error (e.g. a five-digit register is recorded as having four digits).

- You introduce a *new* configuration when you reconfigure the meter. All of the existing information was accurate at the time it was entered, but now something about the meter's configuration has changed. The historical information is retained intact, and the new configuration has its own unique identity on the system.

You are allowed to correct an historical configuration, but be careful. You see, meter reads reference a configuration and its registers. If you change an historical register's unit of measure, you are changing the unit of measure of *all of the meter reads* associated with this register - past *and* future. This system allows you to do this, just be aware of what you're doing.

You cannot introduce a configuration while the meter is installed at a service point (i.e., the effective date of the configuration cannot overlap with the effective date period of any SP Installation History). Think about it, you can't reconfigure the meter while it's measuring consumption. To reconfigure a meter after it's been installed at a service point:

- Remove the meter from the service point using [SP / Meter Installation](#). To do this, you'll be required to specify a meter read showing how the registers looked when the meter was removed (and you can do this from this page).
- Next, add a new meter configuration using [Meter Configuration Maintenance](#) effective on the reconfiguration date. Specify how the registers look after reconfiguration on the new configuration.
- If you need to reinstall the meter at the service point, return to [SP / Meter Installation](#) and add a new installation. To do this, you'll be required to specify a meter read showing how the registers look at installation time (and you can do this from this page). As you know, the registers are typically reset at installation, but we haven't made this assumption in the system.

Note:

Field activities simplify life. Rather than remembering the steps necessary to perform a meter reconfiguration on an installed meter, you should have a field activity type set up with the three steps. If such an activity type exists, you simply create a field activity referencing this type and when you complete it, you can do the three steps all at once.

Meter Configuration Maintenance

All meters must have an initial configuration that should be effective as of the date the meter was received. If you reconfigure the meter in the future, you must add a new effective-dated configuration to reflect how the meter is configured.

Warning:

Do not attempt to maintain a meter configuration unless you are familiar with the concepts discussed in [Changing A Configuration](#).

Meter Configuration - Main Information

Open **Menu** > **Meter** > **Meter Configuration** > **Search** to maintain a meter's configuration.

Please be aware that the information maintained on meter configurations associated with interval meters is slightly different than that for regular meters. The topics in this section describe how this page behaves for both types of meters.

Regular (Non Interval) Meter Configuration Maintenance

The following discussion describes how the **Meter Configuration** page behaves for regular (non interval) meters.

Note:

A meter is viewed as being an interval meter if its [meter type](#) indicates interval registers are allowed.

Description of Page

The following meter configuration information is displayed at the top of the page:

Meter Configuration The description of the meter type concatenated with the meter's badge number, the meter configuration effective date, the description of the meter configuration type and the number of registers.

Meter Configuration ID This is a system-generated unique identifier for the meter configuration. This value is assigned when the meter configuration is added to the database.

Meter ID The system-generated unique identifier for the meter.

Effective Date / Time Defines the date and time the configuration becomes effective.

Meter Configuration Type Controls the types of registers that may be defined on this meter configuration. When you select a meter configuration type, the system defaults these attributes in the register grid. Refer to [Setting Up Meter Configuration Types](#) for more information.

The **Registers** accordion contains information about the meter configuration's registers. To modify existing register information, click on the register's summary bar and then move to a field and change its value. To add a new register, click the + button in the accordion to insert a row then fill in the information for each field. The following fields display:

- **Sequence** defines the relative physical position of the register with respect to the other registers, if any.
- Use **Unit of Measure (UOM)** to define the [unit of measure](#) in which the register is calibrated.
- Use **Time of Use (TOU)** to define the [time-of-use](#) code, if any, that specifies a particular time of day during which the register measures consumption.
- **Register Constant** is used to derive billable consumption. Measured consumption is multiplied by this number to derive billable consumption.
- Use **Consumptive/Subtractive** to define how the system calculates consumption from the register's meter reads. For Subtractive registers, the system has to subtract the previous read from the current read. For Consumptive registers, the dial reading indicates how much was consumed and no subtraction is necessary.
- Most of your registers will be set to Subtractive unless you sell electricity. For most electric meters, kWh registers will be set to Subtractive, and kW meters will be set to Consumptive.
- Use **How To Use** to control how billing uses the consumption from the register. Use Additive if billing adds the register's consumption to other register's consumption (with the same UOM and TOU value). Use Subtractive if billing subtracts the register's consumption from other register's consumption (with the same UOM and TOU value). Use Peak if billing compares this register's consumption against other register's consumption (with the same UOM and TOU value) and uses the higher consumption value. Use Check if billing ignores the consumption associated with this register.
- Most of your registers will be set to Additive unless you sell electricity. On electric meters, kWh registers will be set to Additive, kW meters will be set to Peak.
- Use **Digits Left** and **Digits Right** to define the number of digits to the left and right of decimal place. This information is used to validate meter readings to ensure they do not exceed the dial's capacity.
- **Full Scale** is typically only specified on demand meters (but can be specified on any type). It is downloaded to the meter reading devices so they can warn the reader if the resulting consumption is close to or exceeds the register's maximum capacity.
- **Read Out Type** defines how the readings are displayed on the register.
- **Protocol** defines how the register is read.
- **Tolerance** is typically only specified on demand meters (but can be specified on any type). It is downloaded to the meter reading devices so they can warn the reader if the resulting consumption is close to or exceeds the tolerance of the register.
- **Channel ID** is used to record an external id that may exist for the register.
- **Register ID** is the unique system-assigned identifier of the register. This value is allocated when the register is added to the database. Note, the adjacent context menu is disabled for non-interval registers.

Characteristics

The **Characteristics** collection on the Meter Configuration page contains information that describes miscellaneous information about the meter configuration.

The following fields display:

Characteristic Type Indicate the type of characteristic.

Sequence Controls the order in which characteristics of the same type are displayed.

Characteristic Value Indicate the value of the characteristic.

Interval Meter Configuration Maintenance

The following discussion describes how the **Meter Configuration** page behaves for interval meters.

Note:

A meter is viewed as being an interval meter if its **meter type** indicates interval registers are allowed.

Description of Page

This section only highlights the fields that are different from **regular (non interval) meter configurations**.

Use the **Complete Data Sets** button if you have Pending datasets for the interval registers linked to the meter configuration and you would like the system to Complete them. When this button is clicked, all validation algorithms defined on the registers' **Interval Register Types** will be executed. If no errors are detected from the interval register types' validation algorithms OR if none of the interval register types contains validation algorithms, the pending data sets will be marked as complete. Refer to **Validation of Register Data for more information** about the validation algorithms.

The **Registers** accordion contains information about the meter configuration's registers. The following fields are unique to interval registers or have special behavior for interval registers:

- Turn on **Interval** if this register can have interval datasets associated with it.
- Use **Interval Register Type** to define the **interval register type** that controls business rules associated with an interval register's datasets. This field is disabled if **Interval** is turned off.
- Use **Time of Use (TOU)** to define the **time-of-use** code if any, that specifies a particular time of day during which the register measures consumption. This field is disabled if **Interval** is turned on.
- **Channel ID** is used to specify an external id for the register. It can be used, for example, to store the MV-90 channel ID suffix related to a specific register for interval meters.

Meter Configuration - Meter Configuration Tree

Open **Menu** > **Meter** > **Meter Configuration** > **Search** and navigate to the **Meter Configuration Tree** page to view a meter configuration's tree.

Description of Page

At the top of the page is a summary description of the Meter Configuration. At the right is the system-generated unique **Meter Configuration ID** for the meter.

This page displays a **tree** view of registers linked to the **Meter Configuration**. The root node displays the ID of the meter configuration along with its standard description.

The register nodes contained in the tree view are hyperlinks that navigate to the **Registers** accordion on the **Meter Configuration - Main Information** page.

- If any non-interval registers are associated with the meter configuration, a node is displayed for each register.
- If any interval registers are associated with the meter configuration, a node is displayed for each register. Expanding this node displays information about data sets linked to the interval register.
 - The **Pending Data Sets** node displays if any of the data sets linked to the register are pending. Expanding this node displays each pending data set.
 - The **Error Data Sets** node displays if any of the data sets linked to the register are in error. Expanding this node displays each error data set.
 - The **Data Created Through** node displays the date of the latest complete interval as of the current date. Expanding this node displays the last 10 complete data sets.

Meter Configuration – Meter Configuration Portal

Select **Menu > Meter > Meter Configuration > Search** and navigate to the **Meter Configuration Portal** page to view additional information associated with a Meter Configuration.

Depending on your implementations requirements, you may define additional zones to appear on this Portal.

The contents of this section describe the zones that are available on this portal page.

General Information

Meter Configuration ID, **Meter Configuration Info** are displayed.

Validating Register Constants

You can validate the register constants of all installed electric meters, by service cycle (the service cycle of the service points in which the meters are installed). This allows you to check and confirm, in mass, the entered constants for all meters.

This background process ([REGCNST](#)) selects all electric service points on the input service cycle. It uses CT (current transformer) and PT (potential transformer) equipment linked to SP to calculate register constant using the formula:

Calculated Register Constant = Product of all CT, PT ratios * Dial Constant

If the calculated register constant doesn't match to the actual register constant, a To Do entry is created.

In order for the process to know how to find the correct equipment and the correct ratios, control tables need to be set up appropriately and parameters for the background processes need to be defined accordingly.

- Equipment is set up through the use of Items. You will define an Item Type to be used for CT equipment and another to be used for PT equipment.
- The CT Ratio will need to be defined using a Characteristic Type for the CT Item.
- The PT Ratio will need to be defined using a Characteristic Type for the PT Item.
- The Dial Constant will need to be defined using a Characteristic Type for the Meter.

In order for the background process to work correctly, the following input parameters will need to be populated:

- Service Cycle
- Item Type to identify the CT Equipment
- Item Type to identify the PT Equipment
- Characteristic Type to identify the CT Ratio
- Characteristic Type to identify the PT Ratio
- Characteristic Type to identify the Dial Constant
- To Do Type and To Do Role

Fastpath:

Refer to [Register Constant Validation Process](#) for more information.

Maintaining Items

Item records contain information describing badged items that exist at service points. Item records are also used to describe equipment that is linked to meters, service points, and other items.

Fastpath:

Refer to [Equipment versus Badged Items](#) for more information.

The topics in this section describe the pages on which item-related information is maintained.

Item - Main Information

The Main page contains core item information. To open this page, use **Menu > Meter > Item > Search**.

Description of Page

The following item information is displayed at the top of the page:

Item Info A concatenation of the item's item type, badge number and status.

Item ID This is a system-assigned random number that stays with an item for life. This value only appears after the item exists on the database.

Premise ID The unique identifier of the premise at which the item is installed.

Service Point Information about the service point at which the item is installed.

Install Date The date the item was installed at its current location.

Removal Date The date the item was removed from its last location.

The remaining fields are maintained on the remainder of this page.

Use **Badge Number** to define the identifier stamped on the item. This is NOT the manufacturer's serial number. Rather, it's the number on the badge that typically appears on the face of the item. This number is what most operators use to identify the item.

Indicate the **Item Type**. This field is important as it defines the type of service associated with this item. It also defines characteristics common to all items of a given type and the type of equipment that can be linked to the item.

Use the **Item Status** to indicate if the item is Active, Ordered, or Retired.

Define the item's **Manufacturer** and **Model**.

Enter manufacturer's **Serial Number**.

Use **Date Received** to define the date on which the item was received from the manufacturer.

Use **Date Retired** to define the date when the item is retired from service. This field is gray when the item status is Active or Ordered.

Use **Retire Reason** to define why the item was retired from service. This field is gray when the item status is Active or Ordered.

Enter any comments about the item in the **Comments**.

The tree at the bottom of the page is only relevant for items used to define pieces of equipment as it contains the following information:

- Every service point to which a piece of equipment is linked
- Every meter to which a piece of equipment is linked
- Every item to which a piece of equipment is linked

Item - Characteristics

The characteristics page contains information that describes miscellaneous information about the item. Use **Menu > Meter > Item > Search** and navigate to the **Characteristics** page to maintain Item information.

Description of Page

Item Info is a concatenation of the item's item type, badge number and status.

Item ID is the system-assigned random number that stays with an item for life. This value only appears after the item exists on the database.

To modify a characteristic, simply move to a field and change its value. To add a new characteristic, click the + button to insert a row, then fill in the information for each field. The following fields display:

Effective Date Indicate the date on which the characteristic value becomes effective. The item's date received defaults.

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Note:

Default note. If the item's item type has required characteristics, the respective characteristic types will default in the above grid.

Item - SP Installation History

The SP Installation History is an information-only page that shows the history of service points at which the item has been installed. Use **Menu > Meter > Item** and navigate to the **SP Installation History** page.

This page shows the history of the service points at which the item has been installed. No fields on this page may be modified.

Item - Equipment

The equipment page contains the equipment that is linked to the item. Use **Menu > Meter > Item > Search** and navigate to the **Equipment** page. Refer to [Equipment May Be Associated With Other Items](#) for more information.

Description of Page

To modify a piece of equipment, simply move to a field and change its value. To add a new piece of equipment, click + to insert a row, then fill in the information for each field. The following fields display:

Equipment ID Indicate the unique identifier of the equipment.

Note:

This is actually the unique ID of an item as an item must be set up for each piece of equipment that can be linked to an item. Only items with an item type defined on the item's item type's equipment collection may be defined (in other words, the valid types of equipment are defined on the item's item type).

Badge Number This is a display-only field that contains the equipment's badge number.

Equipment Type This is a display-only field that contains a description of the equipment's item type.

Equipment Count This field should be 1 except when you are using an item to define a generic piece of equipment. If you use an item to define a generic piece of equipment, you can indicate the number of such generic pieces of equipment that are associated with this item.

Install Date Define the date that the equipment was installed at the item.

Removal Date Define the date that the equipment was removed from the item.

Comments Use comments to explain anything unusual about the piece of equipment.

Item - Location History

The item location history page has two purposes:

- You can view the history of the service points and stock locations at which an item has been located.
- You can change an item's current stock location if it is not installed at a service point.

It's important to be aware that location history is only recorded when the item's item type indicates that its location is tracked. Refer to [The Big Picture of Asset Inventory](#) for further information.

Use **Menu > Meter > Item > Search** and navigate to the **Location History** page.

Description of Page

The rows in the grid show where the item has been located over its lifetime. The following types of rows may be displayed:

- When an item is installed at a service point, a stock location history record is created with a **Location History Type** of SP Install.
 - **Location Date/Time** is the time of installation. This may not be modified.
 - **Location** is the service point at which the meter is installed. This may not be modified.
- When an item is removed from a service point, a stock location history record is created with a **Location History Type** of SP Removal.
 - **Location Date/Time** is the time of removal. This may not be modified.
 - **Location** is a stock location. This value is defaulted based on the [service point's postal defaults](#). You may change this **Location** if the defaulted value is incorrect.
- When a new item is added, you must create a location history record to define the stock location at which the item is stored.
 - Enter the **Date/Time** the item was received.
 - The **Location History Type** is defaulted to Stock.
 - Use **Location** to define the stock location where the item is being stored.
- If an item is transferred from one stock location to another, you must create a location history record as described above.

To create a new location history record, click the + button to insert a row, then fill in the information for each field.

Note:

Location history may have gaps. An item's [Stock Location History Is Created Behind the Scenes](#) and is only created if stock location is being tracked.

Installing / Removing A Meter

The installation of a meter is a small part of the process of starting / stopping service. This process begins when a customer requests service at a metered service point that is, at present, without service. It continues with the creation of a field activity required to connect service. When the system is advised of the results of the field activity, it creates a SP / Meter history record (which you can see on this page).

The removal of a meter from a service point involves an exactly analogous process where you use the SP / Meter Installation page to indicate when the meter was removed (and the dial readings at that time).

The remainder of this section is limited to a discussion about how to use the SP / Meter Installation page.

Fastpath:

For more information about starting / stopping service, refer to [The Big Picture Of Starting Service](#) and [The Big Picture Of Stopping Service](#). For more information about how the results of a field activity are advised to the system, refer to [How Does A Field Order Get Completed?](#). **For more information** about setting up field activity types to install and remove meters from service points, refer to [Setting Up Field Activity Types](#).

SP / Meter Installation

The system automatically updates the information on this page when field activities that affect a meter's installation status (i.e., installs, removes, on/off) are completed via [Field Activity Upload Staging](#). You should only have to change the information on this page when you need to fine-tune what the system sets up by default.

Open **Menu > Meter > SP / Meter Installation > Search** to update a meter's installation information.

Description of Page

The following information is displayed at the top of the page:

SP/Meter History This is a concatenation of meter and service point information. This information only appears after the SP/item history record exists on the database.

SP/Meter History ID This is a system-assigned random number that stays with a SP/meter history record for life. This value only appears after the SP/meter history record exists on the database.

The remaining fields are maintained on the remainder of this page.

Service Point ID is the ID of the service point at which the meter is installed.

Note:

SP Type Restrictions. The service point's SP Type controls whether or not a meter can be installed at the service point, and if so, what type of meter can be installed. Refer to [Setting Up Service Point Types](#) for more information.

Meter Configuration ID indirectly identifies the meter that is installed at the service point. A configuration may be associated with exactly one meter at any given point in time. Therefore, identifying the configuration also identifies the meter. Adjacent to the configuration ID is summary information about the configuration and the meter with which it is currently associated. This information consists of the description of the meter type of the meter, the meter's badge number, the effective date and time of the configuration, and the number of registers.

Use the **Installation** information to define the readings on the meter's register(s) when the meter is installed. To do this you must:

- Enter the installation **Meter Read ID** that shows how the meter's register(s) look at installation time. If you need to view or modify the read, click the context menu and transfer to the meter read.

Note:

The installation date and time of the meter is the installation meter read's date/time.

- Use **Meter On/Off Status** to define if the meter is turned on or off when it's INITIALLY installed. Valid values are On and Off. This status does not affect billing in any way. It is purely informational.
- Override the **Installation Constant** (i.e., set it to a value other than 1), if equipment is linked to this service point that affects the calculation of the constant used to manipulate the meter's consumption at billing time. It's important to be aware that this value is multiplied by the meter's registers' respective constants when billing determines the amount of consumption associated with a meter. Typically, only large industrial service points will have a value other than 1. Note that when you want to change the installation constant for a service point you must perform an 'office exchange'. This means that you should remove the current meter and reinstall it. On the new install, specify the new installation constant - this way billing will recognize the new constant and adjust the billable quantities correctly.

Note:

Default note. The **Installation Constant** defaults to a value of 1 for the first meter configuration installed at a service point. The installation constant for subsequent meter configurations is defaulted to the value of the latest meter configuration's installation constant.

Warning:

Entering a meter configuration and install meter read is an important part of installing a meter at a service point. However, if the installation was done in order to activate a service agreement, you also must reference the install meter read as the start read on the respective service agreement / service point linkage. The system sets this linkage up for you if: a) the meter installation is done as part of a field activity, and b) the field

activity is linked to the service agreement / service point linkage as its start activity. Refer to [Starting Service & Field Activities](#) for more information.

Use the **Removal** information to define the readings on the meter's registers when the meter is removed. To do this you must:

- Enter the removal **Meter Read ID** that shows how the meter's register(s) look at removal time. If you need to view or modify the read, click the context menu and transfer to the meter read.

Note:

The removal date and time of the meter is the removal meter read's date/time.

Warning:

Entering a removal meter read is an important part of removing a meter. However, if the removal was done in order to stop service, you must also reference the removal meter read as the stop read on the respective service agreement / service point linkage. The system sets this linkage up for you if: a) the meter removal is done as part of a field activity, and b) the field activity is linked to the service agreement / service point linkage as its stop activity. Refer to [Starting Service & Field Activities](#) for more information.

- **Stock Location** only appears if the meter's meter type tracks location. Enter the stock location where the meter is stored upon removal. Refer to [The Big Picture Of Asset Inventory](#) for more information.

The **Meter On/Off History** grid contains the history of when the meter has been turned on and off while it's installed at a service point.

When a meter's on/off status changes, insert a new entry into the grid by clicking the + button. Then,

- Enter the **On/Off Meter Read ID** that shows how the meter's dials look when the status is changed. When this field is populated, the meter **Read Date/Time** appears adjacent to it.
- Use **Meter On/Off Status** to define if the meter is turned on or off. Valid values are On and Off.

A unique **Sequence** number is given to each entry after the information is saved.

Warning:

The on/off status does not affect billing in any way. So, for example, if you turn a meter off and never expire the service agreement / service point link, the meter will still be amalgamated by billing (although it's consumption should be zero). This is intentional as many meters are turned off as part of the credit and collections process when a customer is delinquent (but the service point is still linked to the service agreement in case the customer pays up).

SP Meter Installation History

The SP installation history page is an information-only page that shows the meters that have been installed at the service point. Use **Menu > Meter > SP / Meter Installation > Search** and navigate to the **SP Installation History** page.

Description of Page

This page shows the history of the meters that have been installed at the service point. No fields on this page may be modified.

Installing / Removing An Item

The installation of an item is a small part of the process of starting / stopping service. This process begins when a customer requests service at an item-based service point without an item. It continues with the creation of a field activity to connect service. When the system is advised of the results of the field activity, it creates a SP / Item history record (which you can see on this page).

The removal of an item from a service point involves an exact analogy where you use the SP / Item Installation page to indicate when the item was removed.

The remainder of this section is limited to a discussion about how to use the SP / Item Installation page.

Fastpath:

For more information about starting / stopping service, refer to [The Big Picture Of Starting Service](#) and [The Big Picture Of Stopping Service](#). For more information about how the results of a field activity are advised to the system, refer to [How Does A Field Order Get Completed?](#). **For more information** about setting up field activity types to install and remove meters from service points, refer to [Setting Up Field Activity Types](#).

SP / Item Installation

The system automatically updates the information on this page when field activities that affect an item's installation status (i.e., installs, removes, on/off) are completed via [Field Activity Upload Staging](#). You should only have to change the information on this page when you need to fine-tune what the system sets up by default.

Open **Menu** > **Meter** > **SP / Item Installation** > **Search** to update an item's installation information.

Description of Page

The following information is displayed at the top of the page:

SP/Item History This is a concatenation of service point AND item information. This information only appears after the SP/item history record exists on the database.

SP/Item History ID This is a system-assigned random number that stays with a SP/item history record for life. This value only appears after the SP/item history record exists on the database.

Enter the ID of the **Service Point** at which the item is installed. Summary information about the service point is displayed adjacent to the service point ID.

Note:

SP Type Restrictions. The service point's SP Type controls whether or not an item can be installed at the service point, and if so, what type of item can be installed. Refer to [Setting Up Service Point Types](#) for more information.

Item ID identifies the item that is installed at the service point. Summary information about the item is displayed adjacent to the item ID.

Use the **Installation** information to define when the item is installed. To do this you must:

- Enter the **Installation Date/Time** showing when the item is installed at the service point.
- Use **Item On/Off Status** to define if the item is turned on or off when it's INITIALLY installed. Valid values are On and Off. This status does not affect billing in any way - it is purely informational.

Use the **Removal** information to define when the item is removed from the service point. To do this you must:

- Enter the **Removal Date/Time** showing when the item is removed from the service point.
- **Stock Location** only appears if the item's item type tracks location. Enter the stock location where the item is stored upon removal. Refer to [The Big Picture Of Asset Inventory](#) for more information.

The **Item On/Off History** grid contains the history of when the item has been turned on and off while it's installed at the service point. When an item's on/off status changes, insert a new entry into the grid by clicking the  button. Then,

- Use **Event Date / Time** to define when the status changed.
- Use **Item On/Off Status** to define if the item is turned on or off. Valid values are On and Off.

Warning:

The on/off status does not affect billing in any way. So, for example, if you turn an item off and never expire the service agreement / service point link, the item will still be amalgamated by billing. This is intentional as items can be turned off as part of the credit and collections process when a customer is delinquent (but the service point is still linked to the service agreement in case the customer pays up).

Note:

Only lamps use on/off status. This grid is only applicable to items that can be switched on and off (e.g., a lamp with a photovoltaic eye can be switched on and off by installing or removing the eye). If the type of item does not possess such a property, set the status to on.

SP Item Installation History

The SP installation history page is an information-only page that shows the items that have been installed at the service point. Use **Menu > Meter > SP / Item Installation > Search** and navigate to the **SP Installation History** page.

Description of Page

This page shows the history of the items that have been installed at the service point. No fields on this page may be modified.

Testing A Device

Device tests record the results of the periodic tests used to determine the accuracy of your meters and item. The topics in this section describe how to record the results of a meter or item test.

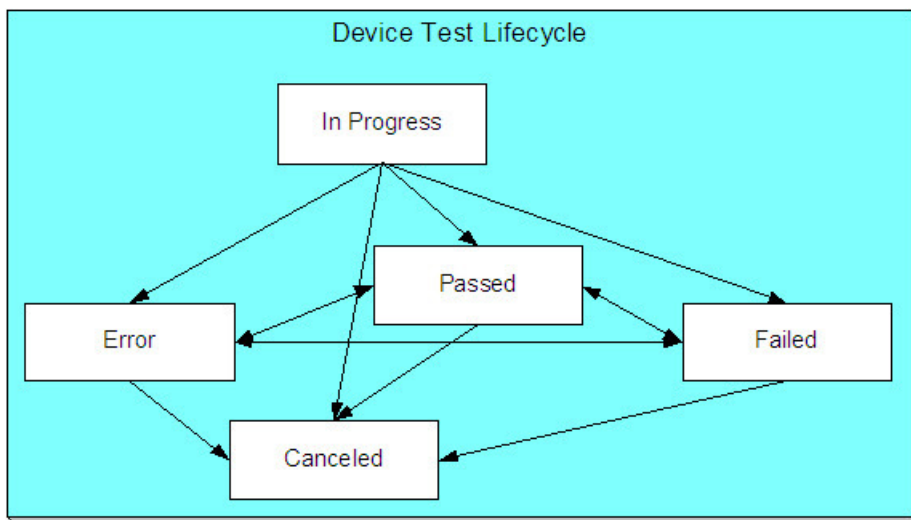

Fastpath:

Refer to [The Big Picture Of Device Testing](#) for more information.

The Lifecycle Of A Device Test

The following diagram shows the possible lifecycle of a device test.

In Progress The system creates a device test in the state of In Progress.

Passed The system automatically changes the state of an In Progress device test to Passed when an operator indicates such on the device test page. Note, if the device test's test type has a validation algorithm, the test must pass the

validation rules embodied in the algorithm before the test will become Passed. If the device test's test type does not use a validation algorithm, the test is assumed to pass when the operator indicates such.

Failed The system automatically changes the state of a device test to Failed when an operator indicates such on the device test page. Note, if the device test's test type has a validation algorithm and the user indicates the test has passed, the system will change the test to Failed if the test fails the algorithm.

Error If the device test's test type has a validation algorithm and the user indicates the test has passed, the system will change the test to Error if a problem is encountered while the validation algorithm executes.

Canceled You may Cancel a device test if it shouldn't exist.

Device Test - Main

The Main page contains core device test information. Open this page using **Menu > Meter > Device Test > Search** to maintain Device Test information.

Description of Page

The top portion of every page in this page contains the following information:

Device Test is a concatenation of summary information about this device test. It is composed the device's badge number, the test date, and the test's status.

Device Test ID is the unique system-generated identifier for this device test.

The remaining fields on the page are described below:

Use **Device Test Type** to define the type of test that was conducted.

Use **Test Start Date/Time** to define when the test was started.

Use **Test Stop Date/Time** to define when the test was completed.

Define the **Meter ID** on which the test was performed. This field will be gray if the **Device Test Type** is used for items.

Note:

You can only select a meter whose meter type indicates this **Device Test Type** can be performed for it.

Define the **Item ID** on which the test was performed. This field will be gray if the **Device Test Type** is used for meters.

Note:

You can only select an item whose item type indicates this **Device Test Type** can be performed for it.

Indicate who performed the test:

- If the test was performed by a 3rd party service provider, enter the tester's **Service Provider ID**.
- If the test was performed by a user, enter the person's **User ID**.

Use **Comments** to describe anything unusual about the test.

If the device test's status is Failed or Error , a **Message** will be displayed describing why.

Test Status defines the state of the device test. The buttons beneath the status are used to change the state of the device test:

- Click the **Validate** button to indicate a test should become Passed. When this button is clicked, one of two things will happen:
 - If the **Device Test Type** has a validation algorithm, the algorithm will be called and the status could become Passed, Failed or Error.
 - If the **Device Test Type** doesn't have a validation algorithm, the status will become Passed.
- Click the **Fail Test** button to indicate the test's status should be Failed.

- Click the **Cancel** button to indicate the test is Canceled .

Device Test - Characteristics

The characteristics page contains device test results. Use **Menu > Meter > Device Test > Search** and navigate to the **Characteristics** page.

Note:

Default note. When a device test is first created, all required characteristics will be defaulted (the operator need only specify their respective characteristic values).

Description of Page

The top portion of every page in this page contains the following information:

Device Test is a concatenation of summary information about this device test. It is composed the device's badge number, the test date, and the test's status.

Device Test ID is the unique system-generated identifier for this device test.

To modify a characteristic, simply move to a field and change its value. To add a new characteristic, click + to insert a row, then fill in the information for each field. The following fields display:

Characteristic Type Indicate the type of characteristic.

Sequence Controls the order in which characteristics of the same type are displayed.

Characteristic Value Indicate the value of the characteristic.

Where Used

The data on this page may be used during the execution of the device test's test type's validation algorithm. Refer to [Device Test Validation](#) for more information.

Device Test - Components

The test components page contains test components associated with the device test (refer to [A Device Test Records Test Results](#) for examples of how and when test components are used to record test results). Use **Menu > Meter > Device Test > Search** and navigate to the **Components** page.

Note:

Default note. When a device test is first created, all test component types defined on the device test type will be defaulted.

Description of Page

The top portion of every page in this page contains the following information:

Device Test is a concatenation of summary information about this device test. It is composed the device's badge number, the test date, and the test's status.

Device Test ID is the unique system-generated identifier for this device test.

The **Device Test Component** scroll controls the display of the test components involved in the device test. The fields that appear in the outer scroll are as follows:

Test Component Type The test component type controls the type of test results that are entered. Note well, only test component types defined as permissible on the device test type may be specified.

Sequence This field along with the **Device Test ID** uniquely identify this record.

Register ID This field is only used if the **Test Component Type** indicates that a register must be specified. This is typically only done with the component test involves the testing of a specific register.

The grid contains fields used to capture the test results. The number and the type of test results is controlled by the respective **Test Component Type**.

Where Used

The data on this page may be used during the execution of the device test's test type's validation algorithm. Refer to [Device Test Validation](#) for more information.

Device Test Selection

The device test selection page will generate field activities to test meters and items. Open this page using **Menu > Meter > Device Test Selection**.

Description of Page

To generate field activities to test you meters / items, follow these steps:

- Add a Device Test Selection record (see the field description below for information about the fields)
- Click the **Complete** button to have the system generate the field activities. The generated field activities will appear in the grid at the bottom on the screen.
- If, after reviewing the field activities, you decide not to perform the tests, you can cancel the field activities by clicking the **Cancel** button. It's important to note that the system will only cancel Pending activities that are allowed to be [canceled](#) automatically.

The remainder of this selection describes the fields associated with a Device Test Selection.

Enter a **Description** of the selection event.

Select a **Selection Algorithm** that will select meters or items for testing. Refer to [Field Activities And Device Testing](#) for more information.

Use **Qty to Select** to define the number of meters or items for which you want field activities generated.

Define the field **Activity Type** to be assigned to the generated field activities.

Define the **Scheduled Date** to be assigned to the generated field activities.

The **Create Date/Time** of the test selection is displayed.

Status defines the state of the device test selection. The buttons beneath the status are used to change the state of the device test selection:

- Click the **Complete** button to have the system select the devices to test and to generate the related field activities. The status will change to Complete.
- Click the **Cancel** button to indicate the test selection is Canceled.

The resultant field activities are displayed in the grid that follows.

Meter Replicator

When a pallet of new meters arrives in your meter shop, you can use the meter replicator to quickly create many copies of a given meter and its configuration. The individual copies may then be edited as needed.

Perform the following steps to create multiple copies of a meter:

- Add a meter using [Meter - Main Information](#).
- Add a meter configuration using [Meter Configuration Maintenance](#).
- Use the meter replicator page to create copies of the meter and its configuration.

The topics in this section describe how to use the meter replicator. Note that there is also an [Item Replicator](#) in the case where you need to replicate other devices.

Meter Replicator - Main Information

You use this page to create many copies of a given meter. Use **Menu > Meter > Meter Replicator** to open this page.

Description of Page

Define the **Meter ID** that is to serve as your template meter.

Note:

Recommendation. Carefully verify the template meter using the other tabs in this page before you save the replicated meters. After you save the replicated meters, any corrections could prove time-consuming.

Indicate the **Number of Meters to Replicate**.

If the meter's meter type tracks location, a meter history location will be created during replication. Use **Stock Location** to define the initial meter stock location to be used in the location history. Refer to [The Big Picture Of Asset Inventory](#) for more information.

Use **Badge Prefix** to define the prefix of the badge numbers assigned to the meters. Use **Start From** to define the suffix of the badge number assigned to the first copy of the meter. Use **Increment by** to define the value to increment successive badge numbers by. The first and last badge numbers to be created by the replicator are displayed adjacent.

For example, if the first badge number you want to create is E99-1021 and the last badge number is E99-1077 you'd enter the following parameters:

Number of Meters would be 57

Badge Prefix would be E99-10

Start From would be 21

Increment by would be 1

Use **Serial Prefix** to define the prefix of the serial number assigned to the meters. Use **Start From** to define the suffix of the serial number assigned to the first copy of the meter. Use **Increment by** to define the value to increment successive serial numbers by. The first and last serial numbers to be created by the replicator are displayed adjacent.

For example, if the first serial number you want to create is GE9101-1000-001 and the last serial number is GE9101-1000-057 you'd enter the following parameters:

Number of Meters would be 9

Serial prefix would be **GE9101-1000-0**

Start From would be 1

Increment by would be 1

After entering the parameters, click **Replicate** to generate your new meters. You can use the frames at the bottom of the page to view the meters that will be created when you click save. The left frame will show how Badge and Serial Numbers will look on the first 10 meters. If you are creating more than 10 meters, the right frame will show how Badge and Serial Numbers will look on the last 10 meters. If everything looks clean, click the save button.

Meter Replicator - Meter

The Meter page is a display-only page provided to let you confirm that the meter you selected is the one to be used as the template by the replicator. Use **Menu > Meter > Meter Replicator** and navigate to the **Meter** page.

Note:

Some equipment may not be copied. Equipment that is linked to the template meter will NOT be replicated on the replicated meters if the equipment references an item type that does NOT permit multiple equipment assignments. Refer to [The Big Picture of Meters, Items and Equipment](#) for more information about equipment linked to meters.

Description of Page

This is a display-only page that displays information about the registers linked to the meter identified in the add dialog. Refer to [Meter - Main Information](#) for a description of the fields.

Meter Replicator - Meter Configuration

The Meter Configuration page is a display-only page provided to let you confirm that the meter you selected is the one to be used as the template by the replicator. Use **Menu > Meter > Meter Replicator** and navigate to the **Meter Configuration** page.

Description of Page

This is a display-only page that displays the characteristics linked to the meter identified in the add dialog. Refer to [Meter Configuration Maintenance](#) for a description of the fields.

Item Replicator

When you receive a set of new badged items or equipment, you can use the item replicator to quickly create many copies of a given item. The individual copies may then be edited as needed.

Perform the following steps to create multiple copies of an item:

- Add a meter using [Item Maintenance](#)
- Use the item replicator page to create copies of the item.

The topics in this section describe how to use the item replicator.

Item Replicator - Main Information

You use this page to create many copies of a given item. Use **Menu > Meter > Item Replicator** to open this page.

Description of Page

Define the **Item ID** that is to serve as your template item.

Note:

Recommendation. Carefully verify the template item using the other tab in this page before you save the replicated items. After you save the replicated items, any corrections could prove time-consuming.

Indicate the **Number of Items to Replicate**.

If the item's item type tracks location, an item history location will be created during replication. Use **Stock Location** to define the initial item stock location to be used in the location history. Refer to [The Big Picture Of Asset Inventory](#) for more information.

Use **Badge Prefix** to define the prefix of the badge numbers assigned to the items. Use **Start From** to define the suffix of the badge number assigned to the first copy of the item. Use **Increment by** to define the value to increment successive badge numbers by. The first and last badge numbers to be created by the replicator are displayed adjacent.

For example, if the first badge number you want to create is E99-1021 and the last badge number is E99-1077 you'd enter the following parameters:

Number of Items would be 57

Badge Prefix would be E99-10

Start From would be 21

Increment by would be 1

Use **Serial Prefix** to define the prefix of the serial number assigned to the items. Use **Start From** to define the suffix of the serial number assigned to the first copy of the item. Use **Increment by** to define the value to increment successive serial numbers by. The first and last serial numbers to be created by the replicator are displayed adjacent.

For example, if the first serial number you want to create is GE9101-1000-001 and the last serial number is GE9101-1000-057 you'd enter the following parameters:

Number of Items would be 9

Serial prefix would be **GE9101-1000-0**

Start From would be 1

Increment by would be 1

After entering the parameters, click **Replicate** to generate your new items. You can use the frames at the bottom of the page to view the items that will be created when you click save. The left frame will show how Badge and Serial Numbers will look on the first 10 items. If you are creating more than 10 items, the right frame will show how Badge and Serial Numbers will look on the last 10 items. If everything looks clean, click the save button.

Item Replicator - Item

The Item page is a display-only page provided to let you confirm that the item you selected is the one to be used as the template by the replicator. Use **Menu > Meter > Item Replicator** and navigate to the **Item** page.

Note:

Some equipment may not be copied. Equipment that is linked to the template item will NOT be replicated on the replicated items if the equipment references an item type that does NOT permit multiple equipment assignments. Refer to [The Big Picture of Meters, Items and Equipment](#) for more information about equipment linked to items.

Description of Page

This is a display-only page that displays information about the registers linked to the item identified in the add dialog. Refer to [Item - Main Information](#) for a description of the fields.

Meter Reading

In this section, we describe how to manage the cyclical reading of your metered service points and how to add and change ad hoc meter reads.

Fastpath: For more information about meters, refer to [Meter Management](#).

Background Topics

The topics in this section provide background information about a variety of meter reading issues.

The Cyclical Meter Read Process

Most meter reads are recorded in the field by meter readers using handheld devices. These meter reads are uploaded into the system for use by billing. In this section, we provide an overview of how this cyclical process works:

- Every metered service point references a service cycle, route, and sequence within the route.
 - The service cycle controls WHEN the service point's meter is read.

- A service cycle typically contains many routes. A route is a logical group of service points whose meters can be read by a meter reader on a given day.
- A service point's sequence defines the order within a route that the service point is read.
- Every service cycle has a service cycle schedule that defines the dates on which the routes within a cycle are read.
- Shortly before the scheduled meter read date, the system creates a download file containing information to be sent to your handheld software. This download file contains information about every register on every meter in every route in the cycle being downloaded.

Note: Overriding a route within a specific schedule. Rather than downloading all routes within a cycle, you can set up the system so that only specific routes are downloaded on any given date. This is a very powerful feature. You can use it, for example, to estimate specific cycles every other month or indicate the customer reads the meter every third month. Refer to [Designing Service Cycles, Routes, And Schedules](#) for more information.

- Your handheld software distributes this information to the handheld devices and then your meter readers do their job. When they finish, the resultant meter reads are uploaded into the system.

Note: Billing recalculates consumption. While the system calculates consumption when a read is added to the system in order to compare it to high / low values, this consumption is not used by billing. Rather, billing recalculates consumption in case something changes between the time the read is stored and the customer is billed for the consumption (e.g., the register's constant is changed, the dial reading is changed due to digit transposition in the field, etc.)

Fastpath: For more information about the how to control when a cycle is read, refer to [Setting Up Service Cycle Schedules](#).

Managing Metered Service Routes

Every metered service point references a service cycle, route, and sequence within the route.

- The service cycle controls WHEN the service point's meter is read.
- A service cycle typically contains many routes. A route is a logical group of service points whose meters can be read by a meter reader on a given day.
- A service point's sequence defines the order within a route that the service point is read.

Fastpath: Refer to [ReNUMBER Service Route Sequences](#) and [Service Route Transfer](#) for more information about changing the service points in a route. Refer to [Service Point - Main Information](#) for more information about how to change a specific service point's cycle, route, and sequence.

High / Low Checks

Regardless of the source (upload or online), whenever a meter read is added, the system checks that the meter read's consumption is reasonable. This check is performed by comparing the actual read to high and low read values. The actual high and low read values are calculated by the Meter Read High Low Limits algorithm specified on the [installation options](#).

The base package is supplied with a sample algorithm type (HILO-FACTBL) that uses the [High Low Factor](#) table to derive the high and low limits for a register read as follows:

- Estimate consumption using the estimation algorithm specified for the *trend area*.
- Calculate the high and low usage amounts using the high and low usage factors for the unit of measure and read type:
 - The low usage amount is calculated by multiplying estimated consumption by the low usage factor.
 - The high usage amount is calculated by multiplying estimated consumption by the high usage factor.
- Determine the high and low read values using the high and low usage amounts and the previous read value.

When a meter reading's consumption is outside of the high / low boundaries, it is flagged accordingly. However, billing still uses the reading unless an operator explicitly disallows the reading.

Fastpath: Refer to [Review High / Low](#) for more information about reviewing readings that failed high / low checks.

Note: Disallowing Readings. You can disallow billing from using a read by unchecking **Use On Bill** on the [Meter Read](#) page.

Meter Reads and Billing

When it's time to create a bill for a customer, the system looks for an appropriate meter read for each metered service point on or around the scheduled meter read date. If a single read is found, billing uses it to calculate consumption. However, challenges exist if either of the following two situations occurs:

- When multiple meter reads exist on or around the scheduled meter read date.
- When no reads exist.

Sorting out multiple reads is easy. Every read contains a read type. Each read type has an associated priority code. If multiple reads exist, billing uses the read with the highest priority. If multiple reads of the highest priority exist, one is selected at random.

Fastpath: For more information about read types and their billing selection priority, refer to the Description of Page under [Meter Read - Main](#).

Sorting out the situation when no reads exist isn't so easy. When no reads exist, billing generates an estimated read (derived by estimating consumption) if all of the following conditions are true:

- The initiator of the bill allows estimation.
 - If a bill is created as a result of a bill cycle schedule, the bill cycle schedule must have an estimation date on or after the current date.
 - If a bill is created real time from one of the bill pages, the requesting operator must specifically allow estimation.
- The service agreement allows estimation.

If estimation is allowed, the billing process estimates consumption as of the scheduled meter read date using the same algorithm used for the purpose of high / low checks.

Whenever billing estimates consumption, it creates a meter read to represent the estimated consumption. You can see this meter read on the meter read queries.

Fastpath: For more information about estimated consumption, refer to [The Theory Behind Consumption Estimation](#).

Meter Read Maintenance

The topics in this section describe how to add or update a Meter read.

Meter Read - Main

To add a meter read, open **Menu > Meter Read > Meter Read > Add**.

Note: There are 4 ways to add meter reads. You can add meter reads using any of the following methods: A) open **Menu > Meter Read > Meter Read > Add**, B) add the read using the [Meter Read Upload Staging](#) page, C) populate the [Meter Read Upload Staging](#) using SQL, and D) you can add a reading using [Field Activity Upload Staging](#). Both options B and C rely on the subsequent execution of the [Meter Read Upload Background Processes](#) to create the reads in the system.

Description of Page

Meter Read is a concatenation of summary information about the meter read.

Meter Read ID is the system-generated unique identifier for the meter read.

Enter the **Meter Configuration ID** of the meter that was read. Adjacent to the ID is summary information about the configuration. This field is protected if the meter read is used on an [SP/Meter Installation](#) history record.

Premise is a display-only field that shows the information about the premise at which the meter configuration was installed when it was read.

Enter the **Read Date/Time**. This field is protected if the meter read is used on an [SP/Meter Installation](#) history record.

Turn off **Use On Bill** if the meter read should not be used by billing. You'd typically turn this off if a meter failed high / low checks and you don't want billing to use it to calculate a customer's consumption.

Use **Meter Read Source** to define the source (e.g., the reader, the reading agency, etc.) of the read. If the read was uploaded with the reader id, **Meter Reader** is displayed.

The **Reread Meter** button can be pressed to create a field activity to reread the meter (note, the field activity type is defined on the field activity type profile associated with the service point at which the meter configuration is currently installed). This button is disabled if the meter configuration is not currently installed at a service point. If there is a Pending reread field activity for the service point, information about the field activity is displayed adjacent. If multiple such field activities exist, information about the earliest activity is displayed.

The scroll that follows contains one row for every register linked to the meter configuration. You cannot insert or remove entries in this scroll because a reading must be entered for every one of the configuration's registers.

Note: Register reads may not be entered for interval registers. Refer to [The Big Picture of Raw Data Collection and Aggregation](#) for more information.

The remaining fields are entered for each register.

Sequence is a display-only field that controls the order in which a register is read.

Register Information consists of the unit of measure, time of day (if any), the format of the register, and the register's constant.

Use **Read Type** to define WHO made the read and HOW the read was made. The value of this field is important because it affects which meter read will be used by billing if multiple reads exist during a billing period. The following table lists the read types and describes how a read with this value typically enters the system.

| Read Type | Description |
|---------------|---|
| Billing Force | Meter reads with this value are entered by a billing administrator who wants to force billing to bill a customer for a given amount of consumption. |
| Verified | Meter reads with this value are recorded by a meter reader using a handheld device. The handheld device deems a read as "verified" if the meter reader typed the same dial reading in twice. Some organizations have their handhelds programmed to require the double entry of dial readings when they entered value is outside normative values (i.e., the resultant consumption fails high / low checks). |
| Regular | Meter reads with this value are recorded by a meter reader using a handheld device. See the description for "verified" above for the difference between a "regular" and a "verified" reading. |

| | |
|---------------------------|---|
| Customer Read | Meter reads with this value are made by a customer. |
| System Prorate | Meter reads with this value are created by the system automatically when prorating normal cycle-based reads for use with an off-cycle start service or stop service. |
| Office Estimate | Meter reads with this value are informed guesses of consumption. These would be used when there was no real reading (i.e., a regular or verified reading), and the system was not allowed to estimate consumption (for whatever reason). This value is rarely used. |
| Service Provider Estimate | Meter reads with this value are estimates of consumption made by a 3rd party service provider, such as an MDMA, the distribution company, or an energy supply company. |
| System Estimate | Meter reads with this value are created by the billing process when a reading cannot be found and the service agreement allows estimation. |
| No Read | Meter reads with this value are entered to indicate that a read was purposefully not performed (for whatever reason - mad dog, nasty rose bush, deep snow, etc.). A read with this value is not a read at all, it's just an audit trail. |

Note: Default note. If the meter configuration has multiple registers, the read type defined for the first register will be defaulted on the remaining registers when you add a new meter read. You can always override this defaulting.

The **Message** column highlights the following:

- **The resultant usage.** For subtractive registers, this is the difference between this read and the prior read. For consumptive registers, this is the register reading.
- **The valid usage.** This is the range of usage that won't trigger a high / low failure. These values are not shown if the read was not subject to high / low checks when it was added.
- **The valid readings.** This is the range of readings that won't trigger a high / low failure. These values are not shown if the read was not subject to high / low checks when it was added. Note, these values are only calculated for subtractive registers as the valid usage is the same as the valid readings for consumptive registers.

The message column is red for those readings that have failed high / low checks.

Fastpath: Refer to [High / Low Checks](#) for more information.

Register Reading contains the dial reading.

The **Previous Reading Information** column contains information about the read that precedes this read (note, meter reads where **Use on Bill** is turned off are ignored). The reading's read type, read date, and register reading are displayed.

The **Review High / Low** switch indicates if this register read has been flagged for consideration by the high / low review background process (**TD-HILO**). If a register read has been checked, you may reset the switch so that the register read is no longer considered for the high / low review background process.

Note: Marking a Read for High / Low Review. Only the system can mark a register read for high / low review. Refer to [High / Low Checks](#) for more information.

Register ID is the unique identifier of the register. This information is shown for informational purposes.

Register Reading Id is the unique identifier of the register read. This information is shown for informational purposes.

The **Meter Reader Remark** grid is used to define anomalies associated with the reading. For example, you can indicate if a read wasn't possible because there was a dangerous situation at the premise.

The **Meter Read Remark Status** is only relevant if a **Meter Read Remark** code has algorithms associated with it. Algorithms are associated with meter read remarks if additional activities should occur after a meter read with such a remark is added. For example, you could create a field activity if a "seals broken" remark is specified on a meter read. The execution of the algorithm is performed by a background process called MRRA (meter read remark algorithm activator). **The Meter Read Remark Status** indicates whether the algorithm has been executed:

- When you add a remark that has an algorithm, the status will be Pending. It will remain in this state until the MRRA process next runs.
- When the MRRA process next runs, if the system is successful in executing the algorithm, the status of the meter read remark will become Complete. If the system is not successful in executing the algorithm, the status becomes Error.

Note: Remarks that are in error. Meter reads that contain meter read remarks whose algorithms could not be successfully executed by the MRRA background process are written to the [Meter Read Remark Exception](#) table. To correct errors, you may have to delete and re-add the meter read's remark code if the error is impossible to fix (e.g., if the remark causes a customer contact to be generated and there is no customer at the meter's premise).

Fastpath: Refer to [Meter Reader Remarks](#) for more information.

Meter Read - Characteristics

To update meter read characteristics, open **Menu > Meter Read > Meter Read > Search** and navigate to the **Characteristics** page.

Description of Page

The **Characteristics** collection contains information that describes miscellaneous information about the meter read.

The following fields display:

Characteristic Type Indicate the type of characteristic.

Sequence Controls the order in which characteristics of the same type are displayed.

Characteristic Value Indicate the value of the characteristic.

Meter Read - Meter Read Portal

Select **Menu > Meter Read > Meter Read** and navigate to the Meter Read Portal tab to view additional information associated with a Meter Read.

Depending on your implementations requirements, you may define additional zones to appear on this Portal.

The contents of this section describe the zones that are available on this portal page.

General Information

Meter Read ID, **Meter Read Info** are displayed.

Correcting Reads Versus Entering New Reads

Assume that a read was performed in the field and the dial reading was entered incorrectly (e.g., digit transposition). You have two choices, you can modify the uploaded read, or you can enter a new read with a higher priority read code. We prefer the latter approach so that a proper audit exists, but both options work; it's up to you.

Meter Read Remark Exception

If a meter read has a remark code that has algorithms associated with it, the system activates the algorithms each time the MRRA (meter read remark algorithm activator) background process is executed. If errors occur during the activation of the algorithms, a record is written to the meter read remark exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, schedule the [TD-MRRER](#) background process. This process generates a To Do entry for every record in the meter read remark exception table.

After correcting the cause of the error, drill into the [meter read](#) page. Then change the status of the remark from Error to Pending. When the MRRA process next runs, it will attempt to execute the remark's algorithm again.

Note: You may have to delete or change the meter read's remark code if the error is impossible to fix (e.g., if the remark causes a customer contact to be generated and there is no customer at the meter's premise).

Setting Up Trends

CAUTION: You must thoroughly understand the information discussed in [Estimating Using Trends](#) before you can understand trends.

Trend information is used to estimate consumption. A separate trend is maintained for every combination of trend area, trend class, unit of measure and time of use code. Each trend maintains a separate record for each day on which consumption was measured. This section deals with the issues associated with the maintenance of trend information.

Trends Are Updated Behind-The-Scenes

The consumption associated with certain register reads is updated on a trend record by the TREND background process when the following conditions are true:

- The register's read type must be Customer, Regular, or Verified .
- If the register is subtractive, the reading's resultant consumption can't exceed the threshold capacity of the register. Note, a register's threshold capacity equals X times the register's maximum capacity (where X is the rollover threshold factor defined on [Installation Options - Billing](#)).
- If the register read was entered online, the resultant consumption can't be outside of the high / low boundaries.
- If the register read was uploaded by the MUP2 background process and the reading was marked for high / low checks, the resultant consumption can't be outside of the high / low boundaries

Warning:

The above points mean that if you do not subject your uploaded meter reads to high / low checks AND the resultant consumption does not exceed the threshold capacity of the register AND the read type is Customer, Regular or Verified, then the trend table will be updated with the register read's consumption.

The specific trend affected by a register read is identified by the following:

- The register's meter's service point's premise defines the trend area.
- The register's meter's service point's SP type defines the trend class.
- The register defines the unit of measure and time of use codes.
- The meter read date defines the trend date.

Important: The system only updates trends with a read type of Customer, Regular or Verified. The system ignores other types of reads when it builds trend information. Refer to [Meter Read - Main](#) for more information about read type.

In addition to updating the trend data, the trend process can create To Do entries for any service point without an active service agreement where significant usage is detected.

Maintaining Trends

All trend data is updated by the system and should not require modification. However, if you need to view or change this information, open **Meter Read, Trend**.

Description of Page

A separate trend is maintained for every combination of **Trend Area**, **Trend Class**, **Unit of Measure**, and **Time of Use** code. The Unit of Measure's **Measures Peak Qty** is displayed adjacent. Each trend contains a separate record for each day on which consumption was measured.

Note: Load functionality. If you enter this page in "add mode" (i.e., you do not select a trend using the search dialog) and you enter a combination of **Trend Area**, **Trend Class**, **Unit of Measure** and **Time of Use** code that already has trend information, a button will appear adjacent to **Trend Area**. This button is called "**Load**" and, if clicked, will cause the information in the following grid to become populated with the respective trend information.

Use the **Read Date** to indicate the starting point for the display of the trend data. Keep in mind that the data is displayed in reverse chronological order.

The following fields display:

Read Date The date on which the consumption information was recorded in the system.

Thread Nbr The system-generated identifier for a group of trend consumption records (rows) used to calculate a trend estimate. Simply enter a value of 1 if you are entering a trend.

Total Service Quantity The total amount of consumption recorded on the read date.

Number of Units For non-peak units of measure (e.g., CCF, therm, kWh), this contains the number of days in which the total service quantity was consumed. For peak units of measure (e.g., kW, kVar), this contains the number of meter reads.

Number of Reads The total number of reads whose consumption was recorded on the trend.

Average Consumption This equals the total service quantity divided by the number of units.

No Trends At Startup

Once you've been in production for about one billing period, there should be enough system-generated trend data (depending on the estimation algorithm and how the trend areas/classes are configured) to generate statistically accurate consumption estimates. However, before this time, you will have little or no trend data and therefore the system will not be able to accurately estimate consumption (and therefore high / low validation will not operate).

If you can live with this, then you don't have to set up trends because the system will automatically build them as meter reads are recorded in the system. However, if you opt for this approach, you must turn off high / low validation on your uploaded register reads during the first few months of production. If you fail to do this, every register read will fail high / low validation and reads that fail high / low checks are not trended. To turn off high / low validation populate the [uploaded register read's](#) REVIEW_HILO_SW with a value of N.

If you can't live with this, then you'll have to populate the trend data manually. To do this, create trend records for every combination of trend area, trend class, unit of measure and time of use code. For each trend, enter the following:

Thread Nbr Enter 1.

Read Date Set this to the day preceding your production date.

Total Service Quantity For peak units of measure (e.g., kW, kVar), this will be the average peak amount of consumption associated with registers belonging to this trend. For non-peak units of measure (e.g., CCF, kWh), this will be the average daily consumption associated with registers belonging to this trend.

Number of Units Enter 1.

Number of Reads Enter 1.

Note: You do not have to change the trend classes to indicate only one read is needed. This is because, if the system cannot find enough trends to satisfy the number of reads required by the trend class, it will use as many as exist. For example, consider a trend class that needs 10,000 reads to form a statistically significant sample for estimation, but at estimation time there is only one trend and this trend contains the results from only one read. In this situation, the system will use the consumption information on the single trend to calculate estimated consumption.

Note: Make sure that your manually entered trend information is accurate and well tested. The quality of the trend information impacts your estimation results (depending on your estimation algorithm) and this in turn impacts the bills you send your customers.

Renumber Service Route Sequences

All metered service points reference the service cycle and route in which they are read. Besides referencing the specific cycle and route, every service point has a meter read sequence that defines its relative position in the route (where sequence 5 is read before sequence 10). If you need to insert a service point between two existing service points but there's no gap between the service points' sequences, open **Menu > Meter Read > Renumber Service Route Sequences** to renumber the sequences in a given cycle and route.

Fastpath: Refer to [The Cyclical Meter Read Process](#) for more information about cycles and routes.

Description of Page

Use the search button to select the **Service Cycle** and **Service Route** whose service points are to be resequenced. When the page opens, you are shown all of the service points in the cycle and route, ordered by current sequence number.

Use the **Sequence Range From** and **To** fields to display service points in the grid within a sequence range.

Use the **Sequence** column in the grid to manually change a service point's sequence number. You can manually change sequence numbers of up to 150 service points at a time. Click the **save** button to apply your changes. Service points with duplicate sequence numbers are highlighted in the **Remarks** column.

To resequence all service points within the route, enter the value from which the system should **Start Sequencing From** and the amount to **Increment Sequences by** and then click **Renumber**. Good values to enter would be 5 and 5 respectively. If you specified values in the **Sequence Range From** fields, only the service points whose sequences fall within the specified range are renumbered.

Note:

A background process, C1-RMRCS, can also be used to renumber service route sequences. It is recommended to use this when the service route to re-sequence has a large number of service points.

Service Route Transfer

The topics in this section describe how to transfer a group of service points from one route to another.

Service Route Transfer - Main

If you need to transfer a group of service points from one route to another, open **Menu > Meter Read > Service Route Transfer**.

Fastpath: Refer to [The Cyclical Meter Read Process](#) for more information about service cycles and routes.

Description of Page

This page's dialog is idiosyncratic. Follow the instructions below to transfer service points from one route to another:

- Use the search button to select the **Service Cycle** and **Service Route** that contains the service points to be transferred. Upon return from the search, you are shown all of the service points in the input cycle and route in the **Transfer From** grid.
- In the **Transfer From** section at the top of the page, enter the sequence number of the first service point to be transferred in **Sequence From**. Enter the sequence number of the last service point to be transferred in **Sequence To**.
- In the **Transfer To** area that follows, enter the **Service Cycle** and **Service Route** into which the service points are to be transferred. Enter the sequence number to be assigned to the first service point when it is transferred to the new route using **Start Sequencing From**. Enter the value by which to increment the sequence number of successive service points using **Increment by**.
- Click the save button to re-sequence the service points. The re-sequenced service points are shown on the **Transfer To** tab.

Note: When there's no room. If the "transfer to" route doesn't have enough space between its sequences to insert the desired service points, navigate to [Renumber Service Route Sequences](#) and renumber the route by a value large enough to make space. Then, return to this page and transfer the service points into the route.

When a service point's service cycle is updated using this transaction, and the account's bill cycle is not protected, the system automatically updates the account's bill cycle to be in sync with the service cycle.

Service Route Transfer - Transfer To

The **Transfer To** page is only populated after you have transferred service points from one cycle/route to another. It shows all service points in the "transfer to" cycle and route specified on the **Main** page.

Description of Page

No information on this page may be modified. The grid only contains information after you have transferred service points from one cycle/route to another. Refer to [Meter Read Route Transfer - Main](#) for instructions describing how to transfer service points from one route to another.

Read History

This page shows the history of a register's reads. Open this page using **Menu > Meter Read > Read History**.

Description of Page

Register ID identifies the register whose reads are shown in the grid.

Note: How to scroll through a meter's registers. If a **Meter** has multiple registers, use the meter's context menu and choose Go to Read History to be presented with a list of all of the meter's registers. Then select the first register. You can then use the Next (Alt-N) and Previous (Alt-P) buttons to scroll through the meter's registers.

Filter by controls the reads that appear in the grid:

- If you want to restrict the history to reads that are eligible to appear on a bill, choose Billable Reads Only. This is the default value.
- If you want to see all reads linked to the register, choose All .
- If you want to restrict the history to reads that are NOT eligible to appear on a bill, choose Non-Billable Reads Only.

The remaining points describe the columns in the grid.

Read Date/Time is the date and time of the meter read.

The **Read Difference** column shows the difference between this read and the previous read.

CAUTION: The value of **Read Difference** does NOT take into account constants; it is purely the difference between the respective read and the previous read. Refer to [Bill History](#) for a query that shows the history of billed consumption.

The **Message** column highlights the following:

- **The resultant usage.** For subtractive registers, this is the difference between this read and the prior read. For consumptive registers, this is the register reading.
- **The valid usage.** This is the range of usage that won't trigger a high / low failure. These values are not shown if the read was not subject to high / low checks when it was added.
- **The valid readings.** This is the range of readings that won't trigger a high / low failure. These values are not shown if the read was not subject to high / low checks when it was added. Note, these values are only calculated for subtractive registers as the valid usage is the same as the valid readings for consumptive registers.

The **Message** column is red for those readings that have failed high / low checks.

Fastpath: Refer to [High / Low Checks](#) for more information.

The **High/Low Failed** column is checked if the read was not within the boundaries of the estimated high and low read values calculated by the system at the time the read was validated.

Refer to [Meter Read - Main](#) for the definition of all other columns.

Downloading Meter Reads

Every metered service point references a service cycle, route, and sequence within the route.

- The service cycle controls WHEN the service point's meter is read.
- A service cycle typically contains many routes. A route is a logical group of service points whose meters can be read by a meter reader on a given day.
- A service point's sequence defines the order within a route that the service point is read.

CAUTION: If your company supplies electric service and uses MV90s, you will need to take advantage of "notional" routes. A "notional" route's service points are never actually read by a human. Rather, the service points' consumption is fed to the system by a sophisticated device (e.g., an MV90). These service points still need to be linked to a route because billing is dependent on the route's cycle to determine the expected meter read date. You would assign a "notional" route a route type that is not processed by the service cycle. Refer to [Setting Up Service Route Types](#) for more information.

A Service cycle has a schedule indicating when its service point should be read. Each entry in the schedule contains two dates:

- **Scheduled selection date.** This is the date the system selects the service points in the cycle for download to your handheld software.
- **Scheduled work date.** This is the date the meter is expected to be read.

On the scheduled selection date, the system creates a download file containing information to be sent to your handheld software. This download file contains information about every register on every meter in the routes being downloaded.

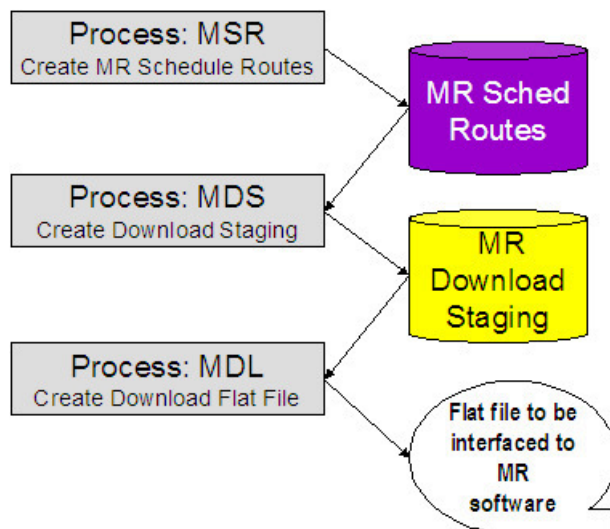

Your handheld software distributes this information to the handheld devices and then your meter readers do their job. When they finish, the resultant meter reads are uploaded into the system for subsequent use by billing.

Note: Rather than downloading all routes within a cycle, you can set up the system so that only specific routes are downloaded on any given date. This is a very powerful feature. You can use it, for example, to estimate specific cycles every other month or indicate the customer reads the meter every third month. Refer to [Designing Service Cycles, Routes, And Schedules](#) for more information.

Meter Read Download Processes

The following diagram illustrates the processes involved in the creation of the flat file that is interfaced to your meter reading software.

MSR - Create Service Schedule Routes

This process looks for all service cycle schedules with a scheduled selection date on or before the supplied business date whose routes haven't been generated. For each record found, the process creates MR schedule route records for every route in the cycle.

MDS - Create Download Staging

This process looks for all MR schedule route records with a schedule type of Download and a status of Pending. For each record found, the system creates a MR download staging record for the meter linked to every service point in the route.

Download staging records get marked with a batch control ID & run number when they're created by the MDS process.

- The batch control ID comes from the service point's route's route type. This ID corresponds with a specific meter read download method. The system comes with a single meter read download program ([MDL - Create Download Flat File](#)). If you require different flat file formats or different routing methods, you will need to create additional programs. Refer to [Setting Up Meter Read Extracts](#) for instructions describing how to add another process.
- The run number is the batch control ID's current run number.

MDL - Create Download Flat File

This process reads all download staging records marked with a given batch control ID & run number and creates the flat file that's passed to the meter read software.

Note: This process is rerunnable. You can reproduce the flat file at any time. Simply request this job and specify the run number associated with the historic run.

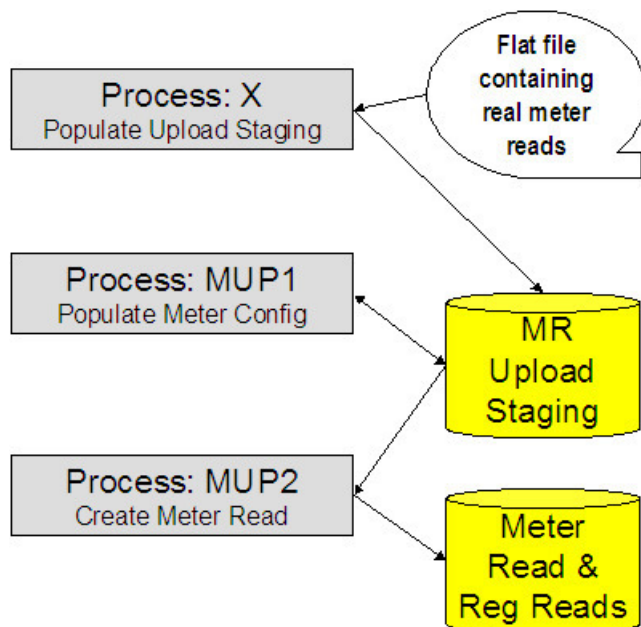

If you require different flat file formats or different routing methods, you will need to create additional versions of this program. Refer to [Setting Up Meter Read Extracts](#) for instructions describing how to add another process.

Uploading Meter Reads

This section describes how the system uploads meter reads from an external source.

Meter Read Upload Background Processes

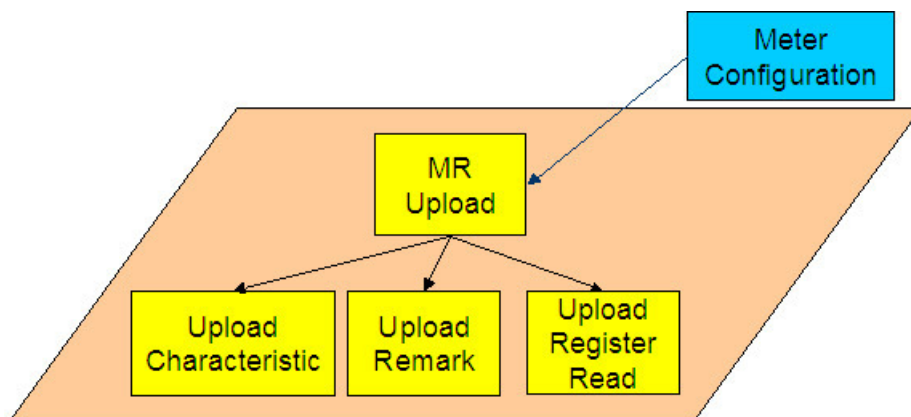

The following diagram illustrates the processes involved in the uploading of meter reads into the system.

The topics in this section describe how these processes work.

Process X - Populate MR Upload Staging

Process X refers to the mechanism used by your organization to populate the various staging tables (shown in the orange section of the following ERD).

The topics in this section describe each of these tables.

Meter Read Upload Staging

You must create an upload staging record for each meter that was read. The name of this table is CI_MR_STAGE_UP. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|------------------|--------|----------|-----------|--|
| MR_STAGE_UP_ID | 12 | Y | A/N | This is the unique identifier of the meter read upload staging record. This key is a sequential number so you can use a database function to assign the value when populating the table. |
| BADGE_NBR | 30 | N | A/N | If specified, this must correspond with a badge number on one of your meters. See the MTR_CONFIG_ID note below for how this field can be used. Also see the note under MTR_ID_NBR if you plan to use the meter's alternate ID's rather than the badge number to identify the meter being read. |
| MTR_CONFIG_ID | 10 | See note | A/N | This must correspond with a meter configuration number on one of your meters. You may leave this column blank if BADGE_NBR or MTR_ID_TYPE_CD / MTR_ID_NBR is populated. |
| READ_DTTM | 15 | Y | DateTime | The date and time of the meter read. |
| MR_UP_STATUS_FLG | 2 | Y | A/N | This must be set to P for Pending. |
| MR_ID | 12 | N | N | Leave this column blank. It will be assigned by the system when it creates a meter read record. |

| | | | | |
|----------------|----|---|-----|--|
| MR_SOURCE_CD | 12 | N | A/N | The source of the meter read. |
| GEO_TYPE_CD | 8 | N | A/N | See the description of the GEO_VAL field. |
| GEO_VAL | 50 | N | A/N | This field along with GEO_TYPE_CD are used to uniquely identify the service point at which the meter read takes places. These fields are only necessary if you have duplicate BADGE_NBR's and you have uniquely identified your service points (with a unique GEO_TYPE_CD and GEO-VAL - e.g., a universal id). It's important to note that you must also specify the BADGE_NBR along with the GEO_TYPE_CD and GEO_VAL. |
| MTR_ID_TYPE_CD | 5 | N | A/N | See the description of the MTR_ID_NBR field. |
| MTR_ID_NBR | 30 | N | A/N | This field along with MTR_ID_TYPE_CD are used to uniquely identify the meter being read. These fields are only necessary if you do not use the meter's BADGE_NBR's or the meter's MTR_CONFIG_ID to identify the meter. If specified, this must correspond with a meter ID type / value associated with one of your meters. |

| | | | | |
|----------------|----|---|-----|---|
| USE_ON_BILL_SW | 1 | Y | A/N | Indicates if the read can be used on a bill. Valid values are Y or N. Note, if the register read's REVIEW_HILO_SW is Y and if the register read fails high/low review, the USE_ON_BILL_SW may be set to N if the Use High/Low Failures on Bill is turned on in the installation record. |
| MTR_READER_ID | 20 | N | A/N | The ID of the meter reader identified by the Meter Read Source, if supplied. |

Upload Register Read

You must create an upload register read record for each meter that was read. The name of this table is CI_RR_STAGE_UP. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|----------------|--------|-------|-----------|--|
| MR_STAGE_UP_ID | 12 | Y | A/N | This must correspond with the prime key of the related CI_MR_STAGE_UP record. |
| READ_SEQ | 2 | Y | N | This must correspond with a sequence number on the meter configuration's register. |
| READ_TYPE_FLG | 2 | Y | A/N | Set this to 20 if the meter was not read. Set this to 60 if the meter read was performed, but not verified. Set this to 70 if the meter read was performed and verified. |

| | | | | |
|----------------|-----|----------|-----|---|
| UOM_CD | 30 | Y | A/N | This must correspond with the unit of measure code on the register associated with this READ_SEQ. Refer to Setting Up Unit Of Measure Codes for more information. |
| TOU_CD | 30 | See note | A/N | If specified, this must correspond with the time of use code on the register associated with this READ_SEQ. Refer to Setting Up Time Of Use Codes for more information. |
| REG_READING | 9.6 | Y | N | This is the register's reading. |
| REVIEW_HILO_SW | 1 | Y | A/N | Indicates if the register reading should be subject to high / low review. Valid values are Y or N. |

Upload Read Remark

You must create a meter read remark upload staging record for each remark that you would like to link to the meter read. The name of this table is CI_MRR_STAGE_UP. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|----------------|--------|-------|-----------|--|
| MR_STAGE_UP_ID | 12 | Y | A/N | This must correspond with the prime key of the related CI_MR_STAGE_UP record. |
| READER_REM_CD | 4 | Y | A/N | This must correspond with a meter read remark code. Refer to Setting Up Meter Read Remarks for more information. |

Upload Read Characteristics

You must create a meter read characteristic upload staging record for each characteristic that you want to link to the meter read. The name of this table is CI_MR_STGUP_CHAR. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|--------------------------------|-----------|-------|-----------|--|
| MR_STAGE_UP_ID | 12 | Y | A/N | This must correspond with the prime key of the related CI_MR_STAGE_UP record. |
| CHAR_TYPE_CD | 8 | Y | A/N | This must correspond with a characteristic type that is defined as valid for meter read upload staging. Refer to Setting Up Characteristic Types & Their Values for more information |
| SEQ_NUM | 3 | Y | N | This should be set to 1 unless you have multiple values for a given meter read upload staging and characteristic type. |
| ADHOC_CHAR_VAL | 254 | N | A/N | Populate this field if your characteristic type is ad-hoc or file location. |
| CHAR_VAL | 16 | N | A/N | Populate this field if your characteristic type is predefined |
| CHAR_VAL_FK1 - CHAR_VAL_FK5 | 50 (each) | N | A/N | Populate these fields if your characteristic type is a foreign key reference. Up to five columns of 50 bytes each are provided to accommodate compound keys. |

MUP1 - Populate Meter Configuration

This process populates the meter configuration ID on all MR upload staging records that don't have a meter configuration ID.

Note: You don't have to know the meter configuration in order to interface a read into the system. Rather, you can specify a SP Geo Type and Value and/or a Meter Id Type and Value and/or the meter's badge number on the [Upload Register Read](#) record. MUP1 will search the system for each (in that order) until a unique match is found.

Any errors detected during this process are written to the [MR Upload Exception](#) table. You can fix errors using MR Upload Staging page (don't forget to change the record's status back to Pending).

MUP2 - Create Meter Read

This process creates a meter read and register read for all MR upload records in the Pending state.

Any errors detected during this process are written to the [MR Upload Exception](#) table. You can fix errors using MR Upload Staging page (don't forget to change the record's status back to Pending).

If a meter read fails high / low checks, the meter read will still be created, but it will be marked for review by the review meter reads for high / low background process ([TD-HILO](#)).

In addition, whether a meter read that fails high / low is marked as usable on a bill is controlled by a switch on the [installation record](#).

MRUP-PRG - Purge Meter Read Upload Objects

Completed meter read upload staging objects should be periodically purged from the system by executing the [MRUP-PRG](#) background process. This background process allows you to purge all Completed meter read upload staging objects older than a given number of days.

We want to stress that there is no system constraint as to the number of Completed meter read upload objects that may exist. You can retain these objects for as long as you desire. However we recommend that you periodically purge Completed meter read upload objects as they exist only to satisfy auditing and reporting needs.

MR Upload Staging

The Meter Read Upload Staging page has three purposes:

- You can view historical meter read upload records.
- You can correct meter read upload records that are in error.
- You can add new meter read upload records to be uploaded by the meter read upload process.

MR Upload Staging - Main

To view the details of a meter read upload record, open **Menu > Meter Read > MR Upload Staging**.

Description of Page

MR Upload Staging ID is the system-generated unique identifier of the staging record.

The **Meter ID Type** identifies what type of Meter ID is listed in the upload record. This along with the Meter ID Number will help the system to identify the correct meter.

The **Badge Number** is the meter's badge number.

The **Meter ID Number** acts as an alternative identifier for the meter in case the badge number is not known or not unique. This along with the Meter ID Type will help the system to identify the correct meter.

Read Date / Time are just that.

Use on Bill is used to indicate whether or not the uploaded meter read may be used by billing.

Upload Status shows the state of the meter read upload record. Potential values are: Pending, Complete, Error. Set the value to Pending for any record that should be processed the next time the meter read upload process runs.

Meter Read ID is the system-assigned, unique identifier of the related meter read. This value is populated after the meter read upload process creates a meter read for the meter read upload record.

Use **Meter Read Source** to define the source (e.g., the reader, the reading agency, etc.) of the read.

Meter Configuration ID is the meter configuration that was read. If this field is left blank, it will be populated by [MUP1 - Populate Meter Configuration](#) during the meter read upload process (the system uses the Badge Number to do this).

Use **Meter Reader** for the ID of the person that read the meter.

If the read is interfaced from an external meter read agency, you can use **Geographic Type** and **Geographic Value** to identify the service point at which the read took place. If this value is specified, the system will look for a service point with the given type and value that has a meter currently installed at it with the specified **Badge Nbr**. This facility is useful if you have duplicate badge numbers but have uniquely identified your service points (e.g., with a universal ID).

The scroll that follows contains the register reading(s). The following information is displayed.

Read Sequence This must correspond with a sequence number on the meter configuration's register.

Read Type Use this field to define WHO made the read and HOW the read was made. The value of this field is important because it affects which meter read will be used by billing if multiple reads exist during a billing period. Refer to the Description of Page under [Meter Read - Main](#) for the list of valid values.

Unit Of Measure This must correspond with the unit of measure code on the register. Refer to [Meter Configuration Maintenance](#) for more information.

Time of Use If specified, this must correspond with the time of use code on the register. Refer to [Meter Configuration Maintenance](#) for more information.

Register Reading This is the register's reading.

Hi/Low Review Indicates if the register reading should be subject to high / low review.

MR Upload Staging - Remarks

To view remarks associated with a meter read upload record, open **Menu > Meter Read > MR Upload Staging** and navigate to the **Remarks** page.

Description of Page

The **Meter Reader Remark** grid is used to record anomalies associated with the reading.

MR Upload Staging - Characteristics

To view characteristics associated with a meter read upload record, open **Menu > Meter Read > MR Upload Staging** and navigate to the **Characteristics** page.

Description of Page

MR Upload Staging ID is the system-generated unique identifier of the staging record.

The **Characteristics** collection contains information that describes miscellaneous information about meter upload staging.

The following fields display:

Characteristic Type Indicate the type of characteristic.

Sequence Controls the order in which characteristics of the same type are displayed.

Characteristic Value Indicate the value of the characteristic.

MR Upload Exception

If errors are detected during the meter read upload process, a record is written to the MR upload exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, schedule the [TD-MRUPL](#) background process. This process generates a To Do entry for every record in the MR upload exception table.

You can fix this error using the [MR Upload Staging](#) page and change the status of the remark from Error to Pending. When the meter read upload process next runs, it attempts to upload this record again.

TD-HILO - To Do for Meter Read High/Low Errors

This process creates To Do entries for each meter read that has at least one register read that failed high / low using the To Do Type TD-HILO.

The process first attempts to complete old To Do entries. If the NO-OF-DAYS parameter is populated, all Open entries of this To Do Type whose create date is before the business date minus this input parameter value are completed.

For each register read linked to the meter read that has review high / low set to Y, the process attempts to classify the reading as "very low", "low", "high" or "very high".

Determine the reading's consumption

- If the register is subtractive, retrieve the previous reading and calculate the difference between the register reading and the previous reading (taking into account rollover).
- Otherwise, the reading is the consumption.

Calculate the following

- Low limit consumption = the difference between the previous reading and the low limit on the current reading.
- High limit consumption = the difference between the previous reading and the high limit on the current reading.

Low / Very Low

If the reading's consumption is less than the low limit consumption, compute the low percentage =

$((\text{Low limit consumption} - \text{Reading's consumption}) / \text{Low limit consumption}) * 100$, round to the nearest integer.

If the low percentage is less than or equal to the input VERY-LOW-PERCENTAGE-CUTOFF, the reading is considered "very low", otherwise it is considered "low".

High / Very High

If the reading's consumption is greater than the high limit consumption, compute the high percentage =

$((\text{Reading's consumption} - \text{High limit consumption}) / \text{High limit consumption}) * 100$, round to the nearest integer

If the high percentage is greater than or equal to the input VERY-HIGH-PERCENTAGE-CUTOFF, the reading is considered "very high", otherwise it is considered "high".

Set Use On Bill

The parameters USE-ON-BILL-VERY-LOW-READS, USE-ON-BILL-LOW-READS, USE-ON-BILL-VERY-HIGH-READS and USE-ON-BILL-HIGH-READS indicate how to set the Use On Bill flag for the meter read based on the classification of the register readings.

If ANY of the register reads that failed high / low should not be used on bill according to the appropriate input parameter flag, then the meter read's Use On Bill flag is set to N. It is only set to Y if all register reads can be used on a bill based on the input parameters.

Multiple Register Priority

If there are multiple register readings for the meter read that failed high low and the readings have different classifications of "very low", "low", "high" or "very high", determine the "worst" register read based on the value of MULTIPLE-REGISTERS-PRIORITY. The register read considered the "worst" is the one used to create the To Do entry.

The value of this parameter indicates how to prioritize multiple registers with different classifications. The first byte indicates the priority of "very low" reads, the second byte indicates the priority of "low" reads, the third byte indicates the priority of "high" reads and the fourth byte indicates the priority of "very high" reads. Use the numbers 1, 2, 3 and 4, where 1 is the worst type of reading (i.e., the one that needs the most attention). For example, if you would like to review reads in the following order

- Very low
- Very high
- Low
- High

Set the value of MULTIPLE-REGISTERS-PRIORITY to 1342.

Create To Do Entry

Create a To Do entry for the "worst" register read linked to the meter read (determined in the previous section). The To Do type is set to TD-HILO. This section describes the sort fields because they are a bit unusual.

- If the reading is less than the low limit:
 - If the low percentage is \leq VERY-LOW-PERCENTAGE-CUTOFF, create a sort field where:
 - Sort sequence number = 1 (associated with the "very low percentage" sort field)
 - Sort key value = low percentage (calculated above)
 - If the low percentage is $>$ VERY-LOW-PERCENTAGE-CUTOFF, create a sort field where:
 - Sort sequence number = 2 (associated with the "between low and very low percentage" sort field)
 - Sort key value = low percentage
- Calculate the low amount. This value is a positive number and equals the low limit's consumption - read's consumption
 - Sort sequence number = 3 (associated with "low amount" sort field)
 - Sort key value = low amount
- If the reading is greater than the high limit:
 - If the high percentage is \geq VERY-HIGH-PERCENTAGE-CUTOFF, create a sort field where:
 - Sort sequence number = 4 (associated with the "very high percentage" sort field)
 - Sort key value = high percentage (calculated above)
 - If the high percentage is $<$ VERY-HIGH-PERCENTAGE-CUTOFF, create a sort field where:
 - Sort sequence number = 5 (associated with the "between high and very high percentage" sort field)
 - Sort key value = high percentage
- Calculate the high amount. This value is a positive number and equals the read's consumption -high limit's consumption
 - Sort sequence number = 6 (associated with "high amount" sort field)
 - Sort key value = high amount
 - Sort sequence 7 equals the low or high amount

- Sort sequence 8 equals the bill date on/after the current date that linked to a bill cycle associated with accounts linked to the reading's meter configuration's non-abolished service points' non-canceled / non-closed service agreements.

Note: Conditional Sort Fields. The creation of certain sort fields for the entry is conditional. This is unusual, as we have never suppressed a sort field before (i.e., every To Do entry of a given type has referenced every sort field). However, this allows the user to only view certain To Do entries on [To Do List](#) when choosing certain sort fields.

Review High / Low

In order to review register reads that failed high / low checks when they were uploaded to the system, you must run an appropriate background process that creates To Do entries. The system supplies the background process ([TD-HILO](#)). If this process doesn't satisfy your implementation's business requirements, you may create your own.

CAUTION: Register reads entered online that fail high / low checks are not marked for high / low review because we assume the user who entered the read was apprised of the failure when the read was initially entered. This means that only reads that failed high / low checks during the meter read upload background process are marked for high / low review.

When reviewing a To Do entry for a register read that has failed high / low, you may choose to do one of the following:

- Update the value of **Use on Bill** on the [meter read](#) page. If a read fails high / low checks during the meter read upload, the system sets the Use On Bill switch as per the value defined on [Installation Options](#). A user investigating a high / low error may choose to override the default value.
- Request that the meter be read again. On the [meter read](#) page a **Reread Meter** button is available if you want to generate a field activity to reread the meter. The field activity type is defined on the meter's service point's SP type's field activity type profile.
- Determine that the reading is ok and nothing else should be done.

In any case, in order to ensure that the register read does not appear on a To Do entry again, update the **Review High / Low** switch on the [meter read](#) page to unchecked when completing your review.

Usage Management

This section describes concepts and procedures related to usage requests and TOU maps.

Usage Requests

Note:

The information in this section applies to the integration with Oracle Utilities Meter Data Management.

Usage request records are created when bill determinants are requested from Oracle Utilities Meter Data Management during billing. The consumption information is then used to create a bill segment for the associated service agreement.

Refer to [The Big Picture of Usage Requests](#) for more details

Use **Menu > Usage > Usage Request** to open this page. When you select a usage request record, the maintenance portal opens and displays the associated information for the usage request record. You can also navigate to the maintenance portal from the [Bill Segment - Usage](#) page.

Refer the embedded help on this portal's zones for more information.

Working with Time of Use (TOU) Maps

This section describes information related to how data is stored for TOU Maps. For information about defining time of use codes and other related topics, refer to [The Big Picture of Time of Use Mapping and Pricing](#).

For information about defining calculation rules for time of use mapping and pricing, refer to [Calculation Rules for TOU Mapping and Pricing](#).

Note: Time of use mapping is supported to enable low volume interval data manipulation (for example, for mapping electric vehicle charging events into time of use quantities). A meter data management application, such as Oracle Utilities Meter Data Management, must be used to manipulate high volumes of interval data and calculating bill determinants for billing purposes.

About Time of Use (TOU) Maps

The data for a TOU map is a collection of date and time intervals and their corresponding time-of-use codes. Even though you may have several consecutive time periods referencing the same time-of-use code, each interval must be separately defined.

A TOU map is typically specified when configuring a calculation rule for TOU mapping. This TOU map's data will then be used when summarizing the interval data for each TOU period.

TOU Map Data are interval date/times and associated TOU periods as defined by a TOU map template. For example, if the schedule defined for a TOU map template specifies that the period on weekdays from 9 AM to 5 PM falls into On-Peak, and the data is hourly, TOU map data for that template would include records with the date/time 5/3/2010 at 10 AM, 5/3/2010 at 11 AM, 5/3/2010 at 12 PM, etc., each with a value of On-Peak.

Generating Time of Use (TOU) Map Data

In order to facilitate the creation of data for a TOU map, the system enables you to define TOU map templates and provides you with the ability to generate data for a TOU map based on this template.

TOU map templates may be used to define standard data for a TOU map as well as data for special periods, such as holidays. Refer to [Designing Your TOU Map Templates](#) for further information.

Data for a TOU Map may be created in the follow ways:

- By using a button on the TOU Map portal that allows a user to generate TOU map data for the TOU Map
- Through a background process that runs periodically

Creating TOU Maps

Use this procedure to create a new TOU map.

Prerequisites: You must define at least one TOU map type before you can create TOU maps.

1. Select **Menu > Usage > TOU Map > Add**.
2. Select the TOU map type that will define the TOU map.
3. Click **OK**.
4. Enter a description for the TOU map.
5. Select the Override TOU map template for the TOU map.
6. Click **Save**.

TOU Map Search

Use this procedure to search for a TOU map on the TOU Map Query portal.

1. Select **Menu > Usage > TOU Map > Search**.
2. Enter your search criteria. You can search by:
 - Description, TOU Map Type, or Creation Date
 - TOU Map ID
3. Click **Refresh**.
4. In the search results list, click the link for the TOU map you want to view or edit.

Maintaining TOU Maps

Use this procedure to maintain an existing TOU map.

You use the TOU Map portal to maintain TOU maps. This portal includes the following zones:

- **TOU Map:** Defines basic information about the TOU map
- **TOU Map Data List:** Lists TOU map data created from the TOU map

To maintain a TOU map:

1. Select **Menu > Usage > TOU Map > Search.**
2. Search for and select the appropriate TOU map.
3. Click the **Edit** or **Delete** button as appropriate.
4. To deactivate the TOU map, click the **Deactivate** button.
5. To generate TOU map data for the TOU map, click the **Generate TOU Map Data** button, enter the Start and End date and time, and click **Generate**. The TOU Map Data List zone will refresh displayed the generated TOU map data.
6. To edit TOU map data, click the **Edit** icon for the record you wish to change.

Service Orders

In this section, we describe how to manage the fieldwork that takes place at your premise's service points.

The Big Picture Of Field Orders

The topics in this section provide background information about a variety of field order issues.

An Illustration Of A Field Order And Its Field Activities

Fastpath:

Refer to [An Example Of A Field Order](#) for an overview of the field order objects.

An Illustration Of The Entities Involved In Field Order Dispatch

Fastpath:

Refer to [An Example Of The Entities Involved In Field Order Dispatch](#) for an overview of the objects involved in the dispatch of field orders.

Field Activity Type Controls What Is Done In The Field

Fastpath:

For information about field activity types, refer to [Designing Your Field Activity Profiles & Types](#). For more information about field activity completion, refer to [How Does A Field Order Get Completed?](#).

The Lifecycle Of Field Activities And Field Orders

The following diagram illustrates the lifecycle of a typical field activity and its field order.

The preceding diagram is referenced in the topics that follow in this section.

How Are Field Activities Created?

Field activities are created as follows:

- Starting or stopping service indirectly causes field activities to be created to perform the fieldwork necessary to connect or disconnect service. Refer to [Starting Service & Field Activities](#) for more information about how field activities are created to start and stop service. Note, if you use the **Order** transaction to start service, field activities will also be created in the same manner described under the [Starting Service & Field Activities](#) discussion.
- The activation of a severance event with fieldwork causes field activities to be generated to disconnect or reconnect service. For more information about severance events and field activities, refer to [The Big Picture Of Severance Events](#).
- When an operator indicates that a reread should be done for a meter read that fails high/low, a field activity is created. For more information about this process, refer to [Review High / Low](#) for more information.

- An algorithm may be designed to generate a field activity. For example, perhaps the activation algorithm for a [workflow event](#) creates a field activity. Or perhaps a field activity is created as a result of a [meter read remark](#) algorithm.
- An operator may create a field activity at their discretion. This is done for ad hoc service investigation orders. For more information about creating an ad hoc field activity, refer to [Field Activity Maintenance](#).

In the above diagram, the event that takes place on 13-Dec-98 shows two field activities created to start service for a customer on 15-Dec-98. Notice that the activities are not linked to a field order when they're first created. Why? Because field activities exist in a state of limbo awaiting dispatch. At dispatch time, a field order is created and one or more field activities are linked to it.

Creating a field activity before a field order may seem counter-intuitive to you. If so, consider that a field activity is created to perform work at a service point ON SOME FUTURE DATE. Close to the date, a dispatcher will look at all field activities to be performed by a given dispatch group at a premise and group them together under a field order.

How Are Field Orders Created And Dispatched?

The diagram in [The Lifecycle Of Field Activities And Field Orders](#) on page 244 shows that on 14-Dec-98, a field order is created using the [Dispatch Field Activities](#) transaction. This transaction is one of several ways in which a field order can be created. The following points describe every possible way in which a field order can be created:

- The [Dispatch Field Activities](#) page allows a user to create (and dispatch) field orders for pending field activities.
- The [Group Premise Field Activities](#) page allows a user to create (and dispatch) field orders for field activities at a premise.
- The [Automatic Dispatch](#) background process automatically creates field orders for field activities.
- A user may create a field order and link field activities to it using the [Field Order](#) page.

After a field order is created, it's ready to be downloaded to the crew who does the work. Refer to [How Does A Field Order Get Routed To A Field Crew](#) for the details.

How Does A Field Order Get Routed To A Field Crew?

Refer to [Downloading Field Orders](#) for a description of how field orders are routed to field crews.

How Does A Field Order Get Completed?

When fieldwork is performed at a service point, the system must be told what happened. We refer to the process of telling the system what happened in the field as "field order completion".

Note:

Between dispatched and completed states. If you want, you can indicate a field order's fieldwork is done before you actually complete the field order. You do this by changing the field order's status from dispatched to work done, not recorded. You don't have to do this; it's really a question of whether you care about this intermittent state.

You can't complete a field order until all of its non-optional activities are either Complete or Canceled. To complete a field activity, you update the system to reflect what happened in respect of the activity's steps. After which, you must have each step reference the object that was updated or created. For example, if a step initiated the installation of a meter at a service point, you must add a new SP/Meter Installation History record and the step should then reference the new SP/Meter Installation History record.

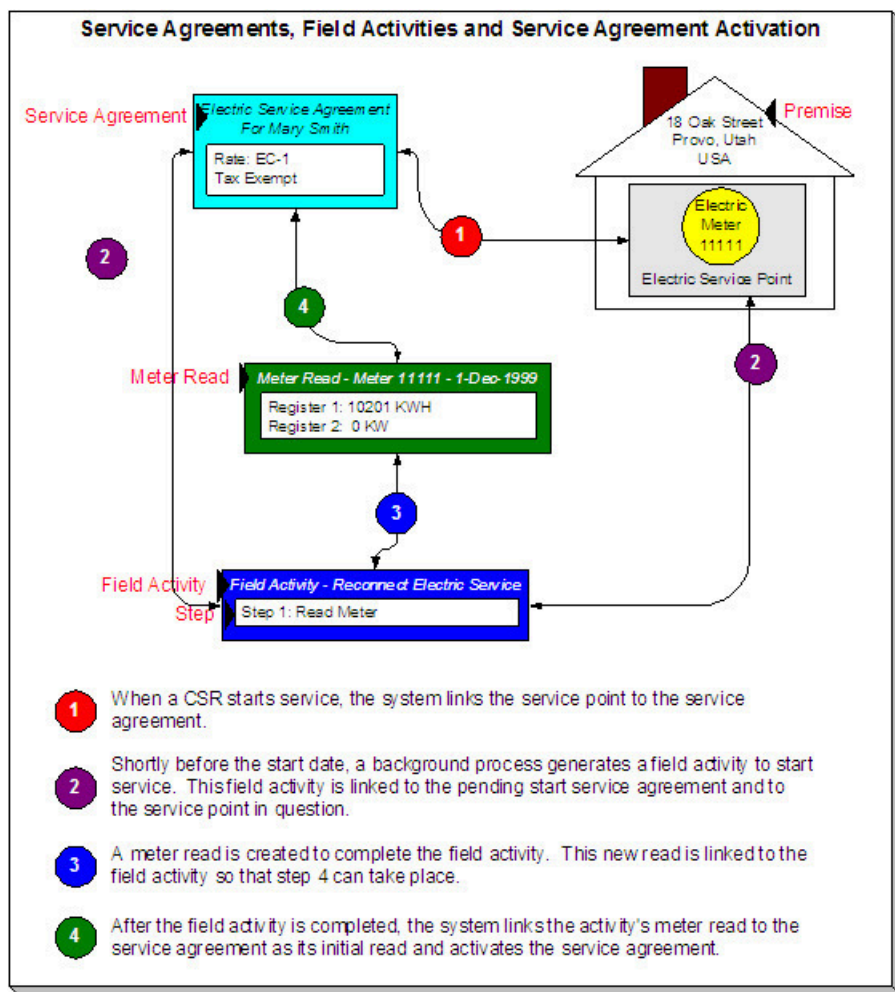

You may wonder why a step needs to reference the object that was updated or created. The reason is a little complex, but it's important you understand the following points:

- After you complete a field activity that is linked to a pending start service agreement, the system automatically activates the service agreement. As part of the activation, if the service point is metered, the system extracts any read that was entered to complete the field activity and uses this as the initial read for the service point. The system extracts the meter read by looking for reads linked to the activity's step(s). Reads may be linked directly

(via a reference to a meter read), or indirectly (via a reference to SP/Meter History). If the step doesn't reference a meter read, the system cannot automatically activate the related service agreement when the field activity is completed.

- An analogous process occurs for field activities linked to pending stop service agreements. The major difference is that the system uses any read linked to the field activity as the service agreement / service point's final read.
- Steps on field activities that are not linked to pending start or stop service agreements exist purely for audit purposes.

The following diagram may help understand the relationship between an activity's read and the service agreement(s) that use the read to start or stop service.

The next thing you may be wondering about is how to reference the updated or created object on a step? There are three ways to do this:

- You can enter completion details on the field activity page. Refer to [Field Activity Maintenance](#) for more information.
- An operator can enter completion details on the field activity upload staging pages. Refer to [Field Activity Upload Staging](#) for the page used to do this. This is the easiest way to complete a field activity.
- You can have your interface team insert rows onto the field activity upload staging tables and let the field activity upload background process complete the activities and orders for you. Refer to [Uploading Field Order Completion Information](#) for more information about the batch completion process.

Completing most field activities is straightforward because the steps performed in the field correspond to the steps on the field activity. Complications arise if a field crew is unable to perform an activity's steps because of any number of reasons (e.g., a field activity instructs a meter to be installed but there's already a meter at the service point). When what took place in the field differs from what was instructed to take place the operator may either:

- Change the activity type on the activity to reflect what happened.
- Cancel the existing field activity and add a new one with the appropriate activity type.

Warning:

If a field activity is linked to a service agreement or a severance event, and what took place in the field isn't consistent with the field activity's steps, we recommend changing the activity type rather than canceling the field activity and adding a new one. Why? Because the object to which a field activity is linked continually checks if the field activity is complete to see if it can take the next logical step in its lifecycle. If you add a new field activity, you'll need to link it to the same object(s) that the original activity was linked. This is a cumbersome process (but possible). It's much easier to simply change the activity's activity type.

What Happens After A Field Activity Is Completed?

After you complete a field activity that is linked to a pending start service agreement, the system automatically activates the service agreement. As part of the activation, if the service point is metered, the system will extract any read that was entered to complete the field activity and use this as the service agreement / service point's initial read.

An analogous process occurs for field activities linked to pending stop service agreements. The major difference is that we use any read linked to the field activity as the service agreement / service point's final read.

After a field activity that is linked to a severance event is completed, the severance event becomes complete. This, in turn, triggers the activation of the next event.

Fastpath:

For more information about field activities linked to pending starts, refer to [Starting Service & Field Activities](#). For more information about field activities linked to pending stops, refer to [Stopping Service & Field Activities](#). For more information about what happens when a field activity that is linked to a pending start or pending stop service agreement is completed, refer to [The System Activates Most Service Agreements Behind-The-Scenes](#) and [The System Finalizes Most Service Agreements Behind-The-Scenes](#). For more information about severance events and field activities, refer to [The Big Picture Of Severance Events](#).

How To Schedule Appointments

Refer to [The Big Picture of Appointments](#) for information about how appointments can be scheduled for field activities.

Dispatch Field Activities Automatically

For large volumes of field activities, it can be useful for the dispatching and extraction of field activities and field orders to be automated.

Dispatching refers to the processes of grouping field activities into related groups by premise and date, etc. The automatic dispatch job (FOD) selects all pending field activities that:

- are not yet connected yet to a FO,
- have a dispatch group,
- are linked to dispatchable FA Type
- have a schedule date \leq today's date + a specified dispatch ahead days AND have a priority = a specified priority (if specified).

The selected field activities are grouped by premise, dispatch group (or alternate dispatch group from the dispatch group table), and date. A field order is created and the grouped field activities are linked to it. The field order will be dispatched on the designated date.

For example, imagine the following field activities:

| Field Activity | Dispatch Group - Primary | Dispatch Group - Alternate |
|----------------|--------------------------|----------------------------|
| 1 | GSR1 | TM1 |
| 2 | GSR2 | GSR1 |
| 3 | TM1 | TM2 |
| 4 | TM2 | MT |
| 5 | MT | MT |

For this set of field activities, the process will group FA 1 and FA 2 based on GSR1, FA 3 and FA 4 based on TM2 and FA 5 will have its own FO.

The rules are:

- Look at the primary dispatch group and try to find a match in the primary or alternate for the other field activities.
- If no match is found, look at the alternate dispatch group and try and match with the primary or alternate for the other field activities.
- If no match is found after step 1 and 2, a separate field order must be created.

The Daily Tasks Of A Dispatcher

In this section, we describe how a dispatcher performs his/her daily tasks.

Dispatching Field Activities

Late in the day, you should review field activities that are scheduled for the next day. A special query exists, [Dispatch Field Activities](#), that shows you all pending field activities that are not linked to field order. From this query, you can define which field activities should be dispatched. The system then creates and dispatches a field order for each unique combination of premise and dispatch group on the selected field activities.

Fastpath:

Refer to [How Are Field Orders Created And Dispatched](#) for other ways to dispatch field activities.

Marking Field Orders As Being Worked

If your organization is told about field orders that have been worked during the day, you can change the status of such field orders to work done, not recorded. You use [Field Order - Main Information](#) to do this.

Look For Orders That Have Slipped Through The Cracks

Occasionally, you should use the [Field Order Search](#) to check if any field orders have been pending by operator for too long. You see, if a user appends a field order, at some point they need to either cancel it or dispatch it. If they don't, the order will sit in limbo forever.

You should also use this query to check for work done, not recorded orders in case someone forgot to complete them.

How To Handle Unusual Situations

In this section, we describe how to handle unusual situations.

Tidying Up Field Orders That Were Not Worked

Sometimes unforeseen events occur and a crew can't work all of their field orders. When this happens, you have two options:

- You can leave the field order in the state of dispatched and give it to the same crew to do the next day.
- You can change the state of the field order to pending by operator, reassign the field order to another dispatch group or representative, and then change the status back to dispatched. This will cause the field order to be dispatched a second time. You use [Field Order - Main Information](#) to do this.

Hold A Field Activity

Sometimes you might want to hold a field activity that was automatically generated by the start/stop/severance processes. Holding an activity prevents it from appearing on the Field Activity Dispatch query (and therefore it shouldn't get dispatched).

At some point in the future, you should either cancel the activity (if you don't want it done) or reset the activity to pending.

Canceling A Field Activity

You should cancel a field activity if it shouldn't be (or wasn't) done.

There are situations when a field activity may be canceled automatically by another process in the system, for example:

- If a field activity is created by start/stop and the start/stop is canceled, the resulting field activity is also canceled
- If a field activity is created by a severance event or cut event and the severance or cut event is canceled, the field activity is also canceled

The processes that attempt to cancel a field activity when a related record is canceled do not continue with the cancel under the following conditions:

- The field activity is already linked to a field order (and is therefore considered dispatched to the field)
- The field activity has been dispatched to an [external system](#) and the FA's intermediate status is one that does not allow auto-cancellation.

Printing Field Orders

The contents of this section describe the technical implementation of field order production.

Dispatch Groups Control The Information Merged Onto Field Orders

Every field order references a [dispatch group](#). The dispatch group controls the following field order print functions:

- It contains an algorithm that is responsible for extracting the information merged onto your field orders. Algorithms of this type are called under the following scenarios:
 - The [background process](#) that interacts with your field order print software calls these algorithms.
 - If your field order print software has the ability to construct a real-time image of a field order, you can plug-in an Online Field Order Image algorithm on the [Installation Record](#). This type of algorithm will call the field order's dispatch group extract algorithm to extract the information that is merged onto the field order. Refer to [Technical Implementation Of Online Field order Image](#) for the details.

Refer to The Field Order Extract Records for examples of the record layouts passed to the document composition application.

- It contains the ID of the background process responsible for interacting with your field order print software in batch.

Technical Implementation Of Online Field Order Image

Users can view an image of any field order if you setup the following:

- Plug-in an Online Field Order Image construction algorithm on the [Installation Record](#).
- Plug-in the appropriate extract algorithm on each [dispatch group](#).

The system provides algorithms that interact with print software that renders an image of the field order in a PDF. The following points describe what takes place when clicking **Display Field Order** when these sample algorithms are used.

- The sample Online Field Order Image algorithm C1-FO-DISP is executed.
- This algorithm calls the field order's dispatch group's extract algorithm. The sample field order extract algorithm C1-FOEX-OX constructs the information that's merged onto the field order and returns it to the Online Field Order Image algorithm. This algorithm, in turn, passes it to your field order print software.
- Your field order print software renders an image of the field order in a PDF and returns it to the Online Field Order Image algorithm. Note that the client must have Adobe Acrobat Reader installed to view PDF files.
- And finally, the Online Field Order Image algorithm displays the PDF in a separate Adobe session.

The system provides an algorithm that interacts with [BI Publisher](#) to render an online image of your field order. The following points describe what takes place when clicking **Display Field Order** when these sample algorithms are used.

- The sample Online Field Order Image algorithm C1-ONFD-CR is executed.
- This algorithm calls the field order's dispatch group's extract algorithm. The sample field order extract algorithm C1-FOEX-CR is supplied for displaying field orders via BI Publisher. This is not actually extracting data because when you use BI Publisher reports, the report itself is responsible for extracting and formatting the data. The base product algorithm supplied returns the appropriate report code to the Online Field Order Image algorithm, which in turn returns the report code to the field order page.
- A user exit on the field order page invokes BI Publisher and displays the field order in a separate browser session.

Fastpath:

Refer to [Field Order Print in BI Publisher](#) for examples of the data extracted for the report.

Technical Implementation Of Batch Field Order Production

A batch process extracts field order information reads all field orders in a given run number that are marked with its batch control ID.

The base package example of this process ([FODL](#)) simply calls the extract algorithm on the dispatch group to format the information placed onto the flat file. Refer to [Dispatch Groups Control The Information On Field Orders](#) for more information on the base processing.

Note:

If your software doesn't support online field order images. The algorithm that formats field order extract records that's plugged in on [dispatch group](#) serves two purposes: 1) it interacts with the online field order image algorithm plugged into the installation record to support online images of a field order, and 2) it interacts with the background process to support printing your field orders in batch. If your field order print software does not support the rendering of field order images real time, there is no need to create an extract algorithm. Rather, you should simply develop your own download process that works with your field order print software to print field orders in batch (and then specify this batch process on your dispatch group).

Reproducing The Field Order Print Flat File

If you use the method of extracting to a flat file, you can reproduce the flat file at any time. Simply request the [FODL](#) process and specify the run number associated with the historic run.

How To Reprint A Specific Field Order

If you need to reprint a specific field order, navigate to [Field Order - Main Information](#) and change the order's status to Dispatched.

If your implementation has [enabled the online creation of field order images](#), you can also click the **Display Field Order** button on this page and then print the resultant online image on your local printer.

Who Gets A Copy Of A Field Order?

Fastpath:

Refer to [The Lifecycle Of Field Activities And Field Orders](#) for more information.

The Field Order Extract Records

Note:

Alternate print / routing methods. This section describes the format of field order extract records that are constructed by base-package algorithms that are passed to the document composition application (which actually produces the field orders). If you require different print formats, you must create new extract algorithms and plug them in on your [dispatch groups](#).

Numerous types of records are interfaced to the document composition application. However, they all share a common structure for field orders:

- The first 4 bytes are called the **Printer Key**. This field is a record type used by the document composition application field order template.
- The next 187 bytes are called the **Sort Key**. This field is used to ensure the various records used to construct a printed field order appear in the correct order in the interface file.
- The remaining bytes contain the **Field Order Information** that appears on the printed field order. The type of information differs for each type of record.

The topics in this section describe each component.

Printer Keys (Record Types)

The following table defines each printer key (i.e., record type) on the field order print flat file.

| Record Type | Description | Notes |
|-------------|----------------------------|------------------------------|
| 0010 | Global extract information | Required. 1 per flat file. |
| 0100 | Field Order record | Required. 1 per field order. |
| 2000 | Service Point record | Required. N per FO. |
| 2200 | Item record | 1 per SP. |
| 2400 | Meter record | 1 per SP. |
| 2450 | Register record | N per SP. |

| | | |
|------|--|----------------------------------|
| 2490 | End Meter record | 1 per SP (dummy). |
| 2600 | SP/Multi-item record | 1 per SP. |
| 2620 | Multi-item Detail record | N per SP. |
| 2690 | End SP/Multi-item record | 1 per SP (dummy). |
| 3000 | Field Activity record | Required, Occurs N. |
| 3100 | Field Activity Credit & Collections record | 1 per FA. |
| 3200 | Field Activity Step record | Required, Occurs N. |
| 3410 | Enter Meter Badge No | 1 per FA Step (dummy). |
| 3430 | Enter Item Badge No | 1 per FA Step (dummy). |
| 3450 | Enter Cust. Contact Info | 1 per FA Step (dummy). |
| 3470 | Enter Reconfig. Register | 1 per FA Step (dummy). |
| 3490 | Enter Discon. Loc. Info | 1 per FA Step (dummy). |
| 3510 | Enter Register Read | 1 per FA Step (dummy). |
| 3530 | Enter Multi Item Info | 1 per FA Step (dummy). |
| 3550 | Enter TO Statistics Info | 1 per FA Step (dummy). |
| 3570 | Enter Misc Changes Info | 1 per FA Step (dummy). |
| 3999 | Generic (placeholder) | 1 per FA Step (dummy). |
| 6100 | End Field Activity Step record | Required. 1 per FA Step (dummy). |
| 6200 | End of Field Activity record | Required. 1 per FA (dummy). |
| 6300 | End of Service Point record | Required. 1 per SP (dummy). |
| 9990 | End of Field Order record | Required. 1 per FO (dummy). |

Sort Key

The field order print records need to be sorted in the right sequence in order for a document composition application to process them. The following is a description of the portion of each record that is responsible for performing this task.

Note that the first ten fields in the Sort Key - DISP_GRP_CD through FO_ID - are all from the CIS database records. For each Field Order in an extract run, there will be a "block" of records of indeterminate size in which the values of these first ten fields will be identical. These ten fields see to it that each block is sorted correctly within the extract as a whole. It is the task of the last six fields to make certain that the records in a particular Field Order's block are sorted correctly within the block. Most of these six are artificial, but two are from the CIS database, where they serve a similar function.

The precise mechanics of the Sort Key may be difficult to envision. This is particularly true with regard to the three-in-one format of the Sequence Number field described in the table below. A look at the Order of Record Types section above may help to make it clearer. Within a given Field Order (FO) block there are several sub-groups. Not only must each sub-group as a whole be in the proper sequence within the FO block, but each record in a sub-group must be in the proper sequence within the sub-group. These sub-groups are Service Point (one or more per FO with one or more Field Activities at each SP), Meter (a Meter and its Registers), Multi-Item (a Multi-Item record and its Detail Lines), and Field Activity (a Field Activity record and its various Steps).

The following table defines the structure of the sort key that appears on each field order print record. Please note that different components are filled in for each printer key.

| Field Name | Format | Source/Value/Description |
|--------------------------|--------|---|
| DISP_GRP_CD | A8 | CI_FO / Dispatch Group code |
| REP_CD | A8 | CI_FO / Representative code |
| STATE | A6 | CI_PREM / State of the Premise address |
| CITY | A30 | CI_PREM / City of the Premise address |
| POSTAL | A12 | CI_PREM / Postal Code of the Premise address |
| ADDRESS1 | A64 | CI_PREM / first line of the Premise street address |
| PREM_ID | A10 | CI_FO / System-assigned identifier for the Premise |
| SCHED_DT | D10 | CI_FO / Scheduled date of the Field Order |
| SCHED_TM | T15 | CI_FO / Scheduled time of the Field Order |
| FO_ID | A10 | CI_FO_STG_DWN / System-assigned identifier of the Field Order |
| FO Group [Artificial] | N2 | This field forces the Service Point record group(s) into a position subordinate to the Field Order. Values: 10 - Field Order 30 - SP 90 - End Field Order |
| SP Sequence [Artificial] | N2 | If there is more than one Service Point on a particular FO, this field forces them into an arbitrary sequence. Each SP is then followed by its device and Field Activity record group(s). |

| | | |
|--|----|---|
| SP Group [Artificial] | N2 | <p>This field forces the device (meter, item or multi-item) and Field Activity record groups into a position subordinate to the Service Point.</p> <p>Values:</p> <ul style="list-style-type: none"> 10 - SP 20 - Item 30 - Meter 35 - End Meter 40 - Multi-Item 45 - End Multi-Item 50 - FA 60 - End SP |
| <p>Sequence Number READ_SEQ [Artificial] [Artificial]</p> | N3 | <p>This field serves the same purpose in three distinct areas:</p> <p>Register Sequence (within a Meter record) (CI_REG)</p> <p>Item Sequence (within a Multi-Item record)</p> <p>FA Sequence (within a Service Point)</p> <p>In each instance, it forces the subordinate records into the correct order within, respectively, the Meter, Multi-item and Service Point record sub-groups.</p> |
| STEP_SEQ_NBR | N3 | <p>CI_FA_STEP</p> <p>In addition to the "natural" values from the CIS database, there are two artificial values that serve to force a particular record into its proper place within the FA sub-group:</p> <ul style="list-style-type: none"> 000 - Credit & Collections record 999 - End FA record |

FA Step Group [Artificial]

N2

Each FA Step will have one or more FA Step (action) records. This field is to force these records into an arbitrary sequence within the FA subgroup. Values:

10 - Enter Meter Badge Number

20 - Enter Item Badge Number

30 - Enter Customer Contact

40 - Enter Reconfigure Register

50 - Enter Disconnect Location

60 - Enter Register Reading

70 - Enter Multi-item

80 - Enter Trouble Order Statistics

90 - Enter Changes

98 - Generic (placeholder)

99 - End FA Step

Field Order Information

The topics in this section describe the information that appears on each field order print record.

- [Global Information Record](#)
- [Field Order Record](#)
- [SP Record](#)
- [Item Record](#)
- [Meter Record](#)
- [Register Record](#)
- [End Meter Record](#)
- [SP/Multi-Item Record](#)
- [Multi-Item Detail Line Record](#)
- [End SP/Multi-Item Step Record](#)
- [Field Activity Record](#)
- [Credit and Collection Record](#)
- [Field Activity Step Record](#)
- [Field Activity Step \(Enter Meter Badge Number\) Record](#)
- [Field Activity Step \(Enter Item Badge Number\) Record](#)
- [Field Activity Step \(Enter Customer Contact\) Record](#)
- [Field Activity Step \(Enter Reconfigure Register\) Record](#)
- [Field Activity Step \(Enter Disconnect Location\) Record](#)
- [Field Activity Step \(Enter Register Read\) Record](#)
- [Field Activity Step \(Enter Multi-Item\) Record](#)
- [Field Activity Step \(Enter TO Stat\) Record](#)
- [Field Activity Step \(Enter Changes\) Record](#)

- [End SP Record](#)
- [End Field Order Record](#)
- [Definition of Address Subrecord \(Sbr\)](#)

Global Information Record

This is a "header" record that contains information about the extract run as a whole.

Note:

Please be aware that if you do not sort your extract file by **CIS Sort Key** after it is produced, this record will physically be the last record on the extract file.

| Field Name | Format | Source/Value/Description |
|---------------------------|--------|--|
| Print Key | A4 | "0010" |
| CIS Sort Key | A187 | Note: For the Global Record only, the Sort Key is all blanks. |
| BATCH_CD | A8 | CI_BATCH_INST / The CIS Batch Process that called the FO Extract routine |
| BATCH_NBR | N10 | CI_BATCH_INST / A sequence number for serial instances of a Batch Process over time |
| BATCH_RERUN_NBR | N10 | CI_BATCH_INST / The number of times a particular batch has been re-run since its initial run |
| FO Count [Artificial] | N10 | Total number of distinct FO record blocks in an extract |
| Date/Time [Artificial] | A26 | System time of extraction. |
| FO Id Start [Artificial] | A10 | The lowest valid FO ID in a particular thread in the extract. If there is only one thread, this will be '000000000'. |
| FO Id End [Artificial] | A10 | The highest valid FO ID in a particular thread in the extract. If there is only on thread, this will be '999999999'. |
| BATCH_THREAD_NBR | N10 | CI_BATCH_THD / Identifies a thread distinctly within a group of threads |
| Thread Count [Artificial] | N10 | Total number of threads in the extract run |

[Top of Page](#)

Field Order Record

One record is produced for every field order to be printed.

| Field Name | Format | Source/Value/Description |
|--|--------|--|
| Print Key | A4 | "0100" |
| CIS Sort Key | A187 | |
| FO_ID | A10 | CI_FO_STG_DWN / System-assigned identifier for a Field Order |
| PREM_ID | A10 | CI_FO / System-assigned identifier for the Premise at which the Field Order will be done |
| SCHEDED_DT | D10 | CI_FO / The scheduled date of the Field Order |
| SCHEDED_TM | T15 | CI_FO / The scheduled time of the Field Order (optional) |
| DISP_GRP_CD | A8 | CI_FO / The Dispatch Group to which the Field Order has been assigned |
| REP_CD | A8 | CI_FO / The Representative within the Dispatch Group |
| DESCR254 | C254 | CI_FO / Free-form notes about the Field Order |
| ACCT_ID | A10 | CI_SA / The Account that is/has been/will be paying for services at the Premise |
| ENTITY_NAME | A64 | CI_PER_NAME / The Primary name of the Main customer on the Account identified above |
| Multiple Account Message [Artificial] | A10 | A message item indicating the existence of more than one active Account associated with a Premise. |
| ADDRESS_SBR | A361 | CI_PREM / A sub-record of address information (Defined in detail later in this section) |
| MR_WARN_CD | A4 | CI_PREM / Meter Read Warning code |
| DESCRIPTION | A60 | CI_MR_WARN / Description of the MR Warning code |
| MR_INSTR_CD | A4 | CI_PREM / Meter Read Instruction code |

| | | |
|------------------|------|--|
| DESCRIPTION | A60 | CI_MR_INSTR / Description of the MR Instruction code |
| MR_INSTR_DETAILS | A250 | CI_PREM / For an expanded version of the Meter Read Instruction above, or for information deemed relevant but for which no code exists. |
| Telephone Info | | Telephone numbers for the Main customer on the Account above. Occurs 3 times per FO Record, consisting of the following three fields: |
| PHONE_TYPE | A12 | CI_PER_PHONE / The type of telephone. Typical values are Home, Business, Dormitory, Cellular, Fax. |
| PHONE | A24 | CI_PER_PHONE / Self-explanatory |
| EXTENSION | A6 | CI_PER_PHONE / Self-explanatory |
| LS_SL_SW | A1 | CI_PER / Life Support or Sensitive Load. Set to "Y" if any Person on any active Account associated with this Premise has this type of information on their record. |
| LS_SL_DESCR | A254 | CI_PER / Description of the Life Support/Sensitive Load |
| LL_ID | A10 | CI_PREM / System-assigned identifier for a Premise's landlord (if one exists) |
| DESCRIPTION | A60 | CI_LANDLORD / Description of the Landlord |
| ACCT_ID | A10 | CI_LANDLORD / The Landlord's account number |
| Geographic Info | | Geographic locator types and their values for the Premise. Occurs 3 times per FO Record, consisting of the following two fields: |
| DESCR | A60 | CI_GEO_TYPE / The description of a geographic locator type |
| GEO_VAL | A50 | CI_PREM_GEO / The actual value of the above locator type at a given Premise |

[Top of Page](#)

SP Record

One record is produced for every Service Point (SP) that has a field activity on the field order. Up to 15 characteristics and their respective values can be listed for a SP. If there is no Characteristic information for the SP on the database, the fields will be blank.

| Field Name | Format | Source/Value/Description |
|-------------------|--------|---|
| Print Key | A4 | "2000" |
| CIS Sort Key | A187 | |
| SP_ID | A10 | CI_SP / Unique system-generated identifier for the Service Point |
| SP_TYPE_CD | A8 | CI_SP / The Service Point's type code |
| DESCR | A60 | CI_SP_TYPE / The description of the SP Type |
| SP_SUBTYPE_FLG | A2 | CI_SP_TYPE / The SP Type's sub-type code. Values: M - Meter I - Item U - Unbadged (multi-item) |
| DESCR | A60 | CI_LOOKUP / The description of the sub-type |
| SP_SRC_STATUS_FLG | A2 | CI_SP / The status of the source of the service delivered through a Service Point. |
| DESCR | A60 | CI_LOOKUP / The description of the source status |
| DISCON_LOC_CD | A4 | CI_SP / If the SP has been disconnected, a code for the location of the disconnection |
| DESCR | A60 | CI_LOOKUP / The description of the disconnect location |
| MTR_LOC_CD | A4 | CI_SP / A code for the location at the Premise of the Service Point's Meter |
| DESCR | A60 | CI_MTR_LOC / The description of the location code |
| MTR_LOC_DETAILS | A250 | CI_SP / Detailed information regarding the location of the SP's Meter |
| SP_MTR_RD_CYCLE | A30 | CI_MR_CYC / Description of the SP's Service Cycle |

| | | |
|---------------------|------|---|
| SP_MTR_RD_ROUTE | A30 | CI_MR_RTE / Description of the SP's Service Route |
| SP_FAC_LVL_1 | A30 | CI_FAC_LVL_1 / Description of the SP's Level 1 Facility |
| SP_FAC_LVL_2 | A30 | CI_FAC_LVL_2 / Description of the SP's Level 2 Facility |
| SP_FAC_LVL_3 | A30 | CI_FAC_LVL_3 / Description of the SP's Level 3 Facility |
| Geographic Info | | Geographic locator types and their values for a Service Point. Occurs 3 times per record, consisting of the following two fields: |
| DESCR | A60 | CI_GEO_TYPE / The description of a geographic locator type |
| GEO_VAL | A50 | CI_SP_GEO / The actual value of the above locator type at a given Service Point |
| Characteristic Info | | Occurs 15 times per record, consisting of the following two fields: |
| SP_CHAR | A30 | CI_CHAR_TYPE / The description of a Characteristic that the Service Point has been deemed to possess |
| SP_CHAR_VALUE | A30 | CI_CHAR_VAL / The description of the Value of the above Characteristic for this Service Point |
| MR_WARN_CD | C4 | Field Warning code |
| DESCRIPTION | C30 | Description of the Field Warning code |
| MR_INSTR_CD | C4 | Field Instruction code |
| DESCRIPTION | C30 | Description of the Field Instruction code |
| MR_INSTR_DETAILS | C250 | For an expanded version of the Field Instruction above, or for information deemed relevant but for which no code exists |

[Top of Page](#)

Item Record

This record is produced if a Service Point is of subtype Item. Because an SP may have at most one badged item installed at any given point in time, there is at most one record for an SP. If there is no Item currently installed, a message is printed to that effect.

| Field Name | Format | Source/Value/Description |
|--------------|--------|---|
| Print Key | A4 | "2200" |
| CIS Sort Key | A187 | |
| ITEM_ID | A10 | CI_SP_ITEM_HIST / The system-generated ID of the Item currently installed at the Service Point |
| BADGE_NBR | A16 | CI_ITEM / The Item's badge number |
| ITEM_TYPE_CD | A8 | CI_ITEM / A code specifying the type of the Item |
| DESCR | A60 | CI_ITEM_TYPE / The description of the Item type |
| MFG_CD | A8 | CI_ITEM / A code for the manufacturer of the Item |
| DESCR | A60 | CI_MFG / The actual name of the manufacturer |
| MODEL_CD | A8 | CI_ITEM / The manufacturer's model number for the Item |
| DESCR | A60 | CI_MODEL / The description of the model |
| SERIAL_NBR | A16 | CI_ITEM / Self-explanatory |
| RECEIVE_DT | D10 | CI_ITEM / The date on which the Item was received by the utility from its manufacturer. This is NOT the install date. |
| DESCR254 | A254 | CI_ITEM / A detailed description of the Item (optional). |
| EVENT_DTTM | D26 | CI_SP_ITEM_EV_I / The date and time of the installation of the Item at its current location. |

[Top of Page](#)

Meter Record

This record is produced if a Service Point is of subtype Meter. Because an SP may have at most one meter installed at any given point in time, there is at most one record for an SP. If there is no Meter currently installed, a message is printed to that effect.

| Field Name | Format | Source/Value/Description |
|---------------|--------|---|
| Print Key | A4 | "2400" |
| CIS Sort Key | A187 | |
| MTR_ID | A10 | CI_MTR_CONFIG / The system-generated identifier for the Meter currently installed at the Service Point. |
| BADGE_NBR | A16 | CI_MTR / The Meter's badge number |
| MTR_TYPE_CD | A8 | CI_MTR / A code for the type of the Meter |
| MFG_CD | A8 | CI_MTR / A code for the manufacturer of the Meter |
| DESCR | A60 | CI_MFG / The actual name of the manufacturer |
| MODEL_CD | A8 | CI_MTR / The manufacturer's model number for the Meter |
| DESCR | A60 | CI_MODEL / A description of the model |
| SERIAL_NBR | A16 | CI_MTR / Self-explanatory |
| RECEIVE_DT | D10 | CI_MTR / The date on which the Meter was received by the utility from its manufacturer. This is NOT the install date. |
| DESCR254 | A254 | CI_MTR / A detailed description of the Meter (optional). |
| INSTALL_DTTM | D26 | CI_CFG_SPMR_VW / The date and time of the installation of the Meter at its current location. |
| MTR_CONFIG_ID | A10 | CI_SP_MTR_HIST / The system-generated identifier for the Meter's current Configuration |
| EFFDT | D10 | CI_MTR_CONFIG / The effective date of the current Configuration |
| EFF_TM | T15 | CI_MTR_CONFIG / The effective time of the current Configuration |

[Top of Page](#)

Register Record

One record is produced for every register on the currently effective Meter Configuration.

| Field Name | Format | Source/Value/Description |
|------------------|--------|--|
| Print Key | A4 | "2450" |
| CIS Sort Key | A187 | |
| REG_ID | A10 | CI_REG / The system-generated unique identifier for the Register |
| READ_SEQ | N2 | CI_REG / The read sequence of the Register |
| UOM_CD | A30 | CI_REG / The Unit Of Measure in which the Register is calibrated |
| TOU_CD | A30 | CI_REG / The Time Of Use period during which the Register measures consumption |
| REG_CONST | N6.6 | CI_REG / The Register Constant (if any) by which the actual reading is multiplied to calculate consumption |
| CONSUM_SUB_FLG | A2 | CI_REG / A flag that indicates whether the Register is a consumptive or subtractive register |
| HOW_TO_USE_FLG | A2 | CI_REG / A flag that indicates whether the Register's measured consumption is to be added to, subtracted from, or used as a check against the measured consumption of other Registers (if the Register is Subtractive) or measures a peak (maximum) value (if the Register is Consumptive) |
| NBR_OF_DGTS_LFT | N1 | CI_REG / The number of digits to the left of the decimal point on the Register's readout |
| NBR_OF_DGTS_RGT | N1 | CI_REG / The number of digits to the right of the decimal point on the Register's readout |
| FULL_SCALE | N9.5 | CI_REG / The maximum value that can be displayed on the Register's readout before it "turns over" to zero |
| READ_OUT_TYPE_CD | A8 | CI_REG / A code indicating the type of physical readout (dials, digital etc.) employed on the Register |

| | | |
|---------------|------|---|
| PROTOCOL_CD | A8 | CI_REG / A code indicating the means by which the register's consumption information is collected |
| TOLERANCE | N9.5 | CI_REG / Tolerance is used to warn the meter reader that a Register is approaching its maximum permitted value |
| READ_DTTM | D26 | CI_MR / The date and time of the most recent Register reading that is either a Customer Read, Regular read or a Verified read |
| REG_READING | N9.6 | CI_REG_READ / The actual value displayed on the Register's readout when it was most recently read |
| READ_TYPE_FLG | A2 | CI_REG_READ / The type code of the Register reading |

[Top of Page](#)

End Meter Record

A "dummy" record used to signal the document composition application that the last Register record for a Meter has been reached.

| Field Name | Format | Source/Value/Description |
|--------------|--------|--------------------------|
| Print Key | A4 | "2490" |
| CIS Sort Key | A187 | |

[Top of Page](#)

SP/Multi-Item Record

This record is produced if a Service Point is of subtype Unbadged. The Multi-Item record on the database has only two fields, the Service Point ID and the Effective Date, both of which form a composite Prime Key. Since this record always appears subordinate to the SP in the SP Group, only the date field is needed here. This record is stipulated in the CIS database as the parent to the detail item records that are its children.

| Field Name | Format | Source/Value/Description |
|--------------|--------|--------------------------|
| Print Key | A4 | "2600" |
| CIS Sort Key | A187 | |
| EFF_DT | D10 | CI_SP_MULT_ITEM |

[Top of Page](#)

Multi-Item Detail Line Record

One record is produced for each distinct type of item on the effective multi-item configuration at the time of printing. There may be any number of distinct item types and any number of individual items of a given type.

| Field Name | Format | Source/Value/Description |
|--------------|--------|---|
| Print Key | A4 | "2620" |
| CIS Sort Key | A187 | |
| ITEM_TYPE_CD | A8 | CI_MULT_ITEM / A code for the type of Item |
| DESCR | A60 | CI_ITEM_TYPE / The description of the Item type |
| ITEM_CNT | N9.2 | CI_MULT_ITEM / The number of individual Items of a given type |

[Top of Page](#)

End SP/Multi-Item Step Record

A "dummy" record to signal the document composition application that the last Item record in a Multi-Item configuration has been reached.

| Field Name | Format | Source/Value/Description |
|--------------|--------|--------------------------|
| Print Key | A4 | "2690" |
| CIS Sort Key | A187 | |

[Top of Page](#)

Field Activity Record

One record is produced for each Pending field activity linked to the field order. Activities in any other Status are ignored.

| Field Name | Format | Source/Value/Description |
|-----------------|--------|---|
| Print Key | A4 | "3000" |
| CIS Sort Key | A187 | |
| FA_ID | A10 | CI_FA / The unique system-generated identifier for a Field Activity |
| FA_TYPE_CD | A8 | CI_FA / A code specifying the Field Activity's type |
| DESCR | A60 | CI_FA_TYPE / The description of the FA type |
| FA_PRIORITY_FLG | A2 | CI_FA / In the case of several Activities being created for the same SP, the Priority Flag stipulates which should be done first. |

| | | |
|-------------------|------|---|
| FA_CREATED_BY_FLG | A2 | CI_FA / A code indicating who or what originated this Field Activity |
| XLATLONGNAME | A30 | CI_LOOKUP / The description of the Created By flag |
| SCHED_DT | D10 | CI_FA / The date on which the Activity is scheduled to be done |
| SCHED_TM | T15 | CI_FA / The time at which the Activity is scheduled to commence (optional). |
| INSTRUCTIONS | A254 | CI_FA / Free form detailed instructions as to exactly what is to be done. |
| DESCR254 | A254 | CI_FA / A more detailed description of the FA Type (optional) |

[Top of Page](#)

Credit and Collection Record

One record is produced for a Field Activity that was created by a Severance Process (*i.e.*, FA_CREATED_BY_FLG = "SE" (Severance Event)).

| Field Name | Format | Source/Value/Description |
|---------------------------------------|--------|---|
| Print Key | A4 | "3100" |
| CIS Sort Key | A187 | |
| SA_ID | A10 | CI_SEV_PROC / The Service Agreement for which a Severance Process has issued a Disconnect field activity as a result of a Severance Event |
| Overdue Amount [Artificial] | N13.2 | The program calls another routine (ProgramCIPFFTBN) that calculates this amount based on the Severance Process Arrears Date |
| Current Amount [Artificial] | N13.2 | The program calls another routine (ProgramCIPFFTBN) that calculates this amount using the current date. |
| Past Severance Processes [Artificial] | N3 | The number of Severance Processes issued against this Service Agreement in the past, excluding the one that generated this Activity |
| ACCT_ID | A10 | CI_SA / The Account associated with the Service Agreement above |

| | | |
|-------------------------------|-------|---|
| ENTITY_NAME | A64 | CI_PER_NAME / The Primary name of the Main customer on the Account above |
| BILL_DT | D10 | CI_BILL / The date of the most recent bill that is charged to the Account above |
| CUR_AMT | N13.2 | The dollar amount of the most recent bill. Calculated from CI_BILL_SA |
| PAY_DT | D10 | CI_PAY_EVENT / The date of the most recent Frozen payment on the Account of the SA above |
| PAY_AMT | N13.2 | CI_PAY / The amount of the most recent Frozen payment on the Account of the SA above |
| Credit Rating [Artificial] | N5 | Calculated from the Beginning Credit Rating Base on the Installation record or the account's CIS Division, and CR_RATING_PTS from CI_ACCT_CR_R_VW |
| Cash-only Switch [Artificial] | A1 | Set to "Y" if the Cash-Only score is above the Cash Only Threshold as defined on the Installation record. Calculated from the Cash Only Base Score on the Installation record or the account's CIS Division, and CASH_ONLY_PTS from CI_ACCT_CR_R_VW |
| Deposit Amount [Artificial] | N13.2 | The program calls another routine (ProgramCIPDFVN) to calculate this amount |

[Top of Page](#)

Field Activity Step Record

One record is produced for each Step within a Field Activity.

| Field Name | Format | Source/Value/Description |
|--------------------|--------|---|
| Print Key | A4 | "3200" |
| CIS Sort Key | A187 | |
| STEP_SEQ_NBR | N3 | CI_FA_STEP / The sequence of a Step within a Field Activity |
| FA_STEP_TY_ACT_FLG | A2 | CI_FA_STEP / A code indicating the FA Step Type Action. |

| | | |
|---------------|-----|---|
| XLATLONGNAME | A60 | CI_LOOKUP / The description of the FA Step Type Action. |
| FA_STEP_DESCR | A60 | CI_FA_STEP_TYPE / Description of the FA Step Type. |
| OPTIONAL_SW | A1 | CI_FA_STEP_TYPE / "Y" indicates that a particular Step is regarded as optional for field activities of this FA Type |

[Top of Page](#)

The following field activity step record types (through End Field Order Record) are all "dummy" records that contain no information and exist only to signal the document composition application to print a pre-specified block of text.

[Top of Page](#)

Field Activity Step (Enter Meter Badge Number) Record

This record is produced if the step requires space for the field worker to write a meter's badge number.

| Field Name | Format | Source/Value/Description |
|--------------|--------|--------------------------|
| Print Key | A4 | "3410" |
| CIS Sort Key | A187 | |

[Top of Page](#)

Field Activity Step (Enter Item Badge Number) Record

This record is produced if the step requires space for the field worker to write an item's badge number.

| Field Name | Format | Source/Value/Description |
|--------------|--------|--------------------------|
| Print Key | A4 | "3430" |
| CIS Sort Key | A187 | |

[Top of Page](#)

Field Activity Step (Enter Customer Contact) Record

This record is produced if the step requires space for the field worker to write customer contact information.

| Field Name | Format | Source/Value/Description |
|--------------|--------|--------------------------|
| Print Key | A4 | "3450" |
| CIS Sort Key | A187 | |

[Top of Page](#)

Field Activity Step (Enter Reconfigure Register) Record

This record is produced if the step requires space for the field worker to write register configuration information.

| Field Name | Format | Source/Value/Description |
|--------------|--------|--------------------------|
| Print Key | A4 | "3470" |
| CIS Sort Key | A187 | |

[Top of Page](#)

Field Activity Step (Enter Disconnect Location) Record

This record is produced if the step requires space for the field worker to write disconnect location.

| Field Name | Format | Source/Value/Description |
|--------------|--------|--------------------------|
| Print Key | A4 | "3490" |
| CIS Sort Key | A187 | |

[Top of Page](#)

Field Activity Step (Enter Register Read) Record

This record is produced if the step requires space for the field worker to write register read information.

| Field Name | Format | Source/Value/Description |
|--------------|--------|--------------------------|
| Print Key | A4 | "3510" |
| CIS Sort Key | A187 | |

Field Order Maintenance

A field order contains the field activities that connect, disconnect, and investigate service at a premise. The topics in this section describe the pages on which field order-related information is maintained.

Fastpath:

For more information about field orders, refer to [The Big Picture Of Field Orders](#) and [How Are Field Orders Created And Dispatched](#).

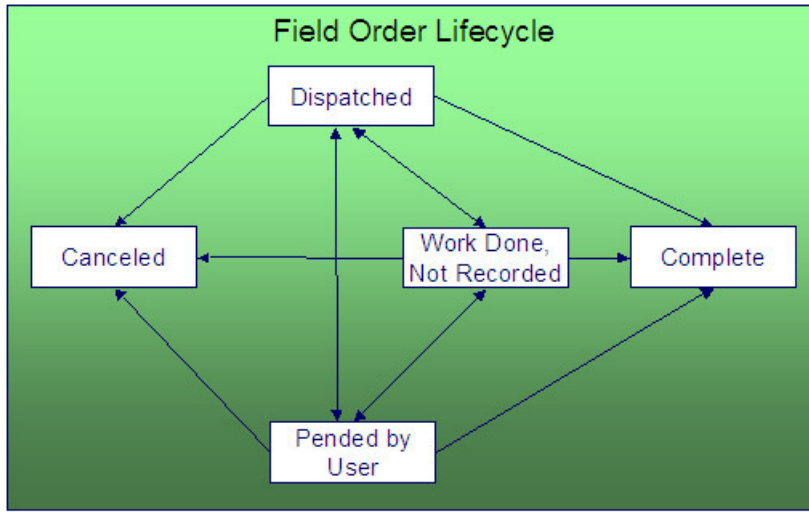

Lifecycle of a Field Order

The following diagram illustrates the lifecycle of a field order.

Fastpath:

Refer to [The Lifecycle Of Field Activities and Field Orders](#) for a more detailed discussion of the lifecycle of a field order. The following diagram merely illustrates the state transition rules.

Dispatched A field order starts its life in the Dispatched state. Please note that when a field order is dispatched, its field activities remain in the Pending state.

Pended by User You Pend a field order when you want to indicate to others that it shouldn't be dispatched (for whatever reason).

Work Done, Not Recorded You may mark a field order as Work Done, Not Recorded if you know the field work is complete, but you lack the details (or time) to actually Complete the field order.

Complete After the related field work has been performed, the system is updated to reflect what happened and the field order becomes complete. No changes may be made to a Complete field order. Refer to [How Does A Field Order Get Completed](#) for more information about completion.

Canceled A field order may be Cancelled.

Field Order - Main Information

The Main page contains core field order information. Open this page using **Menu > Field Order > Field Order > Search**.

Description of Page

Field Order is a concatenation of information about the order. It consists of the address of the premise, the status of the field order, the number of field activities linked to the order and, if the order has been completed, the date on which the work was done.

Field Order ID is the unique system-generated identifier for the field order.

Enter the **Premise ID** of the premise at which the field order will take place.

Use **Schedule Date/Time** to define when the field order is scheduled to be done.

Enter **Reschedule Reason** when changing the field order's schedule date/time.

Note:

Reschedule Reason only appears if the **Fieldwork Options** feature configuration exists with the **Reschedule Reason Required** option set to Y.

Field Order Status defines the state of the field order. The following values may exist:

Dispatched When the system creates a field order due to the dispatch of field activities, the system creates a field order in the Dispatched state. A field order remains in this state until the work is done. At that time, you can change the state to Work Done, Not Recorded. Alternatively, you can enter the results of the fieldwork (if available) and change the state to Completed. If the field order cannot be done for any reason, you should change the state to Canceled. Refer to [How Does A Field Order Get Completed?](#) for more information.

Work Done, Not Recorded You may change a field order to this state if you want to indicate the fieldwork has been done, but you don't have the necessary information to complete the order. After the completion information has been entered, you should change the status to Completed.

Note. You should only use this state if your organization keeps track of the state of dispatched field orders during the workday. If you don't do this, you can transition a field order from Dispatched directly to the Completed state.

Completed A Completed order is one where the fieldwork is done and the results have been entered into the system. An order can only be in this state if all of its field activities are in the state of completed or canceled.

Canceled You cancel an order when, for whatever reason, it cannot be done. You may uncanceled an order by changing its status to an appropriate value.

Pended by User It should be rare to find a field order in this state as it is used when you want to hold a field order pending some event. A field order remains in this state until you decide what to do with it (either dispatch or cancel it). At that time, you change its status to an appropriate value.

Fastpath:

To completely understand the significance of a field order's status, refer to [The Big Picture Of Field Orders](#).

Enter **Cancel Reason** when canceling the order.

Note:

Cancel Reason only appears if the **Fieldwork Options** feature configuration exists with the **Cancel Reason Required** option set to Y.

The **Display Field Order** button displays an online image of the field order when clicked. This button is only available if there is at least one pending field activity linked to the field order. Refer to [Online Field Order Image](#) for more information.

Note:

You can only use the **Display Field Order** button if your system has been configured to display an on-line image; otherwise, a message indicating that the service is not available will appear. This option can only be configured by your technical staff. The system comes with a configuration to display field order images using a document composition application, but can work with other applications.

Data is Not a Snapshot. Unlike other online image displays, such as bill and letters, the data used to produce a field order is not snapshot data. It is always the latest and greatest data from the system. As a result, the Display Field Order button is only available for field orders with pending field work.

Turn on **Extract in Next Run** if the field order should be extracted (downloaded or interfaced) in the next extraction run. This switch is only selectable when the field order's status is Dispatched.

Note:

Default note. When a field order's status becomes Dispatched , the system automatically turns on Extract in Next Run.

Use **Work Date/Time** to define when the fieldwork was done. This field is gray when the status is anything other than Completed.

If the field order has been extracted, the **Extract Date/ Time** are displayed.

Use **Dispatch Group** to define the logical group of representatives located at an operations area that is responsible for the order.

Note:

Dispatch group comes from field activity. When the system creates a field order from the [Dispatch Field Activities](#) query it populates the order's dispatch group using the dispatch group on the field activity(s). After the field order is created, you can change the order's dispatch group as needed.

Dispatch group may be overridden as part of grouping field activities prior to dispatch. When a user creates a field order on the [Group Field Activities](#) page, the order's dispatch group is assigned [Using Alternate Dispatch Groups To Find The Lowest Common Denominator](#) for more information.

Worked By shows the representative that actually performed the fieldwork. This field is gray when the status is anything other than Completed.

The **Representative** is the individual (or crew) assigned to the field order and responsible for the actual performance of the field order's activities. Only representatives defined as valid for the field order's dispatch group may be assigned.

Use **Schedule End Date/Time** if an appointment has been scheduled for this field order. If so, these fields contain the date and time that the fieldwork should be finished.

Enter any **Comments** about the field order.

Enter a **Phone Type**, **Phone Number**, and **Extension** to record a phone number for the field representatives to use if they need to contact someone while in the field. The **Phone Format** for the phone number type is also displayed.

At the bottom of this page is a [tree](#) that shows the accounts, service agreements, field activities and appointments that are currently linked to the field order's service point(s). You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Field Order - Field Activities

The Field Activities page shows the field activities linked to the field order. Open this page using **Menu > Field Order > Field Order > Search** and navigate to the **Field Activities** page.

Description of Page

The following information is displayed in the top portion of every page in this page.

Field Order is a concatenation of information about the order. It consists of the address of the premise, the status of the field order, the number of field activities linked to the order and, if the order has been completed, the date on which the work was done.

Field Order ID is the unique system-generated identifier for the field order.

The **Field Activity** scroll contains the field activities associated with the field order. To modify a field activity, simply move to a field and change its value. To add a new activity, click the + button to insert a row, then fill in the information for each field. The following fields display:

Service Point ID This is the system identifier of the service point at which the activity takes place. Summary information about the service point is displayed adjacent.

Activity Type Indicate the type of field activity. Only those activity types that have been defined as valid for the service point's SP type may be selected. The activity type's description is displayed adjacent.

Field Activity The unique system-generated identifier for this field activity.

Immediately below the Activity Type and Field Activity ID is a message created by the system about the field activity. If an appointment has been made for this field activity, information about the appointment is also displayed.

Field Activity Priority When a field activity is created, the value in this field is a default derived from the field activity's FA type. The operator may override this value so long as the activity is in status Pending or Held .

Field Activity Status A field activity is originally created in the Pending state. It remains in this state until the fieldwork is done and the system is updated with the results. At that time, the activity transitions to the Completed state. If an activity cannot be done, it should be Canceled. Change an activity's status to Held if you want to hold the activity pending some future event.

To completely understand the significance of a field activity's status, refer to [The Big Picture Of Field Orders](#).

Cancel Reason When the field activity is canceled, a reason for the cancellation should be supplied

Instructions Enter any special instructions to be supplied to the field crew.

Comments Use the comments area to describe anything unusual about the activity. For example, if you change the activity's status to Held, it might be a good idea to explain the reason for doing so in the comments.

The **Field Activity Step** grid contains a summary of the field activity's steps.

Fastpath:

The number and type of steps associated with a field activity are defined by the field activity's type (which is maintained on the previous page). Refer to [Designing Field Activity Types](#) for more information.

Field Activity Maintenance

A field activity is a task that takes place at a service point. Examples of field activities include reconnect service, exchange meter and disconnect service.

A field activity contains one or more steps. The steps serve two purposes:

- They provide instructions of the individual units of work to be performed in the field.
- They define what must be done to complete the field activity.

The steps are defined by the field activity's activity type.

The topics in this section describe the pages on which field activity-related information is maintained.

Fastpath:

For more information about field activities, refer to [The Lifecycle Of Field Activities And Field Orders](#).

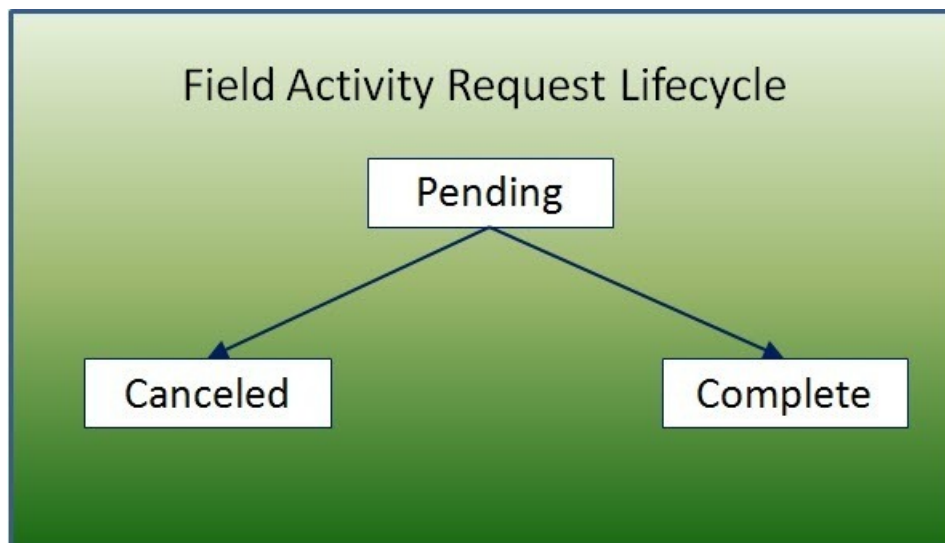

Lifecycle of a Field Activity

The following diagram illustrates the lifecycle of a field activity.

Fastpath:

Refer to [The Lifecycle Of Field Activities and Field Orders](#) for a more detailed discussion of the lifecycle of a field activity. The following diagram merely illustrates the state transition rules.

Pending: A field activity starts its life in the Pending state.

Complete: After the related actions have been performed, the system is updated to reflect what happened and the field activity request becomes complete. No changes may be made to a Complete field activity request.

Canceled: A Pending field activity request may be Canceled.

Field Activity - Main Information

The Main page contains core field activity information. Open this page using **Menu > Field Order > Field Activity > Search**.

Description of Page

The following fields are displayed on every page.

Field Activity is a concatenation of summary information regarding this field activity. It is composed of the address of the premise of the service point at which the activity will occur, a brief description of the activity, the activity's current status, and the activity's scheduled date.

Field Activity ID is the system-generated unique identifier for the field activity.

The remaining fields are specific to the Main page.

Indicate the **Service Point ID** at which the activity takes place. Information about the service point is displayed adjacent.

Use **Activity Type** to define the type of field activity. Only those activity types defined as valid for the service point's SP type's field activity profile may be selected. The activity type's description is displayed adjacent.

Displayed just below the **Activity Type** is a system-generated message regarding how the field activity was created. This message includes the date and time the field activity was created and the process that created it. If a user manually creates a field activity the user's ID is concatenated into the message.

Use **Schedule Date / Time** to define when the field activity is scheduled to be done.

Enter **Reschedule Reason** when changing the field activity's schedule date/time.

Note:

Reschedule Reason only appears if the **Fieldwork Options** feature configuration exists with the **Reschedule Reason Required** option set to Y.

If an appointment is linked to this field activity, the system calls the appointment information algorithm plugged in to the [installation options](#).

Field Activity Status defines the state of the field activity. The following values may exist:

Pending A field activity is originally created in the Pending state.

Completed When an activity's fieldwork is done the system is updated with the results and the activity becomes Completed.

Canceled If an activity cannot be done, it should be Canceled.

Held Change an activity's status to Held if you want to hold the activity pending some future event.

Fastpath:

To completely understand the significance of a field activity's status, refer to [The Big Picture Of Field Orders](#).

To change the status of the field activity, use the **FA Actions**, described below.

If you cancel a field activity, you must supply a **Cancel Reason Code**.

Field Activity Priority is a default value from the field activity's field activity type. It is used by the system to establish the order of precedence if there are several field activities pending for the same service point at the same time. The user may override this value.

Eligible for Dispatch controls whether a **Dispatch Group** can be assigned to the field activity and whether the field activity can be linked to a field order. This field is display-only (it is defined on the activity's activity type)

Use **Dispatch Group** to define the logical group of representatives located at an operations area that is responsible for the activity. For example, in the South West Operations Area you may have the dispatch groups of SW Service Installers, SW Service Investigators, SW Meter Exchangers, etc. Within each dispatch group are representatives with interchangeable skills (i.e., you can assign a field activity to any representative within a dispatch group). You only define the representative when the field activity is linked to a field order. Refer to [Setting Up Dispatch Groups](#) for more information.

Note:

Default note. The type of field activity and the service point's SP type and operations area define the **Dispatch group** that the system assigns to a field activity. Refer to [Designing Who Does Your Field Activities](#) for more information.

A Field Order's dispatch group comes from its field activities. When the system creates a field order from the [Dispatch Field Activities](#) query it populates the order's dispatch group using the dispatch group on the field activity(s). After the field order is created, you can change the order's dispatch group as needed. Changing the dispatch group on the order effectively changes the dispatch group on the order's activities.

Dispatch group may be overridden as part of grouping field activities prior to dispatching. When a user creates a field order on the [Group Field Activities](#) page, the order's dispatch group is assigned [Using Alternate Dispatch Groups To Find The Lowest Common Denominator](#) for more information.

Dispatch group is protected when the field activity is linked to a field order. Once a field order has been created for a field activity, the dispatch group on the field activity cannot be changed. The change to a dispatch group should occur on the field order.

Field Order ID defines the field order to which the activity is linked. This field is gray if the activity type is not eligible for dispatch. This field will be blank when the activity is not linked to a field order. Summary information about the field order appears adjacent.

If the dispatch group for the field activity references an external system feature configuration, the **External ID** is used to reference the unique identifier of the field activity in the external system. The **Intermediate Status** field is used to display interim status of a dispatched field activity.

Note:

Integration Required. The external ID and intermediate status fields are only updated if the integration with your external system passes this information to the system.

The values for the intermediate status field are customizable using the Lookup table. This field name is FA_INT_STATUS_FLG. Many values are supplied with the base product to support different sample integrations. Refer to the documentation related to out-of-the-box integrations supplied with our other products such as Oracle Utilities Mobile Workforce Management and Oracle Utilities Work and Asset Management to see what values are used for integration with those systems.

Use **Instructions** to specify any special instructions to be supplied to the field crew.

Use **Comments** to describe anything unusual about the activity. For example, if you change the activity's status to Held , it might be a good idea to explain why you did so in the comments.

If you have plugged in an FA Additional Information algorithm on the [Installation](#) record, **Additional Info** displays the results of the algorithm, if any.

The **FA Actions** buttons allow you to change the status of the field activity.

- Click **Complete** to change the status of the field activity to complete. This button is only enabled if the status is pending or held.
- Click **Cancel** to change the status of the field activity to canceled. This button is only enabled if the status is pending or held.
- Click **Held** to change the status of the field activity to held. This button is only enabled if the status is pending . This button is not enabled if the field activity is linked to a service order from an external system.

- Click **Pend** to change the status of the field activity to pending. This button is only enabled if the status is held .

At the bottom of this page is a [tree](#) that shows the account(s) and service agreement(s) that are currently linked to the field activity's service point. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Field Activity - Steps

Use this page to reference the objects that were created or updated to reflect what took place in the field. Open this page using **Menu > Field Order > Field Activity** and navigate to the **Steps** page.

Note:

We strongly recommend that you understand the information described in [How Does A Field Order Get Completed?](#) before you use this page.

Fastpath:

The number and type of steps associated with a field activity are defined by the field activity's type (which is maintained on the previous page). Refer to [Setting Up Field Activity Types](#) for more information.

Description of Page

Summary information about the **Service Point** at which the activity will occur is displayed, as well as the service point's system-generated **Service Point ID**.

The **Field Activity Status** is displayed next. See [Field Activity - Main](#) for the valid values of Status and their meanings.

The **Field Activity Steps** grid displays the step(s) involved in the field activity, as defined by the field activity's field activity type. In order to complete a step, you typically need to add or change something in the system to reflect what happened in the field. For example, you would add a meter read for a step that required a new meter read. Refer to [How Does A Field Order Get Completed?](#) for information describing how to enter this information.

If the field activity is linked to an FA upload staging that is in the status pending or error, the **FA Completion** field displays information about the FA upload staging record.

The **FA Actions** buttons allow you to change the status of the field activity. Refer to the [Main](#) page for a description of the fields.

Field Activity - Characteristics/Remarks

Use this page to link additional information to the field activity. Open this page using **Menu > Field Order > Activity > Search** and navigate to the **Characteristics/Remarks** page.

Description of Page

Summary information about the **Service Point** at which the activity will occur is displayed, as well as the service point's system-generated **Service Point ID**.

The **Characteristics** collection contains information that describes miscellaneous information about the field activity.

To modify a characteristic, simply move to a field and change its value. To add a new characteristic, click the + button to insert a row, then fill in the information for each field. The following fields display:

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Note:

Default Note. A field activity's characteristics default from the [field activity type](#).

The **Remarks** grid is used to define anomalies associated with the field activity. For example, you can indicate performing the required task wasn't possible because there was a dangerous situation at the premise.

The **Field Activity Remark Status** is only relevant if a **Field Activity Remark** code has algorithms associated with it. The execution of the algorithm is performed by the field activity remark activation a background process (**FACT**).

- When you add a remark that has an algorithm, the status is **Pending** . It remains in this state until the **FACT** process next runs.
- When the **FACT** process next runs, if the system is successful in executing the algorithm, the status of the field activity remark may become **Complete**. If the system is not successful in executing the algorithm, the status becomes **Error**.

Note:

Algorithm may control status. By default, the field activity remark activation process assumes that if the algorithm does not detect an error, the status of the FA remark should be complete. However, in some cases, the algorithm may not find an error but may also want the status of the FA remark to remain pending. Refer to **FACT-CMPOTG** for an example of such an algorithm.

Remarks that are in error. Field activity remarks whose algorithms could not be successfully executed by the **FACT** background process result in the creation of a **Field Activity Remark Exception** record. To correct errors, you may have to delete and re-add the field activity's remark code if the error is impossible to fix (e.g., if the remark causes a customer contact to be generated and there is no customer at the field activity's premise).

Fastpath:

Refer to [Setting Up Field Activity Remarks](#) for more information.

Field Activity - Field Activity Portal

Select **Menu > Field Order > Field Activity > Search** and navigate to the **Field Activity Portal** page to view additional information associated with a Field Activity.

Depending on your implementations requirements, you may define additional zones to appear on this Portal.

The contents of this section describe the zones that are available on this portal page.

General Information

Field Activity ID, **Field Activity Info** are displayed.

Service Order Management Information

This zone displays the field activity information and status in the Service Order Management application. It applies only to field activity whose type's fieldwork orchestration is set to 'Service Order Management'.

- Clicking FA information navigates to Service Order Management application's Activity Maintenance Portal.
- If the field activity requires appointment, formatted information, indicating that appointment must be booked, appears on top of the field activity tree. Clicking "Book Appointment Now", navigates to Service Order Management application's Appointment Booking Portal.

Field Activity Attachments

This zone provides the ability to add, edit, delete, upload and view attachments related to field activity.

- Clicking attachment information navigates to Attachment Maintenance Portal.

Field Activity - Log

Use this page to view and add log records for a field activity. Open this page using **Menu > Field Order > Activity > Search** and navigate to the **Log** page.

Description of Page

The **Log** grid displays log entries that audit the progress of a field activity. You cannot modify or delete log entries that have been created by the system.

You can manually add a log entry of type User.

The Log grid displays the following information:

Date/Time Displays the date and time when the log entry was created.

Log Type Indicates the entry event for which the log entry was created. The log type for log entries created online is User. Refer to the [FA Log Entry Events](#) table below for information about log types provided for log entries that may be created by sample plug-ins.

Note:

The values for the log type are customizable using the Lookup table. This field name is FA_LOG_TYP_FLG.

Details Contains user-specified or system-generated information about the log entry.

User Displays the user who caused the log entry to be created.

Sequence Displays the sequence that makes up part of the unique identifier of this log record (together with the Field Activity ID).

FA Log Entry Events

Log entries are generated either manually by a user or via a "plug-in". The system provides some sample plug-ins that may be configured to populate the table.

- The [sample FA integration](#) algorithm may be configured to create log entries for certain conditions.
- The sample FA response application services provided by the system create log entries for positive or negative responses to outgoing messages.
- The sample FA completion application service provide by the system may create log entries under certain conditions.

The table below indicates the log types provided by the system and which sample "plug-ins" may create them.

| Log Type | Generated By | Content of Details |
|---|--|--|
| Appointment Book - Negative Acknowledgement | FA Response > application service for a negative response to Appointment Book NDS message. | Negative Acknowledgment. Message ID (%1) - %2. Error (%3) %4 Where %1 is message ID %2 is the Notification Download Type description %3 and %4 are the external message code and its corresponding base message category/number, if the external message code has been specified. |
| Appointment Booked | FA integration algorithm | Appointment booked for <appointment start date/time > - <appointment end date/time>. |
| Appointment Canceled | FA integration algorithm | Appointment for <appointment start date/time > - <appointment end date/time> has been canceled. |

| | | |
|---|--|--|
| Appointment Canceled - Negative Acknowledgement | FA Response application service for a negative response to any Appointment Cancellation NDS message. | Negative Acknowledgment. Message ID (%1) - %2. Error (%3) %4 Where %1 is message ID %2 is the Notification Download Type description %3 and %4 are the external message code and its corresponding base message category/number, if the external message code has been specified. |
| External Message Received | FA completion application service if action is Update Log | Message received from %1. Message text: %2 Where %1 is the description of the external system feature configuration %2 is the message sent from the external system. |
| FA External ID Change | FA integration algorithm | FA External ID changed from <FA External ID - Before Change> to <FA External ID - After Change> |
| FA Intermediate Status Change | FA integration algorithm | FA Intermediate Status changed from <Intermediate Status Description - Before Change> to <Intermediate Status Description - After Change> |
| FA Status Change | FA integration algorithm | FA Status changed from <Status Description - Before Change> to <Status Description - After Change> |
| Order Cancellation - Negative Acknowledgement | FA Response application service for a negative response to FA Cancellation NDS message. | Negative Acknowledgment. Message ID (%1) - %2. Error (%3) %4 Where %1 is message ID %2 is the Notification Download Type description %3 and %4 are the external message code and its corresponding base message category/number, if the external message code has been specified. |
| Order Cancellation Confirmed | FA Response application service for a positive response to FA Cancellation NDS message | Positive Acknowledgment. Message ID (%1) - %2. Where %1 is message ID and %2 is the description of the NDS type of the original outgoing message. |

| | | |
|---|---|--|
| Order Change - Negative Acknowledgement | FA Response application service for a negative response to FA Changed NDS message. | Negative Acknowledgment. Message ID (%1) - %2. Error (%3) %4 Where %1 is message ID %2 is the Notification Download Type description %3 and %4 are the external message code and its corresponding base message category/number, if the external message code has been specified. |
| Order Change Confirmed | FA Response> application service for a negative response to Appointment Book NDS message. | Positive Acknowledgment. Message ID (%1) - %2. Where %1 is message ID and %2 is the description of the NDS type of the original outgoing message. |
| Order Completion | FA completion application service | FA is completed by External System |
| Order Creation - Negative Acknowledgement | FA Response> application service for a negative response to Appointment Book NDS message. | Negative Acknowledgment. Message ID (%1) - %2. Error (%3) %4 Where %1 is message ID %2 is the Notification Download Type description %3 and %4 are the external message code and its corresponding base message category/number, if the external message code has been specified. |
| Order Creation Confirmed | FA Response> application service for a negative response to Appointment Book NDS message. | Positive Acknowledgment. Message ID (%1) - %2. Where %1 is message ID and %2 is the description of the NDS type of the original outgoing message. |
| Order Reschedule - Negative Acknowledgement | FA Response> application service for a negative response to Appointment Book NDS message. | Negative Acknowledgment. Message ID (%1) - %2. Error (%3) %4 Where %1 is message ID %2 is the Notification Download Type description %3 and %4 are the external message code and its corresponding base message category/number, if the external message code has been specified. |

| | | |
|----------------------------|--|--|
| Order Reschedule Confirmed | FA Response > application service for a negative response to Appointment Book NDS message. | Positive Acknowledgment. Message ID (%1) - %2. Where %1 is message ID and %2 is the description of the NDS type of the original outgoing message. |
| Outage Call Interfaced | Processing Outage Call NDS message | Outage call has been sent. |

How To Add A Step To A Field Activity

You are not allowed to add a step to an activity. If you need to add another step, any of the following approaches will work:

- Add a new activity to the order with an activity type containing the desired step (and cancel the pre-existing activity).
- Change the activity's activity type to be one that includes that desired step.
- Navigate to the appropriate maintenance page and make the change. This won't leave an audit of what took place on the field activity but it will change the system appropriately.

Field Activity Remark Exception

If a field activity has a remark code that has algorithms associated with it, the system activates the algorithms each time the [FACT](#) (field activity remark activation) background process is executed. If errors occur during the activation of the algorithms, a record is written to the field activity remark exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, schedule the [TD-FACT](#) background process. This process generates a To Do entry for every record in the field activity remark exception table.

After correcting the cause of the error, drill into the [Field Activity - Characteristics/Remarks](#) tab and change the status of the remark from Error to Pending. When the FACT process next runs, it attempts to execute the remark's algorithm again.

Note:

You may have to delete or change the field activity's remark code if the error is impossible to fix (e.g., if the remark causes a customer contact to be generated and there is no customer at the field activity's premise).

Group Premise FAs (Field Activities)

This page is used to view the pending field work at a premise and to create field order(s) for the pending field activities.

Open this page using [Open this page using Menu > Field Order > Group Premise FAs.](#)

Description of Page

This page has several purposes:

- It shows a **Premise's** pending field activities that are not assigned to a field order and are linked to a dispatch group that is eligible for dispatch. These appear in the first grid.
- It shows a **Premise's** open field orders. These appear in the second grid.
- It allows users to create a new field order(s) and link pending field activities to them (this is done by clicking the **Create Field Order** button).

The **Premise's** address and **Premise ID** are displayed.

Click the **Create Field Order** button to create a field order for the selected field activities (the activities appear in the following grid). You have two options when you click this button:

- Specify an **Override Dispatch Group**. If you do this, a field order will be created for this dispatch group and the selected field activities will be linked to it.
- Leave **Override Dispatch Group** blank. If you do this, the system will look for the "lowest common denominator" dispatch group and assign it to the pending field activities. Refer to [Using Alternate Dispatch Groups To Find The Lowest Common Denominator](#) for more information.

Note:

A field order's dispatch group overrides the activity's dispatch group. Be aware that the dispatch group that is assigned to the field order will replace the original dispatch group assigned to the field activities.

After orders have been created, they appear in the grid at the bottom of this page.

Using Alternate Dispatch Groups To Find The Lowest Common Denominator

When you click the **Create Field Order** button on the [Group Field Activities](#) transaction and leave the **Override Dispatch Group** blank the system attempts to find a "lowest common denominator" dispatch group and assign it to the pending field activities. If it is successful, all of the field activities are grouped under a single field order and dispatched. If it's unsuccessful, a separate field order is created for each activity without a common dispatch group.

The following example will help illustrate how a lowest common denominator dispatch group is assigned to a group of field activities.

| | FA1: Install Meter | FA2: Read Meter | FA3: Test Meter |
|---|---|--------------------------------|----------------------------|
| Initial dispatch group assigned to field activity | NorthWest - Electric - Install and Remove | NorthWest - Electric - Readers | North - Electric - Testers |
| Alternate dispatch group | NorthWest - Electric | NorthWest - Electric | North - Electric |

The above table illustrates the following example:

- There are 3 field activities at a premise and each of which has a different initial dispatch group (see the first row in the table).
- Each initial dispatch group has an alternate dispatch group.
- Of these field activities, FA1 and FA2 have a common alternate dispatch group: NorthWest - Electric. FA3, however doesn't have a common dispatch group. This means 2 field orders will be created:
 - The first field order (associated with the NorthWest - Electric dispatch group) will contain FA1 and FA2.
 - The second field order (associated with the North - Electric - Testers dispatch group) will contain FA3.

Fastpath:

Please refer to [Automatically dispatching field activities](#) for another example of how the lowest common denominator is selected.

Field Order Search

This query is really two queries:

- The search dialog shows groups of field orders that are:
 - Linked to a dispatch group
 - With a given status

- Scheduled on or before a date
- The query page shows individual field orders that are:
 - Linked to the selected dispatch group
 - With a given status
 - Scheduled on the selected dispatch date

Open this page using **Menu > Field Order > Field Order Search**.

The topics described in this section describe the search dialog and the query page.

Field Order Search Dialog

This query's search dialog shows groups of field orders that match your search criteria. You can change the displayed information by changing the search criteria.

Note:

Leaving a search field blank. If you leave a search field blank, the system assumes you want to see all groups of field orders. For example, if you leave dispatch group blank, you will see every dispatch group's orders. You may use this facility on any of the search fields.

Description of Page

Enter a **Dispatch Group** to limit the search to a specific dispatch group. Leave this field blank to view groups of orders linked to all dispatch groups.

Enter a **Field Order Status** to limit the search to groups of orders in a specific state. Valid values are: Dispatched, Canceled, Completed, Pended By User, Work Done, Not Recorded. Leave this field blank to view groups of orders regardless of status.

Enter a **Schedule Date/Time** to limit the search to orders that exist on or before the input date and time. Leave this field blank to view groups of orders throughout time.

When you select a row and proceed to the query page, the system displays the individual field orders for the selected dispatch group, status and schedule date.

Field Order Query Page

The query page shows individual field orders for the selected dispatch group, status, and schedule date.

Description of Page

You can use the **Field Order Filter** to restrict the field orders that appear in the grid. The following options are available:

- All. This option shows all field orders for the selected dispatch group, status, and schedule date.
- Geo Type. This option shows all field orders whose premise has a given **Geographic Type** and **Geographic Value**. If you leave **Geographic Value** blank, all field orders whose premise has a given **Geographic Type** will be displayed (i.e., all geographic values for the selected **Geographic Type** are displayed).

Each row in the query shows an individual field order. Clicking the go to button adjacent to the order will transfer you to the [Field Order Maintenance](#) page with the selected field order displayed.

Dispatch Field Activities

Fastpath:

Refer to [How Are Field Orders Created And Dispatched](#) for other ways to dispatch field activities.

This query is really two queries AND a maintenance transaction:

- The search dialog shows groups of field activities that are:
 - Eligible for dispatch
 - Not linked to a field order
 - Whose service point is serviced by an operations area
 - Linked to a dispatch group
 - In the Pending state
 - Scheduled on or before a date
- The query page shows individual field activities that are:
 - Eligible for dispatch
 - Not linked to a field order
 - Serviced by the selected operations area
 - Linked to the selected dispatch group
 - In the Pending state
 - Scheduled on or before the selected dispatch date
- On the query page, you can create and dispatch field orders.

Open this page using **Menu > Field Order > Dispatch Field Activities**.

The topics described in this section describe the search dialog and the query page.

Field Activity Search Dialog

This query's search dialog shows groups of field activities that match your search criteria. You can change the displayed information by changing the search criteria.

Note:

Leaving a search field blank. If you leave a search field blank, the system assumes you want to see all groups of field orders. For example, if you leave dispatch group blank, you will see every dispatch group's orders. You may use this facility on any of the search fields.

Description of Page

Enter a **Dispatch Group** to limit the search to a specific dispatch group. Leave this field blank to view groups of activities linked to all dispatch groups.

Enter an **Operations Area** to limit the search to a service points serviced by a given operations area. Leave this field blank to view groups of activities linked to all operations areas.

Enter a **On/Before Date** to limit the search to activities that exist on or before the input date. Leave this field blank to view groups of activities throughout time.

When you select a row and proceed to the query page, the system displays the individual field activities for the operations area, dispatch group and schedule date.

Note:

Implied search criteria. In addition to the explicit search criteria shown above, the search is limited to field activities in the Pending state that are eligible for dispatch and that are not already linked to a field order.

Field Activity Query Page

The query page shows individual field activities for the selected operations area, dispatch group and schedule date.

A special facility exists on this page that allows you to create and dispatch field orders for the activities. Refer to the Description of Page information below for the details.

Description of Page

You can use the **Field Activity Filter** to restrict the field activities that appear in the grid. The following options are available:

- All. This option shows all field activities for the selected dispatch group, operations area, and schedule date.
- FA Type. This options shows all field activities for the chosen **Activity Type**. Activity Type is required when choosing the FA Type filter.
- Geo Type. This option shows all field activities whose premise has a given **Geographic Type** and **Geographic Value**. If you leave **Geographic Value** blank, all fields activities whose premise has a given **Geographic Type** will be displayed (i.e., all geographic values are displayed).

Each row in the query shows an individual field activity. Clicking the go to button adjacent to the activity transfers you to the Field Activity Maintenance page with the selected field activity displayed.

When you're ready to dispatch field activities,

- Turn on the **Dispatch?** switch on every activity to be dispatched.
 - If you want to dispatch all activities in the grid, click the **Select All** button. This causes the **Dispatch?** switch to be turned on for every field activity in the grid.
 - If you want to dispatch specific activities, turn on the **Dispatch?** switch on the desired activities.
 - If you want to turn off the **Dispatch?** switch on all activities in the grid, click the **Clear All** button.
- Enter the **Representative** who will do the work.
- Enter the **on Date / Time** on which the work will be performed (time is optional).
- Save the page.

When you save the page, the system:

- Creates a new field order for every unique combination of dispatch group and premise on the selected field activities. The new field order(s) are assigned to the selected representative and scheduled on the selected date and time.
- Links the appropriate field activities to each field order
- Sets the status of the field order to Dispatched.

How Do You Link An Activity To An Existing Order?

If a field order already exists and you want to link another field activity to it, simply drill over to the Field Activity Maintenance page (by clicking the button adjacent to the activity) and update the activity to reference the desired field order.

Downloading Field Orders

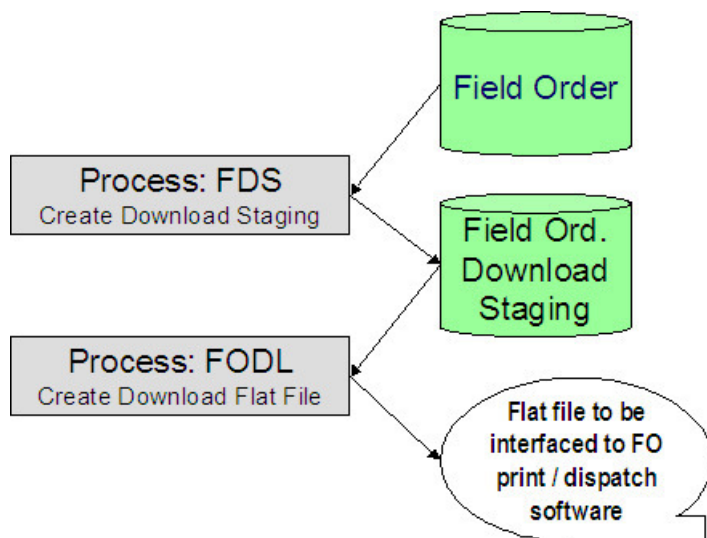

Your field staff must be apprised of all orders for which they are responsible. This communication can take place in many ways:

- A printed order can be given to the field crew
- An electronic version of the order can be routed to the crew's truck

The communication of field orders to the field crews is handled through the field order download process. The topics in this section describe this process.

The Field Order Download Processes

The following diagram illustrates the processes involved in the creation of the flat file that is interfaced to your field order print / dispatch software.

FDS - Create Download Staging

This process looks for all field orders that are marked for extraction (a field order gets marked for extraction when it is first created if its dispatch group is dispatchable). For each record found, the system creates a field order download staging record.

Each download staging record is marked with a batch control ID & run number when it's created.

- The batch control ID comes from the field order's dispatch group. This ID corresponds with a specific extraction method. The system comes with a single field order download program ([FODL - Create Download Flat File](#)). If you require different print formats or different routing methods, you will need to create additional programs. Refer to [Technical Implementation of Batch Field Order Production](#) for more information.
- The run number is the batch control ID's current run number.

Note:

Re-downloading. If you need to download a specific field order, navigate to [Field Order - Main Information](#) and change the order's status to Dispatched.

FODL - Create Download Flat File

This process reads all download staging records marked with a given batch control ID & run number and creates the flat file that's passed to the field order print / dispatch software.

Note:

This process is rerunnable. You can reproduce the flat file at any time. Simply request this job and specify the run number associated with the historic run.

The format of the flat file is determined based on an extract program linked to the field order's dispatch group. Refer to [Dispatch Groups Control The Information Merged Onto Field Orders](#) for more information.

Uploading Field Order Completion Information

This section describes how the system uploads field order completion details.

Warning:

It's important to be aware that only the following types of field activity steps can have their completion details uploaded through this process: Connect Service Point, Disconnect Service Point, Install Meter, Turn On

Meter, Turn Off Meter, Read Meter, Remove Meter, Install Item, Turn On Item, Turn Off Item, Remove Item. [Field Activity Completion Considerations](#) describes a recommendation to use XAI to upload field activity completion information if any of the other step types are included in the field activity, rather than as described in the processes that follow in this section.

Field Order Completion Upload Background Processes

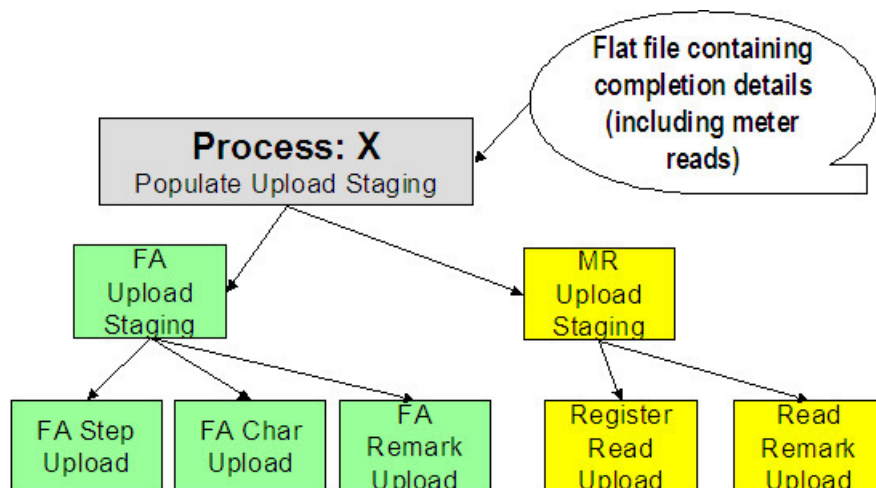

The following diagram illustrates the processes involved in the uploading of field order completion details.

The topics in this section describe how these processes work.

Process X - Populate MR and FA Upload Staging

Process X refers to the mechanism used by your organization to populate the various staging tables.

The topics in this section describe each of these tables.

Meter Read Upload Staging Tables

If the field activity step involved the installation, removal, turning on, turning off, or reading of a meter; a meter read must be provided. Because the standard meter read upload process is used to interface these records into the system, you must create the meter read upload staging records described under [Uploading Meter Reads](#) for every read associated with the completion of field activities.

Field Activity Upload Staging

You must create a field activity upload staging record for each field activity whose completion details are being uploaded. The name of this table is CI_FA_STAGE_UP. The following table describes each column on this file.

| Column Name | Length | Req'd | Data Type | Comments |
|------------------|--------|-------|-----------|---|
| FA_ID | 10 | Y | A/N | This is the ID of the field activity whose completion details are being supplied. |
| FA_UP_STATUS_FLG | 2 | Y | A/N | This must be set to P for Pending. |
| WORK_DTTM | 26 | Y | Date/Time | The date and time the work was done. |
| WORKED_BY | 8 | Y | A/N | The unique ID of the representative who performed the activity. |
| DESCR254 | 254 | N | A/N | Optional comments about the field activity. |

Field Activity Step Upload Staging

You must create a field activity step upload staging record for each step that was completed. The name of this table is CI_FA_STP_STG_UP. The following table describes each column on this file.

| Column Name | Length | Req'd | Data Type | Comments |
|--------------|--------|-------|-----------|---|
| FA_ID | 10 | Y | A/N | This is the ID of the field activity whose completion details are being supplied. |
| STEP_SEQ_NBR | 3 | Y | N | This is the sequence number of the field activity step whose completion details are being supplied. |

| | | | | |
|--------------------------|--|----------|------|---|
| FA_STP_UP_STAT_ 2 FLG | | Y | A/N | This is the status of the upload record. This must be set to P for Pending. |
| FA_STEP_TY_ 2 ACT_FLG | | Y | A/N | This is the type of step whose completion details are being supplied. This must be one of the following values: NS - Connect Service Point, DS - Disconnect Service Point, IM - Install Meter, NM - Turn On Meter, FM - Turn Off Meter, MR - Read Meter, RM - Remove Meter, II - Install Item, NI - Turn On Item, FI - Turn Off Item, RI - Remove Item |
| BADGE_NBR 30 | | See note | A/N | Badge Number is the badge number of the meter or item involved with the field activity step. It is required for the following step types: Install Meter, Turn On Meter, Turn Off Meter, Read Meter, Remove Meter, Install Item, Turn On Item, Turn Off Item, Remove Item |
| READ_DT 10 | | See note | Date | This must correspond with a read date on one of the meter read upload staging records. It is required for the following step types: Install Meter, Turn On Meter, Turn Off Meter, Read Meter, Remove Meter |

| | | | | |
|---------------|----|----------|-------------|--|
| READ_TIME | 15 | See note | Time | This must correspond with a read time on one of the meter read upload staging records. It is required for the following step types: Install Meter, Turn On Meter, Turn Off Meter, Read Meter, Remove Meter |
| DISCON_LOC_CD | 4 | See note | A/N | This is the disconnect location code that identifies where a service point has been disconnected. It is required for the Disconnect Service Point step type. |
| ON_OFF_FLG | 2 | See note | A/N | Set this to 0 if the meter / item was turned off. Set this to 1 if the meter / item was turned on. It is required for the following step types: Install Meter, Install Item. |
| EVENT_DTTM | 26 | See note | Date / Time | This the date and time an item was installed, removed, turned on or off. It is required for the following step types: Install Item, Turn On Item, Turn Off Item, Remove Item |

| | | | | |
|------------|----|----------|-----|--|
| STK_LOC_CD | 12 | See note | A/N | This is the stock location where the meter / item is stored upon removal from a service point. This is required for the following step types if the meter's meter type or the item's item type tracks location: Remove Item, Remove Meter. Refer to The Big Picture Of Asset Inventory for more information. |
|------------|----|----------|-----|--|

Field Activity Characteristic Upload Staging

You must create a field activity characteristic upload staging record for each characteristic that you would like to link to the field activity. The name of this table is CI_FA_STGUP_CHAR. The following table describes each column on this file.

| Column Name | Length | Req'd | Data Type | Comments |
|----------------|--------|----------|-----------|---|
| FA_ID | 10 | Y | A/N | This must correspond with the prime key of the related CI_FA_STAGE_UP record. |
| CHAR_TYPE_CD | 8 | Y | A/N | This must correspond with a characteristic type that is defined as valid for the field activity type for this field activity. |
| SEQ_NUM | 3 | Y | N | This should be set to 10 unless you have multiple values for a given field activity and characteristic type. |
| CHAR_VAL | 16 | See note | A/N | Populate this field if your characteristic type is predefined. |
| ADHOC_CHAR_VAL | 254 | See note | A/N | Populate this field if your characteristic type is ad-hoc or file location. |

| | | | | |
|--------------------------------|---------|----------|-----|--|
| CHAR_VAL_FK1 - CHAR_VAL_FK5 | 50 each | See note | A/N | Populate these fields if your characteristic type is foreign key reference. Up to five columns of 50 bytes each are provided to accommodate compound keys. |
|--------------------------------|---------|----------|-----|--|

Field Activity Remark Upload Staging

You must create a field activity remark upload staging record for each remark that you would like to link to the field activity. The name of this table is CI_FA_STGUP_REM. The following table describes each column on this file.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|--|
| FA_ID | 10 | Y | A/N | This is the ID of the field activity whose completion details are being supplied. |
| FA_REM_CD | 12 | Y | A/N | This must correspond with a field activity remark code. Refer to Setting Up Field Activity Remarks for more information. |

MUP1 - Populate Meter Configuration

Refer to [MUP1 - Populate Meter Configuration](#) for information about this process.

MUP2 - Create Meter Read

Refer to [MUP2 - Create Meter Read](#) for information about this process.

FACOMPL - Upload and Complete Field Activities

FACOMPL processes Pending Field Activity Upload Staging records. For each such record, it processes the Pending Field Activity Step Upload Staging records as per the following table.

| Step Type | What Happens |
|----------------------------|---|
| NS - Connect Service Point | Changes the connection status of the field activity's service point to connected and removes the disconnect location (if any). It then updates the related step to reference the service point. |

| | |
|-------------------------------|--|
| DS - Disconnect Service Point | Changes the connection status of the field activity's service point to disconnected and populates the disconnect location with the supplied value. It then updates the related step to reference the service point. |
| IM - Install Meter | Creates a new SP / Meter record and links to it the meter read inferred from the badge number and read date/ time. Note: the meter read upload process creates this meter read. It then updates the related step to reference the SP / Meter record. |
| NM - Turn On Meter | Creates a new turn on event under an exist SP / Meter record. It links the meter read inferred from the badge number and read date/ time to the turn on event. Note: the meter read upload process creates this meter read. It then updates the related step to reference the SP / Meter record. |
| FM - Turn Off Meter | Creates a new turn off event under an exist SP / Meter record. It links the meter read inferred from the badge number and read date/ time to the turn off event. Note: the meter read upload process creates this meter read. It then updates the related step to reference the SP / Meter record. |
| MR - Read Meter | It's important to note that the meter read upload process creates this meter read. When this type of step is uploaded, the system simply updates the related step to reference the previously created meter read. |
| RM - Remove Meter | Updates an existing SP / Meter record to indicate the meter has been removed. It does this by linking the meter read inferred from the badge number and read date/ time. Note: the meter read upload process creates this meter read. It then updates the related step to reference the SP / Meter record. |
| II - Install Item | Creates a new SP / Item record using the supplied badge number and event date and time. It then updates the related step to reference the SP / Item record. |
| NI - Turn On Item | Creates a new turn on event under an exist SP / Item record. It then updates the related step to reference the SP / Item record. |
| FI - Turn Off Item | Creates a new turn off event under an exist SP / Item record. It then updates the related step to reference the SP / Item record. |
| RI - Remove Item | Updates an existing SP / Item record to indicate the item has been removed. It then updates the related step to reference the SP / Item record. |

After this process updates the related step, it checks if all required steps under the parent field activity reference their appropriate foreign key. If so, it completes the field activity. It then checks if all field activities under the parent field

order are complete, if so it completes the field order (note, it will also update the field order with the work done date / time and worked by information on the related Field Activity Upload Staging record).

Any errors detected during this process are written to the [Field Activity Upload Exception](#) table. You can fix errors using Field Activity Staging page (don't forget to change the record's status back to Pending).

FAUP-PRG - Purge Field Activity Upload Objects

Completed field activity upload staging objects should be periodically purged from the system by executing the [FAUP-PRG](#) background process. This background process allows you to purge all Completed field activity upload staging objects older than a given number of days.

We want to stress that there is no system constraint as to the number of Completed field activity upload objects that may exist. You can retain these objects for as long as you desire. However we recommend that you periodically purge Completed field activity upload objects as they exist only to satisfy auditing and reporting needs.

Maintaining Field Activity Upload Staging

The Field Activity Upload Staging page has three purposes:

- You can view historical field activity upload records.
- You can correct field activity upload records that are in error.
- You can add new field activity upload records to be uploaded by the field activity upload background process (or you can click the **Complete** button to upload and complete the activity (and order) real time).

Fastpath:

This page's dialog is idiosyncratic. Refer to [How To](#) for instructions describing how to perform common maintenance tasks.

The following topics describe this transaction in detail.

FA Upload Staging - Main

The Main page contains core field activity completion information. Open this page using **Menu > Field Order > FA Upload Staging > Search**.

Description of Page

FA Upload Staging ID is the system-generated unique identifier for the field activity upload staging record (note: this will be the same as the unique ID of the associated field activity).

The **Field Activity ID** is the field activity being completed.

The **Service Point ID** and its information are displayed beneath.

Upload Status shows the state of the field activity upload record. Potential values are: Pending, Complete, Error.

If a record is in Error, the error message will be displayed adjacent. You can correct an Error by

- Correcting whatever is wrong,
- Change the **Upload Status** back to Pending
- Click the **Complete** button. Clicking the **Complete** button calls the routine that attempts to update the completion information.

Enter the **Work Date/ Time** when the field work was performed. These values will be populated on the field activity's field order when it is completed.

Worked By is the individual (or crew) who actually performed the work. Only representatives defined as valid for the field order's dispatch group may be assigned.

Comments is appended to the field activity's Comments.

The **FA Upload Staging Steps** scroll contains a summary of the field activity's steps.

Click the **Complete** button to complete the associated field activity. This button is only enabled when the field activity upload staging record has been saved on the database and is in the Pending state.

Click the **Delete** button to delete the field activity upload staging record. This button is only enabled when the field activity upload staging record has been saved on the database and is in the Pending or Error states.

FA Upload Staging - Steps

The Steps page contains completion information related to the field activity's steps. Open this page using **Menu > Field Order > FA Upload Staging > Search** and navigate to the **Steps** page.

Description of Page

FA Upload Staging ID is the system-generated unique identifier for the field activity upload staging record (note: this will be the same as the unique ID of the associated field activity).

The **Steps** scroll contains the field activity's steps. To complete a field activity, you must enter the relevant information for each required step. The type of information that should be entered differs depending on the step type.

| Step Type | What Fields Are Displayed |
|------------------------------|--|
| Contact Customer | No fields related to customer contact are displayed. Customer Contact must be created separately. |
| Change Service Point | No generic fields related to updating a service point are displayed. Service Point must be updated separately. |
| Connect Service Point | None |
| Disconnect Service Point | Disconnect location |
| Install Meter | Badge number, read date, read time, on/off status |
| Change Meter | No generic fields related to updating a meter are displayed. Meter must be updated separately. |
| Change Meter's Configuration | No generic fields related to updating a meter configuration are displayed. Meter Configuration must be updated separately. |
| Turn On Meter | Badge number, read date, read time |
| Turn Off Meter | Badge number, read date, read time |
| Read Meter | Badge number, read date, read time |
| Remove Meter | Badge number, read date, read time, stock location* (see below) |
| Install Item | Badge number, event date, event time, on/off status |
| Change Item | No generic fields related to updating an item are displayed. Item must be updated separately. |

| | |
|------------------------|---|
| Turn On Item | Badge number, event date, event time |
| Turn Off Item | Badge number, event date, event time |
| Reconfigure Multi-Item | No generic fields related to multi-item configuration are displayed. Item configuration must be updated separately. |
| Remove Item | Badge number, event date, event time, stock location* (see below) |
| Test Device | No fields related to device testing are displayed. Device Test must be created separately. |

For step types Remove Meter and Remove Item, enter the **Stock Location** where the meter / item is stored upon removal if the meter's meter type or the item's item type tracks location. Refer to [The Big Picture Of Asset Inventory](#) for more information.

The **Add Meter Read** section can be used to add a meter read for those step types that require a meter read.

The **Add Meter Read** button becomes enabled after you enter a **Badge Number** and **Read Date/Time**. For required steps, the system populates **Read Date/Time** with the values entered for **Work Date/Time**. You can change these values if necessary.

When you click the **Add Meter Read** button, the **Register Readings** grid is populated with one row for each of the meter's registers. Enter each register's reading by specifying a **Read Type** and **Reading**.

Click the **Complete** button to complete the associated field activity. This button is only enabled when the field activity upload staging record and is in the Pending state.

When you press **Complete**, the read is added to the database and is no longer displayed on the FA Upload Staging record. (This information is not actually linked to the Field Activity Upload Staging. When you complete a field activity, the system looks for a meter read to link to the FA. It should find the one you just created.)

Note: If you press **Save** instead of Complete, the FA Upload Staging record will be saved to the database. Meter reading information will disappear, similar to pressing Complete, *but any meter reading information entered will not be saved*.

Click the **Delete** button to delete the field activity upload staging record. This button is only enabled when the field activity upload staging record has been saved on the database and is in the Pending or Error states.

Fastpath:

Refer to [Meter Read - Main](#) for more information about meter reads.

Note:

High/low validation. It's important to note that the read will not be subject to high/low validation. If you require high/low validation, add the read using [Meter Read - Main](#) and then simply reference the read's badge number and date/time on the step.

FA Upload Staging - Characteristics/Remarks

The Characteristics/Remarks page contains additional information related to the field activity. Open this page using **Menu > Field Order > FA Upload Staging > Search** and navigate to the **Characteristics/Remarks** page.

Description of Page

FA Upload Staging ID is the system-generated unique identifier for the field activity upload staging record (note: this will be the same as the unique ID of the associated field activity).

The **Characteristics** grid is used to link additional information to the field activity.

The **Remarks** grid is used to define anomalies associated with the field activity.

How To

The topics in this section describe how to perform common maintenance functions.

How To Complete A Simple Field Activity That Requires A Read

The following steps describe how to complete a simple field activity that requires a meter read.

You navigate through the pages as follows:

- Navigate to [Field Activity Upload Staging](#).
- Enter the ID of the field activity being completed.
- Use **Work Date/Time** to define when the field activity was completed.
- Navigate to the **Steps** tab and enter the **Badge Number** and **Read Date/Time**. For required steps, the system populates **Read Date/Time** with the values entered for **Work Date/Time** but you can change these values if necessary. After entering this information, the **Add Meter Read** button becomes enabled. Click it to open the **Register Reading** grid.
- Specify the **Read Type** and **Register Reading** for each register on the meter. Then click the **Complete** button. When the **Complete** button is clicked, the following events take place:
 - The field activity upload staging record is saved.
 - A meter read is added.
 - The system attempts to complete the field activity using the information on the field activity upload staging record and on the meter read.
 - If the system is not successful in completing the activity due to incomplete information on the field activity upload staging record, the upload staging step's status will be changed to Error and a corresponding error message will be displayed. To complete the activity, fix the cause of the problem and change the step's status back to Pending and then click the **Complete** button again.
 - If the system is successful in completing the activity, the field activity upload staging record's upload status is changed to Complete, the step's upload status is changed to Complete, the field activity's status is changed to Complete, and, if all field activity's linked to the field order are Complete, the field order's status is changed to Complete.

Note:

If after specifying the **Read Type** and **Register Reading** for each register on the meter the **Save** hyperlink is clicked instead of the **Complete** button, the field activity upload staging record is saved *without* adding a meter read. The field activity upload staging record remains in the Pending state.

Field Activity Upload Exception

If errors are detected during the field activity upload process, a record is written to the field activity upload exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, schedule the [TD-FAUPL](#) background process. This process generates a To Do entry for every record in the field activity upload exception table.

You can fix this error using the [FA Upload Staging](#) page and change the status of the remark from Error to Pending. When the field activity upload process next runs, it attempts to upload this record again.

Outage Calls

Note:

The information in this section applies to the integration with the Oracle Utilities Network Management System (NMS).

You can use the Outage Call page to view trouble calls and outage information, and to send outage call reports to NMS for a specific service point. You can also use this page to schedule job site appointments. Open this page using **Menu > Communication > Outage Call > Search**.

Description of Page

The Outage Call Search zone is a standard [multi-query portal](#) used to search for and list existing Outage Call records. In the search results list, click the Outage Call link to view and maintain the information about the outage call.

Outage Call Zone

The outage call zone contains display-only information about the record.

Outage Information

Note:

The information in this section applies to the integration with Oracle Utilities Network Management System (NMS).

The Outage Information portals provide a real-time interface with NMS to search for the following network management items:

- Job History
- Call History
- Planned Outages.

Open this page using **Menu > Communication > Outage Information**.

Job History

You can use the Job History portal to retrieve current and historical outage and non-outage jobs from NMS by a customer service point or account ID, or proximity to a street intersection or street segment, or other identifiers such as a 911 incident identifier, caller name, or call phone number.

Use **Menu > Communication > Outage Information** to search for and view Job History records.

Description of Page

The Job History zone can be used to search for an existing Job History record. If the search results list contains records for a single service point, the service information for that service point and the job history results will be displayed. If the list contains multiple service point's records, a list of service points are displayed and the service information and job history results will be displayed for one of these service points.

Please see the zone's help text for information about this zone's fields.

Call History

You can use the Call History portal to retrieve trouble call history from NMS by a customer service point, or account id, or proximity to a street intersection or street segment, or other identifiers such as a 911 incident identifier, caller name or call phone number.

Use **Menu > Communication > Outage Information** and navigate to the **Call History** page to search for and view these records.

Description of Page

The Call History zone can be used to search for an existing Call History record. If the search results list contains records for a single service point, the service information for that service point and the call history results will be displayed. If the list contains multiple service point's records, a list of service points are displayed and the service information and call history results will be displayed for one of these service points.

Please see the zone's help text for information about this zone's fields.

Planned Outages

You can use the Planned Outages portal to retrieve planned outage information from NMS.

Use **Menu > Communication > Outage Information** and navigate to the **Planned Outages** page to search for and view these records.

Description of Page

The Planned Outages zone can be used to search for current, future and past planned outage status and details from NMS for a particular service point. Planned outage information will only be available once a planned outage has been scheduled and the list of impacted customers for that planned outage has been generated.

Please see the zone's help text for information about this zone's fields.

Service Calls

Note:

The information in this section applies to the integration with an asset management system, such as Oracle Utilities Work and Asset Management (WAM).

The following sections describe the Service Call Process and Service Call Communication.

The Service Call Process and Service Call Communication

Service Call Process

The service call process contains five steps or panels:

Service Call Search. This panel is used input the contact details of the service call.

At least one filter should be populated before search can be performed.

The result is a combination of the following:

- Service calls in the asset system retrieved via a real-time call.
- Local non-final service calls that were not sent to the asset system yet.

By default, the maximum number of search results is **20**. This can be overridden by setting the override search limit in the service call communication type.

The service call information includes the service call number, issue description, required by date and call back indicator. Service call number is the service call's reference number in the asset management system.

Note: The details of a service call can be viewed using the **View Service Call Details** icon. This pops up a window with the details of the service call. Details of service calls in the asset management system are retrieved via real-time call and includes communication logs and related documents. For authorized users, hyperlink to the service call in the asset management system is available. Refer to [Setting Up the System To Enable Asset Management System Integration](#) for more details.

When a service call is selected, either **Add Comment** or **Cancel** action should be selected to continue.

Continuing without selecting a service call means a new service call.

Location. This panel is used to input or display the location of a new or existing service call, respectively. For an existing service call, the location details are displayed for information purposes.

When the process is initiated with a premise in context, the premise is displayed and can be used to populate the location elements and limit the service points that can be selected. If the current premise is used, the location elements are populated and disabled. The geographic type defined in the service call communication type is used to populate the latitude and longitude elements based on the premise's geographic data.

When service point is set, the location elements are populated with the corresponding elements of the service point's premise and are disabled. Clearing the service point will re-enable the location detail elements with their values retained. The geographic type defined in the service call communication type is used to populate the latitude and longitude elements based on the premise's geographic data.

Country and address should be populated to continue.

Contact. This panel is used input the contact details of the service call.

Communication type is defaulted to the default communication type defined in the service call communication type.

When the process is initiated with a person in context, the person is displayed and can be used to populate the name and phone numbers. If the current person is used, the name and phone number elements are populated and disabled:

- First and last names are derived from the person's primary name. Note that installation option's name separator configuration applies.
- Primary phone is set to the person's primary phone contact
- Mobile and home phones are set to the person's phone contact where the contact type is the mobile and home phone contact types defined in the service call communication type, respectively.

Contact details are not required to continue. **For Add Comment or Cancel** actions, either First Name or Last Name or one of the phone numbers must be provided.

Details. This panel is used to capture the issue details of the service call.

For a new service call, enter the details of the issue. Questions linked to the selected service code are presented. Set the resolved switch if based on the answers to the questions, the issue is resolved. Doing so will prevent a message from being sent to the asset system.

Description is required to continue. Service Code may also be required if configured as such in the service call communication type.

For **Add Comment** or **Cancel** action, details of the original service call are displayed for informational purposes.

Review and Submit. This panel provides an opportunity to review the information before submission.

When the service call process is finished, the service call information is copied to a new service call communication record and the service call communication ID is displayed on the Review and Submit panel. If there are questions linked to the service code, the questions and answers are copied to a new response record. The response is linked to the service call communication. The service call process is completed and service call communication takes over.

Service Call Communication

Service call communications are used to and process service call information gathered from interactions with the customer, the public or other external entity. These interactions can be reporting a new issue/request, adding comments to an existing issue/request or cancelation (issue is resolved or request no longer needed). The following service call information can be gathered:

- **Issue/Request Details.** This includes description, service category, service code, call back requirement, require by date, etc.
- **Location.** This is the location of the service call. This can be either a known service point or a freeform address
- **Contact.** This is the contact information the interaction is with. This can be a known customer or freeform contact information. This is information is optional to allow anonymous interactions.

A service call communication record is created for each interaction.

- Determine if a service call information needs to be sent to the asset management system. If the service call process is canceled or if the issue was resolved during communication, the asset management system is not notified.
- Ensure that service call information is sent out to the asset management system in the correct sequence. New service call communication is sent out first, followed by additional comments and finally, cancellation.
- Send a service call communication outbound message to the asset management system. This is an asynchronous interface between Oracle Utilities Customer Care and Billing and the asset management system. Because this asynchronous, there should be no processing after the message is sent out in the same transaction. This is to avoid the case where the transaction is rolled back due to some error, but the message is already sent to the external system. Refer to [Setting Up the System To Enable Asset Management System Integration](#) for more details.
- Once the outbound message is sent, the service call communication will transition and stay in the Sent state until an acknowledgement is received from the asset management system. If a positive acknowledgment is received, the service call communication is completed. If a negative acknowledgment is received, the service call communication is transitioned to the Error state. A service call communication in Error state can be manually canceled or re-sent.

Service Call Communication Acknowledgement

The inbound web service *CI-UpdateServiceCallCommunication* is used to process a service call communication acknowledgement message. The message contains communication ID, service call ID, service call number and error information. This service stores this information into the service call communication. If the message indicates an error, the service call communication is transitioned to the Error state. Otherwise, the service call communication is completed.

Maintaining Service Call Communications

A service call communications is used to process service call information gathered from interactions with the customer, the public or other external entity. These interactions can be reporting a new issue/request, adding comments to an existing issue/request or cancellation (issue is resolved or request no longer needed). Refer to [Service Calls](#) for background information on service calls.

To view and maintain service call communications, open Menu > Field Order > Service Call Communication > Search . You are brought to a query portal with options for searching for service call communications.

Once a service call communication record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones are displayed:

- **Service Call Communication** zone shows the details of the service call .
- **Questions** zone shows the related questions and answers to the service call communication. This information is stored in the *Response* object.

Refer to the zones' embedded help for more information.

Billing

In this section, we describe how to manage your customer's bills.

The Big Picture of Billing

A bill is used to communicate changes in an account's financial obligations to the customer. Over time, a customer receives many bills. The topics in this section provide background information about a variety of billing topics.

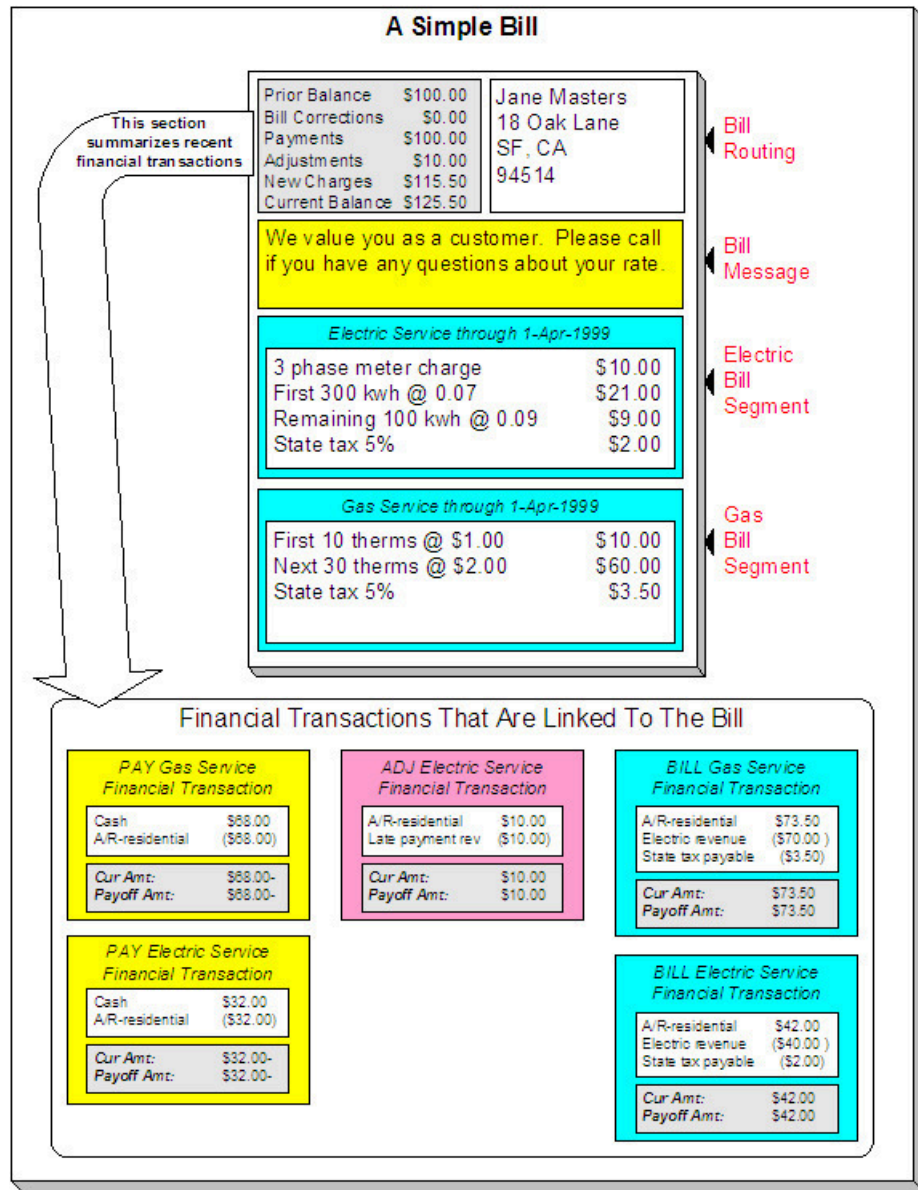

Warning:

Some organizations are responsible for presenting 3 rd party charges on their bills. Others are responsible for sending their charges to a 3 rd party for presentation on their bills. If this describes your organization, refer [The Big Picture of SA Relationships](#) for a description of how this functionality is implemented.

An Illustration Of A Simple Bill

The following diagram illustrates a simple bill:

The following concepts are illustrated above:

A bill is produced for an account A bill is produced for an account. Over time, an account receives many bills.

A bill summarizes financial transactions A bill contains information about the various financial transactions that have taken place since the last bill was produced (i.e., payments, adjustments, and bill corrections). The above illustration shows a bill with financial transactions for new charges, a payment, and an adjustment.

A bill is routed to persons A copy of the bill is sent to every person linked to the account who requires a copy of the bill.

A bill contains messages A bill may contain messages.

A bill typically contains bill segments A bill typically contains one bill segment for every active service agreement linked to its account.

A bill segment contains calculation details A bill segment contains information showing how the segment was calculated and how it should be printed on the customer's bill.

An Overview Of The Bill Creation Process

When the system is asked to produce a bill for an account, it attempts to create one or more bill segments for every non-cancelled / non-closed service agreement linked to the account. Whether or not a service agreement contributes bill segment(s) to a bill is a complicated subject as the system supports a wide variety of bill segment creation methods. For example, a service agreement that charges for metered service is produced as follows:

- The system first calculates the amount consumed (e.g., the number of lamps, the number of gallons of water, the peak kW, etc.). For more information, refer to [How The System Determines How Much Was Consumed](#).
- Next, the system applies the service agreement's rate to the amount consumed in order to calculate how much the customer owes. A bill segment and a financial transaction are generated to reflect the results of this calculation. The details of the calculations are captured in the bill calculation lines. For more information, refer to [How Rates Affect The Information On Bill Segments](#) for the details. Refer to [Effective Dates and Price Proration](#) for information about how the system prorates changes to rates and prices during a bill period.

Note:

There are many bill segment creation algorithms. The above points explain how a bill segment is produced for a **metered** service agreement. It's important to be aware that the system has other bill segment creation algorithms. For example, if the service agreement charges for a deposit, the system neither amalgamates consumption nor does it apply a rate. You may be wondering how the system knows which method to use. It uses the bill segment type on the service agreement's SA type. Refer to [Designing and Defining Bill Segment Types](#) for a description of the various bill segment creation algorithms that are supported in the system.

If errors are detected during the bill segment creation process, the bill segment is saved with its error. The system then proceeds to the account's next service agreement. This way, a user can see all problematic bill segments so they can be corrected en masse. Refer to [Bill Errors](#) for information about how to deal with bill errors.

Note:

Interdependent service agreements. Your organization may have some service agreements whose charges must be calculated in a specific order. For example, you might have a service agreement whose bill segments are calculated using charges from a different bill segment. If this describes your organization, be aware that the system creates the bill segments in the order of the [billing processing sequence](#) on each service agreement's SA type.

When every segment on a bill is error free, the bill is ready to be completed. When a bill is completed, the system:

- Creates a bill routing for each person linked to the account who requires a copy of the bill. The routing information controls the format of the printed bill and how the bill is sent to the person. Refer to [The Source Of Bill Routing Information](#) for the details.
- Links all bill messages to the bill. A bill message can come from a variety of sources. Refer to [The Source Of Bill Messages](#) for the details.
- If the Freeze At Bill Completion [installation option](#) has been turned on:
 - All freezable bill segments will be frozen.
 - All freezable adjustments whose adjustment type indicates Freeze At Bill Completion will be frozen.
- Sweeps recent financial transactions that have been created since the last bill was completed. Refer to [Financial Transactions Created Between Bills](#) for information about how payments, adjustments and bill corrections appear on a bill.

- There are several other functions that happen at completion time. Refer to the description of the Complete button under [Bill Lifecycle](#) for the details.

And that's it; the bill can now be sent to the customer.

The remaining topics in this section provide more information about the creation and completion of bills.

Note:

Batch and real-time bill creation. Anything the batch bill process does for whole sets of accounts, you can do to a specific account on-line / real time. Refer to [How To Create A Bill For All Service Agreements Linked To An Account](#) for information about how to create a bill on-line / real time. Refer to [Batch Billing](#) for more information about the batch bill creation process.

Bill Errors

The topics in this section describe errors that are detected when the system creates a bill.

Bill Segment Errors

If you consider the huge number of variables involved in the creation of a bill segment, it probably won't surprise you to learn that occasionally, some bill segments are in error.

Errors tend to be caused by missing or inconsistent data. Some examples of classic errors:

- **Missing meter reads.** For example, if the system cannot find a relevant read (and it's not allowed to estimate) for a metered service point, it generates an error.
- **Missing master data.** For example, if a bill is supposed to be routed to the account's mailing address and the account doesn't have such an address, an error is generated.
- **Missing rate data.** For example, if a rate contains a customer specific charge and there is no value defined on the customer's service agreement, an error is generated.

The system saves bill segments that are in error just as it saves bill segments that are error-free. This is done because bill segments are nothing more than a snapshot of the data that was used to calculate the charges. By saving the snapshot, you can see the information the system used when it detected the error and therefore more effectively fix the cause of the error. The standard way to fix an error is to:

- Look at the bill segment to determine the cause of the error.
- Correct the cause of the error.
- Regenerate the bill segment. Regeneration simply deletes the offending segment and recreates a new segment using the corrected information.

For every bill segment in error, a record is written to the [Bill Segment Exception](#) table.

Fastpath:

Refer to [How To Correct A Bill Segment That's In Error](#) for instructions describing how to correct a bill segment.

It's obvious but worth stressing that a bill may contain some segments that are perfect and others that are in error. Once all segments that are in error are corrected, the bill can be completed (and sent to the customer).

If the bill segment in error was created as part of the batch bill process, the system attempts to fix the offending segment(s) each night during the account's bill window by regenerating it. Therefore, if the cause of the error is fixed during the day, the system will automatically regenerate the bill segment when batch billing next runs; you don't have to manually correct each bill. And once a bill is error-free, it will be completed and sent to the customer.

Fastpath:

Refer to [Batch Billing](#) for more information.

Bill Completion Errors

In addition to errors on bill segments, there may also be errors detected when the system attempts to complete a bill. For example, if the system cannot find a mailing address, the bill will be in error (as opposed to one of its bill segments).

Errors tend to be caused by missing or inconsistent data. Some examples of classic errors:

- **Missing mailing address.** For example, if the system cannot find an address to which the bill can be routed, it generates an error.
- **Bill segments are in error.** If a bill contains bill segments that are in error, it cannot be completed and an error is generated.

The system saves bills that are in error just as it saves bills that are error-free. This is done because bills are nothing more than a snapshot of the data that was used to calculate the charges. By saving the snapshot, you can see the information the system used when it detected the error and therefore more effectively fix the cause of the error. The standard way to fix an error is to:

- Look at the bill to determine the cause of the error.
- Correct the cause of the error.
- Recomplete the bill.

For every bill in error, a record is written to the [Bill Exception](#) table.

Fastpath:

Refer to [How To Correct A Bill That's In Error](#) for more information.

If the bill completion error was created as part of the batch bill process, the system attempts to recomplete the bill each night during the account's bill window. Therefore, if the cause of the error is fixed during the day, the system will automatically complete the bill when batch billing next runs; you don't have to manually complete each bill.

Fastpath:

Refer to [Batch Billing](#) for more information.

Cancel / Rebill Incorrect Bill Segments

Sometimes the error on a bill segment is not detected by the system. Such errors occur when the data used to calculate the bill is valid, but wrong. For example, the dial reading on the meter read is incorrect due to slipped fingers, or the sales tax percent was entered incorrectly on a bill factor.

There is no way the system can detect such problems and therefore the system freezes the bill segment and routes the bill to the customer. To correct such a bill segment, you must cancel the offending segment and create a new segment (after correcting the cause of the problem). We refer to this process as cancel / rebill.

Fastpath:

Refer to [How To Cancel / Rebill A Bill Segment](#) for more information about how to cancel / rebill a frozen bill segment.

You must use the cancel / rebill process to correct problems on frozen bill segments. This is because a frozen bill segment can be thought of as having been posted to your general ledger (even if the GL interface hasn't run). And once a financial transaction is posted to the general ledger, it can only be removed via a reversal. Contrast this to bill segments that are in error - they can be deleted because they were never posted to the general ledger.

Fastpath:

Refer to [Bill Segment Lifecycle](#) for more information about the differences between bill segments that are frozen and those that are in error.

**Note:**

Bill segments are canceled / rebilled. It's important to stress that bill segments are canceled and rebilled (as opposed to bills). If every bill segment on a bill is incorrect, you must cancel / rebill each individual bill segment.

Using the cancel or cancel/rebill functionality will cause the cancel and rebill details to be swept on to the customer's next bill. If your organization requires cancellation details to be presented to the customer separately from the new bill, then you will need to use Credit Notes. Refer to [Credit Notes - Presenting Cancellation Details on a Separate Bill](#) for more information. If your organization requires cancellation and rebill details to be presented to the customer separately from the new bill, then you will need to use Correction Notes. Refer to [Correction Notes - Presenting Correction Details on a Separate Bill](#) for more information.

Credit Notes - Presenting Cancellation Details on a Separate Bill

The system's [Cancel / Rebill](#) functionality will include cancellation and rebilling details on the customer's next bill. Some organizations are required to present cancellation details to the customer separately and not to commingle them with a new bill. This separate statement containing only the cancellation information is referred to as a Credit Note.

Credit Notes may be created for an individual bill segment or for all the bill segments linked to a bill. To create a credit note, a Credit Note button is available on the [Bill Segment](#) page and on the [Bill](#) page.

**Fastpath:**

Refer to [How To Create A Credit Note](#) for more information about how to create credit notes for a bill or bill segment.

The topics in this section provide describe the impact of this functionality.

Credit Notes Are Only Possible if the Installation Option Is Turned On

The Credit Notes button on the bill segment and bill pages will only be available if you have selected the Credit Note Bill Correction option on the [Installation](#) record.

Credit / Correction Notes and Auto Pay

If a credit or correction note is being created for a customer who is enrolled in Auto Pay, note the following functionality:

When creating a credit or correction note for a bill (and all its bill segments):

- The system will cancel an automatic payment behind-the-scenes if a credit or correction note is issued BEFORE the automatic payment is interfaced to the financial institution. When you recomplete the bill, the system will create a new automatic payment that reflects the new amount due (and the canceled automatic payment will net out the original automatic payment). This is standard auto pay logic. Refer to [How Are Automatic Payments Cancelled?](#) for more information.
- If the customer has automatic payments that have already been interfaced to the financial institution, the creation of the credit or correction note will have no affect on any automatic payment. A warning will be issued in this case.

When creating a credit or correction note for a bill segment:

- Because automatic payments are for an entire bill, creating a credit or correction note at the bill segment level will not affect any automatic payments. A warning is issued in this case.

**Fastpath:**

For more information about correction notes, see [Correction Notes - Presenting Correction Details on a Separate Bill](#).

Adjustments On Credit Notes

Above, we described how a credit note is a separate document that contains the cancellation details of the various bill segments that appeared on a given bill. Some implementations also want the adjustments that appeared on the original bill to be cancelled when a credit note is produced. Then, when the next bill is produced for the customer, they want these same adjustments reproduced. The following points describe how to implement this functionality:

- Plug in a Bill Completion algorithm on the applicable [Customer Classes](#). A base-package algorithm (C1-CN-RADJ) will reverse a bill's adjustments when a credit note is completed.
- Plug in a Post Bill Completion algorithm on the applicable [Customer Classes](#). A base-package algorithm (C1-CN-ADNB) will recreate the adjustments on the original bill after the credit note is completed. These adjustments will be swept onto the next bill produced for the account.

You can restrict the above functionality to specific adjustment types (for whatever reason). You do this by putting a given char type / char value on the adjustment types that should be reversed and recreated when a credit note is created. You define this char type / char value combination as parameters of the two algorithms described above.

Note:

When the original bill contains adjustment cancellations. The above discussion explained how adjustments can be canceled on a credit note and then recreated on the next bill. These same algorithms also do the opposite, i.e., if the original bill contains an adjustment cancellation, the credit note will contain the recreated adjustment, and the next bill will contain its cancellation. Without this, the credit note would not be the reversal of the bill (and this is how some organizations operate).

Credit Note Routing Suppression

Some implementations do not send credit notes to their customers. To implement this functionality, plug in a Bill Completion algorithm on the applicable [Customer Classes](#). A base-package algorithm (C1-CN-BRT) will cause the routing information to be suppressed when a credit note is completed.

Correction Notes - Presenting Correction Details on a Separate Bill

The system's [Cancel / Rebill](#) functionality will include cancellation and rebilling details on the customer's next bill. Some organizations are required to present cancellation and rebilling details to the customer separately and not to commingle them with a new bill. This separate statement containing the cancellation and rebill information is referred to as a Correction Note.

Correction notes may be created for an individual bill segment or for all the bill segments linked to a bill. To create a correction note, a **Correction Note** button is available on the [Bill Segment](#) and [Bill](#) pages.

Fastpath:

Refer to [How To Create A Correction Note](#) for more information about how to create correction notes for a bill or bill segment.

The topics in this section describe correction notes.

Correction Notes Are Only Possible if the Installation Option Is Turned On

The **Correction Note** button on the bill segment and bill pages will only be available if you have selected the Correction Note Bill Correction option on the [Installation](#) record.

Fastpath:

If your implementation uses Correction Notes, it is recommended to also use the Freeze At Bill Completion installation option. For more information, see [Installation Options - Billing](#).

Correction Notes Versus Credit Notes

Correction notes are a mixture of Credit Note and [Cancel / Rebill](#) functionality. However, unlike credit notes, correction notes are like regular bills and are subject to payment.

When you issue a correction note for a bill, the system cancels and rebills the bill segments for that bill. The new bill (the correction note) contains both the cancelled bill segments and the rebilled bill segments.

Similar to credit notes, the new bill (or correction note) is stamped with the ID of the original bill. After you review the bill segments, you can complete the correction note. During completion, the rebilled bill segments and the cancelled financial transactions (of the original bill's bill segments) are swept onto the correction note.

Correction Notes and Auto Pay

Fastpath:

Refer to [Credit / Correction Notes and Auto Pay](#) for a description of how the system handles correction notes for customers using auto pay.

How The System Determines How Much Was Consumed

There are two types of service agreements:

- Those that charge for some commodity (e.g., electricity, water, garbage, street lighting).
- Those that charge for something intangible (e.g., deposit, charitable contribution, payment arrangement).

For service agreements that charge for something intangible, there is no notion of determining how much was consumed and therefore the topics in this section are not relevant. For service agreements that charge for a commodity, the first step in the creation of a bill segment is the determination of how much was consumed. For example,

- If the service agreement bills for electricity, the system must determine how much electricity was consumed.
- If the service agreement bills for lamp service, the system must determine how many lamps the customer uses.

After the system determines how much was consumed during the bill period, it saves the consumption on the bill segment in the following snapshots:

- The **meter read snapshot** contains information about the meter reads that were used to determine consumption for metered service points.
- The **item snapshot** contains information about the items that existed at the service points.
- The **service quantity snapshot** contains the billable service quantities that were derived using the meter read and item snapshots.

The topics in this section describe how each of the above snapshots is built.

Note:

This logic is in a plug-in. The logic described below resides in algorithms that are plugged-in on the [bill segment type](#) referenced on a service agreement's SA type. If you need different logic, you should develop the appropriate algorithm and plug it in on your bill segment types.

Meter Read Snapshot

To understand this section, you have to come to grips with the concept of a "perfect" end meter read. Our definition of perfection is a meter read that results in a number of days of usage that is in sync with the prices on the service agreement's rate. You see, many prices in a rate are expressed in respect of some period of time, e.g., a monthly flat charge of \$10 is expressed in respect of 30 days. If the number of days on a bill segment is not in sync with the days of the prices, the bill segment must be prorated and proration is not desirable because it confuses the customer.

When selecting the perfect read, not only are we trying to prevent the current bill segment from prorating, we're also trying to prevent future bills from prorating. Remember, it's the end read on the current bill segment that serves as the start read on the next bill segment. So, if we don't pick the right read, the next bill will prorate (ad infinitum).

The topics in this section describe how the system selects the perfect reads while it assembles the meter read snapshot.

Determine The Bill Period For Metered Service

First, the system determines a start date and temporary end date for the bill segment. These dates form the boundary of the meter reads to be included on the bill segment.

- If this is the first bill segment for the service agreement, the billing segment start date is set to the start date of the service agreement. If this is not the first bill segment, the start date is the previous bill segment's end date.
- As for the end date, it can only be estimated at this point (the end read determines the actual end date and this read is only selected a few steps later). The temporary end date is either the end date of bill cycle schedule window, the service agreement's end date, or, in the case of on-line billing, determined by the user.

Fastpath:

Refer to [Service Agreement - Main Information](#) for more information about a service agreement's start and end dates.

Determine The Consumption Period For Metered Service

The consumption period is the inclusive period passed in to the rate application. It is used for calculating the charges for the bill segment. The consumption period is visible on the bill calculation header that groups together the [bill calculation lines](#).

- Consider a bill segment that covers June 1 through July 1 and a subsequent bill segment that covers July 1 through August 1. The charges for July 1 are included on the first bill segment, so the second bill segment should not actually bill July 1. In this scenario, the inclusive consumption period provided to rate application for the second bill segment will be July 2 through August 1.
- Consider a bill segment that must include *bill factor value proration*.
- Assume the bill segment dates are July 1 - August 1 and that a new rate version calculation group is effective on July 20 and that the charges should be prorated. The rate application process will be called twice, with the following inclusive dates:
 - Period for charges calculated by old rate version calculation group: July 2 - July 19
 - Period for charges calculated by new rate version calculation group: July 20 - August 1

Two bill calculation headers will be created in this case, each with the appropriate dates and the collection of bill calculation lines that represent the charges for the bill.

- Consider what should occur for the very first bill segment for a service agreement.
 - It is possible that the start date of the new customer's service agreement matches the end date of the previous customer's service agreement. In this case, the stop/start date is billed to the old customer and the new customer should not be billed for it.
 - It is possible that no other service agreement has been billed for the start date. Perhaps this is new service that has never been billed. Perhaps there is a gap in time between when the previous customer stopped service and when the new customer starts service.

You configure your SA types to tell the system what to do for the *initial consumption period*. You may instruct the system to calculate the start of the consumption period from the day after SA start date, to always include the SA start date, or include the SA start date only if no previous customer was billed for that day (i.e., a 'back-to-back' situation).

Determine The Service Agreement's Billable Service Points

The system looks at every service point linked to the service agreement. The system ignores service points that:

- Are not billable (e.g., check meters).
- Were disconnected before the bill period started.
- Have yet to be connected as of the bill end date.

Fastpath:

Refer to [Service Agreement - SA / SP](#) for more information about a service agreement's service points.

Determine The Service Points' Meters

The system retrieves each meter linked to each service point during the bill period (a service point has multiple meters when a meter exchange has occurred during the bill period).

Fastpath:

Refer to [Installing / Removing A Meter](#) for more information about a service agreement's service points.

Determine The Meters' Start And Stop Meter Reads

The system retrieves a start and stop meter read for each meter linked to the service agreement during the bill period.

Note:

Subtractive versus Consumptive meters. The system only looks for both start and stop reads when it has to subtract the start read from the stop read to derive consumption. There are some types of registers that are reset every time the meter is read and therefore each reading contains the total amount consumed. For this latter type of register, the system just looks for a single read. For more information, refer to [Meter Configuration Maintenance](#) for information about the Consumptive / Subtractive indicator.

The start read can come from any of the following sources:

- If this is the first bill segment for a service point, the start read is defined on the service agreement / service point relationship.
- If the meter was installed at an existing service point during the bill period, the start read is defined on the service point installation history. This happens when a meter is exchanged for another meter during a bill period.
- Otherwise, the start read is the same as the end read on the customer's previous bill segment.

The stop read can come from any of the following sources:

- If this is the final bill segment for a service point, the stop read is defined on the service agreement / service point relationship. Refer to [Service Agreement - SA / SP](#) for more information about the start and stop reads.
- If the meter was removed from an existing service point, the stop read is defined on the service point installation history. This happens when a meter is exchanged during a bill period. Refer to [SP / Meter Installation](#) for more information about installing and removing meters while a service agreement is in effect.
- Otherwise, the system looks for the next scheduled meter read date. Not just any date can be used, the system attempts to find a read that meets the following criteria:
 - Is after the end date of the last bill segment plus the rate's frequency's minimum offset days, and
 - Is on/before the cutoff date of the bill

If no such meter read date could be found, the service agreement is skipped. Otherwise, the system then looks for a read that exists in the time period that starts X days before the service point's next scheduled meter read date, and ends Y days after the scheduled meter read date (where X and Y are the rate's frequency's minimum and maximum offset days, respectively).

If more than one such read exists, the selection is based on the priority of read types (the read with the highest priority read type is selected). For example, verified reads are preferred to regular reads. Refer to the Description of Page section under [Meter Read - Main](#) for more information about read types and their billing selection priority.

- If no read can be found, the system estimates consumption and generates a corresponding estimated meter read if:
 - The service agreement allows estimation.

- The user allows estimation (if the bill is produced as a result of an ad hoc request);
- The bill cycle schedule (if one is being used) allows estimation.
- The register is not a peak register (this is an artificial constraint, but most organizations do not estimate peak consumption).
- The rate schedule allows estimation;
- The register is subtractive. This is because only subtractive registers are self-correcting. For example, assume we estimate a reading of 100 and the next real read is 102, the customer will only be charged for 2 units. However, consider what would happen if we estimated a consumptive register - the consumption associated with the next real read would be billed in its entirety.
- The register does not measure peak consumption.
- Negative consumption is not allowed for the SP/meter combination.

Fastpath:

Refer to [Estimation and Negative Consumption](#) for more information about negative consumption.

The number of days in the bill period is then computed (this equals the start date of the bill segment through the date of the end read). If this is less than the SA type's minimum number of days on a bill, the service agreement is skipped.

Item Snapshot

The steps the system follows to build the item snapshot are the same as those used to build the meter read snapshot. The major differences are as follows:

- Items (e.g., lamps, hydrants, traffic lights) are not read so there are no meter reads to access.
- There are two sources of items:
 - Item-based service points have a single, **badged** item that may be installed at any instant in time. These types of service points are used, for example, when your organization keeps track of the installation history of specific lamps. If an item is installed at an item-based service point during the bill period, it will be included in the item snapshot.
 - All types of service points (metered, item-based, and non-badged) may contain one or more **unbadged** items. Multiple items exist at a service point, for example, when your organization chooses to record multiple lamps on a single service point rather than creating a separate service point for each lamp (this might be useful for a parking lot at a shopping mall). Each item referenced in the service point's collection of unbadged items is included in the snapshot.

Fastpath:

Refer to [Service Points With Multiple Items](#) for more information about service points with multiple items. Refer to [SP / Item Installation](#) for more information about installing and removing badged items at a service point. Refer to [Service Point - Multiple Items](#) for more information about the collection of items that may exist at both meter and item-based service points.

Service Quantity Snapshot

For service agreements where the meter reads are maintained in Oracle Utilities Customer Care and Billing, the service quantity (SQ) snapshot is the total amount consumed for each unit of measure referenced on the bill segment's meter read snapshot. For service agreements where the meter reads are not maintained in Oracle Utilities Customer Care and Billing and bill determinants are requested from a meter data management system via a usage request, the service quantity (SQ) snapshot is the total amount consumed (or peak amount) for each unit of measure referenced on the bill segment's usage request

Note:

Pre-Processing Calculation Rules. If the service agreement's rate has pre-processing calculation rules, they may alter the amount of measured consumption or add additional units of measure to the SQ snapshot. Refer

to [All Calculation Rule-Based Rates Share a Common Structure](#) for more information about pre-processing calculation groups.

Lamps and estimated consumption. If any of the items linked to the service agreement's service points indicate the system should estimate consumption (e.g., lamps), additional entries will be added to the SQ snapshot for each such item. Refer to [Setting Up Estimated Consumption For Items](#) for more information.

Meter read details used for [interim calculations](#) are ignored when producing the service quantity snapshot.

Calculation / Audit Read Details

We use the term "calculation / audit read" to describe a meter read that appears on a bill segment but for which no "real" meter read exists. The following points provide examples of when calculation / audit reads may be required:

- Some retail companies upload meter read details when they upload [pass through charges](#). They do this in order to print the read details that were used to calculate the pass-through charges. It should be stressed that these reads are not used to derive billable consumption (because the charges have already been calculated). These reads are only uploaded for printing purposes and therefore "real" meter reads are not created. We categorize these reads as "calculation / audit reads". Refer to [Billable Charge Upload - Read Details](#) for more information about uploading meter reads with pass-through charges.
- You may have interval billing rates where you're required to print the intervals that contain, for example, the intervals with the three highest peak charges. To do this, you setup a "calculation only" calculation rule to find these intervals and create a "calculation / audit read" for each such interval. Refer to the RCCL-CVTOSC algorithm for an example of such an algorithm that would be plugged-in on a "calculation only" calculation rule.
- You may have interval billing rates that map interval consumption into time-of-use consumption. If you use a base-package algorithm to do this (refer to the RCTMPS and RCTMS algorithms for examples), a "calculation / audit read" is created for each resultant time-of-use quantity. These algorithms do this in case you need this information for bill print purposes or in case you have multiple bill lines that need to use the same mapped consumption.
- You may have situations where a meter has been temporarily removed from a service point but the business practice dictates that usage for the service point should be calculated during billing.
- When integrating with an MDM, meter reads are stored outside of CCB and usage calculation requests are sent to MDM during billing. Reads used in the MDM usage calculation might be returned to CCB as part of the usage response. These reads are used for printing purposes and therefore "real" meter reads are not created in CCB. Instead these reads are captured as "calculation / audit reads". Refer to [Usage Requests](#) for more information.

Both real and calculation / audit reads are stored in a bill segment's read details (the name of the table is CI_BSEG_READ). The following points describe the differences between these two types of rows on this table:

- Calculation / audit reads may or may not reference a service point.
- Calculation / audit reads do not reference the prime key of a real read.
- Calculation / audit reads have a usage flag with a value of Calculation .
- Calculation / audit reads do not require a UOM code. If a UOM is not supplied, an SQI must be supplied.

If you encounter other scenarios during your implementation that necessitate calculation / audit reads, you can develop bill segment type and calculation rule algorithms to add additional calculation / audit reads to a bill segment's read details.

In order to avoid confusing end-users, we do not show calculation / audit reads on [Bill Segment - Read Details](#) (this page only shows "real" reads). Rather, calculation / audit reads are shown in a separate section on [Bill Segment - SQ Details](#).

Calculation / Audit Usage Details

We use the term "calculation / audit usage" to describe service quantities retrieved from the bill segment's usage request. An example of when calculation / audit usage may be required:

- You may have situations where meter reads are not maintained in Oracle Utilities Customer Care and Billing and bill determinants are requested from a meter data management system via a usage request. MDM might return both bill determinants and meter reads to print on the bill.

Usage service quantities are also stored in a bill segment's read details (the name of the table is CI_BSEG_READ). The following points describe the differences between these types of rows on this table:

- Calculation / audit usage may or may not reference a service point.
- Calculation / audit usage does not reference the prime key of a real read.
- Calculation / audit usage has a usage flag with a value of Service Quantity.
- Calculation / audit usage does not require a UOM code. If a UOM is not supplied, an SQI must be supplied.

If you encounter other scenarios during your implementation that necessitate calculation / audit usage, you can develop bill segment type and calculation rule algorithms to add additional calculation / audit usage to a bill segment's read details.

In order to avoid confusing end-users, we do not show calculation / audit reads on [Bill Segment - Read Details](#) (this page only shows "real" reads). Rather, calculation / audit usage is shown in a separate section on [Bill Segment - SQ Details](#).

How To Override The Commodity Amount In A Bill Segment

As described earlier, the calculation of the amount consumed is one of the first steps that takes place when a bill segment is created. 99.9% of the time, the system does a perfect job in this effort. However, there are rare circumstances when, due to missing or incorrect data, the quantity calculated by the system is not what you want to charge the customer for (consider what the consumption should be if the meter is broken?).

To help you deal with these rare situations, a "back door" exists that allows a bill segment's billable quantities to be overridden. This truly is a "back door" because the proper way to fix the amount of a commodity is to correct the cause of the error and then cancel / rebill the bill segment.

Fastpath:

Refer to [How To Override Service Quantities On A Specific Bill Segment](#) for more information.

How Rates Affect the Information on Bill Segments

After consumption has been compiled, the system applies the service agreement's rate to the consumption to determine how much to charge the customer. We refer to this process as the "rate application."

The rate application is a very sophisticated process and can affect every aspect of a bill segment. See [Rate Schedule Execution](#) for an overview of how the system processes a rate.

Rates not only control which charges appear on the bill, but also the verbiage. In addition, there are variables that can be used in the configuration to customize the message that the customer receives. See [How to Use Description on Bill](#) for more information

Note:

Not all service agreements use a rate! There are a small number of service agreements that don't use a rate to calculate the charges that appear on their bill segments. For example, a service agreement used to levy a customer's payment arrangement amount doesn't need a rate because the amount to charge is defined on the service agreement. Whether or not a service agreement needs a rate is defined by the service agreement's SA type. Whether or not the system calls the service agreement's rate to calculate charges is controlled by the bill calculation algorithm plugged-in on the bill segment type that's referenced on the service agreement's SA type. Refer to [Designing and Defining Bill Segment Types](#) for a description of the various bill segment creation algorithms that are supported in the system.

Proration. A rate contains a variety of effective-dated information (meaning that the prices are effective-dated, and the structure of the rate is effective-dated) If this effective-dated information changes during a bill period, the system

may need to prorate the charges; for example, if the sales tax percentage changes mid-period, the system can prorate the tax change. Refer to segments. Refer to [Effective Dates and Price Proration](#) for more information.

There are many plug-in spots available on a calculation rule. These plug-ins can manipulate virtually every aspect of the bill segment. This means if you require functionality that isn't support by the base package calculation rule, you can build additional calculation rule plug-ins to do whatever you need. See [Base Package Calculation Rule Descriptions](#) for more information

Fastpath:

Refer to [Rates](#) for more information about how rates are constructed.

Bill Frequency - Bill Cycle vs Bill Segment Duration

An account's bill cycle defines when the system attempts to create bill segments for the account's service agreements. The word "attempt" is stressed because a service agreement may not have a bill segment on every bill created for its account.

Some examples will help make the point:

- An account may be on a monthly bill cycle (meaning we attempt to create a bill every month for the account) but contain only biannual service agreements. However, this is not sensible. Why? Because the system would attempt to create a bill every month for the account's service agreements, but only twice during the year would it succeed (because the service agreements have a biannual duration).
- An account may be on a biweekly bill cycle (meaning we attempt to create a bill every 2 weeks for the account) and contain a mixture of biweekly, monthly, and quarterly service agreements. In this scenario, every two weeks the system would create a bill that contains at least one bill segment (for the biweekly service agreement). However, 12 times a year, the bill will contain an additional bill segment for the monthly service agreement. And 4 times a year, the bill will contain one more bill segment (for a total of 3) for the quarterly service agreement.

In sum, the account's bill cycle controls when the system attempts to create a bill for the account's service agreements. Whether a service agreement contributes a bill segment to the bill is a complicated subject. The topics in this section describe how the system knows it's time to create a bill segment for a service agreement.

Important:

An account's bill cycle should attempt to create bill segments at least as often as the shortest service agreement duration. For example, if an account has both monthly and quarterly service agreements, the account should be placed on a monthly bill cycle. Refer to [How Does An Account Get Its Bill Cycle?](#) for more information.

Fastpath:

For more information about bill cycles, refer to [Defining Bill and Service Cycles](#).

Ways To Control The Start Date Of A Bill Segment

Bill segments produced for a service agreement have two time periods:

- The bill segment period. The bill segment period defines the entire period of time covered by a bill segment's charges.
- The consumption period. The consumption period defines the period of time used to calculate the number of days for daily charges.

The consumption period almost always starts one day after the bill segment period. The consumption period always ends on the bill segment's end date. For example, a bill segment period that spans 5-Jan-2002 through 6-Feb-2002 will almost always have a corresponding consumption period of 6-Jan-2002 through 6-Feb-2002. The reason that the start dates don't match is because a bill segment's start date equals the end date of the prior bill segment (i.e., the start date was already counted in the previous bill segment's consumption period and we don't want to count it twice).

The only time when the previous paragraph isn't true is the first bill segment that's produced for a new service agreement. This is because different companies count the first day of a new service agreement differently than others. Refer to [Initial Consumption Period Considerations](#) for examples and an explanation of how you can control the start date of the consumption period.

Ways To Control The End Date Of A Bill Segment

The following points describe the different methods that can be used to define the end date on a service agreement's bill segments:

- **Meter Read Date.** For service agreements with metered consumption (excluding real time meters), the end date is the date of the meter read used on the last day of the bill segment. This is a deceptively disingenuous statement because the algorithm used to select this end read is complex (and it relies on the service cycle schedule - hence the name of this option).
- **Bill Period Schedule.** Non-metered service agreements may have the end date of their bill segments defined on the user-maintained bill period calendar. This option is used when bill segments must fall on strict calendar boundaries (e.g., quarterly bills that end on the last day of the quarter).
- **Anniversary.** In addition to the Bill Period Calendar method, non-metered service agreements may have their bill segment end date based on the first day of service. For example, if service started on the 16 th of some month, the ongoing bill segments will start on roughly the 16 th of each month. This option is frequently used to bill for garbage or cable service.
- **ASAP.** For non-meter service agreements that use neither the Bill Period Calendar nor Anniversary methods, the system assumes the end date of a bill segment is the current date. This option is frequently used for service agreements that deal with items (e.g., street lamps, phone booths).
- **Billable Charge.** For non-metered service agreements that exist to levy billable charges, the start AND end dates are defined on the billable charge information that is entered by a user or interfaced from an external system.

The topics in this section discuss each of the above methods.

Using The Meter Read Date Method

A metered service agreement's SA type does not contain a specific indication that the service agreement is used to charge for metered service. Rather, if the system finds metered service points linked to the service agreement, it knows to use a meter read date as the end date of the bill segment. The trick is finding the perfect read amongst many possible reads. Refer to [Meter Read Snapshot](#) for a description of how the system finds the perfect end read.

Note:

If the next read date is in the future. The system will not create a bill segment for a metered service agreement if the next expected read date is in the future. The system determines the next expected read date using the service cycle schedule linked to the service agreement's service points.

Multiple scheduled read during a bill period. A base-package Get Consumption algorithm let's you control what happens when a service agreement's service point(s) have multiple scheduled meter readings during a bill period. You have two choices: 1) create a single bill segment using the latest scheduled meter read for the bill period, or 2) create a separate bill segment for every scheduled meter read during the bill period. The choice is yours. Refer to the BSGC-SP algorithm type for a description of the base-package algorithm type.

Using The Bill Period Schedule Method

The bill period schedule method causes the bill segment end date to be calculated using a bill period schedule. The bill period's schedule defines when bill segments are produced and their respective end dates. This method is used when the bill segment needs to fall on strict calendar boundaries (e.g., quarterly bills that end on the last day of the quarter).

The service agreement's SA type indicates if the service agreement uses this method, and if so, the specific bill period whose schedule defines the end dates.

**Note:**

Future and Past End Dates. It's important to be aware that a bill period schedule can be used to generate end dates that are in the future or in the past.

**Fastpath:**

For more information about bill periods, refer to [Designing Bill Periods](#).

Using The Anniversary Method

The anniversary date method causes the bill segment end date to be calculated based on the first day of service. For example, if a service agreement started on the 16 th of some month, the ongoing bill segments will start on roughly the 16 th of each month. This method is frequently used to bill for garbage or cable service. When using this method, you also define the applicable billing frequency (i.e., monthly, bi-monthly, quarterly, etc.).

The following table contains the bill periods for a service agreement's starting on 23-Feb-99 that uses a monthly frequency.

| Start Date | End Date | Billing Days |
|------------|-----------|--------------|
| 23-Feb-99 | 25-Mar-99 | 30 |
| 25-Mar-99 | 25-Apr-99 | 31 |
| 25-Apr-99 | 25-May-99 | 30 |
| 25-May-99 | 25-Jun-99 | 31 |
| 25-Jun-99 | 25-Jul-99 | 30 |
| 25-Jul-99 | 25-Aug-99 | 31 |
| 25-Aug-99 | 24-Sep-99 | 30 |
| 24-Sep-99 | 24-Oct-99 | 30 |
| 24-Oct-99 | 24-Nov-99 | 31 |
| 24-Nov-99 | 24-Dec-99 | 30 |
| 24-Dec-99 | 24-Jan-00 | 31 |
| 24-Jan-00 | 23-Feb-00 | 30 |
| 23-Feb-00 | 25-Mar-00 | 31 |

**Note:**

Future and Past End Dates. It's important to be aware that anniversary billing can generate end dates that are in the future or in the past. The future-option generates the next anniversary date after the current date. The past-option generates the anniversary date that immediately precedes the current date.

The service agreement's SA type indicates if the service agreement uses this method, and if so, the billing frequency.

**Fastpath:**

For more information about the SA Type attributes that control this method, refer to [Setting Up SA Types](#).

Using Billable Charges

Bill segments for billable charge service agreements have both their start and end dates defined on the respective billable charge.

Fastpath:

For more information about billing billable charges, refer to [How To Create A One-Time Invoice](#) . For more information about creating a billable charge, refer to [Maintaining Billable Charges](#). For more information about interfacing a billable charge from an external system, refer to [Uploading Billable Charges](#) .

The service agreement's SA type indicates if the service agreement uses this method, and if so, the billing frequency.

Fastpath:

For more information about the SA Type attributes that control this method, refer to [Setting Up SA Types](#).

Preventing Short Bill Segments

Every SA type contains an attribute defining the minimum number of days on a bill segment. Whenever the system attempts to create a bill segment other than the final bill segment, it checks if the number of days is at least as great as the minimum. If not, the bill segment will not be created as part of this bill run. Rather, the system waits until the number of days in the bill segment is at least as large as the minimum. This is true for all methods of bill duration calculation.

Prorating Charges When a Rate is Applied

It is possible for some of the prices that appear on a bill segment to change during the course of the bill period.

Fastpath:

Refer to [Effective Dates & Price Proration](#) for more information about how charges are prorated during rate application.

Batch Billing

99.9% of all bills are created by the batch billing background process BILLING and require no human intervention before they can be finalized and sent to a customer. The other 0.1% are created by users on-line / real time. This section discusses several important concepts associated with batch billing. If your implementation requires processing of data by CIS Division the BILLING background process provides an optional parameter that allows a CIS Division to be specified as an input parameter.

This process has an optional input parameter for CIS Division. It can be used if you implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

Window Billing And The Bill Cycle Schedule

Fastpath:

Refer to [The Cyclical Billing Process & Window Billing](#) for more information about how an account's bill cycle dictates when a customer is billed.

Confirming A Batch Of Bills Before Completing Them

If you're implementing new rates or if something unusual is being introduced that affects billing, you may want to turn off the bill cycle schedule's Freeze and Complete switch. If this switch is off, the system creates bills, it just doesn't freeze and complete them. You can then review the entire batch of bills to make sure they're clean.

- If you find the bills are wrong, correct the source of the error and rerun the bill cycle. The system will remove all incomplete bills and then reproduce them using the corrected information in the system.
- If you find the bills are correct, turn the Freeze and Complete switch on and rerun the cycle. The system will remove all incomplete bills and then reproduce them. Assuming nothing changed, the bill amounts will be the same.

Fastpath:

Refer to [Setting Up Bill Cycle Schedules](#) for more information.

Canceling A Batch Of Bills After They're Complete

If you need to cancel an entire batch of bills because they were created using faulty data (e.g., the wrong tax rate was defined in the rate), you can. A background process (MASSCNCL) exists for this purpose.

This background process will cancel all the frozen bill segments for the latest run of a given bill cycle's schedule. Optionally, you can cancel bills for a given bill date within the bill cycle's schedule. The cancel reason used on the bill segment is the one marked as the bill cancel reason for mass cancel. Refer to [Setting Up Bill \(Segment\) Cancellation Reasons](#) for more information.

When the cycle is billed again, new bill segments will be created, and the original bill segments and the cancellations will automatically be hidden from the customers.

Reopening A Batch Of Bills After They're Complete

If you need to reopen an entire batch of bills because they were completed prematurely (e.g., payments did not get posted before billing ran, so recent payments were not reflected in the account balances), you can. A background process (MASSROBL) exists for this purpose.

This background process will reopen all the bills for a given bill date for the latest run of a given bill cycle's schedule.

Fixing Errors Detected In Batch Billing

If an "error" bill segment is created by the batch billing process, the system attempts to fix the offending segment each night by regenerating it using the information that exists at that time. Therefore, if the cause of the error is fixed during the day, the system will automatically regenerate the bill segment when batch billing next runs; you don't have to manually correct each bill. And, once a bill is error-free, it will be completed and sent to the customer.

Important:

Automatic regeneration only works during the account's bill window. If an "error" bill segment is not successfully regenerated on the last night of the account's bill cycle, it will remain in error until the next time the account's cycle runs (unless a user corrects it real time). At that time, the system will generate another bill error indicating the prior bill segment is in error (and then there'll be two bill segments in error).

Completing Pending Bills

If you need to complete pending bills created by the batch billing process, you can. A background process (C1-BLCMP), exists for this purpose.

This background process will complete all pending bills on a given bill date for a given bill cycle's schedule. This process does not delete and regenerate freezable bill segments linked to pending bills.

Fastpath:

Refer to [Bill Errors](#) for more information.

Billing Financial Transaction Considerations

The topics in this section provide information about the financial impact of a bill segment.

Billing - Current Balance versus Payoff Balance

A bill segment's financial transaction affects a service agreement's payoff balance and/or current balance. In this section, we describe these two balances.

Warning:

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

When Current Balance Equals Payoff Balance

For most service agreements, payoff balance and current balance are always the same (or in colloquial speech - the amount the customer thinks they owe equals what they really owe). Let's run through a typical example. The values in the payoff balance and current balance columns reflect the amount due after the financial transaction has been applied (i.e., the running balance):

| Date | Financial Transaction | Payoff Balance | Current Balance |
|-----------|-----------------------|----------------|-----------------|
| 1-Jan-99 | Bill: \$125 | 125 | 125 |
| 15-Jan-99 | Payment: \$150 | -25 | -25 |
| 2-Feb-99 | Bill: \$175 | 150 | 150 |
| 14-Feb-99 | Payment: \$150 | 0 | 0 |
| 3-Mar-99 | Bill: \$200 | 200 | 200 |
| 15-Mar-99 | Payment: \$150 | 50 | 50 |
| 2-Apr-99 | Bill: \$225 | 275 | 275 |

As you can see, payoff balance and current balance are always in sync.

When Current Balance Differs From Payoff Balance

For some service agreements, payoff balance and current balance differ (or in colloquial speech - the amount the customer thinks they owe differs from what they would owe if they wanted to pay off their account).

Let's run through an example of a customer on a budget to illustrate a classic service agreement where these two balances are not the same. The values in the payoff balance and current balance columns reflect the amount due after the financial transaction has been applied:

| Date | Financial Transaction | Payoff Balance | Current Balance |
|----------|---------------------------|----------------|-----------------|
| 1-Jan-99 | Bill: \$125, Budget \$150 | 125 | 150 |

| | | | |
|-----------|---------------------------|-----|-----|
| 15-Jan-99 | Payment: \$150 | -25 | 0 |
| 2-Feb-99 | Bill: \$175, Budget \$150 | 150 | 150 |
| 14-Feb-99 | Payment: \$150 | 0 | 0 |
| 3-Mar-99 | Bill: \$200, Budget \$150 | 200 | 150 |
| 15-Mar-99 | Payment: \$150 | 50 | 0 |

The following table describes the various types of service agreements where these balances may differ.

| Type Of Service Agreement | What Payoff Balance Holds | What Current Balance Holds |
|-------------------------------------|---|--|
| Deposit | Payoff balance holds the amount of deposit you are holding on behalf of the customer's debt. This amount is showed as a credit (with a negative sign) because you truly owe the customer this money. | Current balance holds the amount the customer owes for a deposit. |
| Charitable contribution | N/A - charitable contribution service agreements never have a payoff balance. | Current balance holds the amount the customer owes for a charitable contribution. |
| Payment arrangements | Payoff balance holds the total amount of delinquent debt that remains unpaid. When a payment arrangement is started, you transfer the payoff balance from the utility service agreement to the payment arrangement service agreement. Each billing period, the customer pays down this balance. | Current balance holds the amount the customer owes in respect of the billed payment arrangement amounts. |
| Service agreements on a budget plan | Payoff balance holds the actual amount owed (actual bills minus payments). | Current balance holds the amount the customer owes in respect of the billed budget amount. |

Bill Segment Type Controls Which Balance(s) Are Affected

Every bill segment references a bill segment type (the bill segment type comes from its service agreement's SA type). The bill segment type controls how payoff balance and current balance are affected by the bill segment amount. It also controls the algorithm used by the system to calculate the bill segment's bill lines.

Fastpath:

Refer to [Designing and Defining Bill Segment Types](#) for more information about how bill segment type affects how a bill segment is produced and how its financial transaction is generated.

The Source Of GL Accounts On A Bill Segment's Financial Transaction

A bill segment's financial transaction also contains the double-sided accounting entry that defines how the bill segment affects the general ledger.

**Fastpath:**

Refer to [The Source Of GL Accounts On Financial Transactions](#) for a description of where the system extracts the distribution codes used to construct the GL accounts.

Determining the Statistical Quantity

The statistical quantity for each general entry line in the financial transaction is populated by adding together the statistical quantity for all bill calculation lines for the same distribution code. The bill calculation line indicates a statistical quantity if its corresponding calculation rule has marked the GL statistical quantity setting.

The statistical quantity for a bill calculation line is the prorated billable quantity for that line.

- If the corresponding calculation rule for the bill calculation line is not marked **measures peak**, then the statistical quantity corresponds to the billable quantity for the bill line. This is because billable quantities for SQs that do not represent a peak quantity are prorated when applying the rate.
- If the corresponding calculation rule for the bill calculation line is marked **measures peak**, then the statistical quantity may not correspond to the billable quantity for the bill calculation line. SQs that measure peak are not prorated when applying the rate. However, when determining the statistical amount to send to the general ledger, the quantity is prorated in the same manner as quantities that do not measure peak amounts.

**Note:**

Bill Calc Line Statistical Quantity. The statistical quantity for each bill calculation line is calculated when generating the bill segment and used to populate the statistical quantity for the FT GL entry. The calculated value is not saved in the bill calc line record.

The Source Of Bill Routing Information

When a bill is completed, the system creates a [bill routing](#) for each person linked to the account who receives a copy of the bill. The bill routing record contains the information that controls how, where and to whom a bill is sent.

The following points describe how this works:

- Each person who receives a copy of an account's bill is listed on the [account's person information](#).
- A [bill routing](#) is created for each such person when the bill is completed.
- The information that appears on the bill routing record is controlled by the **bill route type** specified on the respective account / person information.
- If the bill route type's routing method is email or fax and the system has been configured to use notification preferences for bill routing, a bill routing is created for each active contact preference whose notification type is associated with the **bill route type** specified on the respective account/person information ; otherwise, bill routings are created as follows:
 - If the bill route type indicates the person's bills are routed via fax, the "address line 1" address constituent is populated with the person's fax number. The system knows which of a person's person contacts is a fax number is by the contact routing or which of a person's phone numbers is a fax number by the phone type.. If person contacts are used, the primary fax is selected. If phone is used and the person has multiple fax numbers, one is selected at random.
 - If the bill route type indicates the person's bills are routed via email, the "address line 1" address constituent is populated with the person's [Email address](#). The system knows which of a person's person contacts is an email or knows where to find the person email. If person contacts are used, the primary email is selected.
 - If the bill route type indicates the person's bills are routed via the postal service, the address constituents are populated with the address specified on the [account / person's bill address source](#). Note, if the person has a [seasonal address](#) effective on the business date, the seasonal address will be used regardless of the value of **bill address source**.

**Fastpath:**

Refer to [Printing Bills](#) and [How To Reprint A Bill \(For The Original Recipients or For Someone New\)](#) for more information. Refer to [Account - Person Information](#) for information regarding how to control who receives a copy of a bill, where the bill is sent, and how the bill is formatted.

Bill Messages

The topics in this section describe how messages are linked to a bill and bill segment.

The Source Of Bill Messages

When a bill is completed, the system sweeps bill messages from the following sources onto the bill.

Note:

Bill or Bill Segment Messages. Bill messages will be linked either to the bill or to one its bill segments depending on the source of the bill message code. In other words, messages associated with a service agreement (directly or indirectly) will be linked to the bill segment; messages associated with an account (directly or indirectly) will be linked to the bill.

- All permanent and temporary bill messages linked to an account are linked to the bill when it is completed. Refer to [Account - Bill Messages](#) for more information. Note well that all temporary bill messages are removed from the account when they are swept onto a bill (a temporary message is swept onto the next bill produced for the account).
- The system checks if the bill's account's customer class has bill messages. If so, it links all such messages that are effective on the bill date to the bill when it is completed. Refer to [Setting Up Customer Class Bill Messages](#).
- All permanent and temporary bill messages linked to service agreements that contributed bill segments to the bill are linked to their respective bill segment when the bill is completed. Refer to [Service Agreement - Miscellaneous](#) for more information. Note well that all temporary bill messages are removed from the service agreement when they are swept onto a bill segment (a temporary message is swept onto the next bill segment produced for the service agreement).
- The system checks if each bill segment's rate has bill messages. If so, it links all such messages that are effective on the bill segment's start date to the bill segment when the bill is completed. Refer to [Defining Calculation Rules](#) for more information.
- The system checks if the service provider associated with each sub bill segment has bill messages. If so, it links all such messages that are effective on the bill segment's start date to the bill segment when the bill is completed. Refer to [Setting Up Service Providers](#).
- The system checks if the meter read remarks referenced on meter reads used on a bill segment have bill messages. If so, it links all such messages that are effective on the bill segment's start date to the bill segment when the bill is completed. Refer to [Meter Read Remark - Bill Messages](#).

In addition, a user may manually add an [ad hoc message to a bill](#).

And finally, you can develop your own background processes and algorithms that add bill messages to accounts, service agreements, bills and/or bill segments. Refer to [Substituting Field Values Into A Bill Message](#) for examples.

Substituting Field Values Into A Message

Many bill messages contain static text (i.e., the message is the same on every bill). However, the system supports messages whose contents are dynamic. For example, consider the bill message Thank you for your charitable contributions in 2000 for \$123.12, please keep this bill for tax purposes. This message contains two substitution values (the year and the amount) as is therefore considered dynamic.

Dynamic messages can be implemented as follows:

- Create a bill message code whose Message on Bill contains substitution values. For example, the bill message code to produce the message illustrated above would contain the following Message on Bill - Thank you for your charitable contributions in %1 for %2, please keep this bill for tax purposes.

- Use either of the following methods to link the message code and its substitution parameters to the bill:
 - Create a background process or algorithm to insert a permanent or temporary bill message on the appropriate accounts. Then, when an account's bill is next completed, the system will sweep the message (and its substitution parameters onto the bill).

In addition to inserting the appropriate bill message code, your background process / algorithm must also insert the appropriate substitution values. The name of the table in which account messages are inserted is **CI_ACCT_MSG**. The name of the table in which a message's substitution values are inserted is **CI_ACCT_MSG_PRM** (you will insert one row for each substitution field).

Please see the background process (REACH) for an example of a background process that performs this type of function. Please see the algorithm identified by DEP PIF MSG for an example of an algorithm that performs this type of function.

- Rather than adding the dynamic message to account (and then letting the bill completion logic transfer the account message to the bill), you could construct a bill completion algorithm that adds the message code and substitution values on the bill (during bill completion). The name of the table in which bill messages are inserted is **CI_BILL_MSGS**. The name of the table in which a message's substitution values are substituted is **CI_BILL_MSG_PRM** (you will insert one row for each substitution field).

A Bill May Affect More Than Just Customer Balances

The topics in this section provide information about obscure things that may happen when a bill is created, frozen, or canceled.

Auto Cancel / Rebill If A Service Agreement Is Stopped Retroactively

If the system detects a bill segment with a bill date after the stop date of the service agreement (because the service agreement was retroactively stopped), the system automatically cancels the bill segment and creates a new one with an end date equal to the service agreement's stop date.

Cancel Historical, Estimated Bill Segments When A Real Read Is Found

A special plug-in spot exists on bill segment type that can be used to automatically cancel historical, estimated bill segments when a “real” read is used on the current bill. This plug-in spot is invoked only when an excessive read (the prior read is more than the current read) situation is detected. The base product provides the BSAXERLIM (Auto-Cancel Old Bill Segments Due To Estimated Reads) algorithm.

If you wish that the spot be invoked all the time and not only when an excessive read situation is encountered, you must setup the *Always Call Auto Cancel* option type of the **Financial Transaction Options** [Feature Configuration](#). You will normally do this if you want the type of readings to be the basis of the auto cancellation. For example, you want to cancel estimated bills and rebill distributing usage more accurately across a tiered rate. The base product provides the C1-BSAXMINGR (Auto-Cancel Old Bill Segments Until Minimum Good Read) algorithm that works in conjunction with the feature configuration.

These algorithm would typically be specified on bill segment types that calculate bills using meter reads.

Note:

This plug-in spot is typically used on bill segment types that calculate bills using meter reads.

This algorithm is called by the system when creating bills in batch. It does not get called when a user creates a bill online.

Deposits May Be Refunded

Fastpath:

Refer to [Refunding Deposits](#) for how deposits may be refunded when a deposit service agreement is "final billed".

FT Freeze Repercussions

Fastpath:

Refer to [Obscure Things That Can Happen](#) for more information about things that can happen when an FT is frozen (and FT's get frozen during billing).

Budget Billing

The topics in this section provide background information about a variety of budget billing issues.

Fastpath:

We strongly recommend familiarizing yourself with the topics described in [Designing and Defining Budget Plans](#) to fully appreciate how budgets fit into the system's financial architecture.

Account versus Service Agreement

Customers who pay on a budget plan tend to believe that there is one budget amount applied to their account's bill each month. This is not true. Rather, each service agreement has an individual budget amount (stored in the recurring charge array). The sum of an account's service agreements' budget amount is the account's budget amount.

Why does each service agreement have a unique budget amount? Because all financial accounting in the system is performed at the service agreement level, not for an entire account.

While a unique budget amount is defined for each service agreement, a user can use a simple page to view and change the budget amount for all eligible service agreements linked to an account.

It's important to be aware that some service agreements linked to an account may not be eligible for budget plans. For example, assume you have a customer with a deposit service agreement and one or more utility service agreements. This customer will be billed for their deposit regardless of the utility service agreements' budget amounts. You define whether a service agreement may participate in a budget plan on the service agreement's SA type.

How To Set Up A Customer To Participate In A Budget Plan

If a customer wants to participate in a budget billing plan, simply transfer to [Account - Budget](#) and generate a new budget for the customer.

The Financial Impact Of Budget Plans

The only difference between a customer who participates in budget billing and one who doesn't is that budget billing customer have bill segments where payoff amount differs from current amount. Why? Because the payoff amount is the actual amount of the bill. The current amount is the amount the customer is expected to pay (i.e., their budget amount).

Let's run through an example of a customer on a budget to illustrate a service agreement where these two balances are not the same. The values in the payoff balance and current balance columns reflect the amount due after the financial transaction has been applied:

| Date | Financial Transaction | Payoff Balance | Current Balance |
|----------|---------------------------|----------------|-----------------|
| 1-Jan-99 | Bill: \$125, Budget \$150 | 125 | 150 |

| | | | |
|-----------|---------------------------|-----|-----|
| 15-Jan-99 | Payment: \$150 | -25 | 0 |
| 2-Feb-99 | Bill: \$175, Budget \$150 | 150 | 150 |
| 14-Feb-99 | Payment: \$150 | 0 | 0 |
| 3-Mar-99 | Bill: \$200, Budget \$150 | 200 | 150 |
| 15-Mar-99 | Payment: \$150 | 50 | 0 |

Fastpath:

For more information about current and payoff amounts, refer to [Current Balance versus Payoff Balance](#).

Budget Billing Background Processes

The topics in this section describe the background processes that automate management of customer who participate in budget billing plans.

Note:

Budget Processing. The budget background processes only calculate budget amounts for pending start, active and pending stop SAs whose start and end date (if any) includes the budget date. Additionally, the budget date is used to select the rate schedule that is in effect for an SA if estimating consumption is necessary.

Budget True Up

The Budget True Up background process (BUDTRUP) examines all accounts who participate in budget billing plans. If enough time has passed since the customer's budget was last tried up, the system will calculate the account's recommended budget amount. If the recommended amount differs from their existing budget amount by more than a given tolerance percentage, the customer's budget amount (actually, the recurring charge amount on the account's service agreements) will be changed.

Fastpath:

The amount of time between true ups and the true up method used to true up is defined on the account's budget plan. The tolerance percentages are defined as parameters of the true-up algorithm that is plugged in on the account's budget plan. Refer to [Designing and Defining Budget Plans](#) for all the details.

Budget Monitor

The Budget Monitor background process (BUDMON) examines all accounts that participate in budget billing plans. If the account's existing budget amount is out-of-sync with predefined tolerance percentages as defined by the algorithm plugged into the monitor budget plug-in spot, the system will perform the action indicated by the monitor algorithm. The base product supports highlighting the account on the [Budget Review](#) page or updating the account's budget.

Fastpath:

The tolerance percentages are defined as parameters of the budget monitor algorithm that is plugged in on the account's budget plan. Refer to [Designing and Defining Budget Plans](#) for all the details.

Canceling A Budget

The following points describe when a budget is cancelled:

- A user can cancel a budget at any time by using the Cancel Budget action on the [Account - Budget](#) page.
- The system may cancel a budget during a collection process (if the collection process contains a Cancel Budget collection event). Refer to [Types Of Collection Events](#) for more information.
- When a service agreement is [stopped](#), the system automatically cancels the budget.

When a customer's budget is cancelled, the following events transpire:

- Any recurring charge entry whose effective date is after the cancel date is deleted. This is possible if you are entering a back-dated stop date for the service agreement. For example, perhaps you run the [Budget True Up](#) process, which adds a new budget amount to the service agreement (effective today). Then imagine that the customer calls you and informs you that they moved out last week. If you stop the customer's service as of last week, the recurring charge effective today is deleted when the stop is finalized.
- A new recurring charge amount of zero is created for each of the customer's service agreement.
- Each service agreement's current balance is synchronized with its payoff balance (using the sync adjustment code defined on the service agreement's SA type).

Net Energy Metering

The topics in this section provide background information on net energy metering.

What Is Net Energy Metering?

Customers in a distributed generation energy market may have renewable energy devices such as solar panels or wind turbines connected to their meters. The energy generated at this service point, as well as any energy used, could possibly be measured by a single meter, with the energy generated being netted against the energy used. This is called net energy metering (NEM). The meter records a positive number when customers use more energy than they generate, and a negative number when they generate more than they consume. These customers may owe a minimum charge each month. Their actual energy charges and generation credits are accrued until the account is adjusted at the end of a specified period, called the true up period. When the account is trued up, the consumption charges and generation credits for the period are combined to determine if the customer owes money to the utility.

Net Energy Metering Service Agreements

As mentioned in the previous section, net energy metering (NEM) customers typically owe a minimum charge each month while their actual energy charges and generation credits are accrued until true up time. This is accomplished by setting up a master service agreement (SA) to hold the monthly minimum charge and a sub service agreement to hold the customer's actual energy charges and generation credits.

For more information about service agreement relationships, refer to [Defining SA Relationship Options](#).

Net Energy Metering True Up

To facilitate the true up process, each true up period will be represented by a sub service agreement. Each sub service agreement will be monitored by a true up monitor (TUM), a service task which is responsible for: performing the true up process at the end of the true up period; reversing true up transactions when cancel/rebills affect a period that has been trued up; synchronizing itself with any changes on its master service agreement or service agreement relationship (e.g., if the service agreement relationship is deleted, the true up monitor will cancel itself); and creating the service agreement relationship and sub service agreement for the next true up period.

A service agreement creation algorithm on the master service agreement type is responsible for creating the initial sub service agreement and service agreement relationship. Subsequent sub service agreements are created in the true up monitor lifecycle. A service agreement creation algorithm on the sub service agreement type is responsible for creating the true up monitor. A link to the true up monitor service task is available from the characteristics page of the sub service agreement. It is important to note that the true up monitor is not a user-maintained object. End-users will not normally need to access the true up monitor. All that is visible on the true up monitor is its type, status, related sub service agreement and account. As always, relevant financial history will be accessible from the sub service agreement.

The Lifecycle of a True Up Monitor

The following diagram shows the lifecycle of the True Up Monitor business object:

Active State: The true up monitor starts out in the Active state. Here the true up monitor is evaluated for true up processing or possible cancellation. The system will perform a true up if either the true up period has come to an end, or the service agreement is final billed.

The amount of time between true ups is defined on the true up task type. See [Setting Up the System for Net Energy Metering](#) on page 330 for a description of how true up task types are configured.

Canceled State: The true up monitor is transitioned to the Canceled state if its service agreement is canceled or deleted. Because the service agreement associated with a true up monitor is a sub service agreement, it is possible that the stop date on the sub service agreement is backdated to a point prior to the start of its associated service agreement relationship. In this case, the true up monitor is also canceled.

Trued Up State: If it is time for true up, the true up monitor is transitioned to the Trued Up state. True up processing involves summing the sub service agreement's bill segments to see if the customer owes any debt (i.e., the energy they generated was not enough to cover the energy they consumed). If the sum is positive, the amount is transferred to the master service agreement for the customer to pay off. If the sum is negative, the sub service agreement balance is brought to zero (the utility keeps the credit). If your implementation wants to issue refunds to customers who generate more energy than they consume, you will need to design your own algorithm for the true up process.

The adjustment types used to transfer or zero out the sub service agreement balance are defined on the true up monitor type. See [Setting Up the System for Net Energy Metering](#) on page 330 for a description of how true up monitor types are configured.

Reverse True Up State: Once the financial true up is done, a new service agreement relationship and sub service agreement are created for the subsequent true up period. If cancel/rebills occur after the true up process has been performed, the true up monitor is transitioned to the Reverse True Up state. Any adjustments that were previously created are canceled as part of this processing. Thereafter the true up monitor is transitioned back to the Active state, where it waits until bill completion attempts another true up.

Setting Up the System for Net Energy Metering

This section summarizes the various tasks required for setting up your system for net energy metering.

Adjustment Types

The following adjustment types are used at true up time:

- **Current Balance True Up.** This is the adjustment type used in syncing the payoff and current amounts on the sub service agreement associated with the true up period. This adjustment type should reference an FT algorithm of **Payoff Amount = 0 / Current Amount = Adj Amount (no GL)**.
- **Transfer To Master.** This is the adjustment type used to transfer the customer's balance from sub service agreement to master service agreement if a positive payoff balance exists on the sub service agreement after true up.
- **Write Down.** This is the adjustment type used to bring the payoff balance of the sub service agreement to zero if a negative payoff balance exists after true up.

Adjustment Type Profile

Create an adjustment type profile that references the adjustment types used in net energy metering billing.

True Up Task Type

To enable billing for net energy metering, your implementation must configure a **True Up Task Type**. This service task type captures the various configuration options that are used by the true up monitor's algorithms:

- **Minimum Days In True Up Period** defines the minimum number of days covered by the bill segments within a true up period before true up processing can occur
- The task type captures the adjustment types used at true up time
- **Reversal Adjustment Cancel Reason** is used on true up adjustments that are canceled as a result of cancel/rebill activity occurring after a true up

Algorithms

Add the following algorithms:

- The sub service agreement and service agreement relationship are initially created by an **SA Creation** algorithm on the master service agreement type. The base package provides algorithm type C1-SAT-SARL for this purpose. An algorithm should be configured with the service agreement relationship type to use.
- Creation of the true up monitor is handled by an **SA Creation** algorithm on the sub service agreement type. The base provides algorithm type C1-SAT-TUM for this purpose. The true up monitor service task type is defined as an algorithm parameter.
- Whenever a net energy metering sub service agreement is canceled, its associated true up monitor should also be canceled. The base provides algorithm C1-CNC-TUM to be plugged in as an **SA Cancel** algorithm on the sub service agreement type to accomplish this.
- The true up monitor is transitioned out of the Active or Reverse True Up state by the billing process. To that end, a **Bill Completion** algorithm needs to be configured on the master service agreement type. This algorithm is responsible for transitioning any true up monitor that is in an Active or Reverse True Up state that is related to the master service agreement. The base provides the algorithm C1-TRN-TUM for this purpose.
- When cancel/rebills occur, financial transactions related to the true up need to be reversed. To accomplish this, an **FT Freeze** algorithm must be plugged in on the sub service agreement type. The base provides algorithm C1-RV-TRUP for this purpose.

For more information on setting up service agreement Relationships, refer to [Defining SA Relationship Options](#). For more information on service agreement type algorithms, refer to [SA Type - Algorithms](#).

Your implementation must also decide if the sub service agreement's bill segment financial transactions should impact the general ledger or not. This is controlled by the **Financial Algorithm** on the bill segment type defined for the sub service agreement type. The base provides algorithms C1-C0-GL and C1-C0-NOGL for this purpose. For more information on configuring Bill Segment Types, refer to [Designing and Defining Bill Segment Types](#).

Net Energy Metering Billing Examples

This section contains billing examples for net energy metering. The examples assume the following:

- The customer is billed quarterly using the following tariff:
 - Customer charge of \$3/day (billed on master service agreement)
 - \$0.10 per kWh (billed on sub service agreement and trued up after 12 month period)
- The GL Accounting distribution codes used in the following tables, such as A/R-NEM and NEM-Liability, are for example only. Your implementation will specify its own distribution codes.
- A True Up Task Type that references the base product NEM business objects with the following configuration:
 - **Minimum Days In True Up Period:** 365
 - **Sync Current Adjustment Type:** NEM SYNC

This is the adjustment type used to synchronize (make equal) the sub service agreement's current amount with the payoff amount at true up time.
 - **Transfer Adjustment Type:** NEM XFER

This is the adjustment type used to transfer debt from the sub service agreement to the master service agreement at true up time.

- **Write Down Adjustment Type: NEM WDWN**

This is the adjustment type used to write down any remaining amount on the sub service agreement after we attempt to transfer debt to the master service agreement at true up time.

Example 1: Customer Consumes More Than They Generate

The following table outlines the customer's master service agreement financial transactions in 2010. Adjustments created in the true up period are in bold. In this example the customer's net energy results in an outstanding balance of \$330 which is transferred from the sub service agreement to the master service agreement, leaving the sub service agreement for that true up period with a zero balance.

| Event | GL Accounting | Effect On Payoff Amount | Effect On Current Amount | Payoff Balance | Current Balance |
|--|---|-------------------------|--------------------------|----------------|-----------------|
| Bill Segment (1/1–3/31) (90 days * \$3/day = \$270) | A/R-NEM 270 NEM-Liability <270> | 270 | 270 | 270 | 270 |
| Payment | Cash 270 NEM-A/R <270> | -270 | -270 | 0 | 0 |
| Bill Segment (4/1–6/30) (91 days * \$3/day = \$273) | A/R-NEM 273 NEM-Liability <273> | 273 | 273 | 273 | 273 |
| Bill Segment (7/1–9/30) (92 days * \$3/day = \$276) | A/R-NEM 276 NEM-Liability <276> | 276 | 276 | 549 | 549 |
| Payment | Cash 549 A/R-NEM <549> | -549 | -549 | 0 | 0 |
| Bill Segment (10/1–12/31) (92 days * \$3/day = \$276) | A/R-NEM 276 NEM-Liability <276> | 276 | 276 | 276 | 276 |
| NEM XFER true up adjustment (transfer from sub service agreement) | A/R-NEM 330 XFER <330> | 330 | 330 | 606 | 606 |

The following table outlines the customer's sub service agreement financial transactions (FTs). Note that bill segment financial transactions affect the customer's pay off balance only. Adjustments created in the true up period are in bold below and reflect the following:

- First, the current balance to the payoff balance is set using the sync adjustment type (NEM SYNC) on the service task type.
- Second, any debt from the sub is transferred to the master service agreement using sync adjustment type on the service task type (NEM XFER).

| Event | GL Accounting | Effect On Payoff Amount | Effect On Current Amount | Payoff Balance | Current Balance |
|---|---|-------------------------|--------------------------|----------------|-----------------|
| Bill Segment (1/1–3/31) (1200kWh * \$0.10 = \$120) | A/R-NEM 120 NEM-Liability <120> | 120 | 0 | 120 | 0 |
| Bill Segment (4/1–6/30) (500kWh * \$0.10 = \$50) | A/R-NEM 50 NEM-Liability <50> | 50 | 0 | 170 | 0 |
| Bill Segment (7/1–9/30) (600kWh * \$0.10 = \$60) | A/R-NEM 60 NEM-Liability <60> | 60 | 0 | 230 | 0 |
| Bill Segment (10/1–12/31) (1000kWh * \$0.10 = \$100) | A/R-NEM 100 NEM-Liability <100> | 100 | 0 | 330 | 0 |
| NEM SYNC adjustment (sync current to payoff) | n/a | 0 | 330 | 330 | 330 |
| NEM XFER adjustment (transfer to master service agreement) | XFER 330 A/R-NEM <330> | -330 | -330 | 0 | 0 |

Example 2: Customer Generates More Than They Consume

The following table outlines the customer's master service agreement financial transactions (bill and payment segments are exactly the same as in example 1 above). In this example the customer's net energy results in a credit balance on the NEM sub service agreement which is written off, leaving the sub service agreement for that true up period with a zero balance (credits are not transferred to the master service agreement).

| Event | GL Accounting | Effect On Payoff Amount | Effect On Current Amount | Payoff Balance | Current Balance |
|--|------------------------------------|-------------------------|--------------------------|----------------|-----------------|
| Bill Segment (1/1–3/31) (90 days * \$3/day = \$270) | A/R-NEM 270 NEM-Liability <270> | 270 | 270 | 270 | 270 |
| Payment | Cash 270 A/R-NEM <270> | -270 | -270 | 0 | 0 |
| Bill Segment (4/1–6/30) (91 days * \$3/day = \$273) | A/R-NEM 273 NEM-Liability <273> | 273 | 273 | 273 | 273 |
| Bill Segment (7/1–9/30) (92 days * \$3/day = \$276) | A/R-NEM 276 NEM-Liability <276> | 276 | 276 | 549 | 549 |
| Payment | Cash 549 A/R-NEM <549> | -549 | -549 | 0 | 0 |
| Bill Segment (10/1–12/31) (92 days * \$3/day = \$276) | A/R-NEM 276 NEM-Liability <276> | 276 | 276 | 276 | 276 |

The following table outlines the customer's sub service agreement financial transactions (FTs). Note that bill segment financial transactions affect the customer's pay off balance only. Adjustments created in the true up period are in bold below and reflect the following:

- First, the current balance is set to the payoff balance using the sync adjustment type (NEM SYNC) on the service task type.
- Because a credit remains on the sub service agreement, this amount will be written off using the write down adjustment type on the service task type (NEM WDN).

| Event | GL Accounting | Effect On Payoff Amount | Effect On Current Amount | Payoff Balance | Current Balance |
|---|----------------------------------|-------------------------|--------------------------|----------------|-----------------|
| Bill Segment (1/1–3/31) (80kWh * \$0.10 = \$8) | A/R-NEM 8 NEM-Liability <8> | 8 | 0 | 8 | 0 |
| Bill Segment (4/1–6/30) (-120kWh * \$0.10 = -\$12) | A/R-NEM <12> NEM-Liability 12 | -12 | 0 | -4 | 0 |

| Event | GL Accounting | Effect On Payoff Amount | Effect On Current Amount | Payoff Balance | Current Balance |
|---|--|-------------------------|--------------------------|----------------|-----------------|
| Bill Segment (7/1–9/30) (-80kWh * \$0.10 = \$-8) | A/R-NEM <8> NEM-Liability 8 | -8 | 0 | -12 | 0 |
| Bill Segment (10/1–12/31) (100kWh * \$0.10 = \$10) | A/R-NEM 10 NEM-Liability <10> | 10 | 0 | -2 | 0 |
| NEM SYNC true up adjustment (sync current to payoff) | n/a | 0 | -2 | -2 | -2 |
| NEM WDWN true up adjustment (write down credit) | NEM A/R 2 E - W/O <2> | 2 | 2 | 0 | 0 |

For more information about current and payoff amounts, refer to [Billing - Current Balance versus Payoff Balance](#) on page 322.

Using Billable Charges For Pass Through / Convergent Billing

The term "pass through" billing is used to describe the practice of receiving charges calculated by third parties and presenting them on the customer's bill along with your own charges. "Pass through" billing is implemented in the system using [Billable Charges](#).

The following points provide information to help you decide the most appropriate way to implement "pass through" billing given your specific requirements:

- Customers with pass through charges will need a separate service agreement to hold the pass through charges. We refer to this type of service agreement as a "billable charge" service agreement.

Note:

A service agreement's SA type controls whether a service agreement can have billable charges linked to it. Specifically, the SA type must have a "special role" of Billable Charge.

- A billable charge service agreement holds the billable charges until the customer is next billed. At that time, a separate bill segment will be created for each unbilled billable charge linked to the billable charge service agreement.
- While it is not required, we recommend creating a separate billable charge service agreement for each type of pass through charge. For example, if you can receive "pass through" charges from the local water company and the local cable company, we'd recommend having two billable charge service agreements for each customer.
- As described under [We Bill For Them](#), you can setup the system to automatically create billable charge service agreements when you start regular service for your customers. If you take this approach, you can also have the system create the payable transaction to pay the 3rd party. Refer to [Pay At Bill Time vs. Pay At Pay Time](#) for more information.

- You can interface billable charges using the [Billable Charge Interface](#). The interfaced charges can consist of any of the following:
 - Pre-calculated bill lines that will be presented "as is" to the customer.
 - Service quantities that are used by the system to calculate the charges on behalf of the third party. For example, the 3rd party may pass through the number of kilowatt-hours and you calculate the bill lines for them. Refer to [Uploading Consumption Rather Than Bill Lines](#) for more information.
 - Meter read details that you want printed on the bill. Note, the base package bill segment creation algorithm simply sweeps billable charge read details onto the related [bill segment's read detail](#). This algorithm does NOT use these reads to derive service quantities. This is intentional as most implementations that import reads also import service quantities and therefore deriving service quantities is unnecessary (and also error prone). If your implementation needs to derive service quantities from these reads, you can develop your own bill segment creation algorithm to do just this.
- All of the above. You might interface both bill lines and service quantities if the third party calculated the charges but did not calculate the taxes. The dollar amount for which taxes will be calculated would be defined using a service quantity. Refer to [Calculating Taxes On Uploaded Charges](#) for more information.

**Note:**

You cannot interface interval data via the billable charge interface. Rather, you would need to interface the interval data using the standard interval data set interface and then let the system calculate the charges for you.

- The bill lines on a billable charge can fit into any of the following categories:
 - Memo-only (i.e., don't affect the general ledger). A bill line that is memo-only contain information that is purely informational. For example, the 3rd party might pass the start and end meter reads that they used to calculate the charges. You can use memo-only bill lines to show this information on the customer's bill. If a bill line is not memo-only (i.e., it affect the general ledger), a distribution code must also be specified to define how the lines affects the general ledger.
 - Show on the customer bill. It is possible to create bill lines that affect the general ledger, but are not shown on the customer's bill. This is an unusual practice, but it happens.
 - Summary / detail. Each bill line has an indication of whether it is a summary or detail line. This only impacts bill presentation.

**Note:**

The above indicators can be defaulted onto a billable charge line by using [Billable Charge Line Types](#) when you interface the lines into the system.

- Characteristics (i.e., user-defined fields) can be associated with billable charge lines. You might populate this information if you are interfaced information that may be useful during bill presentation or for reporting purposes.
- If service quantities are specified on a billable charge, they are saved on the bill segment created when the billable charge is billed. This means that they system can support creation of a graph of historical usage on the bill, as well as other queries on customer usage. In addition, it might be possible to event estimate consumption based on these service quantities (but such a plug-in is not supplied with the base package).

**Note:**

The system does not support passing in items (e.g., street lamps). This could be a problem if you need to perform ratable calculations for the 3rd party based on, say, the number of street lights. However, if you require ratable, street light pass through billing, you can calculate a service quantity for each type of street light and save this information on the billable charge. The associated rate would then have a price per service quantity rather than a price per item type.

The system does not support sending in raw meter reads with billable charges. This consumption needs to be passed in as a service quantity. However, you can pass in meter read details to be printed on the bill segment.

- Cancel / rebill for billable charges is quite different than for normal bill segments. A billable charge bill segment can be cancelled, and this will reverse the financial effects of the billable charge. But without new information from the source, there is no way to rebill the customer. Therefore, if the original charges were incorrect, the source

system would send both a reversal of the charges and a newly revised set of information. These could be passed as two separate billable charges or they could be combined on a single billable charge.

- In terms of the customer information setup, while a service agreement that holds billable charges does not need a service point, there are advantages to having this information in the system. For one thing, if jurisdictional taxes are being calculated by the system, the definition of the jurisdiction(s) is held on the service point or premise. Also, the link to the service point defines the service address, facilitates customer lookup, causes information to appear in Control Central's trees, etc.
- For most other functionality, the billable charge service agreement supports the same functionality as normal service agreements. This includes budget billing, payment distribution, credit & collection tracking and events, current & payoff balances, movement of old debt onto payment arrangements, etc.

Fastpath:

For more information about billing billable charges, refer to [How To Create A One-Time Invoice](#). For more information about creating a billable charge, refer to [Maintaining Billable Charges](#). For more information about creating sub service agreements to hold billable charges, refer to [We Bill For Them](#). For more information about interfacing a billable charge from an external system, refer to [Uploading Billable Charges](#).

Printing Bills

The contents of this section describe the technical implementation of both an online and batch bill production.

Bill Routings Are Created For Each Recipient Of A Bill

Refer to [The Source Of Bill Routing Information](#) for a description of how the system constructs the information used to route a bill to one or more recipients.

Bill Route Types Control The Information Merged Onto Bills

Every bill routing record references a [Bill Route Type](#).

The bill route type controls the following for interacting with a document composition application:

Note: CIS Division can override the extract algorithm and/or the background process found on the bill route type. The system processes first check the bill's account's CIS Division for an override specific for the bill route type.

- It contains an algorithm that is responsible for extracting the information merged onto your bills. Algorithms of this type are called under the following scenarios:
 - The [background process](#) that interacts with your bill print software calls these algorithms.
 - If your bill print software has the ability to construct a real-time image of a bill, you can plug-in an Online Bill Display algorithm on the [Installation Record](#). This type of algorithm will call the bill extract algorithm for an appropriate bill route type to extract the information that is merged onto the bill. Refer to [Technical Implementation Of Online Bill Display](#) for the details.
- It contains the ID of the background process responsible for interacting with your bill print software in batch.

The bill route type controls the following for interacting with a reporting engine, such as BI Publisher:

- It contains an algorithm that is responsible for returning the appropriate report code and other information in order to extract the information to be merged onto your bills. Typically, the reporting engine itself is responsible for extracting and formatting the data. Algorithms of this type are called under the following scenarios:
 - The [background process](#) that interacts with your reporting engine calls these algorithms.
 - If your reporting engine has the ability to construct a real-time image of a bill, you can plug-in an Online Bill Display algorithm on the [Installation Record](#). This type of algorithm will call the bill extract algorithm for an

appropriate bill route type to return the appropriate report code. Refer to [Technical Implementation Of Online Bill Display](#) for the details.

- It contains the ID of the background process responsible for interacting with your reporting engine in batch.

Technical Implementation Of Online Bill Display

Users can view an image of any bill that is sent to a customer on [Bill - Main](#) if you plug-in an Online Bill Display construction algorithm on the [Installation Record](#)

Note: Some display algorithms rely on the bill extract algorithm on each [Bill Route Type](#)

The system can make a call to an external system to retrieve a bill image. Many bill print vendors support this functionality.

The system provides an Installation – Online Bill Display algorithm type (C1GENBILLURL) that can generate a dynamic URL.

- The algorithm of this algorithm type supports dynamic variables such as the bill ID and static variable such a vendor or implementation supplied security key.
- The algorithm constructs a URL including generating HASH or security keys.
- The system displays the retrieved image in a separate browser session
- Refer to the algorithm type description for information about this algorithm type.

The system can interact with either document composition applications, or a reporting engine (such as BI Publisher).

The system provides an Installation – Online Bill Display algorithm type (C1-BL-DISP) that interacts with Documaker to render an online image of your bill. The following points describe what takes place when clicking **Display Bill**.

- The algorithm based on this algorithm type calls the bill extract algorithm for an appropriate bill route type (as determined by the algorithm).
- The bill extract algorithm will construct the information that appears on the bill (refer to algorithm type C1-BLEX-XML for further details).
- The constructed information is passed to document composition software that will reconstruct the bill's image in a PDF format.
- The system displays the PDF in a separate browser session. Note that the client must have Adobe Acrobat Reader installed to view PDF files.

Note:

Refer to [The Bill Extract Records](#) for examples of the record layouts passed to the document composition software.

The system also provides an Installation – Online Bill Display algorithm type (C1-ONLN-CR) that interacts with [BI Publisher](#) to render an online image of your bill. The following points describe what takes place when clicking **Display Bill**:

- The algorithm based on this algorithm type calls the bill extract algorithm for an appropriate bill route type (as determined by the algorithm).
- The bill extract algorithm returns the appropriate report code to the Online Bill Display algorithm, which in turn returns the report code to the bill page (refer to algorithm type C1-BLEX-BIP for further details). This algorithm is not actually extracting data because when you use BI Publisher reports, the report itself is responsible for extracting and formatting the data.
- A user exit on the bill page invokes BI Publisher and displays the bill in a separate browser session.

Note:

Refer to [Bill Print in BI Publisher](#) for examples of the data extracted for the report.

Technical Implementation Of Printing Bills In Batch

The batch process that extracts bill related information reads all bill routing records in a given run number that are marked with its batch control ID

The base package example of this process ([POSTROUT](#)) simply calls the bill extract algorithm on the routing record's route type. The algorithm formats the information to be passed to the bill print software or reporting engine. Refer to [Bill Route Types Control The Information On Bills](#) for more information.

Note:

If your software doesn't support online bill display. The algorithm that formats bill extract records that's plugged in on *bill route type* serves two purposes: 1) it interacts with the online bill display algorithm plugged into the installation record to support online images of a bill, and 2) it interacts with the background process to support printing your bills in batch. If your bill print software does not support the rendering of bill images real time, there is no need to create an extract algorithm. Rather, you should simply develop your own download process that works with your bill print software to print bills in batch (and then specify this batch process on your bill route type).

Reproducing The Bill Print Flat File

You can reproduce the flat file at any time. Simply request the download process and specify the run number associated with the historic run.

How To Reprint A Specific Bill

Refer to [How To Reprint A Bill \(For The Original Recipients or For Someone New\)](#) for instructions describing how to reprint a specific bill.

Who Gets A Copy Of A Bill?

A copy of a bill is sent to every individual / business specified in the [bill's routing details](#).

There are two ways in which a bill routing detail can be created:

- When a bill is completed, the system creates a routing detail for every person linked to the account that wants to receive a copy of the bill (as specified on [Account - Person Information](#)). Refer to [The Source Of Bill Routing Information](#) for more information.
- After a bill is completed, you may insert a bill routing record. Refer to [How To Reprint A Bill \(For The Original Recipients or For Someone New\)](#) for more information.

Final Bills and Bill Print

If a bill is produced for an account where all of the accounts SAs are stopped, closed or cancelled; the bill is flagged as being the final bill on the flat file produced by the postal routing process (refer to [Bill Record - 0100](#) for the details of this switch).

If a bill is considered to be a final bill and the amount owing for the entire account is less than the final bill threshold amount on the installation record, the bill will be skipped (i.e., it won't appear on the flat file produced by the postal routing process). Note, this logic also suppresses bills from being produced when a payment is received AFTER the final bill and the account's balance falls beneath the installation record's final bill threshold amount. Refer to [Installation Options - Billing](#) for more information.

The Bill Extract Records

Numerous different types of records are interfaced to the document composition application. However, they all share a common structure for bills:

- The first 4 bytes are called the **Printer Key**. This field is a record type used by the document composition application bill template.
- The next 244 bytes are called the **Sort Key**. This field is used to ensure the various records used to construct a printed bill appear in the correct order in the interface file.
- The next 12 bytes are called the **Mailing Key**. This field is used to control the order in which the formatted bills are printed.
- The next 3 bytes are a filler that is available for future use.
- The remaining bytes contain the **Bill Information** that appears on the printed bill. The type of information differs for each type of record.

The topics in this section describe each component.

Printer Keys (Record Types)

The following table defines each printer key (i.e., record type) on the bill print flat file.

| Record Type | Description | Notes |
|-------------|----------------------------|---|
| 0010 | Global extract information | Required. 1 per flat file. |
| 0100 | Bill record | Required. 1 per bill. |
| 0150 | Account Balance Record | Required. 1 per Special Role. |
| 0300 | Current charge record | 1 per current charge. |
| 0600 | Payment record | 1 per payment. |
| 0900 | Premise record | 1 per premise. |
| 1100 | Service agreement record | 1 per SA linked to the premise. |
| 1300 | Bill segment record | 1 per bill segment linked to the SA. |
| 1500 | Bill calculation header | 1 per bill calculation header linked to the bill segment. |
| 1700 | Bill calc line | 1 per bill calculation line linked to the bill calculation header |
| 1900 | End of record type 1500 | 1 for each bill calculation header |
| 2100 | Read detail | 1 for each meter read detail linked to the bill segment |
| 2400 | Service quantity detail | 1 for each service quantity detail linked to the bill segment |
| 2700 | Item detail | 1 for each item detail linked to the bill segment |
| 2840 | Bill segment messages | 1 for each message detail linked to the bill segment |

| | | |
|------|---------------------------------|--|
| 2900 | End of record type 1300 | 1 for each bill segment |
| 3100 | Consumption history (for graph) | 1 for each historical consumption period that appears on the graph |
| 3400 | Adjustment detail | 1 for each adjustment |
| 3420 | Adjustment Calc Line | 1 or more per adjustment |
| 3600 | End of record type 1100 | 1 for each service agreement |
| 3700 | End of record type 0900 | 1 for each premise |
| 3900 | Bill message detail | 1 for each message |
| 9999 | End of record type 0100 | 1 for each bill |

Sort Key

The following table defines the structure of the sort key that appears on each bill print record. Please note that different components are filled in for each printer key.

| Field Name | Format | Source/Value/Description |
|----------------------|--------|---|
| Bill Print Intercept | A8 | This is the user ID, if any, who reviews the bill (as specified on the account record) |
| Bill ID | A12 | |
| Sequence Number | N2 | The sequence number of the account / person information associated with this bill routing information. |
| Copy Number | N2 | The number of copies desired by the account / person associated with this bill routing information. |
| Bill record group | A2 | 10 Bill 20 Payment 30 Current charge 40 Message 50 Non-Premise 55 Non-Premise end 60 Premise 70 Bill end |
| Filler | A2 | |

| | | |
|-----------------------|-----|--|
| Premise State | A6 | Only applicable for Premise based records. |
| Premise City | A90 | Only applicable for Premise based records. |
| Premise Address 1 | A64 | Only applicable for Premise based records. |
| Premise Id | A10 | Only applicable for Premise based records. |
| Premise record group | A2 | 10 Premise record 20 SA level record 30 Premise end record |
| SA Print Priority | A2 | |
| SA Id | A10 | |
| SA Group | A2 | For Premise based records: 10 SA 20 Histogram 30 Current charge 40 Adjustment 50 SA end record For Non-Premise based records: 10 SA 20 Current Charge 30 Adjustment 40 SA end record |
| Bill Segment End Date | A10 | If the record is related to an adjustment, this is the adjustment creation date. If the record is for histogram detail, this contains the histogram detail number. |
| Bill Segment Id | A12 | If the record is related to an adjustment, this is the adjustment ID. |

| | | |
|---------------------------|----|---|
| Bill Segment Group | A2 | 10 Bill segment 20 Bill segment calculation group 30 Bill segment read detail 40 Bill segment SQ detail 50 Bill segment item detail 55 Bill segment message 60 Bill segment end |
| Bill Calc Header Sequence | N2 | For records related to read detail, SQ detail, item detail or bill message detail, this field contains the related sequence number for that record. |
| Bill Calc Header Group | A2 | 10 Bill calculation header 20 Bill calculation line 30 Bill calculation end |
| Line Seq | N3 | Defines order of rows for similar record types |
| Filler | 47 | Only applicable for non-premise based records. (This makes up for the premise address related fields that are not applicable above). |

Mailing Key

The following table defines the structure of the mailing key that appears on each bill print record.

| Field Name | Format | Source/Value/Description |
|-------------|--------|---|
| Postal code | A12 | This is the postal code on the bill routing record. |

Bill Information

The topics in this section describe the information that appears on each on each bill print record.

- [Global Extract Information Record \(0010\)](#)
- [Bill Record \(0100\)](#)
- [Account Balance Record \(0150\)](#)
- [Current Charge Record \(0300\)](#)
- [Payment Record \(0600\)](#)
- [Premise Record \(0900\)](#)
- [Service Agreement Record \(1100\)](#)
- [Bill Segment Record \(1300\)](#)
- [Bill Calc Header Record \(1500\)](#)
- [Bill Calc line Record \(1700\)](#)

- End Bill Calc Header Record (1900)
- Bill Segment Read Record (2100)
- Bill Segment SQ Record (2400)
- Bill Segment Item Record (2700)
- Bill Segment Message Record (2840)
- End Bill Segment Record (2900)
- Histogram Record (3100)
- Adjustment Record (3400)
- Adjustment Calc Lines Record (3420)
- End Service Agreement Record (3600)
- End Premise Record (3700)
- Message Record (3900)
- End Bill Record (9999)
- Address Sub-Record

Global Extract Information Record (0010)

This is a "header" record that contains information about the extract run as a whole.

Note:

Please be aware that if you do not sort your extract file by **CIS Sort Key** after it is produced, this record will physically be the last record on the extract file.

| Field Name | Format | Source/Value/Description |
|-----------------|--------|--|
| BATCH_CD | A8 | Batch Control Code of the extract process. |
| BATCH_NBR | N10 | Batch Number of the extract process |
| BATCH_RERUN_NBR | N10 | Batch Rerun number of the extract process. |
| BILL_CNT | N10 | Count of bills on this extract. Multiple copies of a bill are counted multiple as well. |
| EXTRACT_DTTM | A26 | System time of extraction. Also updated in bill routing table. |
| BILL_ID_START | A12 | This is only used when a bill is produced as a result of an online request (from Bill - Main). It contains the Bill Id to extract. |
| BILL_ID_END | A12 | This is only used when a bill is produced as a result of an online request (from Bill - Main). It contains the Bill Id to extract. |
| THREAD_NBR | N10 | This field is only used if bills are extracted in batch. It contains the thread number in which the bill was extracted. |

| | | |
|------------|-----|---|
| THREAD_CNT | N10 | This field is only used if bills are extracted in batch. It contains the total number of threads that were extracted. |
|------------|-----|---|

Address Sub-Record

The address sub-record that appears in both the bill record (0100) and the premise record (0900) is composed of the following:

| Field Name | Format | Description |
|---------------|--------|---|
| COUNTRY | A3 | |
| ADDRESS1 | A254 | Refer to The Source Of Bill Routing Information for a description of conditions when this field will contain a fax number or an Email address rather than the first line of a postal address (this only occurs for a bill record (0100)). |
| ADDRESS2 | A254 | |
| ADDRESS3 | A254 | |
| ADDRESS4 | A254 | |
| CITY | A90 | |
| NUM1 | A6 | |
| NUM2 | A4 | |
| HOUSE_TYPE | A2 | |
| COUNTY | A90 | |
| STATE | A6 | |
| POSTAL | A12 | |
| GEO_CODE | A11 | |
| IN_CITY_LIMIT | A1 | |

XML Bill Extracts

The system includes a sample bill extract algorithm that produces an XML document to interface to a document composition application. This is an alternative to the fixed flat file format described above. For additional details, see the algorithm type **Create XML bill extract records (C1-BLEX-XML)**.

Algorithms of this type construct the XML file records that contain the information that appears on a printed bill. Each record in the extract is constructed using an extendable data area and may be extended by an implementation using the Post Processing Script parameter. The following steps should be followed to include additional elements in the extract:

- Create a data area that includes the additional elements for the record you wish to extend. This data area must reference the base product data area used in the extract. For example, to extend the bill record, create a data area that references data area C1-BillPrintBillRecord as its extended data area. See the C1-BLEX-XML algorithm type for a complete list of the data areas available.
- Create a service script to retrieve the additional elements. This service script must be defined as the Post Processing Script on your algorithm and its schema must include the main bill extract data area (C1-BillPrintRecord).

For an example of how to extend the XML bill extract to include additional elements, see the CI_BillPrintXMLExtract export bundle included in the demo data.

Sequential Bill Numbers

Every bill is uniquely identified by its bill ID. Bill ID is a random, system-assigned number. In some locales, bills have an additional identifier known as a "sequential bill number". Sequential bill numbers are system-assigned, sequential numbers. For example, the first bill produced by the system is assigned a sequential bill number of 1, the next bill is assigned a value of 2, etc. An additional requirement is that no gaps may exist between the sequential bill numbers.

The topics in this section describe how sequential bill numbers are implemented in the system.

Sequential Numbers Are Only Assigned If The Installation Option Is Turned On

Sequential bill numbers will only be assigned if you have selected Sequential Bill Numbers as the Alternative Bill ID Option on the [Installation](#) record.

Pending Bills Do Not Have A Sequential Bill Number

Bills are assigned a sequential bill number after they are completed. This means that pending bills will not have a sequential bill number. This is intentional as pending bills can be deleted and if a deleted bill had a sequential bill number, gaps would result. Refer to [Bill Lifecycle](#) for more information about a bill's state transition lifecycle.

When / How Is The Sequential Bill Number Assigned

Warning:

This section is a technical explanation of how sequential bill numbers are assigned. It contains background information for those who wish to understand the rationale of the design.

The batch billing background process BILLING takes advantage of parallel processing to allow multiple bills to be produced concurrently. In addition, we allow groups of bills to be committed in "chunks" (based on the commit frequency assigned to the billing background process). These two facts make it impossible to allocate sequential bill numbers during batch billing (because back outs could result in gaps and parallel processing could result in duplicates). This is why sequential bill numbers are allocated as follows:

- A sequential bill number is allocated when a bill is completed online (by clicking the **Complete** button on [Bill - Main](#)).

- If you submit the batch billing process with the following [parameters](#), sequential bill numbers will be allocated when bills are completed:
- **Batch thread number** must equal 1.
- **Batch thread count** must equal 1.
- **Override maximum records between commits** must equal 1.

The above parameters mean that bills are not being produced in parallel and they are not being committed in "chunks". This allows the system to allocate sequential bill numbers when the bills are completed.

- If you do not run batch billing single-threaded, you must schedule the Assign Sequential Bill Numbers background process (ASSGNSBN) to run immediately after batch billing. This single-threaded process assigns sequential bill numbers to completed bills.
- The following measures are in place as a fail-safe:
- If the bill print download background process (POSTROUT) encounters a bill without a sequential bill number, it will abort with an appropriate error message.
- Users are not allowed to delete a completed bill with a sequential bill number. Note, deletion of completed bills is typically prohibited due to the presence of frozen bill segments. However, it's possible to create a bill without frozen bill segments and additional logic exist to inhibit the deletion of such bills if they have sequential bill numbers.

Additional Functionality for Sequential Bill Numbering

The following points describe additional features that are enabled when the [Installation](#) record indicates sequential bill numbers are used:

- The bill's number appears in "bill info". "Bill info" is the concatenated string of information that summarizes a bill on many pages in the system.
- The Bill Search page includes an additional search option to search by bill number.
- The match type algorithm (DSO BILL-ID) that allows payments to be matched to a given bill id will try to match the payment to a bill with a matching sequential bill number.

Document Numbers

Every bill is uniquely identified by its bill ID. Bill ID is a random, system-assigned number. In some locales utilities may be required to assign and print an additional document number. For example, in Argentina a utility must obtain authorization from the national tax agency before they are allowed to print bills at a local office. Once authorized, the utility is assigned a printing authorization code valid for a period. The printing authorization code and expiration, as well as an official document number are printed on the bill at the location where the bill is issued.

The topics in this section describe how document numbers are implemented in the system.

Document Numbers Are Only Assigned If the Installation Option Is Turned On

Document numbers will only be assigned if you have selected Document Numbers as the Alternative Bill ID Option on the [Installation](#) record. In addition, the Document Number (C1-DOC-NBR) and Document Number Details (C1-DOCNBR-DT) algorithms must be enabled on the [Installation](#) record. These algorithms contain the logic used by the system to assign a document number to a bill.

The logic used to assign a document number can be quite complex. For example, the document number may depend on the issuing center, the bill's document type (credit memo, invoice or debit memo), the account's VAT category and the CIS division. Depending on your implementations complexity, you may choose one of the following possible configurations for document numbers:

- Populate the Document Number, Document Number Details and Document Sequence Number algorithms on the Installation record. The system will behave as follows:

- During online bill completion, a document type is derived and captured on the bill along with other required bill characteristics and a document number is assigned
- During batch billing, a document type is derived and captured on the bill along with other required bill characteristics. Assigning a document number is deferred to the Assign Bill Document Numbers background process. The idea here is that all complex logic is executed during the multi-threaded batch billing process leaving the minimal amount of work for the single-threaded batch process that assigns the document number.
- Populate the Document Number and Document Number Details algorithms on the Installation record. Here, the system assigns a document number during online bill completion, but skips the assignment of document type and number during batch billing. The Assign Bill Document Numbers background process is responsible for deriving the bill's characteristics (document type, document classification, etc.) and assigning a document number.

Pending Bills Do Not Have a Document Number

Similar to sequential bill numbers, bills are assigned a document number after they are completed. This means that pending bills will not have a document number. Refer to [Bill Lifecycle](#) for more information about a bill's state transition lifecycle.

When/How Is the Document Number Assigned

Warning:

This section is a technical explanation of how document numbers are assigned. It contains background information for those who wish to understand the rationale of the design.

- An installation algorithm assigns a document number to a bill.

Similar to sequential bill numbers, document numbers are allocated as follows:

- A document number is allocated when a bill is completed online (by clicking the **Complete** button on [Bill - Main](#)).
- The Assign Bill Document Numbers background process (C1-BNBAS) should be scheduled to run immediately after batch billing. This single-threaded process assigns document numbers to completed bills.
- The logic used to assign a document number resides in the installation options Document Number (C1-DOC-NBR) algorithm.
- The following measures are in place as a fail-safe:
 - If the billing download process (POSTROUT) encounters a bill without a document number, it will abort with an appropriate error message.
 - Users are not allowed to delete a completed bill with a document number. Note, deletion of completed bills is typically prohibited due to the presence of frozen bill segments. However, it's possible to create a bill without frozen bill segments and additional logic exist to inhibit the deletion of such bills if they have sequential bill numbers.

Additional Functionality Exists When Document Numbers Are Used

The following points describe additional features that are enabled when the [Installation](#) record indicates that document numbers are used:

- The Bill Search page includes an additional search option to search by Document Number and Document Type.
- The bill's document number and type appear in "bill info". "Bill info" is the concatenated string of information that summarizes a bill on many pages in the system.
- The match type algorithm (C1-PDOV-PYBN) that allows payments to be matched to a given bill id will try to match the payment to a bill with a matching document number and type.

Digital Signatures

In some locales, billing software is required to generate and store digital signatures for each bill. Digital signatures are used to secure bills that are stored in the database, and the digital key for the bill will be known only to the vendor.

CCB supports digital signatures with the following features:

- An Encryption feature configuration must be configured with an algorithm info option for the key alias and signing algorithm
- The installation algorithm, C1-BILLSIG, generates the digital signature for a bill and captures this on the bill itself. The algorithm also stores an alias of the private/public key pair on the Bill as a characteristic. See the installation algorithm, C1-BILLSIG, for a description of how the signature is generated.
- Bills are assigned a digital signature when they are completed.
 - The Assign Bill Document Numbers background process (C1-BNBAS) is responsible for generating digital signatures for a batch of bills. This batch job should be scheduled to run immediately after batch billing. See the description of the batch control and parameter settings for generating digital signatures.
 - A digital signature is also generated when a bill is completed online (by clicking the **Complete** button)

Note: The digital signatures features are only appropriate for customers who use document number in generating bill signatures.

For an example of the objects and instructions used for implementing this feature, see the `CI_BillDocNumber & DigitalSignature` export bundle included in the demo data.

For details about setting up the required keystore for this feature, see the Installation Guide.

Writing Off Bills

If your organization practices [open-item accounting](#) and your credit and collections rules revolve around [collecting on unpaid bills](#), you can set up the system to automatically write-off bills.

If you've enabled this functionality, [Bill - Main](#) will contain a button that a user can click to manually write off a bill. A corresponding button exists that a user can click to reverse a written-off bill.

Fastpath:

Refer to [Writing Off Bills](#) for a description of how to set up the system to allow both automated and manual bill write off.

Idiosyncratic Manual Bill Cancellation

If a bill's account is associated with a Customer Class that has a Cancel Bill algorithm, the system invokes this algorithm before the bill is displayed to determine if the bill is "cancellable". If the algorithm indicates the bill is cancellable, a button appears on [Bill - Main](#). When clicked, the Cancel Bill algorithm is invoked again to cancel the bill. This functionality is meant to support unique cancellation needs required by some implementations; the sample base-package algorithm is empty.

Maintaining Bills

A bill is used to communicate changes in a customer's financial obligations to the customer. The topics in this section describe how to maintain bills.

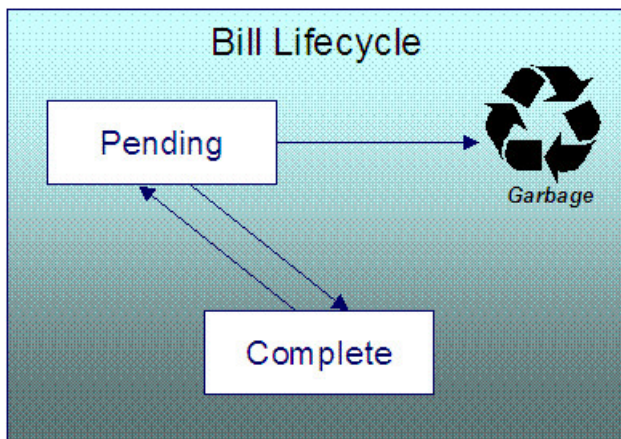

Note:

The system creates most bills behind-the-scenes. Most bills are created by the system when it processes the bill cycle schedule. You should only have to access the bill pages to correct a bill or to add a bill real-time. For information about how the system creates bills, refer to [The Big Picture of Billing](#).

It's important to be aware that there are very few fields that are directly modifiable by a user. To modify most fields on a bill, you have to change source information (e.g., service agreement, rate, meter read) and then regenerate the bill. For example, if you want to change a bill's amount, you must cancel or add bill segments; you cannot change the bill's amount by modifying the bill amount field. Refer to [How To](#) for step-by-step instructions that explain how to perform common bill maintenance functions.

Bill Lifecycle

The following diagram shows the possible lifecycle of a bill.

Warning:

This explanation only makes sense in the context of the page used to maintain bills. Refer to [Bill - Main Information](#) for the details.

A bill is initially saved in the Pending state. You may create one or more bill segments for the account's service agreements at this point. Refer to [How To](#) for information about generating bill segments for the bill.

A bill becomes Complete when it is ready to be sent to the customer. Completing a bill triggers many things to occur. Refer to the section below for information about what happens when a bill is completed.

When you complete a bill, several things may happen:

- Pre-completion algorithms associated with the account's service agreements' [SA types](#) are executed. The system executes these algorithms first in the order of the [billing processing sequence](#) on each service agreement's SA type then in the order of the algorithm's sequence. These are not executed for the completion of [credit notes](#).
- Pre-completion algorithms associated with the account's [customer class](#) are executed.
- The bill's due date is calculated. This is equal to the bill date plus the number of days defined on the account's customer class. If the resultant date is not a workday, the due date is set to the next workday. Note, this due date can be overridden if an override algorithm exists on the account's customer class.
- The bill's routing information is set up using [Account - Person Information](#).
- If the Freeze At Bill Completion [installation option](#) has been turned on, freezable bill segments and adjustments linked to the account are frozen. Note, only freezable adjustments whose [adjustment type](#) indicates Freeze At Bill Completion will be frozen at this time. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) for more information.
- If a final bill segment of a deposit service agreement is detected, the deposit is refunded to the customer using the refund method algorithm plugged-in on the deposit SA's deposit class. Refer to [Deposit Refund](#) for more information. This step is skipped during the completion of [credit notes](#), or if the bill is linked to an [off cycle bill generator](#).
- Bill completion algorithms associated with the account's service agreements' [SA types](#) are executed. The system executes these algorithms first in the order of the [billing processing sequence](#) on each service agreement's SA type then in the order of the algorithm's sequence.
- Bill completion algorithms associated with the account's [customer class](#) are executed.

- Bill messages are amalgamated from various sources and linked to the bill. Refer to [The Source Of Bill Messages](#) for more information.
- Other financial transactions that have been frozen since the last bill and are marked to show on bill are linked to the new bill
- For open-item customers adjustments and corrections are linked
- For [correction notes](#) or [credit notes](#), the bill cancellation financial transactions are linked
- For off cycle bill generator bills:
 - Adjustments linked to the off cycle bill generator are linked to the bill
 - If the off cycle bill generator is linked to a service agreement, then all non-payment financial transactions associated with the SA are linked to the bill
- For all other situations, payments, adjustments and corrections are linked assuming the adjustments are not linked to an off cycle bill generator
- All financial transactions that don't already have a user-defined aging date will be dated with the current date. In other words, they start aging from the date the bill is completed.
- If the account pays automatically and the installation's Autopay Creation Option is to Create At Bill Completion, an automatic payment is created. Refer to APAY-CREATE for more information about the auto pay creation algorithm. This step is skipped during the completion of [credit notes](#).
- If the account's customer class indicates the account is an open-item customer, a match event is created. The bill's FTs and the automatic payment's FTs are linked to it. Refer to [Payments and Match Events](#) for more information about match events. This step is skipped during the completion of [credit notes](#).
- If the account pays automatically and the installation's Autopay Creation Option is to Create On Extract Date, the bill is stamped with the date when the automatic payment is to be created. Refer to APAYCRET, the background process that creates the automatic payment, and APAYDSFR, the background process that distributes and freezes the automatic payment, for more information. This step is skipped during the completion of [credit notes](#).
- The bill's late payment date is calculated. This is equal to the due date plus the grace days defined on the account's customer class. If the resultant date is not a workday, the LPC date is set to the next workday. This step is skipped during the completion of [credit notes](#).
- The account is marked for review by the account debt monitor on its due date plus a grace period defined on its customer class. This step is skipped during the completion of [credit notes](#).
- If the account's customer class indicates the account is an open-item customer, the system will create a match event if the new charges are offset by other financial transactions. Refer to [Payments and Match Events](#) for more information about match events. This step is skipped during the completion of [credit notes](#).
- The bill's status becomes Complete.
- Post bill completion algorithms associated with the account's [customer class](#) are executed.

If the system cannot complete the bill (for whatever reason), the bill remains Pending and an error message is shown on the main bill page. After correcting the cause of the problem, attempt to complete the bill again.

A complete bill may be changed back to pending using the [Reopen](#) button on [Bill - Main Information](#). You would reopen a bill when

- Add more bill segments to a completed bill. Refer to the [How To](#) section for information about linking bill segments for a bill.
- Fine-tune the payments, adjustments, and corrections that were linked to a completed bill. Refer to the [How To](#) section for detailed instructions.

When you're happy with the bill, you can complete it again.

Note:

Cannot reopen historical bills. You may only reopen an account's most recent bill (except if this bill is linked to an off cycle bill generator) because recompleting the bill causes the ending-balance to change, and we don't want this to happen to historical bills.

Automatic payments. If an automatic payment was created when the bill was completed and it has already been interfaced to the financial institution, you cannot reopen the bill. If the automatic payment exists, but it has not yet been interfaced, the system will automatically cancel the payment when you reopen the bill.

Certain bill completion algorithms prevent reopening. If a bill contains a service agreement whose SA type has a "transfer accounts receivable to service provider" algorithm, the system will not allow the bill to be reopened. Refer to [If You Deal With TBFU Service Providers You Can't Reopen Bills](#) for more information about this bill completion algorithm.

You may [delete](#) a Pending bill from the database. You may not delete a pending bill if: a) there are frozen bill segments linked to the bill, or b) if financial transactions were linked to the bill (and this can only happen if the bill had been previously completed).

In addition to removing the bill, the system will also remove unfrozen bill segments linked to the bill.

Bill - Main Information

Open **Menu** > **Financial** > **Bill** > **Search** to maintain core bill information.

The following discussion describes the fields on this page. Refer to [How To](#) for a description of how to perform common bill maintenance functions.

Description of Page

Bill Info contains a concatenation of important information about the bill (e.g., the bill date, its status, due date, ending balance, etc.). If [sequential bill numbering](#) has been enabled, the bill's number also appears. If document numbering has been enabled, the assigned document number and document type will also appear. If this bill is a [correction note](#) or [credit note](#), a message will appear indicating this along with the ID of the original bill. If the batch billing background process generates the bill, the bill information includes the bill cycle and window start date. Bills generated manually, i.e., off-schedule, do not have this information.

Bill ID is the system-assigned unique identifier of the bill.

Account ID identifies the customer who is responsible for the bill. The name of the main customer on the account appears adjacent.

If this bill is a [credit note](#) or [correction note](#), a message appears adjacent to the account information indicating that this bill is a credit note or correction note for another bill; this hyperlink will drill you to the original bill. If a credit note or correction note has been issued for one or more of this bill's bill segments, a message appears indicating such. **Bill Status** is the bill's status. Refer to [Bill Lifecycle](#) for the potential values and how to handle a bill when it exists in a given state. Adjacent to the bill status is the **Display Bill** button, which will display an online image of the bill when clicked. Refer to [How To Display A Bill On-line](#) for more information.

If the bill is associated with an off cycle bill generator, a message appears adjacent to the bill status indicating this and the hyperlink will take the user to the related off cycle bill generator.

Note:

You can only use the **Display Bill** button if your system has been configured to display an on-line image; otherwise, a message indicating that the service is not available will appear. This option can only be configured by your technical staff. The system comes with configurations to display bill images using a document composition application such as *BI Publisher* or to retrieve a bill image from an external source such as a bill print vendor. This feature can also work with other applications.

Due Date is the date on which the bill is due. A bill's due date is calculated as follows:

- Add the due days specified on the account's customer class to the bill date.
- The resulting date is the due date unless it's not a workday. In this case, the due date is set to the next workday (workdays are defined in the installation options tables).
- If the account's customer class has an override due date calculation algorithm, the due date may be overridden. Refer to [Setting Up Customer Classes](#) for more information.

Note:

Late payment charges. Late payment charges are calculated on the due date plus the grace period. Refer to [Defining Late Payment Charge Options](#) for more information.

Bill Date is the business date that was used when the bill was completed. For example, if batch billing starts on 11:55 pm on 1-Jan-2000 and a bill is produced at 1:00 am on 2-Jan-2000, this bill's bill date would be 1-Jan-2000.

Create Date/Time is the date and time on which the bill was originally created.

Completion Date/Time is the date and time on which the bill was completed.

If the customer [pays automatically](#) and the automatic payment has not yet been created, a brief message appears highlighting the date and amount of the future automatic payment. In addition, a button appears called **Stop Autopay**, that, when clicked, causes the associated automatic payment to stop. You might click this button if the customer indicates that they will send in a payment. After you click the **Stop Autopay** button, a message appears highlighting the stoppage. Refer to [How And When Are Automatic Payments Created](#) for more information about how to setup the system to defer the creation of automatic payments until the future automatic payment extract date.

In the **Message** area, a brief error message appears if there's a problem with the bill. The message area is suppressed if there are no problems with the bill.

Click the magnifying button to view the long explanation. The long explanation will provide information about the cause of the error (and how to fix it).

The **Late Payment Charge Details** section contains information about how the system determines when and whether to levy late payment charges:

- **Eligible for Late Payment Charge** can be checked if a charge should be levied for late payment. This field is defaulted based on the customer's customer class. If you want to excuse a bill from late payment charge processing uncheck this box.
- **Late Payment Charge Date** is the date on which the system will levy a late payment charge if payment is not received. This date is calculated when the bill is completed. It is equal to the bill's due date plus the account's customer class's grace days. If this date does not fall on a workday, the date is set to the next available workday when the bill is completed. If you want to manually delay the onset of late payment charge processing, extend this date into the future.

Fastpath:

Late payment charges. Late payment charges are calculated on the due date plus the grace period. Refer to [How Late Payment Charges Get Calculated](#) for more information.

Bill Summary summarizes the financial impact of the bill. The information that appears differs depending on whether the account is a [balance-forward](#) or [open-item account](#). If the account is a balance-forward customer, the following information appears:

- **Previous Period's Balance** is the balance from the account's last bill.
- **Total Payments** is the total amount of frozen or canceled payment segment financial transactions linked to this bill. Frozen payment segments appear as negative numbers (decreasing the amount owed by the customer), while canceled payment segments appear as positive numbers (increasing the amount owed). You can drill down on this balance to view the financial transactions that contribute to this total. Refer to [How To Remove Unwanted Payments From A Completed Bill](#) for a description of how to perform common maintenance functions.
- **Total Adjustments** is the total amount of frozen or canceled adjustment financial transactions linked to this bill. You can drill down on the balance to view the financial transactions that contribute to this total. Refer to [How To Remove Unwanted Adjustments From A Completed Bill](#) for a description of how to perform common maintenance functions.
- **Total Bill Corrections** is the total amount of canceled and / or rebilled bill segment financial transactions linked to this bill. You can drill down on the balance to view the financial transactions that contribute to this total.
- **Total Current Billing Charges** is the total amount of frozen bill segment financial transactions linked to this bill. You can drill down on the balance to view the financial transactions that contribute to this total.
- **Ending Balance For This Period** is the sum of the five amounts above. It is the amount owed by the customer as of the end of the bill period.

If the account is an [open-item customer](#), the following information appears under **Bill Summary**:

- **New Charges** is the total amount of frozen bill segment financial transactions linked to this bill. You can drill down on this value to view the financial transactions that contribute to this total.

- **Adjustments** is the total amount of frozen or canceled adjustment financial transactions linked to this bill. You can drill down on this value to view the financial transactions that contribute to this total. Refer to [How To Remove Unwanted Adjustments From A Completed Bill](#) for a description of how to perform common maintenance functions.
- **Corrections** is the total amount of canceled and / or rebilled bill segment financial transactions linked to this bill. You can drill down on this value to view the financial transactions that contribute to this total.
- **Total** is the sum of the above amounts. You can drill down on this value to view the financial transactions that contribute to this total.

If the account is an [open-item customer](#), the following information appears under **Match Summary** (note, this section is not displayed for balance-forward accounts):

- **X Balanced Item(s)** contains the count and total amount of financial transactions linked to this bill that are linked to balanced match events.
- **X Unbalanced Item(s)** contains the count and total amount of financial transactions linked to this bill that are linked to unbalanced match events.
- **X Disputed Item(s)** contains the count and total amount of financial transactions linked to this bill that are linked to disputed match events.
- **X Unmatched Item(s)** contains the count and total amount of financial transactions linked to this bill that are not linked to any match event.

Total Changes After Completion only appears if bill segments that appeared on the original bill have been subsequently [canceled or rebilled](#). The amount displayed is the net effect of all cancels and rebills. Note, you can use the **Remarks** column in the bill segments grid (to the right) to see which bill segments have been cancelled / rebilled.

If 25 or fewer bill segments are linked to this bill, the grid in the lower right portion of the page contains one row for every bill segment linked to the bill.

The following points describe each column in the grid:

- The **Bill Segment** column contains a concatenation of each bill segment's division, SA type, status and bill period. The division and SA type come from the bill segment's service agreement.
- The **Current Amount** column contains the bill segment's effect on the service agreement's current balance.
- The **Status** column shows the bill segment's status. Refer to [Bill Segment Lifecycle](#) for the possible values.
- The **Remarks** highlight special situations. The following remarks may appear:
 - Rebill after completion appears if the bill segment is a rebill that was created after the bill was sent to the customer. The financial impact of this bill segment appears as a "bill correction" on the next bill produced for the customer.
 - Rebill prior completion appears if the bill segment is a rebill that was created before the bill was sent to the customer.
 - Canceled after completion appears if the bill segment was canceled after the bill was sent to the customer. The financial impact of this bill segment appears as a "bill correction" on the next bill produced for the customer.
 - Canceled prior completion appears if the bill segment was canceled before the bill was sent to the customer.
 - If the bill segment's status is Error or Incomplete, this column contains an estimated value of this bill segment. The estimated value is calculated by computing an average daily amount from the service agreement's frozen bill segments in the last 365 days. This average is then applied to the number of days in this bill segment's bill period. If the bill segment doesn't have a bill period (rare, but possible), the historical average is not displayed.
 - If the bill segment's status is Error, this column also contains the error message.
 - Rebilled due to correction appears if a correction note was generated for the bill segment. This remark appears only if you have the Correction Note Billing Option specified in the [Installation](#) record.
 - Rebilled due to correction. Canceled after completion appears for a correction note that spawns another correction note. This remark appears only if you have the Correction Note Billing Option specified in the [Installation](#) record.

If more than 25 bill segments are linked to this bill, the grid in the lower right portion of the page contains a summary of the various bill segments linked to the bill.

The following points describe each column in the grid:

- The **Status** column shows the bill segment's status. Refer to [Bill Segment Lifecycle](#) for the possible values. Click on the hyperlink to transfer to the Bill Segments tab where the associated bill segments can be viewed.
- The **Total Bill Segments** column contains the number of bill segments linked to the bill with this **Status**. If the status is Error or Incomplete, this column contains an estimated value of these bill segments. The estimated value is calculated by computing an average daily amount from frozen bill segments in the last 365 days for each service agreement. This average is then applied to the number of days in each bill segment's bill period. Please note, an historical average cannot be computed if an Error or Incomplete bill segment does not have a bill period (rare, but possible).
- The **Total Amount** column contains the sum of the current amount of these bill segments.

At the bottom of the scroll is shown the **Total Generated Charge**. This represents the total amount of the bill segments. This amount may differ from the Total Current Billing Charges when:

- The bill is not Complete. A bill segment's financial effect is not shown on the bill until the bill is completed.
- A bill segment has been canceled / rebilled since the bill was completed.

The topics that follow describe each of the actions that appear in the **Bill Segment Action** and **Bill Action** areas. Refer to [How To](#) for a description of typical business processes that use these buttons.

Generate

The **Generate** button causes a bill segment to be created for each service agreement linked to the account. The system generates bill segments in the order of the [billing processing sequence](#) on each service agreement's SA type.

This button is enabled when you are in add mode (i.e., you are not displaying an existing bill) and you have selected an **Account ID**.

When clicked, the **Generate** window opens.

You must specify the following parameters in the **Generate** window to generate the bill segments:

- **Cutoff Date** is the last possible day of each bill segments bill period. The current date defaults when the window opens. Refer to [Ways To Control The End Date Of A Bill Segment](#) for more information.
- **Accounting Date** defines the financial period to which the new bill segments' financial transactions are booked. The current date defaults when the window opens.
- Check **Allow Estimates** if the system is allowed to estimate consumption if it can't find a meter read.
- If the service agreements use meter reads, use the **Billing Option** to control how the system retrieves meter reads that appear on the bill. Choose Use Cut off Date if the meter reads must exist on the **Cutoff Date** (defined above). Choose Use Schedule if you want the service agreement's service point(s) service cycle schedule to control the meter reads that are used (the schedule effective on the cutoff date is used to select the meter reads).

After specifying the parameters, click **Calculate** to create a new bill and new bill segments for the account. You see a summary of the bill segments in the lower right portion of the page.

Freeze

Clicking **Freeze** causes all freezable bill segments to become frozen. Refer to [Bill Segment Lifecycle](#) for more information about freezing.

This button is enabled if:

- the Freeze At Will **Bill Segment Freeze Option** on the [installation option](#) has been selected AND
- freezable bill segments exist AND
- there are no error, incomplete or pending cancel bill segments.

Note:

Freezing a day or more after generation. If, during freezing, bill segments in closed accounting periods are detected, a pop-up appears in which you can specify a new accounting date; this date is updated onto the

offending bill segments. This only happens if the accounting period closes before you freeze the bill segments (the accounting date is stamped on a bill segment when it's generated).

If, after freezing, you're ready to send the bill to the customer click [Complete](#) to finalize the bill.

Note:

If problems are detected after freezing. A bill segment may not be changed after it is frozen. All subsequent changes must occur by canceling the frozen bill segment and creating a new bill segment. Refer to [How To Cancel A Bill Segment](#) and [How To Cancel / Rebill A Bill Segment](#) for more information.

Cancel Frozen

Clicking **Cancel Frozen** causes all frozen bill segments to become canceled. Refer to [Bill Segment Lifecycle](#) for more information about cancellation. This button is disabled if the bill is written off.

Note:

Pending cancels are not affected. Clicking **Cancel Frozen** does not affect bill segments that are pending cancel. To make a pending cancel bill segment canceled, transfer to [Bill Segment - Main](#) and click [Cancel](#).

If you need to cancel a specific bill segment, either transfer to the next tab and cancel the bill segment in question or follow the instructions under [How To Cancel A Bill Segment](#).

This button is enabled if frozen bill segments are linked to the bill.

When clicked, the **Cancel Frozen Bill Segments** window opens.

In the **Cancel Frozen Bill Segments** window, you must specify the following parameters to cancel the frozen bill segments:

- **Cancel Reason** defines why you are performing the cancellation.
- **Accounting Date** defines the financial period to which the canceled bill segments' financial transactions are booked. The current date defaults when the window opens.

After specifying the parameters, click **Calculate** to cancel the frozen bill segments.

Note:

There is no Undo. Unlike cancellations performed on [Bill Segment - Main](#), there is no Undo action. This transaction moves the pending cancel bill segments to the cancel state immediately; whereas the bill segment transaction lets you examine the cancellation before you commit it. If you cancelled bill segments by mistake, you must generate and freeze new bill segments.

If the bill is pending, the cancellation causes the bill segments to be suppressed on the version of the bill sent to the customer (but they remain in the database for audit and financial reporting purposes).

If the bill is complete and you do not [Reopen](#) the bill, the financial impact of the canceled bill segments appears on the next bill created for the account (under Bill Corrections).

If the bill is complete you may be able to [Reopen](#) the bill and then [Complete](#) it. By doing this, you can suppress a frozen bill segment on a previously completed bill. This means that if you catch a problem after completion you don't necessarily have to show the problem to the customer. Rather, cancel the problem, reopen and then recomplete the bill (when you recomplete the bill the system marks the bill segment to be suppressed on the version sent to the customer because its cancellation appears on the same bill as the original charges).

Freeze / Complete

The **Freeze / Complete** button performs a variety of functions:

- all freezable bill segments (including rebills) become frozen
- all pending cancel bill segments become canceled
- all freezable adjustments whose [adjustment type](#) indicates Freeze At Bill Completion become frozen

- the bill is finalized and marked for transmission to the customer

Refer to [Bill Lifecycle](#) for information about what happens during bill completion. Refer to [Bill Segment Lifecycle](#) for more information about freezing.

This button is enabled if:

- the Freeze At Bill Completion Bill Segment Freeze Option on the [installation option](#) has been selected AND
- the bill is pending AND
- there are no bill segments or there are bill segments and all are freezable, pending cancel, frozen or canceled AND
- there are no error or incomplete bill segments.

When clicked, the **Complete** window opens.

If the **User May Override Bill Date** option has been enabled on the [Installation Record](#), you may override the **Bill Date** prior to completion. Otherwise, the **Bill Date** is the current date and cannot be changed. The current date defaults when the window opens.

Note:

Freezing a day or more after generation. If, during freezing, bill segments in closed accounting periods are detected, a pop-up appears in which you can specify a new accounting date; this date is updated onto the offending bill segments. This will only happen if the accounting period closes before you freeze the bill segments (the accounting date is stamped on a bill segment when it's initially generated).

After specifying the parameter, click **Calculate** to freeze and complete the bill.

Complete

The **Complete** button causes a bill to be finalized and marked for transmission to the customer. Refer to [Bill Lifecycle](#) for information about what happens during bill completion.

This button is enabled if:

- the Freeze At Will Bill Segment Freeze Option on the [installation option](#) has been selected AND
- the bill is pending AND
- there are no bill segments or there are bill segments and all are frozen or canceled.

When clicked, the **Complete** window opens.

If the **User May Override Bill Date** option has been enabled on the [Installation Record](#), you may override the **Bill Date** prior to completion. Otherwise, the **Bill Date** is the current date and cannot be changed. The current date defaults when the window opens. If completing a correction note, the user is prompted to enter a **Correction Note Date instead of a bill date** in the **Complete** window.

After specifying the above parameters, click **Calculate** to complete the bill.

Delete

The **Delete** button deletes a bill and its bill segments.

This button is enabled if:

- the bill is pending AND
- all bill segments are incomplete, freezable or in error.

Reopen

The **Reopen** button causes a bill to be reopened. Refer to [Bill Lifecycle](#) for information about why you would reopen a bill.

This button is enabled if:

- the bill is complete AND
- the bill is not written off AND
- this is the most recent bill produced for the account AND
- the bill is not linked to an off cycle bill generator AND
- reopening hasn't been prohibited for the bill. Refer to [Bill Lifecycle](#) for information about conditions that can prevent a bill from reopening.

After reopening a bill, it returns to the pending state and you can make changes to the account's financial transactions (e.g., add payments, adjustments, and bill segments). After which, you click [Complete](#) or [Freeze / Complete](#) to finalize the bill. Only one of these buttons is shown - the specific one depends on how your organization has set the **Bill Segment Freeze Option** on the [installation record](#).

Credit Note

The **Credit Note** button is used to cancel ALL bill segments and create a new bill that contains the cancellation details. We refer to this "negative bill" as a credit note. Refer to [Credit Notes - Presenting Cancellation Details on a Separate Bill](#) for more information.

This button is enabled if:

- the **Use Credit Notes** option on the [Installation](#) record is turned on AND
- the bill is not written off AND
- The bill has frozen bill segments.

To create credit notes for all frozen bill segments, click the **Credit Note** button without selecting any bill segments. A system message asks for confirmation that credit notes will be created for all frozen bill segments.

To create credit notes for specific frozen bill segments, select just those bill segments.

When clicked, the **Credit Note** window opens.

You must specify the following parameters in the **Credit Note** window to cancel the frozen bill segments:

- **Cancel Reason** defines why you are performing the cancellation.
- **Accounting Date** defines the financial period to which the canceled bill segments' financial transactions are booked. The current date defaults when the window opens.
- **Credit Note Date** defines the date of the credit note on which the cancellation details appear. The current date defaults when the window opens.

After specifying the parameters, click **Calculate** to cancel the frozen bill segments and create a credit note.

It should be noted that if this operation is successful, the new "negative bill" is complete. It is ready for transmission to the customer and for interface to the general ledger.

Note:

If you want to issue a credit note for a specific bill segment. Rather than cancel all bill segments on a bill, you can create a credit note for a specific bill segment on a bill. To do this, drill down on the bill segment in question and then click the Credit Note button on the [bill segment page](#). You can also issue a credit note for selected bill segments on the next tab by selecting the desired bill segments and clicking the **Credit Note** button.

Correction Note

The **Correction Note** button is used to cancel and rebill ALL bill segments and create a new bill that contains the cancellation and rebill details. We refer to the resultant bill as a correction note. Refer to [Correction Notes - Presenting Correction Notes on a Separate Bill](#) for more information.

This button is enabled if:

- the **Correction Note** Billing Option is specified on the [Installation](#) record AND

- the bill is complete AND
- there is at least one frozen bill segment on the bill or all of the bill's bill segments are frozen or cancelled AND
- there are no bill segment financial transactions that have been transferred out of the system.

When clicked, the **Correction Note** window opens.

You must specify the following parameters in the **Correction Note** window to correct the bill segment:

- **Cancel Reason** defines why you are performing the correction.
- **Cutoff Date** is the last possible day of each bill period for a bill segment. The current date defaults when the window opens. Refer to [Ways To Control The End Date Of A Bill Segment](#) for more information.
- **Accounting Date** defines the financial period that the financial transactions are booked for a bill segment. The current date defaults when the window opens.
- Check **Allow Estimates** if the system is allowed to estimate consumption if it can't find a meter read.
- Use the **Billing Option** to define how the system looks for meter reads:
 - Select Use Schedule if the system should select reads based on the SA's SP service cycle schedule. Refer to [How The System Determines How Much Was Consumed](#) for more information.
 - Select Use Cut off Date if the system should only select reads from the end date of the existing bill segment.
- If you prefer to have the system use the consumption details used on the original bill segments, check **Use Old Read/Item/SQ**. If this switch is on, neither **Allow Estimates** nor **Billing Option** is relevant.
- After specifying the parameters, click **Calculate** to correct the bill segments and create a correction note. The Bill Page opens and displays the Correction Note.

Once you complete a correction note, it cannot be reopened.

After you create a correction note, the **Undo Correction Note** button is activated.

The button is enabled if:

- the **Correction Note** Billing Option is specified on the [Installation](#) record AND
- the bill is a correction note AND
- the bill is not linked to an off cycle bill generator AND
- all of the bill segments for the correction note are freezable.

Note:

If you want to issue a correction note for a specific bill segment. You can create a correction note for a specific bill segment on a bill. To do this, drill down on the bill segment in question and then click the **Correction Note** button on the [bill segment page](#). You can also issue a correction note for selected bill segments by selecting the desired bill segments and clicking the **Correction Note** button.

Write Off

Refer to [Writing Off Bills](#) for a description of when the **Write Off** button appears and what happens if the button is clicked.

Reverse Write Off

Refer to [Writing Off Bills](#) for a description of when the **Reverse Write Off** button appears and what happens if the button is clicked.

Cancel Bill

Refer to [Idiosyncratic Manual Bill Cancellation](#) for a description of when the **Cancel Bill** button appears and what happens if the button is clicked. Note that if the bill is linked to an off cycle bill generator, this button is not enabled.

Bill - Bill Segments

You can use this page to view all or selected bill segments linked to a bill. In addition, you can also perform certain maintenance functions on this page (see the details below).

Open **Menu > Financial > Bill > Search** and navigate to the **Bill Segments** page to view this information.

Note:

If the bill has more than 25 bill segments and you don't use the go to buttons in the bill segment grid on the Main tab to drill over to this information, the search criteria are intentionally left blank in order to avoid retrieving all bill segments (with the resultant slow response times). You must therefore use the **SA Filter** and the **Status Filter** to define the type of bill segments that should be retrieved. See the Description of page below for more information about this page's search criteria.

The Description of page section below describes the fields on this page. Refer to [How To](#) for a description of how to perform common maintenance functions.

Description of page

Bill Info contains a concatenation of important information about the bill (e.g., the bill date, its status, due date, ending balance, etc.).

Bill ID is the system-assigned unique identifier of the bill.

Note:

If the bill has more than 25 bill segments and you don't use the hyperlinks in the bill segment grid on the Main tab to drill over to this page, the **Filters** are intentionally left blank in order to avoid retrieving all bill segments (with the resultant slow response times). You must therefore use the **SA Filter** and the **Status Filter** to define the type of bill segments that should be retrieved.

The area beneath **Bill Info** provides you with options that control which bill segments appear in the grid. The following points describe the various options:

- Use the **SA Filter** to define the types of service agreements whose bill segments appear in the grid. The following options are available:
- Address. Use this option to restrict bill segments to those whose service agreements are linked to service points associated with a given **Address**, **City** and/or **Postal** code. Note, you can specify any combination of these fields.
- All. Use this option if you do not wish to restrict bill segments based on service agreement attributes.
- Geographic Type. Use this option to restrict bill segments to those whose service agreements are linked to service points associated with a given **Geo Type** and **Value**.
- SA Type. Use this option to restrict bill segments to those whose service agreements are linked to a given **CIS Division** and **SA Type**.
- Use **Status Filter** to restrict the bill segments based on their status. The following options are available:
- All. This option shows all bill segments regardless of status.
- Refer to [Bill Segment Lifecycle](#) for the various status values.

Don't forget to click the search button after changing the filters.

The **Select All / Clear All** buttons are used to select bill segments if you plan on issuing any of the mass update actions at the bottom of the page. These buttons are enabled if either of the following conditions is true:

- All bill segments that appear in the grid are in the Error, Freezable and/or Incomplete states.
- All bill segments that appear in the grid are in the Frozen state

Refer to the description of the "mass update" actions below for more information.

Note:

20 bill segments at a time. Clicking **Select All** selects the first 20 bill segments in the grid. If more than 20 bill segments exist, you must select them in batches.

The grid that follows contains the bill segments that match your search criteria. The following information appears in the grid:

- **Select box.** See the mass update description immediately above for conditions under which this checkbox can be used to select bill segments for mass update actions.
- The **Bill Segment** column contains a concatenation of the bill segment's division, SA type, status and bill period. The division and SA type come from the bill segment's service agreement. Click the hyperlink to transfer to [Bill Segment - Main Information](#). On this page you can perform maintenance functions (e.g., cancel/rebill, delete, cancel, etc., depending on the segment's status) on the bill segment in question.
- The **Current Amount** column contains the bill segment's effect on the service agreement's current balance.
- The **Status** shows the bill segment's status. Refer to [Bill Segment Lifecycle](#) for the possible values.
- The **Remarks** column highlights special circumstances associated with the bill segment.
- Rebill after completion appears if the bill segment is a rebill that was created after the bill was sent to the customer. The financial impact of this bill segment appears as a "bill correction" on the next bill produced for the customer.
- Rebill prior completion appears if the bill segment is a rebill that was created before the bill was sent to the customer.
- Canceled after completion appears if the bill segment was canceled after the bill was sent to the customer. The financial impact of this bill segment appears as a "bill correction" on the next bill produced for the customer.
- Canceled prior completion appears if the bill segment was canceled before the bill was sent to the customer.
- If the bill segment's status is Error or Incomplete, this column contains an estimated value of this bill segment. The estimated value is calculated by computing an average daily amount from the service agreement's frozen bill segments in the last 365 days. This average is then applied to the number of days in this bill segment's bill period. If the bill segment doesn't have a bill period (rare, but possible), the historical average is not displayed.
- If the bill segment's status is Error, this column also contains the error message.
- Rebilled due to correction note appears if the correction note was generated for the bill segment. This remark is generated only if you have Correction Note specified in the [Installation](#) record.
- Rebilled due to correction. Canceled after completion appears for a correction note that spawns another correction note. This remark is generated only if you have Correction Note specified in the [Installation](#) record.
- The **Service Quantity** and **UOM** (unit of measure) columns contain the amount of consumption that was billed. The UOM is defined on the service agreement's [SA type](#).
- The **Bill Segment ID** is the system-assigned unique identifier of the bill segment.

This transaction has sophisticated logic that can be used to perform "mass updates" to the bill segments that appear in the grid (using the buttons at the bottom of the page). The following points describe these mass update actions:

Generate (Bill - Bill Segments)

The **Generate** button is used to delete and recreate one or more bill segments. This button is enabled if you select at least one row from the bill segments grid that's in the Error, Freezable and/or Incomplete state.

Note that you can only select a bill segment for regeneration if ALL bill segments in the grid are in the Error, Freezable and/or Incomplete states. Note, you can use the **Status Filter** to restrict the type of bill segments in the grid.

When clicked, the **Generate** window opens.

You must specify the following parameters in the **Generate** window to regenerate a new bill:

- **Accounting Date** defines the financial period to which the new bill segments' financial transactions will be booked. The current date defaults when the window opens.
- Check **Allow Estimates** if the system is allowed to estimate consumption if it can't find a meter read.
- If the service agreements use meter reads, use the **Billing Option** to control how the system retrieves meter reads that appear on the bill. Choose Use Cut off Date if the meter reads must exist on the **Cutoff Date** (defined above). Choose Use Schedule if you want the service agreement's service point(s) service cycle schedule to control the meter reads that are used (the schedule effective on the cutoff date is used to select the meter reads).

After specifying the parameters, click **Calculate** to regenerate the selected bill segments. A summary of what the system does is presented next.

Freeze (Bill - Bill Segments)

The **Freeze** button is used to freeze one or more bill segments. This button is enabled if you select at least one row from the bill segments grid that's in the Freezable state AND the [installation option](#) indicates users are allowed to "freeze at will".

Note that you can only select a bill segment for freezing if ALL bill segments in the grid are in the Freezable state. Note, you can use the **Status Filter** to restrict the type of bill segments in the grid.

When clicked, the **Freeze** window opens.

Accounting Date is used to define the financial period to which the frozen bill segments' financial transactions are booked. The current date defaults when the window opens.

After specifying the above parameters, click **Freeze** to freeze the selected bill segments. A summary of what the system does is presented next.

Delete (Bill - Bill Segments)

The **Delete** button is used to delete one or more bill segments. This button is enabled if you select at least one row from the bill segments grid that's in the Error, Freezable and/or Incomplete state.

Note that you can only select a bill segment for deletion if ALL bill segments in the grid are in the Error, Freezable and/or Incomplete states. Note, you can use the **Status Filter** to restrict the type of bill segments in the grid.

If the system is successful in deleting the selected bill segment(s), a confirmation window summarizes what the system just did (i.e., it shows the number of bill segments that were deleted).

Cancel/Rebill/Freeze (Bill - Bill Segments)

If problems are detected with a frozen bill segment, it should be canceled and a new bill segment should be created. We refer to this process as cancel / rebill. Refer to [Cancel / Rebill Incorrect Bill Segments](#) for more information.

Before you cancel / rebill, you'll probably need to fix the cause of the problem. The following table describes common problems and how to fix them.

| Problem | How To Fix It |
|--|---|
| The wrong rate was used | Go to Service Agreement - Rate Info and correct the rate. |
| The wrong meter read was used | Add a meter read with a more powerful read type for the service point in question. |
| The wrong meter was connected to the service point | Go to SP / Meter Installation and correct the SP / Meter linkage. Then go to Service Agreement - SA / SP and indicate the appropriate start read for the service point's correct meter. |
| A contract rider was applied incorrectly | Go to Service Agreement - Rate Info and correct the contract rider information. |
| The wrong tax exemption amount was calculated | Go to Service Agreement - Rate Info and correct the tax exemption information. |

**Note:**

Multi-Cancel/Rebill Saves Time. If the cause of the problem impacts many bill segments related to a service agreement, you should use the [Multi Cancel Rebill](#) transaction as it allows you to cancel / rebill an unlimited number of bill segments at once.

Credit Notes. Using the cancel/rebill functionality causes the cancel and rebill details to be swept on to the customer's next bill unless you [Reopen](#) the bill. If your organization requires cancellation details to be presented to the customer separately from the new bill, you should not use the **Rebill** functionality. Rather, you should issue a [Credit Note](#) and then generate a new bill containing the revised charges.

The **Cancel/Rebill/Freeze** button is used to cancel, rebill and freeze one or more bill segments. This button is enabled if you select at least one row from the bill segments grid that's in the Frozen state AND the bill is not written off.

Note that you can only select a bill segment for cancel/rebill/freeze if ALL bill segments in the grid are in the Frozen state. Note, you can use the **Status Filter** to restrict the type of bill segments in the grid.

When clicked, the **Cancel/Rebill/Freeze** window opens.

- **Cancel Reason** defines why the bill segment(s) are being canceled.
- **Accounting Date** defines the financial period to which the canceled and new bill segments' financial transactions are booked. The current date defaults when the window opens.
- Check **Allow Estimates** if the system is allowed to estimate consumption if it can't find a meter read.
- Use the **Billing Option** to define how the system looks for meter reads:
 - Select **Use Schedule** if the system should select reads based on the SA's SP service cycle schedule. Refer to [How The System Determines How Much Was Consumed](#) for more information.
 - Select **Use Cut off Date** if the system should only select reads from the end date of the existing bill segment.
 - If you prefer to have the system use the consumption details used on the original bill segments, check **Use Old Read/Item/SQ**. If this switch is on, neither **Allow Estimates** nor **Billing Option** is relevant.

**Warning:**

If the cause of the rebill is an incorrect rate and the new rate requires service quantities that were not calculated when the bill was originally calculated, do not turn on **Use Old Read/Item/SQ**. Why? Because you want the system to derive new service quantities during the rebill process.

After specifying the parameters, click **Calculate** to cancel, rebill and freeze the selected bill segments.

**Note:**

Errors. Bill segment errors may occur when you cancel / rebill the bill segments. For example, if you change the SA's rate to a rate that requires a unit-of-measure that doesn't exist on the SA's meter, a bill segment error is generated. If this occurs, you must go to [Bill Segment - Main](#) for the pending cancel bill segment and use the **Undo** action to remove the offending bill segment (and restore the original segment to the Frozen state). Alternatively, you can drill down on the Error bill segment and use the **Regenerate** action after correcting the cause of the problem.

There is no Undo. Unlike cancel / rebills performed on [Bill Segment - Main](#), there is no Undo action. This is because this transaction freezes the newly created bill segments after it cancel/rebills; whereas the bill segment transaction lets you examine the new bill segment before you freeze it. If you made a mistake, simply correct the cause of the mistake and then cancel / rebill again. The erroneous financial transactions are automatically suppressed on the next bill produced for the customer.

A confirmation window summarizes what the system just did (i.e., it shows the number of bill segments that were deleted / generated).

Cancel (Bill - Bill Segments)

The **Cancel** button is used to cancel one or more bill segments. This button is enabled if you select at least one row from the bill segments grid that's in the Frozen state AND the bill is not written off.

Note that you can only select a bill segment for cancellation if ALL bill segments in the grid are in the Frozen state. Note, you can use the **Status Filter** to restrict the type of bill segments in the grid.

When clicked, the **Cancel** window opens.

- **Cancel Reason** defines why the bill segment(s) are being canceled.
- **Accounting Date** is used to define the financial period to which the canceled bill segments' financial transactions are booked. The current date defaults when the window opens.

After specifying the above parameters, click **Calculate** to cancel the selected bill segments.

Note:

There is no Undo. Unlike cancellations performed on [Bill Segment - Main](#), there is no Undo action. This transaction moves the pending cancel bill segments to the cancel state immediately; whereas the bill segment transaction lets you examine the cancellation before you commit it. If you cancelled bill segments by mistake, you must generate and freeze new bill segments.

Credit Note (Bill - Bill Segments)

The **Credit Note** button is used to cancel selected bill segments and create a new bill that contains the cancellation details. We refer to this "negative bill" as a credit note. Refer to [Credit Notes - Presenting Cancellation Details on a Separate Bill](#) for more information.

This button is enabled if:

- the **Use Credit Notes** option on the [Installation](#) record is turned on AND
- if you select at least one row from the bill segments grid that's in the Frozen state AND
- the bill is not written off.

Note that you can only select a bill segment for this action if ALL bill segments in the grid are in the Frozen state. Note, you can use the **Status Filter** to restrict the type of bill segments in the grid.

When clicked, the **Credit Note** window opens.

You must specify the following parameters in the **Credit Note** window to cancel the frozen bill segments:

- **Cancel Reason** defines why you are performing the cancellation.
- **Accounting Date** defines the financial period to which the canceled bill segments' financial transactions are booked. The current date defaults when the window opens.
- **Credit Note Date** defines the date of the credit note on which the cancellation details appear. The current date defaults when the window opens.

After specifying the parameters, click **Calculate** to cancel the frozen bill segments and create a credit note.

It should be noted that if this operation is successful, the new "negative bill" is complete. Refer to [Bill Lifecycle](#) for information about the steps that take place during completion. It is ready for transmission to the customer and for interface to the general ledger.

Note:

If you want to issue a credit note for an entire bill. Rather than cancel a specific bill segment, functionality exists that allows you to create a credit note for ALL bill segments on a bill. To use this feature, display the bill in question and then click the Credit Note button on the [bill page](#).

Correction Note (Bill - Bill Segments)

The **Correction Note** button is used to cancel and rebill bill segments and create a new bill that contains the cancellation and rebill details. We refer to the resultant bill as a correction note. Refer to [Correction Notes - Presenting Correction Notes on a Separate Bill](#) for more information. This button is enabled if:

- the **Correction Note** option is specified on the [Installation](#) record AND

- the bill is complete AND
- the bill segment is frozen AND
- there are no bill segment financial transactions that have been transferred out of the system.

When clicked, the **Correction Note** window opens.

You must specify the following parameters in the **Correction Note** window to correct the bill segment:

- **Cancel Reason** defines why you are performing the correction.
- **Cutoff Date** is the last possible day of each bill segments bill period. The current date defaults when the window opens. Refer to [Ways To Control The End Date Of A Bill Segment](#) for more information.
- **Accounting Date** defines the financial period to which the corrected bill segments' financial transactions are booked. The current date defaults when the window opens.
- Check **Allow Estimates** if the system is allowed to estimate consumption if it can't find a meter read.
 - Select **Use Schedule** if the system should select reads based on the SA's SP service cycle schedule. Refer to [How The System Determines How Much Was Consumed](#) for more information.
 - Select **Use Cut off Date** if the system should only select reads from the end date of the existing bill segment.
- Use the **Billing Option** to define how the system looks for meter reads:
- If you prefer to have the system use the consumption details used on the original bill segments, check **Use Old Read/Item/SQ**. If this switch is on, neither **Allow Estimates** nor **Billing Option** is relevant.
- After specifying the parameters, click **Calculate** to correct the bill segments and create a correction note. The Bill Page opens and displays the Correction Note.

Note:

If you want to issue a correction note for an entire bill. You can create a correction note for ALL bill segments on a bill. To use this feature, display the bill in question on the [Bill page](#) and click the **Correction Note** button.

Bill - Bill Routings

This page is used to view the recipients of a bill. Refer to [Printing Bills](#) for a discussion of how this information is used to produce bill images.

This page is also used to request a new copy of a bill. Refer to [How To Reprint A Bill \(For The Original Recipients or For Someone New\)](#) for a description of how to do this.

Note:

No routing information until completion. A bill has no routing details until it is completed. At completion time, the system creates a routing detail for every person linked to the account that receives a copy of its bills. Refer to [The Source Of Bill Routing Information](#) for more information about how this information is constructed.

Use **Menu > Financial > Bill > Search** and navigate to the **Bill Routings** page.

Description of Page

Bill Info contains a concatenation of important information about the bill (e.g., the bill date, its status, due date, ending balance). If [sequential bill numbering](#) has been enabled, the bill's number also appears.

Bill ID is the system-assigned unique identifier of the bill.

The **Bill Routing Information** scroll contains an entry for each recipient of the bill. This information is disabled after the bill has been routed to the recipient. The remainder of this discussion describes the fields that can be defined for each recipient of the bill.

Person ID identifies the person who was originally associated with the routing record. You may change the **Person ID** to any person in the system as this information is only used to default the recipient's name and address information, below.

The **Bill Routing Parameters** area contains information explaining how and when the bill is routed to the recipient. This information is gray when the bill routing information has been extracted or if a bill is reopened:

- **Bill Route Type** is the method used to transmit the bill to the customer. If the **Person ID** is linked to the account, the bill route type defaults from the person's [Account - Person Information](#).
- **Sequence** is the system-assigned identifier assigned to this bill routing.
- **Batch Control** is the identifier of the batch of bills in which the recipient's copy was downloaded. The batch process is defined on the **Bill Route Type** or CIS Division.
- **Extract Date/Time** is the date and time the bill was downloaded. This information only appears after the download has commenced.
- **Format** indicates if the customer should receive a Detailed or a Summary bill. If the **Person ID** is linked to the account, this information defaults from [Account - Person Information](#).
- **Reprint** is checked if a user created this routing. This switch is populated by the system and is always protected.
- Turn on **Do Not Extract** if the bill should not be routed to the individual for whatever reason.
- **Copies** indicates the number of copies of the bill the person receives. If the **Person ID** is linked to the account, this information defaults from [Account - Person Information](#).
- **PO ID** is the purchase order Id the customer wants printed on their copy of the bill. If the **Person ID** is linked to the account, this information defaults from [Account - Person Information](#).
- **Intercept** is the User ID of the individual who wants to review the bill before it is sent to the customer. This field is automatically populated when the account has a Bill Print Intercept specified (intercept information is defined on [Account - Main Information](#)). For a one-time intercept, a user can enter their ID in this field before the bill, or reprint, has been extracted.

Note: Adding a User ID to the Intercept field will not automatically populate the Bill Print Intercept field on the Account's Main page; nor, will it affect future bill routings.

The **Mailing Address Information** area contains the recipient's name and address.

- If the recipient has an *override mailing name*, **Name1**, **Name2** and **Name3** contain the person's override mailing name. Otherwise, **Name1** contains the recipient's primary name (this name might also include a prefix or suffix if the related [Account - Person](#) relationship has these fields defined).
- The remaining fields are the recipient's address. Refer to [The Source Of Bill Routing Information](#) for information about how the system constructs the recipient's address. Note:
- If the recipient's address is a mailing address (as opposed to fax or email), the **Country** associated with the address controls the fields that appear in the address. Refer to [Defining Countries](#) for more information on the address constituents.
- If a user manually adds a routing record, the mailing address information defaults from the information on the current routing record.
- If a user specifies a **Person ID** that is linked to the bill's account, the **Bill Route Type** defined on the [Account - Person](#) record is defaulted.
- If a user specifies a **Person ID** that is not linked to the bill's account, the **Bill Route Type** on the *installation record* is defaulted. Note, if the bill route indicates the bill is routed via the postal service, the system will only be able to default the person's address if the person has an override mailing address on their [correspondence information](#).
- If the user changes the **Bill Route Type** after the initial default, the system populates the address information as described under [The Source Of Bill Routing Information](#).
- The Validate button on the bill page will only be available if you have set the Allow Address Validation option type to Y on the General System Configuration feature configuration. Once clicked, the Address Validation Script on the General System Configuration feature configuration will be invoked to validate the entered address. Refer to [Implementing Address Validation](#) for more information.

Bill - Bill Messages

The Messages page is a grid containing one row for every message that appears on the bill. Open **Menu > Financial > Bill > Search** and navigate to the **Bill Messages** page to view this information.

**Note:**

No messages until completion. A bill has no messages until it is completed (unless you insert them manually). At completion time, the system assembles messages from the various message sources. Refer to [The Source Of Bill Messages](#) for information about these sources.

The bill segment(s) may also have messages. Be aware that only account-oriented messages are linked to a bill. There may also be service agreement-oriented messages linked to the bill's bill segments. Refer to [Bill - Bill Messages](#) for information about the page on which service agreement-oriented messages are displayed. Refer to [The Source Of Bill Messages](#) for information about the various message sources and whether each is linked to a bill or a bill segment.

Bill messages may contain dynamic information. Refer to [Substituting Field Values Into A Bill Message](#) for more information.

The **Description of Page** section below describes the fields on this page. Refer to [How To Add Ad Hoc Messages To A Bill](#) for a description of how to perform common maintenance functions.

Description of Page

Bill Info contains a concatenation of important information about the bill (e.g., the bill date, its status, due date, ending balance). If [sequential bill numbering](#) has been enabled, the bill's number also appears.

Bill ID is the system-assigned unique identifier of the bill.

The following columns are displayed in the grid:

- **Bill Message** is the code that identifies the bill message.
- **Message On Bill** is the message associated with the code.
- **Priority** is the bill messages priority (on the printed bill).
- **Insert Code** defines if the bill message causes an insert in the envelope.

Bill - Characteristics

The Characteristics page is a grid containing one row for each characteristic linked to the bill. Bill characteristics are purely informational.

**Note:**

You can only choose characteristic types defined as permissible on a bill record. Refer to [Setting Up Characteristic Types and Their Values](#) for more information.

Open **Menu > Financial > Bill > Search** and navigate to the **Characteristics** page to view this information.

Description of Page

The following fields display on the grid:

- **Characteristic Type** must be a type of characteristic defined as permissible on a bill record.
- **Sequence** Controls the order in which characteristics of the same type are displayed.
- **Characteristic Value** indicates the value of the characteristic if the characteristic type is pre-defined or foreign key reference.

How To

The topics in this section describe how to perform common bill maintenance functions.

How To Create A Bill For All Service Agreements Linked To An Account

99.9% of all bills are created by the batch bill process and require no human intervention before they are finalized and sent to a customer. The other 0.1% are created by users on-line / real time. This section explains how to create the 0.1%.

The following points describe how to use this page to create a new bill:

- Navigate to the [Bill - Main Information](#) page:
- If you have already selected the customer (say on Control Central), select **Go To Bill > Add** option on the account context menu. [context menu](#). This will transfer you to this page with the respective account populated.
- If you haven't selected the account, use Menu to navigate to this page (**Menu > Financial > Bill > Add**) and then select the **Account ID** using the adjacent [search button](#).
- Click the [Generate](#) button to create a new bill.
- You will see a summary of the bill segments in the lower right portion of the page. If there are errors, refer to [How To Correct A Bill Segment That's In Error](#). If there are no errors, the **Bill Segment Freeze Option** on the [installation option](#) controls the next step:
- If this option is set to Freeze At Bill Completion, click the [Freeze / Complete](#) button.
- If this option is set to Freeze At Will, click the [Freeze](#) button and, if everything looks clean, click the [Complete](#) button.

How To Create A Bill For A Specific Service Agreement

Most bills contain a bill segment for every service agreement linked to the account. If you want to produce a bill that contains bill segments for a subset of service agreements (e.g., you want to create a one-time invoice for an account's billable charge service agreement), follow these steps:

- Navigate to the [Bill - Main Information](#) page:
- If you have already selected the customer (say on Control Central), select **Go To Bill > Add** option on the account context menu. [context menu](#). This will transfer you to this page with the respective account populated.
- If you haven't selected the account, use Menu to navigate to **Menu > Financial > Bill > Add**, and then select the **Account ID** using the adjacent [search button](#).
- Click the [save](#) button to create a bill without bill segments for the account.
- Select **Go To Bill Segment +** option on the Bill's [context menu](#) to transfer to [Bill Segment - Main](#).
- Select the **SA ID** of the service agreement for which you want to create a bill segment.
- Click the [Generate](#) button to generate a bill segment.
 - If an error exists, refer to [How To Correct A Bill Segment That's In Error](#).
 - If there are no errors, the **Bill Segment Freeze Option** on the [installation option](#) controls the next step:
 - If this option is set to Freeze At Bill Completion, return to [Bill - Main](#) (using the bill context menu) and click the [Freeze / Complete](#) button.
 - If this option is set to Freeze At Will, click the [Freeze](#) button and, if everything looks clean, return to [Bill - Main](#) and click the [Complete](#) button.

How To Create a Bill with no Bill Segments

You may wish to generate a bill that contains no bill segments. For example, perhaps your customer is billed quarterly but pays monthly. During the months where no charges are calculated, you may choose to send a "bill" that does not show new charges, but includes the payments received. To produce a bill with no bill segments, follow these steps:

- Navigate to the [Bill - Main Information](#) page:
- If you have already selected the customer (say on Control Central), select **Go To Bill > Add** option on the account context menu. [context menu](#). This will transfer you to this page with the respective account populated.
- If you haven't selected the account, use Menu to navigate to this page (**Menu > Financial > Bill > Add**) and then select the **Account ID** using the adjacent [search button](#).
- Click the [save](#) button to create a bill without bill segments for the account.

- At this point either the **Complete** or **Freeze / Complete** button (based on the value of Bill Segment Freeze Option on [installation options](#)) becomes enabled. Click the applicable button for your installation to complete the bill. At this point, all the steps described for completing a bill in Bill Lifecycle are performed, including sweeping onto the bill any payments received since the last bill was generated.

How To Create A One-Time Invoice

The following points describe the steps necessary to create and bill a one-time invoice:

- If the customer to be invoiced doesn't already have an appropriate billable charge service agreement, create one. The easiest way to do this is from [Start/Stop Service](#).
- Use [Maintaining Billable Charges](#) to add a billable charge for the service agreement. The billable charge contains the invoice lines and amounts. The system will produce the bill for this charge when the account's bill cycle next executes. If you can't wait until that time, proceed to the next step.
- If you created a new billable charge service agreement in step 1, you must activate it before billing can bill it. To do this, transfer to [Service Agreement - Main Information](#) and click the activate button.
- Refer to [How To Create A Bill For A Specific Service Agreement](#) for instructions describing how to create a bill with a bill segment for the billable charge service agreement.

How To Correct A Bill Segment That's In Error

A bill segment will exist in the Error state if a problem was encountered during the generation of a bill segment. To fix an error bill segment you must correct the cause of the error and then regenerate the bill segment. Refer to [Bill Segment Errors](#) for background information.

Note:

Error segments created during batch billing. If the error bill segment was created as part of the batch bill process, the system attempts to fix the offending segment(s) each night during the account's bill window by regenerating it. Therefore, if the cause of the error is fixed during the day, the system will automatically regenerate the bill segment when batch billing next runs; you don't have to manually correct each bill. And once a bill is error-free, it will be completed and sent to the customer. Refer to [Batch Billing](#) for more information.

Correcting the cause of a bill segment error can be difficult or trivial; we hope that the error messages (along with their long descriptions) provide a good description of how to resolve the issue.

After you have corrected the cause of the error, you should regenerate the bill segment. There are two ways to do this:

- You can use the [Generate](#) action on [Bill - Bill Segment](#) to regenerate one or more bill segments. We recommend using this method if the cause of the error affected many bill segments because you can regenerate many bill segments at a time on this page. Also, be aware that this transaction shows the estimated value of error bill segments so you can gauge whether to invest a lot of time in correcting the problem. For example, if the bill segment's estimated value is \$10,000, it's probably worth correcting the problem before sending the bill out. However, if the bill segment's value is small, you may decide to simply delete the error bill segment and send the bill without it (the system will attempt to create a bill for the deleted period the next time the account is billed).
- You can use the [Generate](#) action on [Bill Segment - Main](#) to regenerate an individual bill segment. We'd recommend using this method if the problem is bill segment-specific and you need to examine the information that is snapshot on the bill segment to resolve the error (e.g., you need to look at the meter reads and service quantities).

Note:

Drilling Into Bill Segment Errors. When you use the bill segments in error To Do list to work through errors, you will be transferred to [Bill Segment - Main](#) with the bill segment displayed.

After all errors have been resolved on a bill, return to [Bill - Main](#). The **Bill Segment Freeze Option** on the [installation option](#) controls the next step:

- If this option is set to Freeze At Bill Completion, click the [Freeze / Complete](#) button.

- If this option is set to Freeze At Will, click the [Freeze](#) button and, if everything looks clean, click the [Complete](#) button.

How To Correct A Bill That's In Error

Besides errors on bill segments, there may also be errors detected when the system attempts to complete a bill. For example, if the system cannot find a mailing address, the bill will be in error (as opposed to one of its bill segments). Refer to [Bill Errors](#) for background information.

To correct such an error:

- Navigate to [Bill - Main](#).
- Look at the bill's error message. Push the view button to view the long explanation that will provide suggestions as to the cause of the error (and how to fix it). Transfer to the appropriate page to fix the problem.
- After fixing the cause of the error, return to [Bill - Main](#). The **Bill Segment Freeze Option** on the [installation option](#) controls the next step:
- If this option is set to Freeze At Bill Completion, click the [Freeze / Complete](#) button.
- If this option is set to Freeze At Will, click the [Freeze](#) button and, if everything looks clean, click the [Complete](#) button.

How To Cancel A Bill Segment

If a bill segment was frozen and it should never have been created in the first place, the bill segment must be canceled. There are several ways to do this:

- You can use the [Cancel Frozen](#) action on [Bill - Main](#) to cancel all frozen bill segments linked to the bill. We recommend using this method if you need to cancel everything on a bill.
- You can use the [Cancel](#) action on [Bill - Bill Segments](#) to cancel selected bill segments. We recommend using this method if you need to cancel multiple bill segments.
- You can use the [Cancel](#) action on [Bill Segment - Main](#) to cancel an individual bill segment. We'd recommend using this method if you need to examine the information on the bill segment before canceling it.

If the related bill is pending, the cancellation will cause the bill segment to be suppressed on the version of the bill sent to the customer (but it remains in the database for audit and financial reporting purposes).

If the related bill is complete and you do not [Reopen](#) the bill, the financial impact of the canceled bill segment(s) will appear on the next bill created for the account (under Bill Corrections).

If the related bill is complete you may be able to [Reopen](#) the bill and then [Complete](#) it. By doing this, you can suppress a frozen bill segment on a previously completed bill. This means that if you catch a problem after completion you don't necessarily have to show the problem to the customer. Rather, cancel the problem, reopen and then recomplete the bill (when you recomplete the bill the system will mark the bill segment to be suppressed on the version sent to the customer because its cancellation appears on the same bill as the original charges).

How To Cancel / Rebill A Bill Segment

If a bill segment was frozen but it contains incorrect information, it should be canceled and a new bill segment should be created. We refer to this process as cancel / rebill. Refer to [Cancel / Rebill Incorrect Bill Segments](#) for more information.

Before you cancel / rebill, you must correct the cause of the problem. The following table describes common problems and where to go to fix them.

| Problem | How To Fix It |
|-------------------------|---|
| The wrong rate was used | Go to Service Agreement - Rate Info and correct the rate. |

| | |
|--|---|
| The wrong meter read was used | Add a meter read with a more powerful read type for the service point in question. |
| The wrong meter was connected to the service point | Go to SP / Meter Installation and correct the SP / Meter linkage. Then go to Service Agreement - SA / SP and indicate the appropriate start read for the service point's correct meter. |
| A contract rider was applied incorrectly | Go to Service Agreement - Rate Info and correct the contract rider information. |
| The wrong tax exemption amount was calculated | Go to Service Agreement - Rate Info and correct the tax exemption information. |

After correcting the cause of the problem, you're ready to cancel and rebill the offending bill segment(s). There are several ways to do this:

- You can use the [Cancel / Rebill / Freeze](#) action on [Bill - Bill Segments](#) to cancel, rebill and freeze selected bill segments. We recommend using this method if you need to cancel / rebill multiple bill segments due to a pervasive problem.
- You can use the [Rebill](#) action on [Bill Segment - Main](#) to cancel and rebill an individual bill segment. We'd recommend using this method if you need to examine the information on the bill segment before and after canceling it. If you use this method, you must also use the [Freeze](#) action to freeze the newly created bill segment.
- If the cause of the problem impacts many bill segments related to a service agreement, you should use the [Multi Cancel Rebill](#) transaction as it allows you to cancel / rebill an unlimited number of bill segments at once.

If the related bill is pending, the cancellation will cause the erroneous bill segment to be suppressed on the version of the bill sent to the customer (but it remains in the database for audit and financial reporting purposes).

If the related bill is complete and you do not [Reopen](#) the bill, the financial impact of the canceled bill segment(s) and their rebill bill segment(s) will appear on the next bill created for the account (under Bill Corrections).

If the related bill is complete you may be able to [Reopen](#) the bill and then [Complete](#) it. By doing this, you can suppress an erroneous frozen bill segment on a previously completed bill. This means that if you catch a problem after completion you don't necessarily have to show the problem to the customer. Rather, cancel / rebill the problem, reopen and then recomplete the bill (when you recomplete the bill the system will mark the bill segment to be suppressed on the version sent to the customer because its cancellation appears on the same bill as the original charges).

How To Create A Credit Note

A credit note is used to cancel bills segments and present the results of this cancellation on a separate bill. This separate bill is referred to as a credit note. Refer to [Credit Notes - Presenting Cancellation Details on a Separate Bill](#) for more information.

Note:

Installation option must be turned on. If your organization creates credit notes, be sure to select the Credit Note Billing Option on the [Installation Options](#). If you don't select this option, the credit note buttons will not be enabled.

Before creating a credit note, you must first determine whether a single bill segment must be canceled or whether all bill segments for a bill must be canceled:

- If you need to issue a credit note for the entire bill, navigate to the [Bill](#) page and click the [Credit Note](#) button.
- If you need to issue a credit note for a specific bill segment, navigate to the [Bill Segment](#) page and click the [Credit Note](#) button.

**Note:**

Open-item customers. If any of the bill segments are associated with an open-item customer class AND the original bill segment is an open item, the match event will be created and balanced with the original FT and the cancellation FT, assuming you have the appropriate FT freeze algorithm plugged-in on the customer class.

Issuing a credit note for a specific bill segment. You may also issue a credit note for an individual bill segment. When you create a credit note for an individual bill segment, that bill segment is canceled and a new credit note bill is created for that single bill segment's cancellation information.

How To Create A Correction Note

The **Correction Note** button is used to cancel and rebill bill segments and present the cancellation and rebill details on a separate bill. Refer to [Correction Notes - Presenting Correction Notes on a Separate Bill](#) for more information.

**Note:**

Installation option must be turned on. If your organization creates correction notes, be sure to select the Correction Note Billing Option on the [Installation Options](#). If you don't select this option, the correction note buttons will not be enabled.

Before creating a correction note, you must first determine whether the note should impact a single bill segment or whether all bill segments for a bill must be corrected:

- If you need to issue a correction note for the entire bill, navigate to the [Bill](#) page and click the [Correction Note](#) button.
- If you need to issue a correction note for a specific bill segment, navigate to the [Bill Segment](#) page and click the [Correction Note](#) button.

**Note:**

Open-item customers. If any of the bill segments are associated with an open-item customer class AND the original bill segment is an open item, the match event will be created and balanced with the original FT and the cancellation FT, assuming you have the appropriate FT freeze algorithm plugged in on the customer class.

Issuing a correction note for a specific bill segment. You can also issue a correction note for an individual bill segment. When you create a correction note for an individual bill segment, that bill segment is canceled and a new correction note bill is created for that single bill segment's cancellation information.

How To Create An Off Cycle Bill Generator

An off cycle bill generator is used to create an off cycle bill for an account. You control the financial transactions that are linked to the bill. To create a bill using the base off cycle bill generator business object, follow these steps:

- With an account in context, select **Account Context Menu > Go To Off Cycle Bill Generator +**. (See [context menu](#) for more information about Context Menus.) This will transfer you to this portal with the respective account populated.
- Select the adjustments, billable charges and/or service agreements that you wish to include in the bill.
- Enter the required bill information to be used when creating the bill; this includes the Cutoff Date, Accounting Date, Allow Estimates switch, Billing Option and Bill Date.
- Click the [save](#) button.
- Click the Complete button to transition the off cycle bill generator to the complete state and create the bill. Any errors encountered while attempting to create the bill will be captured in the off cycle bill generator's log.
- Refer to [Off Cycle Bill Generator](#) for more information.

How To Override Service Quantities On A Specific Bill Segment

Warning: The following functionality is not applicable when using bill determinants.

Determining how much was used by the customer is one of the first steps that happens when a bill segment is created. (Refer to [How The System Determines How Much Was Consumed](#) on page 311 for details. 99.9% of the time, the system does a perfect job in this effort. However, there are rare circumstances when, due to missing or incorrect data, the quantity calculated by the system is not correct (consider what the consumption should be if the meter is broken).

To help you deal with these rare situations, a "back door" exists that allows a [bill segment's service quantities](#) to be overridden. This truly is a "back door" because the proper way to fix the amount of a commodity is to correct the cause of the error and then [cancel / rebill](#) the bill segment (or issue a [credit note](#)).

This section describes how to override the total amount of service quantity consumption billed on a bill segment. You would do this in the rare situation when you cannot get the meter reads (and exchanges) to reflect the amount of consumption you need to bill.

- Display the error or freezable bill segment on [Bill Segment - Main](#).

Important:

You can only override consumption on a bill segment that is in Error or Freezable. This means you must generate a bill segment before you can override the SQ details.

- Transfer to the [Bill Segment - SQ Details](#) tab.
- Insert one row in the service quantity (SQ) grid (click the + button) for each service quantity you need to add. You may also change service quantities that were populated by the system when it initially generated the bill segment by overwriting the respective values.
- Save the bill segment.
- [Generate](#) the bill segment.
- If the bill segment still looks wrong, repeat the above points until the bill segment is correct.
- The **Bill Segment Freeze Option** on the [installation option](#) controls the next step:
- If this option is set to Freeze At Bill Completion, return to [Bill - Main](#) (using the bill context menu) and click the [Freeze / Complete](#) button.
- If this option is set to Freeze At Will, click the [Freeze](#) button and, if everything looks clean, return to [Bill - Main](#) and click the [Complete](#) button.

Warning:

Even though the system doesn't use the consumption associated with the bill segment's meter reads when you override consumption, it will use the end reading(s) as the start read(s) on the NEXT bill segment produced for the service agreement. Therefore, make sure the end read(s) are correct, otherwise you'll have to override the service quantities on the next bill segment.

Note:

Override Calculation/Audit Read Details. The above steps may also be taken to override entries in the [calculation/audit read details](#) collection.

How To Override The Items Billed On A Specific Bill Segment

The [How The System Determines How Much Was Consumed](#) used by the customer is one of the first steps that happens when a bill segment is created. 99.9% of the time, the system does a perfect job in this effort. However, there are rare circumstances when, due to missing or incorrect data, the quantity calculated by the system is not correct.

To help you deal with these rare situations, a "back door" exists that allows a bill segment's billable quantities to be overridden. This truly is a "back door" because the proper way to fix the amount of a commodity is to correct the cause of the error and then [cancel / rebill](#) the bill segment.

This section describes how to override the total number of items billed on a bill segment. You would do this in the rare situation when you cannot get the [item snapshot](#) to reflect the amount of consumption you need to bill.

- Display the error or freezable bill segment on [Bill Segment - Main](#).

Important:

You can only override consumption on a bill segment that is in Error or Freezable. This means you must generate a bill segment before you can override the item details.

- Transfer to the [Bill Segment - Item Details](#) tab.
- Insert one row in the item grid (click the + button) for each item you need to add. You may also change item amounts that were populated by the system when it initially generated the bill.
- Save the bill segment.
- [Generate](#) the bill segment.
- If the bill segment still looks wrong, repeat the above points until the bill segment is correct.
- The **Bill Segment Freeze Option** on the [installation option](#) controls the next step:
- If this option is set to Freeze At Bill Completion, return to [Bill - Main](#) (using the bill context menu) and click the [Freeze / Complete](#) button.
- If this option is set to Freeze At Will, click the [Freeze](#) button and, if everything looks clean, return to [Bill - Main](#) and click the [Complete](#) button.

How To Remove Unwanted Adjustments (or Payments) From A Completed Bill

If the system (or a user) has created adjustments that have been swept onto a recently completed bill but you don't want them to appear on the bill (e.g., the system generated a late payment charge but you want to forgive it) perform the following steps:

- Cancel the adjustment ([Adjustment - Main Information](#)).
- Navigate to the [Bill - Main](#) page.
- Click the [Reopen](#) button to reopen the previously completed bill.
- Click the [Complete](#) button to recomplete the bill. When the bill is recompleted, the system will see that an adjustment that was swept onto the bill when it was originally completed has been canceled and it will mark the adjustment for suppression on the printed bill.

You can remove unwanted payments using an analogous approach - Cancel the payment, Reopen the bill, Complete the bill.

Note:

Cannot reopen historical bills. You may only reopen an account's most recent bill because reCompleting the bill causes the ending-balance to change, and we don't want this to happen to historical bills.

How To Add An Adjustment (or Payment) To A Completed Bill

If you want to add an adjustment to a completed bill perform the following steps:

- Add and freeze the adjustment ([Adjustment - Main Information](#)).
- Navigate to the [Bill - Main](#) page.
- Click the [Reopen](#) button to reopen the previously completed bill.
- Click the [Complete](#) button to recomplete the bill. When the bill is recompleted, the system will sweep the recently created financial transactions onto itself.

You can add a payment to a bill using an analogous approach - Add the payment, Reopen the bill, Complete the bill.

Note:

Cannot reopen historical bills. You may only reopen an account's most recent bill because reCompleting the bill causes the ending-balance to change, and we don't want this to happen to historical bills.

How To Reprint A Bill (For The Original Recipients or For Someone New)

A copy of a bill is sent to every individual / business specified in the [bill's routing details](#). The system creates the routing details when a bill is completed. Refer to [The Source Of Bill Routing Information](#) for more information about how this information is compiled during bill completion.

If you want to reprint a bill OR if you want to send a bill to someone other than the original recipient(s):

- Navigate to the [Bill - Main](#) page.
- Transfer to the [Bill - Bill Routings](#) tab.
- Insert a new row (click the + button). Note well, you can only insert information on a bill that is Complete.
- Specify the name and address to which the bill should be sent. If you want to send the bill to someone other than the original recipient, simply specify the individual's name and address. If the recipient is a person in the system, you can select their person ID and let the system default this information for you.
- Save the bill.

Note:

If a bill is Complete but the print process hasn't yet executed, you don't have to insert a new routing row. Rather, you can simply change the name and address on the original routing details.

How To Add Ad Hoc Messages To A Bill

If you want to add a message to a completed bill:

- Navigate to the [Bill - Main](#) page.
- Transfer to the [Bill - Bill Messages](#) tab.
- Insert a new row (click the + button). Note, you can only insert a message on the most recent bill that is Complete.
- Specify the desired message code.
- Save the bill.
- Reprint the bill as per [How To Reprint A Bill \(For The Original Recipients or For Someone New\)](#).

Fastpath:

Refer to [The Source Of Bill Messages](#) for more information about the messages the system automatically links to a bill when the bill is completed.

How To Remove A Completed Bill

You can't physically remove a completed bill from the system. However, you can remove all financial transactions from the bill (and therefore end up with a zero value bill). You can also suppress the bill from being printed. To do this, perform the following steps:

- If the bill has bill segments, cancel each bill segment. Refer to [How To Cancel A Bill Segment](#) for instructions describing how to do this.
- If the bill has payment amounts or adjustment amounts that were entered incorrectly, navigate to the payment and/or adjustment pages and cancel the payments / adjustments.
- Navigate to the [Bill - Main](#) page.
- Click the [Reopen](#) button to reopen the previously completed bill.
- Transfer to the [Bill - Bill Routings](#) tab. Turn on the Do Not Print switch for every routing entry.
- Click the [Complete](#) button to recomplete the bill. When the bill is recompleted, the system will sweep the canceled segments onto it and the net effect should be zero current charges.

Note:

Cannot reopen historical bills. You may only reopen an account's most recent bill because reCompleting the bill causes the ending balance to change, and we don't want this to happen to historical bills.

If the bill has payment amounts or adjustment amounts that are valid, but you don't want them to appear on this bill, navigate to the **Menu > Financial > Bill > Search** and navigate to the **Financial Details** page. Drill over to each respective financial transaction by clicking the drill down button. Clicking this button transfers you to [Financial](#)

[Transaction - Main](#). On this page, clear out the value of the Bill ID. Clearing out the Bill ID unlinks the financial transaction from the bill. When the system next completes a bill for the account, it will find the unbilled financial transaction and link it to the bill.

How To Display A Bill On-line

There are multiple ways to display a bill. Each requires the use of the Installation Option — Online Bill Display plug-in spot.

- One method is to make a call to retrieve a bill image from an external source. Many bill print vendors support this method and support REST or web service calls to request the bill image, often in the PDF format. The system is delivered with an algorithm that can construct a URL to retrieve a bill image.
- Another method uses software to render the bill in a format suitable for displaying. You must configure the system to invoke this software; otherwise, you will get a message indicating that the service is not available. This option can only be configured by your technical staff. The system can be configured to work with different bill production software, and is delivered with an algorithm that can display a bill on-line using BI Publisher or a document composition application. With a document composition application, the bills are presented in PDF format.

To view a bill on-line, click the **Display Bill** button. For any method that present the bill as a PDF, you must have Adobe® Acrobat® Reader installed.

Financial Transactions On A Bill

Open **Menu > Financial Query > Financial Transactions On A Bill** to view this information.

Note:

You can also open this page using the go to buttons that prefix the financial transaction summaries on [Bill - Main](#).

Description of page

Bill Id is the system-assigned unique identifier of the bill.

Account ID is the bill's account.

The area beneath **Account ID** provides you with options that control which financial transactions appear in the grid. The following points describe the various options:

- Use the **SA Filter** to define the types of service agreements whose financial transactions appear in the grid. The following options are available:
 - Address. Use this option to restrict financial transactions to those whose service agreements are linked to service points associated with a given **Address, City** and/or **Postal** code.
 - All. Use this option if you do not wish to restrict financial transactions based on service agreement attributes.
 - Geographic Type. Use this option to restrict financial transactions to those whose service agreements are linked to service points associated with a given **Geo Type** and **Value**.
 - SA ID. Use this option to restrict financial transactions to those of a specific service agreement.
 - SA Type. Use this option to restrict financial transactions to those whose service agreements are linked to a given **CIS Division** and **SA Type**.
- Use **FT Type Filter** to restrict the type of financial transactions that appear in the grid. The following options are available:
 - Adjustments. This option shows all financial transactions associated with adjustments.
 - All. This option shows all financial transactions.
 - Corrections. This option shows all financial transactions associated with corrections (i.e., cancel / rebills that have occurred after the bill was completed).

- **Current Charges.** This option shows all financial transactions associated with bill segments (that aren't Corrections).
- **Payments.** This option shows all financial transactions associated with payments.
- Use **Match Event Status Filter** to restrict the financial transactions based on the status of their [match event](#). This filter only appears if the bill's account is an [open-item](#) customer. The following options are available:
 - **All.** This option shows all financial transactions.
 - **Balanced.** This option shows all financial transactions whose match event is balanced.
 - **Disputed.** This option shows all financial transactions whose match event is disputed.
 - **Unbalanced.** This option shows all financial transactions whose match event is unbalanced.
 - **Unmatched.** This option shows all financial transactions that are not linked to a match event.

Warning:

Don't forget to click the search button after changing the filters or after selecting a new Bill ID.

The grid that follows contains the financial transactions that match your search criteria. The following information is displayed:

- **Match Event Status** shows the status of the financial transaction's [match event](#). This column only appears if the bill's account is an [open-item](#) customer.
- **FT Type** displays the type of financial transaction except for adjustments. For adjustments, the adjustment type's description is shown. Click on the hyperlink to transfer to [Financial Transaction - Main](#). On this page, you can change certain aspects of the FT in question. Refer to [How To Remove Unwanted Adjustments \(or Payments\) From A Completed Bill](#) for a description of how to perform common maintenance functions.
- **Accounting Date** is the date the system uses to determine the financial transaction's accounting period in your general ledger.
- **Current Amount** contains the financial transaction's effect on the service agreement's current balance.
- **Payoff Amount** contains the financial transaction's effect on the service agreement's payoff balance. The **Payoff Amount** will be dim if it equals the **Current Amount**.
- **Show on Bill** indicates if information about the financial transaction appears on the customer's bill.
- **SA Information** contains a summary of the respective service agreement.
- **Financial Transaction ID** is the system-assigned unique identifier of the financial transaction.

At the bottom of the page is a summary of the financial transactions that match the search criteria.

Maintaining Bill Segments

A bill typically contains one bill segment for every active service agreement linked to its account. A bill segment contains information showing how the segment was calculated and how it should be printed on the customer's bill.

The actions taken to create a bill segment are dependent on the service agreement's SA type. For example, a service agreement that charges for metered service is produced as follows:

- The system calculates the amount of the commodity that was consumed; for example, the number of lamps, the number of gallons of water, or the peak kW. Refer to [How The System Determines How Much Was Consumed](#) on page 311 for more information.
- The service agreement's rate is applied to the amount consumed to calculate how much the customer owes for the service. A bill segment and a financial transaction are generated to reflect the results of this calculation. Refer to [How Rates Affect The Information On Bill Segments](#) for the details. Refer to [Effective Dates & Price Proration](#) for information about how the system prorates changes to rates and prices during a bill period.

Note:

SA type controls everything. The above points explain how a bill segment is produced for a **metered** service agreement. It's important to be aware that the system has other bill segment creation algorithms. For example, if the service agreement charges for a deposit, the system neither amalgamates consumption nor does it apply a rate. You may be wondering how the system knows which method to use? It uses the bill

segment type on the service agreement's SA type. Refer to [Designing and Defining Bill Segment Types](#) for a description of the various bill segment creation algorithms that are supported in the system.

It's important to be aware that there are very few fields that are directly modifiable by a user. To modify most fields on a bill segment, you have to change source information (e.g., service agreement, rate, meter read) and then regenerate the bill segment. For example, if you want to change the rate used to calculate a bill segment, you must change the rate history on the respective service agreement and then cancel / rebill the bill segment. Refer to [How To](#) for step-by-step instructions that explain how to perform common bill segment maintenance functions.

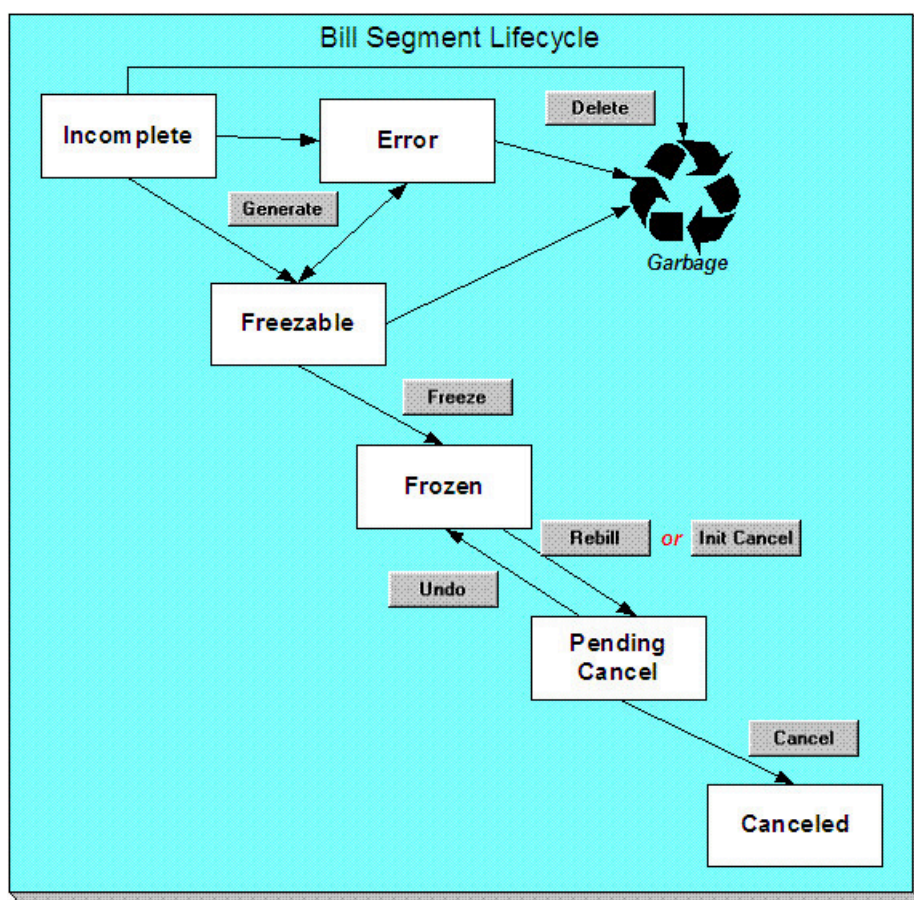

Bill Segment Lifecycle

The following diagram shows the possible lifecycle of a bill segment.

Warning:

This diagram only makes sense in the context of the page used to maintain bill segments. Refer to [Bill Segment - Main Information](#) for the details.

Bill segments are initially created in the Incomplete state. Bill segments in this state don't have bill lines or a financial transaction; they are simply a stub awaiting generation.

Click **Generate** to generate the bill segment's bill lines and its financial transaction.

- If the system cannot generate the bill segment (for any number of reasons), the bill segment is moved to the Error state. You may regenerate the bill segment after correcting the source of the error (by clicking **Generate**). You may also delete such a bill segment.
- If the system successfully generates a bill segment, the bill segment becomes Freezable. If the bill segment is incorrect, correct the cause of the problem (e.g., fix the meter read, change the service agreement's rate) and regenerate the bill segment (by clicking **Generate**).

Click the delete button to physically remove an Incomplete, Error or Freezable bill segment from the database. Note, batch billing will delete unfrozen bill segments when it attempts to create bill segments for an account that has unfrozen bill segments. Also note, if you've plugged-in the appropriate pre-completion algorithm, the system will delete bill segments in error on the last night of the bill cycle. Refer to DEL-BSEG for more information.

Click **Freeze** to freeze a bill segment and its financial transaction. After doing this, the bill segment's state becomes Frozen and the bill segment may now appear on a customer's bill. Also note, when a bill segment is frozen, its financial details will be interfaced to the general ledger the next time the [GL interface](#) executes.

You may not change a bill segment once it is frozen. However, you have two options if you want to change a frozen bill segment's financial impact:

- If you need to remove the financial effects of a bill segment, click **Init Cancel**. Clicking this button causes a new financial transaction to be generated and linked to the bill segment. This financial transaction reverses the financial effects of the original bill segment. The bill segment becomes Pending Cancel after the system successfully generates this financial transaction. At this point, you have two options:
- Click **Cancel** to freeze the cancellation. Clicking this button causes the bill segment to move to the Canceled state. Once canceled, the bill segment cannot be uncanceled or changed.
- Click **Undo** to return the pending cancellation to the Frozen state.
- Click **Rebill** if you need to recalculate the bill segment because something has changed since it was originally created (e.g., the service agreement's rate was changed, a new read was entered). Clicking this button causes the following events to take place:
 - The original bill segment is moved to the Pending Cancel state.
 - A new bill segment is created in the Freezable (or Error) state.

At this point, you have two options.

- Click **Freeze** to make the new bill segment Frozen and make the original bill segment Canceled.

Note:

Multi-Cancel/Rebill Saves Time. If you need to rebill many bill segments related to a service agreement (e.g., because many bill segments were created using the wrong rate), you should use the [Multi Cancel Rebill](#) transaction as it allows you to cancel / rebill an unlimited number of bill segments at once.

Using the cancel and cancel/rebill functionality will cause the cancel and rebill details to be swept on to the customer's next bill. If your organization requires cancellation details to be presented to the customer separately from the new bill, then you will need to use Credit Notes. Refer to [Credit Notes - Presenting Cancellation Details on a Separate Bill](#) for more information.

- Click **Undo** to delete the new bill segment and return the original bill segment to the Frozen state.

Bill Segment - Main Information

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To](#) for a description of how to perform common bill maintenance functions.

The Main page contains core bill segment information. Open **Menu > Financial > Bill Segment > Search** to view this information.

Note:

Most bill segments are created by a background process. Refer to [A High Level Overview Of The Bill Creation Process](#) for information describing how the system creates a bill segment.

Description of Page

Bill Seg Info is a concatenation of the bill segment's division, SA type, status, bill period and amount. **Bill Segment ID** is the system-assigned unique identifier of the bill segment.

Account ID references the bill segment's account.

Current Amount is the bill segment's effect on the service agreement's current balance. **Payoff Amount** is only shown if it differs from current amount. Refer to [Billing - Current Balance versus Payoff Balance](#) for more information.

Bill ID is the system-assigned unique identifier of the bill on which the bill segment appears. A concatenation of its bill date, status, due date and amount is displayed.

SA ID contains information about the bill segment's service agreement. A concatenation of the service agreement's division, SA type, start option (if any), status and start date is displayed.

If the [quotation](#) module is not [turned off](#), you can generate [simulated bill segments](#) when you create a quote. You can view simulated bill segments by drilling down on the desired bill segment from [Quote - Quote Details](#). When a simulated bill segment is displayed on this page, the **Billing Scenario ID** that controlled the bill segment's billing period (and consumption) is displayed. Refer to [Creating Quotes And Quote Details](#) for more information.

Period is the start and end dates of the bill segment.

Usage Period is the period used by the meter data management system to determine the correct interval data to process for the bill segment. This field appears when the bill segment is for an SA that has Bill Determinants Required for the special role flag.

Bill Cycle displays the bill cycle and window start date of the bill segment's bill. This information is only populated on bills when they are generated on-schedule by the batch billing background process. Bills generated manually, i.e. off-schedule, do not have this information.

Status is the bill segment's status. Refer to [Bill Segment Lifecycle](#) for the potential values and how to handle a bill segment when it exists in a given state.

If the **Closing** switch is on, this is the final bill segment for the service agreement (i.e., the service agreement has been stopped and this is the final bill segment).

Note:

The closing switch is not set for sub SA bill segments nor billable charge SA bill segments.

If the **Estimate** switch is on, consumption on this bill segment has been estimated by the system. Refer to [The Theory Behind Consumption Estimation](#) for more information.

If the **SQ Override** switch is on, a user has overridden the service quantities (i.e., the amount of consumption for which the customer is charged is not consistent with the customer's meter reads). This switch is also set if a user has overridden the [calculation/audit read details](#). Refer to [How To Override Service Quantities On A Specific Bill Segment](#) for more information.

If the **Item Override** switch is on, a user has overridden the type and/or number of items (i.e., the type/number of items for which the customer is charged is not consistent with the customer's service point information). Refer to [How To Override The Items Billed On A Specific Bill Segment](#) for more information.

If this bill segment was created for a [sub service agreement](#) where we calculate the charges (i.e., not for a "pass through" billing situation):

- **SA Rel ID** shows the unique identifier of the record that defines the relationship between the sub service agreement and the master service agreement (this record shows the service provider associated with the bill segment). Click the go to button to transfer to this record.
- **Master Bseg ID** shows the unique identifier of the master bill segment whose bill triggered the creation of this sub service agreement. This bill segment's consumption was used to calculate the charges on this bill segment.

Premise is the address of the main premise associated with the service agreement (as defined on the service agreement's characteristic premise). It's important to note that the service agreement may cover service at multiple premises, but only one may be defined as the main premise.

Create Dt/Tm is the date and time on which the bill segment was created or regenerated.

In the **Message** area, a brief error message appears if there's a problem with the bill segment. The message area is suppressed if there are no problems with the bill.

Push the magnifying glass button to view the long explanation. The long explanation will provide information about the cause of the error (and how to fix it).

If the bill segment is a rebill of a canceled bill segment, a reference to the original bill segment is displayed. Click the adjacent go to button to transfer to the bill segment that was canceled.

If the bill segment was canceled and rebilled by another segment, a reference to the new bill segment is displayed. Click the adjacent go to button to transfer to the new bill segment that superseded the canceled segment.

The topics that follow describe each of the actions on that appear in the **Bill Segment Actions** area. Refer to [How To](#) for a description of typical business processes that use these buttons.

Note:

Mass update actions. This page allows you to work on individual bill segments. If you want to update many bill segments linked to a bill at once, try using the mass update actions available on [Bill -Bill Segments](#).

Generate (Bill Segment)

Click the **Generate** button to create a new a bill segment.

This button is enabled when either of the following conditions is true:

- You are in add mode (i.e., you are not displaying an existing bill segment) and you have selected an **Account ID**, **Bill ID** and **SA ID**.
- You are displaying a bill segment that is Incomplete, Error, or Freezable. Refer to [Bill Segment Lifecycle](#) for more information about these status values.

When clicked, the **Generate** window opens.

You must specify the following parameters to generate a new bill segment:

- **Cut-off Date** is the last possible day of the bill segment's bill period. The current date defaults when the window opens. Refer to [Ways To Control The End Date Of A Bill Segment](#) for more information.
- **Accounting Date** is used to define the financial period to which the new bill segment's financial transaction will be booked. The current date defaults when the window opens.
- Turn on **Allow Estimates** if the system is allowed to estimate consumption if it can't find a meter read.
- If the service agreement uses meter reads, use the **Billing Option** to control how the system retrieves meter reads that appear on the bill. Choose Use Cut off Date if the meter reads must exist on the **Cutoff Date** (defined above). Choose Use Schedule if you want the service agreement's service point(s) service cycle schedule to control the meter reads that are used (the schedule effective on the cutoff date is used to select the meter reads).

After specifying the above parameters, click the **Calculate** button to create a new bill segment for the bill.

If an error exists, refer to [How To Correct A Bill Segment That's In Error](#).

If there are no errors, the **Bill Segment Freeze Option** on the [installation option](#) controls the next step:

- If this option is set to Freeze At Bill Completion, return to [Bill - Main](#) (using the bill context menu) and click the [Freeze / Complete](#) button.
- If this option is set to Freeze At Will, click the [Freeze](#) button and, if everything looks clean, return to [Bill - Main](#) and click the [Complete](#) button.

Delete (Bill Segment)

The **Delete** button deletes a bill segment.

This button is enabled if you are displaying a bill segment that is Incomplete, Error, or Freezable. Refer to [Bill Segment Lifecycle](#) for more information about these status values.

Freeze (Bill Segment)

Clicking the **Freeze** button causes a freezable bill segment to become frozen. Refer to [Bill Segment Lifecycle](#) for more information about freezing.

This button is enabled if:

- the Freeze At Will **Bill Segment Freeze Option** on the [installation option](#) has been selected AND
- the bill segment is freezable.

Note:

Freezing a day or more after generation. If the bill segment is linked to a closed accounting period, a pop-up appears in which you can specify a new accounting date. This will only happen if the accounting period closes before you freeze the bill segment (the accounting date is stamped on a bill segment when it's initially generated).

If problems are detected after freezing. A bill segment may not be changed after it is frozen. All subsequent changes must occur by canceling the frozen bill segment and creating a new bill segment. Refer to [How To Cancel A Bill Segment](#) and [How To Cancel / Rebill A Bill Segment](#) for more information.

Rebill (Bill Segment)

If problems are detected with a frozen bill segment, it should be canceled and a new bill segment should be created. We refer to this process as cancel / rebill. Refer to [Cancel / Rebill Incorrect Bill Segments](#) for more information.

Before you cancel / rebill, you'll probably need to fix the cause of the problem. The following table describes common problems and where to go to fix them.

| Problem | How To Fix It |
|--|---|
| The wrong rate was used | Go to Service Agreement - Rate Info and correct the rate. |
| The wrong meter read was used | Add a meter read with a more powerful read type for the service point in question. |
| The wrong meter was connected to the service point | Go to SP / Meter Installation and correct the SP / Meter linkage. Then go to Service Agreement - SA / SP and indicate the appropriate start read for the service point's correct meter. |
| A contract rider was applied incorrectly | Go to Service Agreement - Rate Info and correct the contract rider information. |
| The wrong tax exemption amount was calculated | Go to Service Agreement - Rate Info and correct the tax exemption information. |

Note:

Multi-Cancel/Rebill Saves Time. If the cause of the problem impacts many bill segments related to a service agreement, you should use the [Multi Cancel Rebill](#) transaction as it allows you to cancel / rebill an unlimited number of bill segments at once.

Credit Notes. Using the cancel/rebill functionality will cause the cancel and rebill details to be swept on to the customer's next bill unless you [Reopen](#) the bill. If your organization requires cancellation details to be presented to the customer separately from the new bill, you should not use the **Rebill** functionality. Rather, you should issue a [Credit Note](#) and then generate a new bill containing the revised charges.

The **Rebill** button causes an existing bill segment to be canceled, and a new bill segment to be created.

This button is enabled when you display a Frozen bill segment AND the bill segment's bill is not written off AND the bill segment's bill is not linked to an off cycle bill generator. Refer to [Bill Segment Lifecycle](#) for more information about these status values.

When clicked, the **Rebill** window opens.

You must specify the following parameters to cancel and rebill a new bill segment:

- **Cancel Reason** defines why the bill segment is being canceled.
- **Cutoff Date** is the last day of the new bill segment. The cutoff date on the bill segment defaults when the window opens.
- **Accounting Date** is used to define the financial period to which the canceled and new bill segments' financial transactions will be booked. The current date defaults when the window opens.
- Turn on **Allow Estimates** if the system is allowed to estimate consumption if it can't find a meter read.
- Use the **Billing Option** to define how the system looks for meter reads. Select Use Schedule if the system should select reads based on the SA's SP's service cycle schedule. Select Use Cut off Date if the system should only select reads from the end date of the existing bill segment.
- Turn on **Use Old Read/Item/SQ for Regen** if you want the system to use the consumption details on the original bill segment when it calculates the new bill segment.

Click the **Calculate** button to cancel the original bill segment and create a new bill segment.

At this point, there are now two bill segments - the original bill segment is in the state of Pending Cancel, the new bill segment is in the Freezable (or Error) state. If you want to back out, click the go to button to return to the original bill segment and then click **Undo** (this will delete the new bill segment and return the original bill segment to the Frozen state). If the new bill segment looks correct, click **Freeze** to move the original bill segment to the Canceled state and the new bill segment to the Frozen state.

Init Cancel (Bill Segment)

The **Init Cancel** button causes the first step of the bill segment cancellation process to be executed. You'd click this button if a frozen bill segment should never have been created (i.e., you want to remove the financial impact of a bill segment from a customer's balance).

This button is enabled when you display a Frozen bill segment AND the bill segment's bill is not written off. Refer to [Bill Segment Lifecycle](#) for more information about these status values.

When clicked, the **Cancel** window opens.

You must specify the following parameters to cancel and rebill a new bill segment:

- **Cancel Reason** defines why the bill segment is being canceled.
- **Accounting Date** is used to define the financial period to which the canceled bill segment's financial transactions will be booked. The current date defaults when the window opens.

Click the **Calculate** button to cancel the original bill segment.

At this point, the bill segment is in the state of Pending Cancel. If you want to back out, click **Undo**; the bill segment will be returned to the Frozen state. Click **Cancel** to move the bill segment to the Canceled state.

Note:

Credit Notes. Using the cancel functionality will cause the cancel details to be swept on to the customer's next bill unless you **Reopen** the bill. If your organization requires cancellation details to be presented to the customer separately from the new bill, you should not use the cancel functionality. Rather, you should issue a **Credit Note** and then generate a new bill containing the revised charges.

Undo (Bill Segment)

The **Undo** button returns a Pending Cancel bill segment to the Frozen state. If a Pending Cancel bill segment was created during a Cancel / Rebill, the newly created Freezable bill segment is also deleted.

This button is enabled when you display a Pending Cancel bill segment. Refer to [Bill Segment Lifecycle](#) for more information about this status.

Cancel (Bill Segment)

Clicking the **Cancel** button causes a Pending Cancel bill segment to become Canceled. Refer to [Bill Segment Lifecycle](#) for more information about cancellation.

This button is enabled if a Pending Cancel bill segment is displayed AND the bill segment's bill is not written off.

When clicked, the **Cancel** window opens.

You must specify the following parameters to cancel the frozen bill segments:

- **Cancel Reason** defines why you are performing the cancellation.
- **Accounting Date** defines the financial period to which the canceled bill segments' financial transactions will be booked. The current date defaults when the window opens.

After specifying the above parameters, click the **Calculate** button to cancel the frozen bill segments.

If the related bill is pending, the cancellation will cause the bill segment to be suppressed on the version of the bill sent to the customer (but it remains in the database for audit and financial reporting purposes).

If the related bill is complete and you do not [Reopen](#) the bill, the financial impact of the canceled bill segment will appear on the next bill created for the account (under Bill Corrections).

If the related bill is complete you may be able to [Reopen](#) the bill and then [Complete](#) it. By doing this, you can suppress a frozen bill segment on a previously completed bill. This means that if you catch a problem after completion you don't necessarily have to show the problem to the customer. Rather, cancel the problem, reopen and then recomplete the bill (when you recomplete the bill the system will mark the bill segment to be suppressed on the version sent to the customer because its cancellation appears on the same bill as the original charges).

Credit Note (Bill Segment)

The **Credit Note** button is used to cancel a bill segment and create a new bill that contains the cancellation details. We refer to this "negative bill" as a credit note. Refer to [Credit Notes - Presenting Cancellation Details on a Separate Bill](#) for more information.

Note:

If you want to issue a credit note for an entire bill. Rather than cancel a specific bill segment, functionality exists that allows you to create a credit note for ALL bill segments on a bill. To use this feature, display the bill in question and then click the **Credit Note** button on the [bill page](#).

This button is enabled if:

- the **Use Credit Notes** option on the [Installation](#) record is turned on AND
- the bill segment is frozen AND
- the bill segment's bill is not written off.

When clicked, the **Credit Note** window opens.

You must specify the following parameters to cancel the frozen bill segment:

- **Cancel Reason** defines why you are performing the cancellation.
- **Accounting Date** defines the financial period to which the canceled bill segment's financial transaction will be booked. The current date defaults when the window opens.
- **Credit Note Date** defines the date of the credit note on which the cancellation details will appear. The current date defaults when the window opens.

After specifying the above parameters, click the **Calculate** button to cancel the frozen bill segment and create a credit note.

It should be noted that if this operation is successful, the new "negative bill" will be complete (meaning that it will be ready for transmission to the customer and for interface to the general ledger).

Bill Segment - Read Details

The Read Details page contains information about the meter reads that were used to derive the bill segment's metered consumption. Open **Menu > Financial > Bill Segment > Search** and navigate to the **Read Details** page to view this information.

Note:

Refer to [How The System Determines How Much Was Consumed](#) for how the system assembles this information.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To](#) for a description of how to perform common bill maintenance functions.

Description of Page

Bill Seg Info is a concatenation of the bill segment's division, SA type, status, bill period and amount. **Bill Segment ID** is the system-assigned unique identifier of the bill segment.

The meter read grid is a snapshot of the meter reads used to calculate the bill segment's consumption. One row exists for every register linked to every meter linked to every service point linked to the service agreement. This information is for audit purposes only and may not be modified. The following information is displayed in the grid:

- **Final Unit of Measure** is the unit of measure of the resultant billing quantity.
- **Final Time of Use** is the time-of-use code of the resultant billing quantity.
- **Final Service Quantity ID** is the service quantity identifier of the resultant billing quantity.
- **Register Quantity** is the resultant billing quantity. See Measured Quantity below for more information.
- **Service Point ID** is the unique identifier of the service point at which the meter was located.
- **Meter Configuration ID** is the unique identifier of the meter's configuration.
- **Sequence** is the sequence number of the register on the meter.
- **Unit of Measure** is the register's unit of measure.
- **Time of Use** is the register's time-of-use code.
- **SQI** is reserved for future use.
- **Start Register Reading** is the start register reading. If the register is consumptive, (as opposed to subtractive) the word N/A - Consumptive is displayed, as the start read is not relevant. Click the Go to button to drill down into the meter read.
- **End Register Reading** is the end register reading. Click the Go to button to drill down into the meter read.
- **Measured Quantity** is the resulting measured quantity.

Note:

Measured quantity isn't necessarily the difference between the start and end read. The measured quantity is equal to the Measured Quantity * Register Constant * Installation Constant * Use Percent.

Measured quantity isn't necessarily the quantity that's billed. If the rate used to calculate the bill segment has a pre-processing calculation group, this consumption will be transformed further. For example, a cubic foot of gas can be transformed by a calculation rule to a therm of gas. When calculation rules convert measured consumption, they do NOT overwrite the measured quantity. Rather, they populate the Final UOM, Final TOU, Final SQI, and Register Quantity with the final billable quantity. Refer to [All Calculation Rule-Based Rates Share a Common Structure](#) for more information about pre-processing calculation groups.

- **Register Constant** is the constant on the register multiplied by the installation constant on SP Meter History. The resulting value is then used in calculating Measured Quantity.
- **How To Use** is the register's how to use code.

- **How To Use (SP)** is the SA/SP's how to use code.
- **Use Percent** is the SA/SP's usage percentage.
- **Measures Peak Qty** indicates if the unit of measure is one that measures peak consumption.
- **Start Read Date/Time** is the date and time of the start meter read. If the register is consumptive, (as opposed to subtractive) nothing will be displayed.
- **End Read Date/Time** is the date and time of the end meter read.
- **Start Reg Read ID** is the unique identifier of the start register read. If the register is consumptive, (as opposed to subtractive) nothing will be displayed.
- **Read Type** is the read type of the start meter read.
- **End Reg Read ID** is the unique identifier of the end register read.
- **Read Type** is the read type of the end meter read.
- **Multiplier** is the composite multiplier that converts the measured quantity to the registered quantity.

Note:

The multiplier is calculated by dividing the Register Quantity by the Measured Quantity (if the Measured Quantity is 0, then the result is 0). This is not stored on the database. There is a chance that the value is not precise due to round-off.

Bill Segment - Item Details

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Override The Items Billed On A Specific Bill Segment](#) for a description of how to override this information.

The Item Details page contains information about the items located at the service agreement's service points. Open **Menu > Financial > Bill Segment > Search** and navigate to the **Item Details** page to view this information.

Note:

Refer to [How The System Determines How Much Was Consumed](#) for how the system assembles this information.

Description of Page

Bill Seg Info is a concatenation of the bill segment's division, SA type, status, bill period and amount. **Bill Segment ID** is the system-assigned unique identifier of the bill segment.

The item details grid is a snapshot of the items that existed at the service agreement's service points at the time the bill segment was created. One row exists for every type of item linked to every service point linked to the service agreement.

This information may be modified on a bill segment in the Error or Freezable state. Insert one row in the item grid (click the + button) for each item you need to add. You may also change item amounts that were populated by the system when it initially generated the bill by simply overwriting the information.

Warning:

The proper way to fix the number and type of items on a bill segment is to correct the service point / item information and then regenerate the bill segment. Overriding the item details on a bill segment is a last resort that should only be used when you cannot fix the service point / item information (for whatever reason).

The following information is displayed in the grid:

- **Seq No** is the system-assigned unique identifier of the item detail row.
- **Item Type** is the type of item.
- **Item ID** is the unique identifier of the item (this is only displayed if a badged item is linked to the service point; non-badged items don't have unique identities).
- **Start Date** is the first day in the bill segment's bill period that the item was linked to the service point.
- **End Date** is the last day in the bill segment's bill period that the item was linked to the service point.

- **Item Count** is the number of items of this type that were linked to the service agreement's service points.
- If the item's item type indicates the system must estimate consumption (e.g., lamps), **UOM** is the unit of measure of the estimated consumption. **Daily Service Quantity** is the item's estimated amount of daily consumption.

Fastpath:

Refer to [Setting Up Item Types](#) for more information about item types. Refer to [Setting Up Estimated Consumption For Items](#) for more information about defining the estimated consumption amount for items.

Fastpath:

Bill Segment - SQ Details

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Override Service Quantities On A Specific Bill Segment](#) for instructions describing how to override this information.

The SQ Details page contains information about the [service quantities \(SQ\)](#) that will be priced by the service agreement's rate. In addition to showing SQ details, this page shows any [Calculation / Audit Read Details](#) and [Calculation / Audit Usage Details](#) on page 315 that are linked to the bill segment. Open **Menu > Financial > Bill Segment > Search** and navigate to the **SQ Details** page to view this information.

Description of Page

Bill Seg Info is a concatenation of the bill segment's division, SA type, status, bill period and amount. **Bill Segment ID** is the system-assigned unique identifier of the bill segment.

The **Service Quantity** details grid is a snapshot of the service quantities amassed from:

- The [bill segment's meter reads](#).
- The bill segment's usage request.
- Those items for which the system estimates consumption. Refer to [Setting Up Estimated Consumption for Items](#) for more information.
- [Billable charges](#) that supply service quantities.

One row exists for every unique combination of unit of measure (UOM), time-of-use (TOU) code, and service quantity identifier (SQI) associated with the service agreement. Refer to [UOM versus TOU versus SQI](#) for more information.

This information may be overridden on a bill segment in the Error or Freezable state. Insert one row in the service quantity grid (click the + button) for each UOM/TOU/SQI you need to add. You may also change amounts that were populated by the system when it initially generated the bill by simply overwriting the information.

Warning:

The proper way to fix the SQ details on a bill segment is to correct the cause of the error (e.g., correct the meter reading). Overriding the SQ details on a bill segment is a last resort that should only be used when you can't fix the cause of the problem. Refer to [How To Cancel / Rebill A Bill Segment](#) for ways to fix common problems.

The following information is displayed in the grid:

- **Unit of Measure** is the unit of measure of the service quantity.
- **Time of Use** is the time-of-use of the service quantity.
- **SQI** is the service quantity identifier of the service quantity.
- **Initial Service Quantity** is the initial quantity amassed by the system before application of the rate's pre-processing calculation group(s), if any exists.
- **Billable Service Quantity** is the service quantity that will be priced by the service agreement's rate. This amount differs from the initial service quantity when the rate's pre-processing calculation rule(s) manipulate consumption.

The **Calculation/Audit Read Details** section contains [Calculation / Audit Read Details](#). This section only appears if any of the following conditions are true:

- The service agreement has a special role of , Bill Determinants Required, or Interval Billing.
- The bill segment has one or more reads with a usage flag of Calculation/Audit .

The following information may be defined for each calculation / audit read:

- **Final Unit of Measure** is the final unit of measure of the calculation / audit read.
- **Final Time of Use** is the final time-of-use code of the calculation / audit read.
- **Final SQI** is the final service quantity identifier of the calculation / audit read.
- **Start Date/Time** is the date and time of the calculation / audit read.
- **End Date/Time** is the date and time of the calculation / audit read.
- **Quantity** is the quantity of the calculation / audit read. This would typically contain the amount that was billed during the **Start Date/Time** through the **End Date/Time** for the **Final Unit of Measure**, **Final Time of Use** and **Final SQI**.
- **Unit of Measure** is the initial unit of measure of the calculation / audit read (if any).
- **Time of Use** is the initial time-of-use code of the calculation / audit read.
- **SQI** is the initial service quantity identifier of the calculation / audit read.
- **Start Quantity** is the "start" quantity (if any). This value would typically only be displayed if the calculation / audit read is subtractive (i.e., you must subtract the end quantity from the start quantity to determine billable consumption).
- **End Quantity** is the "end" quantity (if any). This value would typically only be displayed if the calculation / audit read is subtractive (i.e., you must subtract the end quantity from the start quantity to determine billable consumption).
- **Measured Quantity** is the resulting measured quantity (if any). This value would typically only be displayed if the calculation / audit read is subtractive (i.e., you must subtract the end quantity from the start quantity to determine billable consumption). It should contain the difference between the **Start Quantity** and the **End Quantity**.
- **Constant** is the constant of the measuring device that was multiplied by the **Measured Quantity** to derive the calculation / audit read's **Quantity**.
- **How To Use** is a code that indicates if the "calculation / audit" read was is considered to be additive, subtractive, peak or check.
- **Use Percent** is the percentage of the total consumption that was billed.
- **Meas Peak Qty** indicates if the unit of measure is one that measures peak consumption.
- **Multiplier** is the ratio of the **Quantity** and the **Measured Quantity**. This value only appears if a non-zero value exists in both of these fields.
- **Seq No** is the sequence number (if any).
- **Service Point** is the unique identifier of the service point at which the readings were calculated (if applicable).

This information may be overridden on a bill segment in the Error or Freezable state. Insert one row in the calculation / audit details grid (click the + button) for each entry you need to add. You may also information populated by the system when it initially generated the bill by simply overwriting the information.

Warning:

The proper way to fix the calculation/audit details on a bill segment is to correct the cause of the error. Overriding the calculation/audit details on a bill segment is a last resort that should only be used when you can't fix the cause of the problem.

Fastpath:

Refer to [Calculation / Audit Read Details](#) for more information about this section.

The **Calculation/Audit Usage Details** grid contains usage service quantities for the bill segment. This section appears when the service agreement has a special role of Bill Determinants Required. The following information is displayed in the grid:

- **Final Unit of Measure** is the final unit of measure of the calculation / audit usage.

- **Final Time of Use** is the final time-of-use code of the calculation / audit usage.
- **Final Service Quantity ID** is the final service quantity identifier of the calculation / audit usage.
- **Start Date/Time** is the date and time of the calculation / audit usage.
- **End Date/Time** is the date and time of the calculation / audit usage.
- **Quantity** is the quantity of the calculation / audit usage. This would typically contain the amount that was billed during the **Start Date/Time** through the **End Date/Time** for the **Final Unit of Measure**, **Final Time of Use** and **Final SQI**.
- **Sequence** is the sequence number.
- **Service Point ID** is the unique identifier of the service point at which the usage was calculated.

Fastpath:

Refer to [Calculation / Audit Usage Details](#) for more information about this section.

Bill Segment - Calc Lines

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Cancel / Rebill A Bill Segment](#) for instructions describing how to regenerate this information if the bill segment is incorrect.

The Calc Lines page contains information about the bill calculation lines produced when the system generates the bill segment. These lines are the source of the details printed on the customer's bill. Open **Menu > Financial > Bill Segment > Search** and navigate to the **Calc Lines** page to view this information.

Fastpath:

Most service agreements use a rate to calculate the information that appears on this page. Refer to [How Rates Affect The Information On Bill Segments](#) for more information.

Description of Page

Bill Seg Info is a concatenation of the bill segment's division, SA type, status, bill period and amount. **Bill Segment ID** is the system-assigned unique identifier of the bill segment.

The Bill Segment Header (**Bill Seg Hdr**) scroll contains one entry for every version of the rate that was used to calculate the bill segment's lines. Because most bill segments use a single rate version calculation group, you typically only see one entry in the scroll.

The following information is displayed above the bill calculation line grid.

- **Sequence** will be 1 unless multiple versions of the rate were in effect during the bill period. If there was more than one effective rate version calculation group, there will be a separate set of calc lines for each version applied. The lines that apply to the first part of the bill period would have a Sequence of 1, the lines for the next part of the bill period would have a Sequence of 2 and so on.
- **Start Date - End Date** is the portion of the bill segment period that the calculation details apply. For metered service, this period is referred to as the [consumption period](#).
- **Amount** is the sum of the bill calculation lines in the grid.
- **Desc on Bill** is summary information about the calculation details that will be printed on the customer's bill.
- **Rate Version** is the ID of the rate version calculation group and its effective date. This information only appears if a rate was used to calculate the charges.

The calculation lines grid is a snapshot of how the system calculated the bill segment amount. One row exists for every calculation involved in this process. This information is for audit purposes only and may not be modified. The following information is displayed in the grid:

- An extra column with a drill down button appears if the bill calculation line is the result of an interval pricing rate component or a TOU pricing rate component that contains an audit algorithm. For more information, refer to [Interval Billing Calculation Details](#).

- A drill down button appears in the **Calc Line Char** column if the bill calculation line has characteristics. The **Calc Line Char** column only appears if at least one of the calculation lines has a characteristic.
- **Sequence** is the system-assigned unique identifier of the calculation detail row.
- **Description on Bill** is the information about the bill line that appears on the customer's bill.
- **Calculated Amount** is the calculated amount associated with the bill line.
- The **Print** switch controls whether information about this line will print on the customer's bill.
- The **Appears in Summary** switch defines if this line's amount also appears on a summary line. This switch plays a part at bill print time - those lines that appear in a summary print in the left dollar column, those that don't appear in a summary print in the right dollar column.

The system automatically populates this switch as follows:

- Bill segments created by applying a rate have this switch turned on if the corresponding calculation rule is summarized on a summary calculation rule
- Bill segments created from billable charges use the value of this switch as defined on the billable charge. Refer to [Maintaining Billable Charges](#) for more information.
- **Unit of Measure (UOM)** is the unit of measure of the service quantity priced on the calculation line.
- **Time of Use (TOU)** is the time-of-use code of the service quantity priced on the calculation line.
- **SQI** is the service quantity identifier of the service quantity priced on the calculation line.
- **Billable Service Quantity** is the service quantity priced on the calculation line. This quantity will be different from the measured consumption is there are pre-processing calculation group in effect.
- **Base Amount** is used by calculation lines (e.g. taxes) that are cross-referenced to other calculation lines and whose value(s), therefore, depend on the amounts calculated by those other lines. The Base Amount shows the total amount derived from the cross-referenced line(s) that the current line then used to calculate its billed amount.
- **Rate Component Sequence** refers to the sequence number of the rate component on the applicable rate version calculation group that was used to calculate the line. This is only populated if the original rate engine calculated the charges.
- **Calculation Rule** is the rule that calculated the line. This is only populated if the new rate engine calculated the charges.
- **Measures Peak Qty** is checked if the UOM priced on the calculation line is used to measure a peak quantity.
- **Exempt Amount** is the amount of the calculated charge that the customer doesn't have to pay because they are tax exempt.
- **Distribution Code** is the distribution code associated with the calculation line. This distribution code is used to build the general ledger details on the bill segment's financial transaction.
- **Description** describes the characteristic value that was used when the line's amount was calculated. This information is only displayed if the line was calculated using a bill factor (because only bill factors use characteristic values). Refer to [An Illustration Of A Bill Factor And Its Characteristics](#) for more information.

Bill Segment - Financial Details

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Cancel / Rebill A Bill Segment](#) for instructions describing how to regenerate this information if it is incorrect.

The Financial Details page contains information about the financial effects of the bill segment. Open **Menu > Financial > Bill Segment > Search** and navigate to the **Financial Details** page to view this information.

Note:

Refer to [The Source Of GL Accounts On A Bill Segment's Financial Transaction](#) for how the system compiles this information.

Description of Page

Bill Seg Info is a concatenation of the bill segment's division, SA type, status, bill period and amount. **Bill Segment ID** is the system-assigned unique identifier of the bill segment.

The **Bill Segment FT** scroll contains one entry for every financial transaction (FT) associated with the bill segment. All bill segments have an FT that shows the impact of the bill segment on the general ledger. A bill segment may have an additional FT (for a maximum of two) if it is cancelled. The second FT shows the impact of the cancellation on the general ledger.

The following financial transaction information is displayed above the general ledger distribution grid.

- **FT Type** displays the type of financial transaction (FT).
- **Show on bill** indicates if information about the FT appears on the customer's bill.
- **FT ID** is the system-assigned unique identifier of the FT. Click the go to button to transfer to the [Financial Transaction - Main](#) page. On this page you can change certain aspects of the FT in question. Refer to [How To Remove Unwanted Adjustments \(or Payments\) From A Completed Bill](#) for a description of how to perform common maintenance functions.
- The posted by information that appears adjacent to the FT ID shows the date on which the FT was frozen and the user ID of the user who performed the operation.
- The "Linked to bill on" message appears when the financial transaction is linked to a bill. A FT is linked to a bill the next time a bill is completed for the account. Therefore, if a user cancels a bill segment, the FT associated with the cancellation will not be linked to a bill until the next bill is completed (although the financial effect of the cancellation takes place immediately). Click the adjacent go to button to transfer to the bill on which the FT appears.
- **Current Amount** contains the FT's effect on the service agreement's current balance.
- **Payoff Amount** contains the FT's effect on the service agreement's payoff balance. This field is only visible when the payoff amount differs from the current amount.
- **Accounting Date** is the date the system uses to determine the FT's accounting period in your general ledger.
- **Arrears Date** is the date the FT starts aging.

The journal details grid is a snapshot of the distribution codes used to generate the GL accounts that are affected by the FT. This information is for audit purposes only and may not be modified. The following information is displayed in the grid:

- **Seq** is the system-assigned unique identifier of the distribution line.
- **Distribution Code** is the distribution code used to generate the GL account affected by the distribution line. Drill over to the FT if you need to see the actual GL account.
- **Amount** is the amount debited / credited (credits are shown as negative values).
- **Statistics** and **Statistics Amount** are only specified when a statistical quantity is associated with the distribution line. For example, if the line is associated with a charge for the total number of kilowatt-hours consumed, the statistics code will be the kWh and the statistics amount will be the number of kilowatt-hours associated with the charge.
- **Description** describes the characteristic value that was used when the line's amount was calculated. This information is only displayed if the distribution line was derived from bill calculation lines that were calculated using a bill factor (because only bill factor's use characteristic values). Refer to [An Illustration Of A Bill Factor And Its Characteristics](#) for more information.
- If you have configured your installation options to indicate that **fund accounting** is practiced, the description of the **Fund** associated with this distribution code is displayed.

Bill Segment - Bill Segment Messages

The Messages page is a grid containing one row for every message that appears on the bill segment. Open **Menu > Financial > Bill Segment > Search** and navigate to the **Bill Segment Messages** page to view this information.

Note:

No messages until completion. A bill segment has no messages until it is completed (unless you insert them manually). At completion time, the system assembles messages from the various message sources. Refer to [The Source Of Bill Messages](#) for information about these sources.

The bill may also have messages. Be aware that only service agreement-oriented messages are linked to a bill segment. There may also be account-oriented messages linked to the bill. Refer to [Bill - Bill Messages](#) for information about the page on which account-oriented messages are displayed. Refer to [The Source Of Bill Messages](#) for information about the various message sources and whether each is linked to a bill or a bill segment.

Description of Page

Bill Seg Info is a concatenation of the bill segment's division, SA type, status, bill period and amount. **Bill Segment ID** is the system-assigned unique identifier of the bill segment.

The following columns are displayed in the grid:

- **Msg Code** is the code that identifies the bill message.
- **Message On Bill** is the message associated with the code.
- **Priority** is the bill messages priority (on the printed bill).
- **Insert Code** defines if the bill message causes an insert in the envelope.

Bill Segment - Sub Bill Segments

The Sub Bill Segments page contains the sub bill segments that are associated with the master SA's bill segment. Open this page using **Menu > Financial > Bill Segment > Search** and navigate to the **Sub Bill Segment** page.

Note:

Sub bill segments are only linked to the master SA's bill segment when the master SA has an SA relationship with a We Bill For Them - Rate Ready or an It's Us service provider. Refer to [The Rate Ready Calculation Method](#) for the details.

Description of Page

Bill Seg Info is a concatenation of the bill segment's division, SA type, status, bill period and amount. **Bill Segment ID** is the system-assigned unique identifier of the bill segment.

The following information is displayed in the grid.

- Click the adjacent **Go To** button to transfer to the bill segment.
- The **Bill Segment** column contains a concatenation of the bill segment's business unit, SA type, status, bill period and amount. The business unit and SA type come from the bill segment's service agreement.
- The **Current Amount** column contains the bill segment's effect on the sub service agreement's current balance.
- The **Status** column contains the bill segment's current status.

Bill Segment - Bill Segment Portal

Select **Menu > Financial > Bill Segment > Search** and navigate to the **Bill Segment Portal** page to view additional information associated with a Bill Segment.

Depending on your implementations requirements, you may define additional zones to appear on this Portal

The contents of this section describe the zones that are available on this portal page.

General Information

Bill Segment ID, **Bill Seg Info** are displayed.

Bill Segment - Usage

This Usage portal is available when the bill segment has associated usage requests. It displays all usage requests related to the bill segment. Select **Menu > Financial > Bill Segment > Search** and navigate to the **Usage** page to view bill segment's usages.

General Information

Bill Segment ID and Bill Segment Info are displayed.

Bill Segment Usage

The following information is displayed in the Bill Segment Usage zone:

- The **Create Date/Time** of the usage request.
- The **Usage** column contains a concatenation of the bill segment's division, SA type, status, and period of the usage request. The usage information links to the Usage Portal for the usage request.
- The **Usage ID** for the usage request.

Financial - Bill Segment Calculation Line Characteristics

This page displays the characteristics that are linked to a specific bill segment calculation line. The information on this page is for audit purposes only and cannot be changed.

Open this page by clicking the **Go To Calc Line Characteristic** button on the calculation lines grid of the [Bill Segment - Calc Lines](#) page.

Description of Page

Account is the account to which the bill segment is linked. The name of the main person on the account appears next to the account ID.

The **SA** is the service agreement to which the bill segment applies. Basic information about the service agreement appears adjacent.

Premise shows the service agreement's characteristic premise (i.e., the primary premise associated with the service agreement).

The **Bill Seg ID** and **Bill Seg Header** displays the identification of the bill segment and header associated with the calculation line characteristic.

Calc Line displays the calculation line number with which the characteristics are associated.

The **Description on Bill** displays the description of the calculation line that appears on the customer's bill.

The characteristics grid displays the **Characteristic Types** and the **Characteristic Values** associated with the calculation line.

Fastpath:

For more information about characteristics, refer to [Setting Up Characteristic Types and Their Values](#).

Off Cycle Bill Generator

The Off Cycle Bill Generator portal may be used to create an off cycle bill for an account where you control which financial transactions are linked to the resultant bill. For example, you can create a bill for a specific adjustment or billable charge. Navigate using **Menu > Financial > Off Cycle Gill Generator > Add**.

Off Cycle Bill Generator Query

Use the [query portal](#) to search for an existing off cycle bill generator. Once an off cycle bill generator is selected, you are navigated to the maintenance portal to view and maintain the selected record.

Off Cycle Bill Generator Portal

This portal appears when an off cycle bill generator has been selected from the Off Cycle Bill Generator Query portal.

The topics in this section describe the base-package zones that appear on this portal.

Off Cycle Bill Generator Actions

This is a standard [actions zone](#).

If the off cycle bill generator is in a state that has valid next states, buttons to transition to each appropriate next state are displayed.

Fastpath:

Refer to [How To Create An Off Cycle Bill Generator](#) for more information about how to create an off cycle bill on-line / real time.

Off Cycle Bill Generator Zone

The Off Cycle Bill Generator zone contains display-only information about the off cycle bill generator.

Please see the zone's help text for information about this zone's fields.

Financial Transactions On Bill

The Financial Transactions On Bill zone shows financial transactions linked to the off cycle bill generator's bill. Information displayed on this zone is similar to that displayed on the [Financial Transactions On A Bill](#) transaction.

Off Cycle Bill Generator Log

An off cycle bill generator log contains an entry for every recorded event during the lifecycle of the off cycle bill generator. There are two general types of log entries:

- **Automatic entries.** The system automatically creates an entry in the log when an off cycle bill generator is created or there is a status change or when a related entity is created. This also includes any implementation-specific log entries. Users cannot modify or delete these log entries.
- **Manual entries.** Users can add manual entries to record significant events at their discretion.

Multi Cancel/Rebill

The Multi-Cancel/Rebill transaction is used to cancel / rebill (and freeze) one or more bill segments linked to a service agreement.

Note:

You would typically use this transaction when something has been wrong for an extended period of time. For example, if the customer was assigned the wrong rate when they first started service, you would correct the customer's rate using [Service Agreement - Rate Info](#) and then use this transaction to cancel / rebill the customer's historical bill segments.

The following topics describe how to use this transaction.

Multi Cancel/Rebill - Main

The main page is used to select the bill segments to be cancel/rebilled and to initiate the cancel/rebill request. Open **Menu > Financial > Multi-Cancel/Rebill** to use this function.

Description of Page

This page contains all non-cancelled bill segments associated with a given **SA ID**. The service agreement's **SA Info**, **Account ID** (and name), characteristic **Premise** (and address), **Current Balance** and **Payoff Balance** are displayed at the top of page.

When the page first opens, the grid is populated with ALL non-cancelled bill segments displayed in reverse chronology order. All frozen bill segments are pre-selected for cancel/rebill processing. The following information appears in the grid:

- **Selected Switch.** If this switch is turned on, the bill segment will be cancel / rebilled when the **Cancel/Rebill/ Freeze** button is clicked. You can use the mouse to toggle the value of this switch on a specific bill segment. Alternatively, you can click the **Select All** button or **Clear All** button to toggle the switch for all frozen bill segments. The checkbox is disabled if the bill segment's bill is written off. Note: the total number of selected bill segments is shown above the grid for confirmation purposes.
- **Start Date.** This is the first day of the bill segment.
- **End Date.** This is the last day of the bill segment.
- **Create Date/Time.** This is the day/time the bill segment was created.
- **Amount.** This is the payoff amount of the bill segment.
- **Original Amount.** This column only contains a value if the bill segment is a rebill of another bill segment. In this situation, one of the following values will be displayed:
 - If the amount of the new bill segment differs from the amount of the original bill segment, the amount of the original bill segment will be displayed.
 - If the amount of the new bill segment equals the amount of the original bill segment, the word No change will be displayed.
- **Bill Segment Information.** This is the standard bill segment summary information.

Note:

Sorting By Values In The Grid. Just like all grids in the system, you can click on a column heading to resort the grid by the value of the respective column. This might be useful to sort the bill segments in **Amount** order.

After selecting the bill segments to be cancel/rebilled, click the **Cancel/Rebill/Freeze** button. When this button is clicked, an additional informational page displays. Specify the following information and then click **Calculate** to cancel the selected bill segment and create new bill segments:

- **Cancel Reason** defines why the bill segment(s) are being canceled.
- **Accounting Date** is used to define the financial period to which the canceled and new bill segments' financial transactions will be booked.
- Turn on **Allow Estimates** if the system is allowed to estimate consumption if it can't find a meter read.
- Use the **Billing Option** to define how the system looks for meter reads:
 - Select Use Schedule if the system should select reads based on the SA's SP's service cycle schedule.
 - Select Use Cut off Date if the system should only select reads from the end date of the existing bill segment.
- Select Use Schedule if the system should select reads based on the SA's SP's service cycle schedule.
- Select Use Cut off Date if the system should only select reads from the end date of the existing bill segment.
- If you'd prefer to have the system use the consumption details snapshot on the original bill segments, turn on **Use Old Read/Item/SQ**. If this switch is on then neither **Allow Estimates** nor **Billing Option** is relevant.

Note: The **Use Old Read/Item/SQ** switch is not available if the bill's SA references an SA type with a special role flag of Bill Determinants Required.

Warning:

If the cause of the rebill is an incorrect rate and the new rate requires service quantities that were not calculated when the bill was originally calculated, do not turn on **Use Old Read/Item/SQ**. Why? Because you want the system to derive new service quantities during the rebill process.

Note:

Default note. The Accounting Date is defaulted to the current date and the **Use Old Read/Item/SQ** switch is turned on.

After specifying the above information, the system cancel / rebills each segment in chronological order (i.e., earlier segments will be cancel / rebilled before later segments). The new amount of each bill segment is shown in the **Original Amount** column. You can navigate to the [Graph](#) page to graphically view the financial ramifications of the cancel/rebills.

Note:

Errors. It's possible that bill segment errors will occur when you cancel / rebill the bill segments. For example, if you change the SA's rate to a rate that requires a unit-of-measure that doesn't exist on the SA's meter, a bill segment error will be generated. If this occurs, you must go to [Bill Segment - Main](#) for the pending cancel bill segment and use the **Undo** action to remove the offending bill segment (and restore the original segment to the Frozen state). Alternatively, you can drill down on the Error bill segment and use the **Regenerate** action after correcting the cause of the problem.

There is no Undo. Unlike cancel / rebills performed on [Bill Segment - Main](#), there is no Undo action. This is because the multi-cancel/rebill transaction freezes the newly created bill segments after it cancel/rebills; whereas the bill segment transaction lets you examine the new bill segment before you freeze it. If you made a mistake, simply correct the cause of the mistake and then cancel / rebill again. The erroneous financial transactions will be automatically suppressed on the next bill produced for the customer.

Usage Requests. If a bill segment is linked to a service agreement that requires bill determinants from Oracle Utilities Meter Data Management, an off cycle bill generator (OCBG) is created to perform the cancel/rebill. Refer to [Multi Cancel/Rebill — Usage Requests](#) for more details on the off cycle bill generator. If the bill segment needs to wait on its usage request to complete, a message will appear on this grid indicating that cancel/rebill is in progress. The checkboxes for these bill segments and the **Cancel/Rebill**, **Select All** and **Clear All** buttons will all be disabled. You will need to refresh the page to check the progress of rebilling.

Multi Cancel/Rebill - Graph

This page contains a graph that shows the rebilled and original payoff amounts for a service agreement's non-cancelled bill segments. Open **Menu > Financial > Multi Cancel/Rebill** and navigate to the **Graph** page to view this information.

Description of Page

This page contains a graph that shows the payoff amounts for a service agreement's non-cancelled bill segments (represented by the blue bars in the graph). If a bill segment is a rebill of another bill segment, the payoff amount of the original bill segment is displayed on a red-colored bar adjacent to the respective blue bar.

Note:

Click a bar. You can click on a bar to drill down to a bill segment.

SA Billing History

Open **Menu > Financial Query > SA Billing History** to view a history of all bill segments produced for a service agreement.

Description of Page

The **Account ID** is displayed with the account's name adjacent.

The **SA Information** shows a summary of information about the service agreement. The **SA ID** is the unique identifier of this SA.

One row is displayed for every bill segment ever produced for the selected service agreement.

The following information is displayed for each bill segment:

- The **Start Date** and **End Date** of the bill segment.
- The number of **Days** in the bill segment consumption period.
- The **Status** of the bill segment
- The **Current** and **Payoff Amounts** of the bill segment.
- The **UOM** (Unit of Measure) of the service quantity designated as the "graph UOM" for the SA's SA type.
- The total amount of the service **Billable Service Quantity** that was billed.
- The **Avg Daily Qty** is the **Billable Service Quantity** divided by the numbers of days of service.

If you need to see more detailed information about the bill segment, click the go to button to transfer to the bill segment page.

Bill Exception

If errors are detected during the billing process, it may cause a record to be written to the bill exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, schedule the [TD-BIERR](#) background process. This process generates a To Do entry for every record in the bill exception table.

Fastpath:

Refer to [How to Correct a Bill That's In Error](#) for instructions describing how to correct a bill.

Bill Segment Exception

If errors are detected during the billing process, it may cause a record to be written to the bill segment exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, schedule the [TD-BSERR](#) background process. This process generates a To Do entry for every record in the bill segment exception table.

Fastpath:

Refer to [How To Correct A Bill Segment That's In Error](#) for instructions describing how to correct a bill segment.

Maintaining Billable Charges

You create a billable charge whenever a customer should be charged for a service that occurs outside the normal course of business. For example, you would create a billable charge to charge a contractor for the repair of a ruptured gas line.

Note:

Billable charges can be uploaded from an external system. Refer to [Uploading Billable Charges](#) and [Using Billable Charges For Pass Through Billing](#) for more information.

A billable charge must refer to a service agreement. This service agreement behaves just like any other service agreement:

- **Bill segments are created for the service agreement.** Whenever billing is performed for an account with billable charge service agreements, the system creates a bill segment for each billable charge. This means that if a service agreement has many unbilled billable charges, it will have many bill segments.
- **Payments are distributed to the service agreement.** Payments made by an account are distributed to its billable charge service agreements just like any other service agreement.
- **Overdue debt is monitored.** The credit and collections process monitors billable charge service agreements for overdue debt and responds accordingly when overdue debt is detected.

- This service agreement must reference an SA Type that has a Special Role of Billable Charge. If such a service agreement does not already exist for the account, one must be created before you can levy a billable charge. See "For more information" at the end of this section for links to other sections that will help you with this process.

Billable charge templates exist to minimize the effort required to create a billable charge for a customer. A billable charge template contains the standard bill lines, amounts and distribution codes used to charge for a one-off charge.

A user may override the information on the template when the billable charge is created. For example, you can create a billable charge template to levy charges when a contractor ruptures a gas main. This template would contain the bill lines, amounts and distribution codes associated with a ruptured pipe repair. Then, when a contractor ruptures a line, a user can create a billable charge using the template and override the amount to reflect the actual repair amount (if it differs from the norm).

Note:

Templates aren't required. A billable charge can be created without a template for a truly unexpected charge. If you don't use a template, you'll have to enter the bill information manually.

Fastpath:

Refer to [Setting Up Billable Charge Templates](#) for more information.

Note:

Adding taxes and other calculation lines to a billable charge. Refer to [Billable Charge - SQ Details](#) for information about how to have the system calculate tax lines and append them to the billable charge.

Billable Charge - Main

Open **Menu** > **Financial** > **Billable Charge** > **Search** to maintain a billable charge.

Description of Page

The **Billable Charge ID** is system generated. The **Account ID** of the account responsible for the charge is displayed at the top.

Use **SA ID** to define the ID of the billable charge service agreement that will hold the billable charge's debt. The **Account ID** for the service agreement is displayed for information purposes.

Use **Start Date** and **End Date** to define the charge's bill period.

Note:

Installment billable charges. You can create many future dated billable charges to implement unusual installment plans. For example, if you want to bill a customer \$250 today, \$150 next month, and \$1000 three months from now; you could create three billable charges with a date that reflects the earliest bill date. When a bill is produced for the account, the system will create a bill segment for every billable charge whose start date is on or before the current date.

If you want to create the billable charges from an existing template, enter the ID of the **Billable Charge Template** from which the billable charge information defaults. If your **SA Type** indicates a billable charge template, that value will be defaulted. The billable charge template is stored with the billable charge, to reference what was used to create it.

Note: Actual billable charge lines can differ from what was originally defaulted from the billable charge template if user overrides were done after defaulting. Refer to [Maintaining Billable Charges](#) on page 406 for more details.

Use **Description on Bill** to define the verbiage that should print on the customer's bill above the line item details.

Billable Charge Status defines the state of the billable charges. Possible values are Billable and Cancelled. Click the **Cancel** button to cancel a billable charge.

Bill Segment ID is the ID of the bill segment on which the billable charge's charge details appear. This information is only populated AFTER the billable charge has been swept onto a bill.

The **Total Bill Amount** displays the sum of all billable charge lines except those that are **Memo Only**. The **Total Line Amount** displays the sum of all billable charge lines except those that **Appear In Summary**.

The information in the scroll defines the line item details associated with the billable charge. Click the drill down button to navigate to the line characteristics. The following fields are required for each line:

Sequence Sequence controls the order in which the line items appear on the bill segment.

Description on Bill Specify the verbiage to print on the bill for the line item.

Charge Amount Specify the amount to charge for the line item.

Show on Bill Turn this switch on if the line item should appear on the customer's printed bill. It would be very unusual for this switch to be off.

Appears in Summary Turn this switch on when the amount associated with this line also appears in a summary line. This switch plays a part at bill print time - those lines that appear in a summary print in the left dollar column, those that don't appear in a summary print in the right dollar column. Also note, those lines that appear in a summary line are not included in the total amount associated with the billable charge.

Memo Only, No GL Turn this switch on if the billable charge line does not contribute to the total amount due (e.g., this switch would be on for "information only" lines).

Distribution Code Specify the distribution code that identifies the GL account associated with this line item. The description of the code appears adjacent.

Fastpath:

For more information about billing billable charges, refer to [How To Create A One-Time Invoice](#). For more information about billable charge templates, refer to [Setting Up Billable Charge Templates](#).

Billable Charge - Line Characteristics

Characteristics may be associated with billable charge lines. Typically, this is done to categorize billable charge lines for reporting purposes.

Open **Menu > Financial > Billable Charge > Search** and navigate to the **Line Characteristics** page to maintain characteristics that are associated with billable charge.

Description of Page

The **Billable Charge Line** scroll defines the billable charge line to which you wish to assign characteristic values. The following fields display:

Characteristic Type The type of characteristic.

Characteristics Value The value of the characteristic.

Note:

You can only choose characteristic types defined as permissible on a billable charge line. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Billable Charge - SQ Details

Optionally, you may specify service quantities associated with a billable charge. These are most commonly used when you want the system to calculate charges *in addition to the billable charge lines* (e.g., adding tax to the billable charge lines).

Note:

The SA must specify a rate. If you want the system to calculate additional charges based on the service quantities defined on this page, the related billable charge service agreement must reference a rate. This rate must have calculation rules that calculate charges based on the service quantities specified on this page. When

the service agreement is next billed, the system will sweep on the billable charges and then call the rate and pass it the service quantities defined on this page. The rate will calculate the additional charges and these will be appended to the bill segment.

Open **Menu > Financial > Billable Charge > Search** and navigate to the **SQ Details** page to maintain a billable charges service quantities.

Description of Page

The following fields display:

Sequence Specify the sequence number of the SQ.

UOM Select the unit of measure of this SQ. One or more of **UOM**, **TOU**, or **SQ Identifier** must be selected.

TOU Select the time of use period.

SQ Identifier Select the SQ identifier.

Service Quantity Specify the number of units of this service quantity.

Billable Charge - Read Details

Optionally, you may specify meter read details associated with a billable charge. These are most commonly used when you need to print the read details that were used to calculate the bill lines that appear on the main tab.

Note:

Using these reads to derive billable consumption. The base package bill segment creation algorithm (BSBC-BC) simply sweeps billable charge read details onto the related bill segment as [calculation / audit reads](#). This algorithm does NOT use these reads to derive billable consumption. This is intentional as most implementations that import reads also import billable consumption and therefore deriving billable consumption is unnecessary (and also error prone). If your implementation needs to derive billable consumption from these reads, you can develop your own bill segment creation algorithm to do just this.

Open **Menu > Financial > Billable Charge > Search** and navigate to the **Read Details** page to maintain a billable charges service quantities.

Description of Page

The grid is a snapshot of the meter reads whose consumption was billed using the bill lines shown on the main tab. One row exists for every read that should be swept onto the related bill segment as a [calculation / audit read](#) when the system creates a bill segment for this billable charge. The following information is displayed in the grid:

- **Final Unit of Measure** is the unit of measure of the resultant billing quantity.
- **Final Time of Use** is the time-of-use code of the resultant billing quantity.
- **Final Service Quantity Identifier** is the service quantity identifier of the resultant billing quantity.
- **Register Quantity** is the resultant billing quantity.
- **How To Use (SP)** is the SA/SP's how to use code.
- **Service Point ID** is the unique identifier of the service point at which the meter was located.
- **Meter Configuration ID** is the unique identifier of the meter's configuration.
- **Sequence** is the sequence number of the register on the meter.
- **Unit of Measure** is the register's unit of measure.
- **Time of Use** is the register's time-of-use code.
- **SQI** is reserved for future use.
- **Start Register Reading** is the start register reading.
- **End Register Reading** is the end register reading.
- **Measured Quantity** is the resulting measured quantity.
- **Register Constant** is the constant on the register that is multiplied by the measured quantity to derive the register's billable consumption.

- **How To Use** is the register's how to use code.
- **Use Percent** is the SA/SP's usage percentage. A value of 100% is defaulted.
- **Measures Peak Qty** indicates if the unit of measure is one that measures peak consumption.
- **Start Read Date/Time** is the date and time of the start meter read. If the register is consumptive, (as opposed to subtractive) nothing will be displayed.
- **End Read Date/Time** is the date and time of the end meter read.
- **Start Reg Read ID** is the unique identifier of the start register read. If the register is consumptive, (as opposed to subtractive) nothing will be displayed.
- **Read Type** is the read type of the start meter read.
- **End Reg Read ID** is the unique identifier of the end register read.
- **Read Type** is the read type of the end meter read.
- **Multiplier** is the composite multiplier that converts the measured quantity to the registered quantity.

Note:

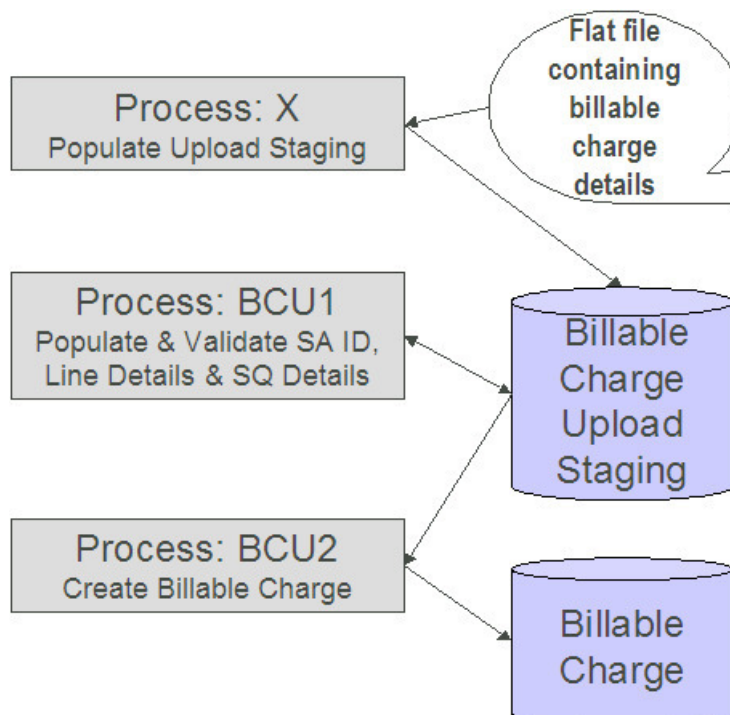

The multiplier is calculated by dividing the Register Quantity by the Measured Quantity (if the Measured Quantity is 0, then the result is 0). This is not stored on the database. There is a chance that the value is not precise due to round-off.

Uploading Billable Charges

This section describes how the system uploads billable charges from an external source. This mechanism is used when you need to "pass through" charges that have been calculated by a third party but appear on your bill.

Billable Charge Upload Background Processes

The following diagram illustrates the processes involved in the uploading of billable charges into the system.

The topics in this section describe how these processes work.

Process X - Populate BC Upload Staging

Process X refers to the mechanism used by your organization to populate the various staging tables (shown in the yellow section of the following ERD).

The topics in this section describe each of these tables.

Billable Charge Upload Staging Layout

You must create an upload staging record for each billable charge. The name of this table is **CI_BCHG_UP**. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|------------------|--------|-------|-----------|---|
| BCHG_UP_ID | 30 | Y | Char | This is the unique identifier of the record. This value does NOT have to be a random number, but it does need to be unique. If your process that inserts records on this table is capable of calling a routine, call ProgramCIPZKEYG and it will supply a 12 digit random number for you. |
| BCHG_UP_STAT_FLG | 2 | Y | Char | This must be set to P for Pending. |

| | | | | |
|-----------------|----|---|-----------|--|
| NT_XID_CD | 30 | N | Char | This is the external system id of the sender of the billable charge. See the description of the SA_EXT_REFT_ID field for how this field is used to determine the billable charge's SA_ID. Refer to Designing External Systems for more information about this field. |
| SA_EXT_REF_ID | 36 | N | Varchar2 | This field along with NT_XID_CD are used to uniquely identify the service agreement against which the billable charge will be stored. These two fields are used to identify a SA relationship record; the SA relationship record, in turn, has a sub SA and it is this SA that the billable charge will be linked to. Note well: these fields are only necessary if you do not know the billable charge SA ID. Refer to Maintaining SA Relationships for more information. |
| BCHG_EXT_REF_ID | 50 | N | Varchar2 | This is the identifier of the billable charge in the sender's system. |
| CRE_DTTM | 26 | N | Date/Time | The date and time the upload staging row was inserted (this can be used for audit purposes). |
| START_DT | 10 | Y | Date | The start date of the period encompassed by the billable charge. |

| | | | | |
|-----------------|-----|----------|----------|---|
| END_DT | 10 | Y | Date | The end date of the billable charge period. |
| DESCR_ON_BILL | 254 | Y | Varchar2 | This is the description that should prefix the charges on the printed bill. |
| SA_ID | 10 | See note | Char | This must correspond with a SA ID of a billable charge service agreement. You may leave this column blank if NT_XID_CD and SA_EXT_REF_ID are populated. |
| BILLABLE_CHG_ID | 12 | N | Char | Leave this column blank. It will be assigned by the system when it creates a billable charge record. |

Billable Charge Line Upload Staging Layout

You must create a billable charge line upload record for each line to be uploaded. The name of this table is **CI_BCHG_LINE_UP**. The following table describes each column on this table.

Note:

Defaulting from BCHG_UP_XTYPE. Please pay special attention to the **Comments** column below as many fields, if left blank, will default from each record's BCHG_UP_XTYPE.

| Column Name | Length | Req'd | Data Type | Comments |
|---------------|--------|-------|-----------|---|
| BCHG_UP_ID | 30 | Y | Char | This is the foreign key to the billable charge upload staging record. |
| LINE_SEQ | 3 | Y | N | This is the unique line number of the billable charge line. This value must be unique within the billable charge. |
| DESCR_ON_BILL | 254 | Y | Varchar2 | This is the description that will be printed on the bill for the line. |

| | | | | |
|-----------------|------|----------|----------|--|
| CHARGE_AMT | 13.2 | N | N | This is the amount associated with the billable charge line. |
| BCHG_LINE_XID | 20 | N | Varchar2 | This is the unique identifier of the billable charge line in the sender's system. |
| BCHG_UP_XTYPE | 30 | N | Char | This is the type of billable charge line. This is a foreign key reference to the billable charge line type control table. This control table is used to populate the remaining fields (if they are blank). If this field is blank, the remaining fields must be specified as they cannot be defaulted from the billable charge line type control table. Refer to Billable Charge Line Type for more information. |
| CURRENCY_CD | 3 | See note | Char | This is a foreign key reference to the currency code of the billable charge line. This field must be specified if CHARGE_AMT is non-zero. |
| SHOW_ON_BILL_SW | 1 | See note | Char | This should be Y if the line should appear on the customer's printed bill. This should be N if the line should not appear on the customer's printed bill. If left blank, this value will be populated from the line's BCHG_UP_XTYPE. |

| | | | | |
|----------------|----|----------|------|---|
| APP_IN_SUMM_SW | 1 | See note | Char | This should be Y if the line appears in a summary line. This should be N if the line does not appear in a summary line. This switch plays a part at bill print time - those lines that appear in a summary print in the left dollar column, those that don't appear in a summary print in the right dollar column. If left blank, this value will be populated from the line's BCHG_UP_XTYPE. |
| MEMO_SW | 1 | See note | Char | This should be Y if the line does NOT affect the general ledger. This should be N if the line affects the general ledger. If left blank, this value will be populated from the line's BCHG_UP_XTYPE. |
| DST_ID | 10 | See note | Char | If the line affects the general ledger, the set ID (the previous field) and the distribution code of the GL account must be specified. If left blank, this value will be populated from the line's BCHG_UP_XTYPE. |

Billable Charge Line Characteristic Upload Staging Layout

If you want to upload characteristics on your billable charge lines, you must create a billable charge line characteristic upload record for each characteristic on each line. The name of this table is **CI_B_LN_UP_CHAR**. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|----------|
|-------------|--------|-------|-----------|----------|

| | | | | |
|----------------|----|---|----------|---|
| BCHG_UP_ID | 30 | Y | Char | This is the foreign key to the billable charge upload staging record. |
| LINE_SEQ | 3 | Y | N | This is the foreign key to the billable charge line upload staging record |
| CHAR_TYPE_CD | 8 | Y | Char | This is the unique identifier of the billable charge line characteristics. This value must be unique within the billable charge line characteristics. |
| ADHOC_CHAR_VAL | 30 | N | Varchar2 | An ad hoc characteristic value must be supplied if the ad hoc switch on characteristic type is Y. Otherwise, it is not allowed. |
| CHAR_VAL | 16 | N | Char | A characteristic value must be supplied if the ad hoc switch on characteristic type is N. Otherwise, it is not allowed. |
| CHAR_VAL_FK1 | 50 | N | Varchar2 | A characteristic value foreign key must be supplied if the ad hoc switch on characteristic type is Y. Otherwise, it is not allowed. |
| CHAR_VAL_FK2 | 50 | N | Varchar2 | A characteristic value foreign key must be supplied if the ad hoc switch on characteristic type is Y. Otherwise, it is not allowed. |

| | | | | |
|--------------|----|---|----------|---|
| CHAR_VAL_FK3 | 50 | N | Varchar2 | A characteristic value foreign key must be supplied if the ad hoc switch on characteristic type is Y. Otherwise, it is not allowed. |
| CHAR_VAL_FK4 | 50 | N | Varchar2 | A characteristic value foreign key must be supplied if the ad hoc switch on characteristic type is Y. Otherwise, it is not allowed. |
| CHAR_VAL_FK5 | 50 | N | Varchar2 | A characteristic value foreign key must be supplied if the ad hoc switch on characteristic type is Y. Otherwise, it is not allowed. |

Billable Charge Service Quantity Upload Staging Layout

You must create a billable charge service quantity upload record for each service quantity to be uploaded. The name of this table is **CI_BCHG_UP_SQ**. The following table describes each column on this table. Refer to "[pass through charges](#)" for more information about how this type of information is used.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|--|
| BCHG_UP_ID | 30 | Y | Char | This is the foreign key to the billable charge upload staging record. |
| SEQ_NUM | 3 | Y | N | Sequence of the service quantity within the Billable Charge Upload |
| UOM_CD | 30 | N | Varchar | The unit of measure of the Billable Charge Upload SQ row. If specified, it must reference a valid value on CI_UOM. Note, at least one of the following fields should be specified: SQI_CD, TOU_CD, UOM_CD. |

| | | | | |
|---------|------|---|---------|--|
| TOU_CD | 30 | N | Char | The time of use of the Billable Charge Upload SQ row. If specified, it must reference a valid value on CI_TOU. Note, at least one of the following fields should be specified: SQI_CD, TOU_CD, UOM_CD. |
| SQI_CD | 30 | N | Varchar | The service quantity identifier of the Billable Charge Upload SQ row. If specified, it must reference a valid value on CI_SQI. Note, at least one of the following fields should be specified: SQI_CD, TOU_CD, UOM_CD. |
| SVC_QTY | 12.6 | N | N | Quantity of the service used for the UOM / TOU / SQI combination |

Billable Charge Read Details Upload Staging Layout

You must create a billable charge read details upload record for each read detail to be uploaded. The name of this table is **CI_BCHG_UP_READ**. The following table describes each column on this table. Refer to "[pass through charges](#)" for more information about how this type of information is used.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|---|
| BCHG_UP_ID | 30 | Y | Char | This is the foreign key to the billable charge upload staging record. |
| SP_ID | 10 | Y | Char | Note, if USAGE_FLG is calculation, you can set this field to 0 if you do not know the SP ID. The only thing that's important is that the combination of BCHG_UP_ID, SP_ID and SEQNO are unique. |

| | | | | |
|------------------------|------|---|----------|---|
| SEQNO | 5 | Y | Number | This should be a value greater than zero. See SP_ID comment for more information. This is typically the sequence number of the register on the meter. |
| END_READ_DTTM | 26 | Y | DateTime | This is the date and time of the end read |
| END_REG_READ_ID | 12 | N | Char | This field must reference an existing register read ID if USAGE_FLG is anything other than a calculation. |
| END_REG_READING | 9.6 | Y | Number | This is the reading of the end read. |
| FINAL_REG_QTY | 12.6 | Y | Number | This is the final amount of the reading (this is the amount of billable consumption the read detail contributed to the entire billed consumption). |
| FINAL_SQI | 8 | N | Char | The service quantity identifier of the FINAL_REG_QTY . If specified, it must reference a valid value on CI_SQI . Note, at least one of the following fields should be specified: FINAL_SQI , FINAL_UOM_CD . |
| FINAL_TOU_CD | 8 | N | Char | The time-of-use code of the FINAL_REG_QTY . If specified, it must reference a valid value on CI_TOU . |

| | | | | |
|------------------------|------|---|---------|---|
| FINAL_UOM_CD | 4 | N | Char | The unit of measure of the FINAL_REG_QTY . If specified, it must reference a valid value on CI_UOM . Note, at least one of the following fields should be specified: FINAL_SQI , FINAL_UOM_CD . |
| HOW_TO_USE_FLG | 2 | Y | Char | See the field description in the data dictionary for the valid values (CI_BCHG_UP_READ). |
| MSR_PEAK_QTY_SW | 1 | Y | Char | Y or N |
| MSR_QTY | 12.6 | Y | Number | This is the difference between END_REG_READING and START_REG_READING for subtractive registers. |
| REG_CONST | 6.6 | Y | Number | This is the register's constant (the value used to adjust the measured quantity due to something associated with the physical meter). Set this to a value of 1 if it is not known. |
| SQI_CD | 30 | N | Varchar | The service quantity identifier of END_REG_READING and START_REG_READING . If specified, it must reference a valid value on CI_SQI . Note, at least one of the following fields should be specified: SQI_CD , TOU_CD , UOM_CD . |

| | | | | |
|--------------------------|-----|---|----------|--|
| START_READ_DTTM | 26 | Y | DateTime | This is the date and time of the start reading. |
| START_REG_READ_ID | 12 | Y | Char | This field must reference an existing register read ID if USAGE_FLG is anything other than a calculation. |
| START_REG_READING | 9.6 | Y | Number | This is the reading of the start read. |
| TOU_CD | 30 | N | Char | The time-of-use code of END_REG_READING and START_REG_READING . If specified, it must reference a valid value on CI_TOU . |
| UOM_CD | 30 | Y | Char | The unit of measure of END_REG_READING and START_REG_READING . |
| USAGE_FLG | 2 | Y | Char | See the field description in the data dictionary for the valid values (CI_BCHG_UP_READ). |
| USE_PCT | 3 | Y | Number | This is the percentage of the consumption that was billed (this will typically be 100). |

BCU1 - Validate & Populate Billable Charge Upload Staging

This process has several functions:

- It populates the SA ID on all BC upload staging records where SA ID is left blank. This means that you don't have to know the SA ID in order to interface a billable charge into the system. The program populates SA ID with the service agreement related to the SA relationship with the most recent effective date for a given combination of service provider's external system ID and customer's ID in the sender's system. The system can only do this if the following points are true:
- You use the system's SA relationship functionality to define that you provide bill ready billing services for a service provider. On the customer's SA relationship record you must define the customer's ID in the service provider's system. Refer to [Maintaining SA Relationships](#) for more information.
- You identify the service provider's external system ID on the billable charge upload staging record.

- You identify the customer's ID in the sender's system.

Note:

You can still interface billable charges if you don't use the system's SA relationship functionality. How? You simply need to derive the SA ID associated with the uploaded billable charge.

- It populates various fields (e.g., the GL distribution code, memo only switch) on the billable charge upload line records from the billable charge line type specified on each respective record.

Any validation / population errors detected during this process are written to the [BC Upload Exception](#) table. You can fix errors using BC Upload Staging page (don't forget to change the record's status back to Pending).

BCU2 - Create Billable Charge

This process creates a billable charge and billable charge lines (shown in the yellow section of the following ERD) for all BC upload records in the Pending state.

If the billable charge's SA is Closed, it will Reactivate it so that the billable charges will be swept onto the next bill produced for the account.

Note:

This process will override the values of the various switches referenced on billable charge upload staging line if the respective service agreement's SA type has an override value for the line's billable charge line type. Refer to [SA Type - Billable Charge Overrides](#) for more information.

Any errors detected during this process are written to the [Billable Charge Upload Exception](#) table. You can fix errors using BC Upload Staging page (don't forget to change the record's status back to Pending).

BCUP-PRG - Purge Billable Charge Upload Objects

Completed billable charge upload staging objects should be periodically purged from the system by executing the [BCUP-PRG](#) background process. This background process allows you to purge all Completed billable charge upload staging objects older than a given number of days.

We want to stress that there is no system constraint as to the number of Completed billable charge upload objects that may exist. You can retain these objects for as long as you desire. However we recommend that you periodically purge Completed billable charge upload objects as they exist only to satisfy auditing and reporting needs.

Billable Charge Upload Staging

The Billable charge Upload Staging page has three purposes:

- You can view historical billable charge upload records.
- You can correct billable charge upload records that are in error.
- You can add new billable charge upload records. These will be uploaded by the billable charge upload process (although it's probably easier to just add the billable charges using the [Maintaining Billable Charges](#) page).

The topics in the section describe how to maintain this information.

Billable Charge Upload - Main

Open this page using **Menu > Financial > Billable Charge Upload Staging > Search**.

Description of Page

Fastpath:

Refer to [Billable Charge Upload Staging](#) for more information about these fields.

Note:

Correcting Errors. If a Billable Charge Upload record's status is Error , you should correct the problem and then change its status back to Pending. The next time the billable charge upload process runs, it will revalidate the record and, if valid, it will create a billable charge record.

Billable Charge Upload - Lines

Open this page using **Menu > Financial > Billable Charge Upload Staging > Search** and navigate to the **Lines** page.

Description of Page

Fastpath:

Refer to [Billable Charge Line Upload Staging](#) for more information about these fields.

Billable Charge Upload - SQ Details

Open this page using **Menu > Financial > Billable Charge Upload Staging > Search** and navigate to the **SQ Details** page.

Description of Page

Fastpath:

Refer to [Billable Charge Service Quantity Upload Staging](#) for more information about these fields.

Billable Charge Upload - Read Details

Optionally, you may specify meter read details associated with a billable charge. These are most commonly used when you need to print the read details that were used to calculate the bill lines that appear on the main tab.

Note:

Using these reads to derive billable consumption. The base package bill segment creation algorithm (BSBS-BC) simply sweeps billable charge read details onto the related [bill segment's read detail](#). This algorithm does NOT use these reads to derive billable consumption. This is intentional as most implementations that import reads also import billable consumption and therefore deriving billable consumption is unnecessary (and also error prone). If your implementation needs to derive billable consumption from these reads, you can develop your own bill segment creation algorithm to do just this.

Open **Menu > Financial > Billable Charge Upload Staging > Search** and navigate to the **Read Details** page to view this information.

Description of Page

Fastpath:

Refer to [Billable Charge Read Details Upload Staging](#) for more information about these fields.

Billable Charge Upload Exception

If errors are detected during the billable charge upload process, a record is written to the billable charge upload exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, schedule the [TD-BCUPL](#) background process. This process generates a To Do entry for every record in the billable charge upload exception table.

You can fix this error using the [Billable Charge Upload Staging](#) page and change the status of the record from Error to Pending. When the billable charge upload process next runs, it attempts to upload this record again.

Budget Review

This portal shows account budgets that require manual review, as identified by the [Budget Monitor](#) process.

You can access this portal from **Menu > Financial Query > Budget Review**.

Refer to the embedded help text for more information.

Payments

In this section, we describe how to manage your customer's payments.

The Big Picture of Payments

A payment reduces how much an account owes. The topics in this section provide background information about a variety of payment topics.

A Payment Event Has Payments And Tenders

The explanation in [The Financial Big Picture](#) provides an accurate, but incomplete view of payments. The missing pieces concern *payment events* and *tenders*. The following diagram illustrates the difference between a payment event, its payment(s) and its tender(s).

The following concepts are illustrated above:

A payment event defines the event A payment event is required whenever any form of payment is received. The payment event defines the payment date (and that's all).

A payment event has tender(s) A tender exists for every form of tender remitted as part of the payment event. A payment event must have at least one tender otherwise nothing was remitted. A payment event may have many tenders when multiple payment methods are associated with an event (e.g., paying with cash, a check, and a credit card).

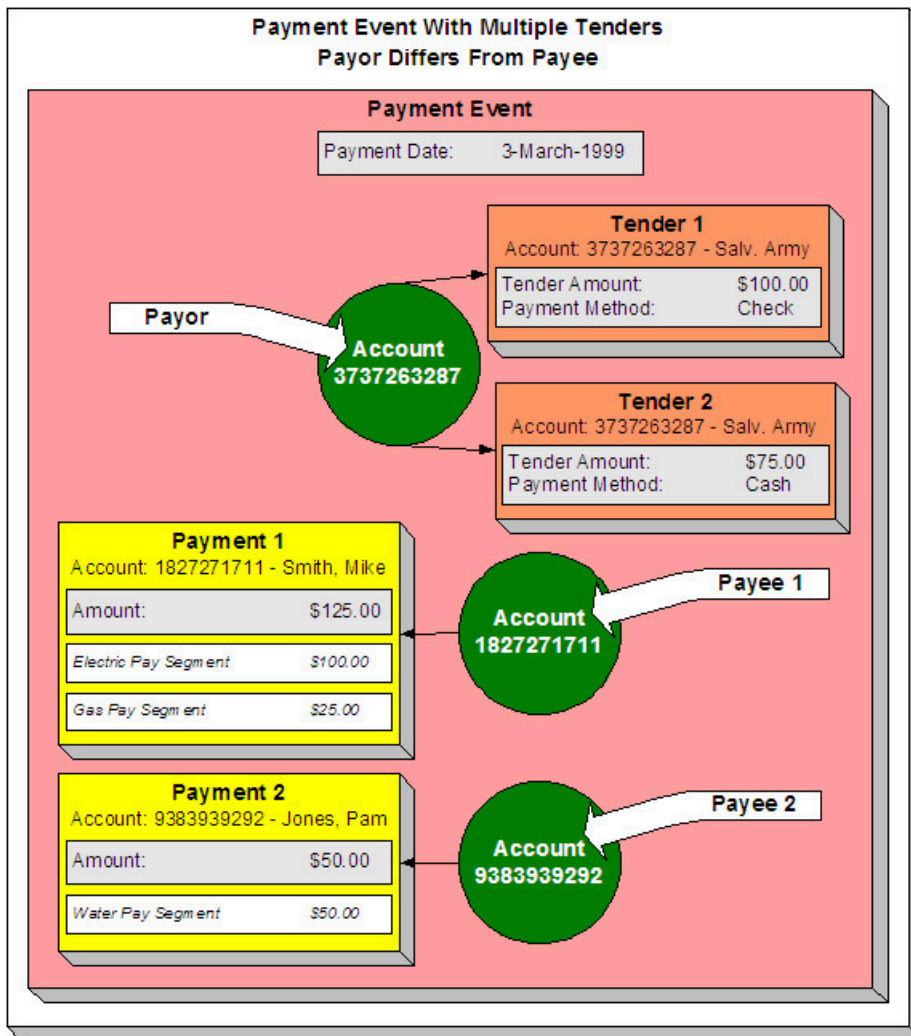

A payment is allocated to account(s) The total amount of tenders under a payment event is distributed to one or more accounts.

A payment is distributed to SAs The system allocates an account's payment amount amongst its service agreements. The system creates a payment segment for each service agreement that receives a portion of the payment.

Payor and payee are frequently the same The account remitting the tender (the payor) is frequently the same as the account to which the funds are allocated (the payee). The next illustration provides an example when this is not the case.

Multiple Tenders Used To Pay For Multiple Accounts

The following diagram illustrates a payment event with multiple tenders where the payor of the tender is not the same as the account(s) receiving the payment.

A payment event may have many tenders A single payment event may have many tenders. While the above example shows both tenders being paid by the same account, each tender may reference a different account.

Many accounts may be paid under 1 event The total amount of tenders under a payment event are distributed to one or more accounts.

Payor may differ from payee The account(s) remitting the tender may differ from the account(s) whose debt is relieved.

An Overview Of The Payment Event Creation & Allocation Process

When a payment event occurs, the system stores a tender for each form of remittance (e.g., cash, check, charge). It then allocates the sum of the tenders to one or more accounts.

By default, the system allocates the sum of the tenders to the account that remits the tenders. You may override this default and specify any number of accounts and their respective payment allocation amount. This is useful, for example, when a social service agency pays for many accounts. If applicable, you may also configure the system to use your own payment event distribution rule(s).

Fastpath:

Refer to [Distributing A Payment Event](#) for more information.

The system distributes a payment amongst an account's service agreements based on the age of each service agreement's debt AND distribution priority. The system creates a payment segment for each service agreement that receives part of the payment.

Fastpath:

Refer to [Distributing A Payment Amongst An Account's Service Agreements](#) for more information.

You may manually redistribute the payment amount amongst the account's service agreements before you commit the distribution. When the distribution is acceptable, you freeze the payment. Freezing a payment causes the system to create a financial transaction for each related payment segment. It is the financial transaction(s) that causes the service agreements' payoff and current balances to be reduced. The financial transaction also contains the journal details that debit "cash" and credit some other GL account.

And that's it. The remaining topics in this section provide more information about the creation and allocation of payment events.

Note:

Batch and real-time payment event creation / allocation. There is only one payment event creation / allocation routine and therefore anything the batch payment process does for whole batches of payments, you can do to a payment on-line.

Distributing A Payment Event

Warning:

This section deals with the concept distributing a payment amount into payment(s). It does not discuss the distribution of a single payment into segments. **For more information** about payment distribution, refer to [Distributing A Payment Amongst An Account's Service Agreements](#).

The base-package, by default, creates a single payment for a payment event. Some business practices require potentially many payments to be created when payment events are added.

A few examples of when multiple payments may be necessary are:

- A payment amount needs to be distributed towards different distribution types:
 - \$50 in interest
 - \$60 in collection charges
 - \$70 in taxes
- Each of the above distributions is realized as a separate payment identified by its own match type (i.e., there'll be one match type called Interest, another called Collection Charges, etc.).

In this example, the debt of a single service agreement may be relieved by each of these payments.

- In a similar way, you may want to create a separate payment for an overpayment to differentiate it from regular payments (using yet another match type).
- In the case of a social service agency that pays for many accounts, a single payment event may be distributed amongst multiple accounts.

The method by which a payment amount is distributed to create payment(s) is contained in [Create Payment algorithms](#) plugged in on a distribution rule.

There is yet another aspect to having control over how payment events are created. The default method of creating payment events assumes knowledge of account IDs (of the payor and the payee) when making a payment. In cases where payments are made by and towards business entities other than accounts, knowledge of their corresponding account IDs may not be available at payment time. Consider the following examples:

- A payment is made to pay a person's bill, providing the person's identification at payment time.
- A payment is made towards a specific service agreement using a "contract number" defined as SA characteristic.

The method by which the tender account is determined by means of an alternate identifier is contained in Determine Tender Account [algorithm](#) plugged in on a distribution rule.

Fastpath:

Refer to [Making Payments Using Distribution Rules](#) for information on how to configure your system to use this distribution method.

Distributing A Payment Amongst An Account's Service Agreements

Warning:

This section deals with the concept of distributing a payment amongst an account's service agreements. It does not discuss how the sum of a payment event's tenders is balanced out by payment allocations. **For more information** about payment event balance, refer to [Unbalanced Payment Events](#).

A payment must be distributed to one or more service agreements for its financial impact to be realized. When a payment satisfies an account's entire debt, you don't have to worry about how the system distributes the payment. The concept of payment distribution is only relevant when a partial or excess payment is distributed.

The first important point to understand is that the method of distributing a payment amongst an account's service agreements is contained in an algorithm that's plugged in on to [Customer Class](#). This means that you can have different distribution algorithms for different customer classes.

Note:

Manual overrides. Most of the time, you'll let the payment distribution algorithm distribute the payment amongst an account's service agreements. However, you may manually distribute a payment when a customer directs a payment to specific service agreement(s).

The following explanation describes one of the base package payment distribution algorithms (refer to Payment Distribution - Pay Priority and Debt Age (PYDIST-PPRTY) for information about this algorithm). This algorithm distributes a payment based on:

- The age of each service agreement's debt.
- The payment distribution priority of each service agreement's SA type.

The following diagram helps illustrate how the distribution algorithm works.

Distributing A Payment Amongst An Account's Service Agreements Is Controlled By The Age Of The Debt And The SA's Distribution Priority

| | | Priority 10 (Highest) | | Priority 90 (Lowest) | | |
|---------------------------------|----------------|--------------------------|-------|-------------------------|----------------|--|
| | | SA #1 | SA #2 | SA #3 | | |
| Excess Credits | | 16 | | | | |
| New Debits* | | 13 | 14 | 15 | | |
| Non-Delinquent | | 10 | 11 | 12 | | |
| A r r e a r s | 35-day Arrears | 5 | 6 | 9 | 35-day Arrears | |
| | 66-day Arrears | 3 | 4 | 8 | 52-day Arrears | |
| | 93-day Arrears | 1 | 2 | 7 | 93-day Arrears | |

*--Includes all charges not yet invoiced to the customer.

The above example shows three columns, one for each service agreement linked to a hypothetical account. Notice that two of the service agreements have the same distribution priority, the third has a lower priority. The numbers in the cells indicate the order in which the system distributes a partial payment.

Note:

Debt terminology. Before we can discuss the distribution algorithm, you must understand the terminology we use to categorize debt. **Delinquent** debt is associated with financial transactions that appear on overdue bills. **Non-delinquent** debt is associated with financial transactions that appear on current bills. **New debits** debt is associated with financial transactions that do not yet appear on a completed bill (e.g., a late payment charge that hasn't been billed yet).

The following points describe the algorithm used to distribute the partial payment:

- The system pays off delinquent debt of the highest priority service agreements first. In the above example, where multiple service agreements have the same distribution priority, the system does NOT payoff one service agreement before it starts on the next (which one would it pick?). Rather, it distributes the payment amongst the service agreements based on the age of the respective debt on each service agreement. In the above example, this is represented by steps 1 through 6 (notice how the distribution jumps between SA1 and SA2).
- After all delinquent debt has been relieved from the highest priority service agreement(s), the system pays off the next priority until all delinquent debt is relieved. In the above example, this is represented by steps 7 through 9.
- The system next pays off non-delinquent debt using each service agreement's respective distribution priority. Note well, the payment distribution algorithm doesn't associate an age with non-delinquent debt and therefore the distribution is based purely on the service agreements' respective distribution priority. In the above example, this is represented by steps 10 through 12.

- After all non-delinquent debt is relieved, the system next pays off "new debit" debt based on the service agreements' respective distribution priority. In the above example, this is represented by steps 13 through 15.
- Refer to [Overpayment](#) for a description of what happens if money still exists after the above distribution is complete.

Note:

Payment segments and financial transactions. A payment segment exists for each service agreement that receives a portion of a payment. Linked to each payment segment is a financial transaction. It is the financial transaction that causes the service agreement's debt to be relieved and the general ledger to be impacted.

Fastpath:

Refer to [Payment Exception](#) for more information about how the system handles errors detected during the payment distribution process.

Note:

Overriding the distribution algorithm for uploaded payments. The standard distribution algorithm is used for payments that are [Interfaced From An External System](#) unless you specify a MATCH_VALUE and MATCH_FLG on the [Payment Staging](#) row associated with the uploaded payment. These fields are used in conjunction to indicate that the distribution of the payment should be restricted in some way (i.e., the standard payment distribution algorithm should not be used). MATCH_FLG indicates how the payment should be distributed (e.g., only distribute to a specific service agreement), MATCH_VALUE contains the ID of the restriction (e.g., the SA ID).

Open item customers. For an [open-item customer](#), you MUST override the standard distribution algorithm because the payment is distributed as per the open items that it is relieving. Refer to [Payments And Match Events](#) for more information.

Overpayment

Overpayment refers to the situation where money is left over after a payment has been distributed to all eligible service agreements, and all debt is relieved. Refer to [Overpayment Segmentation](#) for a description on how to configure the system to handle your overpayment requirements.

Canceling A Tender Versus Canceling A Payment

A payment event has tender(s) and payment(s). You can cancel a tender when it's not valid, e.g., when a check bounces. You can cancel a payment when the account should not have received the payment (e.g., a misdistribution or a canceled tender).

When you cancel a tender, the system automatically cancels ALL frozen payments. We do this because if the tender is canceled, there are no funds to distribute to accounts (unless there are other non-canceled tenders under the event). However, when you cancel a payment, the system does NOT cancel the tender(s) because we assume that, if the tenders were incorrect, you would have canceled them rather than the payment.

NSF Cancellations

When a tender is canceled, a cancellation reason must be supplied. If the cancellation reason indicates a NSF (non sufficient funds) charge should be levied, the system invokes the NSF charge algorithm specified on the tender's account's [customer class](#). Algorithms of this type will typically create an adjustment or billable charge to levy the NSF charge. Refer to NSFC-DFLT for an example of such an algorithm.

Note:

The payor gets the NSF adjustments. It's possible for the payor of a tender to differ from the payee (e.g., when a social service agency pays for other customers' debt). When you cancel a tender you must specify a

cancellation reason. If the cancellation reason indicates an NSF charge should be levied, the sample algorithm provided with the system levies the NSF charge on the PAYOR's account. Because adjustments must be linked to a service agreement, the algorithm picks the payor's service agreement with the highest payment distribution priority and levies the adjustment specified in the service agreement's SA type's NSF adjustment type.

Besides calling this algorithm, a NSF cancellation may affect the tendering [account's credit rating and cash-only score](#). The cancellation reason indicates the extent to which the account's ratings are affected.

And finally, whenever a tender is canceled due to non-sufficient funds, the account is scheduled for review by the [Account Debt Monitor](#).

Transferring A Payment

If the account on an event's tender and payment are wrong, you can use the [Transfer](#) button on the Payment Event page to transfer the payment to another account.

If the account on the payment is wrong - but the tender is correct, you can use the [Transfer](#) button on the Payment page to transfer the payment only to another account.

Unbalanced Payment Events

The system, by default, distributes the sum of a payment event's tenders to the account that remits the tender with a single payment. After distribution the sum of the tenders equals the sum of the payments when the event is first created. We refer to such an event as being balanced.

However, it is possible for an event's tender amount to not equal the sum of the payment allocations (i.e., the event becomes unbalanced). How? Well, there are several ways this can happen:

- While the system DEFAULTS the payment amount to be the tender amount, you can override the payment amount and therefore make a previously balanced event unbalanced.
- While the system DEFAULTS the payment account to be the tender account, you can add additional accounts / amounts and therefore make a previously balanced event unbalanced.
- When you cancel a tender (e.g., because a check bounces), the system cancels ALL payments linked to the tenders payment event. If the payment event has multiple tenders, this will cause the event to become unbalanced. To correct this situation, you must add payment allocations to equal the amount of uncanceled tenders.
- If you cancel a payment and forget to add another payment for the same amount, the event becomes unbalanced. To correct this situation, you must add another payment (or cancel the tender).
- You may delete a tender from an event while its tender control is open. If you delete a tender and don't do anything about the related payments, the event becomes unbalanced.
- You may add a tender to an event at any time. If you don't allocate the tender amount to an account, the event becomes unbalanced.

Fastpath:

Refer to [Payment Event Exception](#) for more information about how the system reminds you about unbalanced payment events.

How And When Payments Appear On Bills

Fastpath:

Refer to [Financial Transactions Created Between Bills](#) for more information.

Tender Management and Workstation Cashiering

When you add a tender, you must identify its **Tender Source**. For example,

- A specific cash drawer ID is the source of tenders remitted to a cashier.
- The notional lockbox ID is the source of tenders interfaced from a lockbox.
- The remittance processor is the source of tenders interfaced from a remittance processor.

Note:

Default note. When a user adds a tender control the system attempts to default a tender source based on the currency of the deposit control and the tender source(s) defined on the user's record. If your organization accepts alternate currency payments, then a tender source must exist for each currency code accepted at a location.

Fastpath:

For more information, refer to [Setting Up Tender Sources](#).

A tender source's tenders must be balanced against an expected total before they can be deposited at a bank. This periodic balancing requires all tenders to exist in respect of a **Tender Control**. Over time, a tender source may have many tender controls (one per balancing event).

An example of a cashier's cash drawer will help clarify the tender control concept:

- When a cashier starts in the morning, they start with a fresh cash drawer (i.e., one without tenders). Whenever a drawer starts afresh, a new Tender Control must be created because you balance the contents of a drawer.
- A cash drawer typically contains funds to make change. These funds are the tender control's **Opening Balance**.

Note:

Default note. A tender control's starting balance defaults from its tender source.

- During the day, customers remit tenders to the cashier. Every tender put into the drawer is associated with the drawer's tender control created at the start of the day.
- A tender control's balance increases during the day as tenders are recorded. A cashier can view the balance at any time.
- The cashier can turn in funds to the head cashier during the day. Each turn in event can be recorded in the system. Note well, if the amount of funds in a tender control exceeds the maximum balance defined on the tender control's tender source, a warning is issued to the cashier to remind them to turn in funds.
- At some point, the contents of the drawer must be balanced against the total tenders linked to the tender control. When balancing starts, no additional tenders may be put into the tender control. If the cashier receives additional tenders after balancing starts, a new tender control must be created (and the above process starts afresh).
- During the balancing process, some modifications may be made to the tenders associated with the tender control, but no additional tenders may be added. When the tender control is balanced, neither it nor its tenders may be modified.

Fastpath:

For more information, refer to [Managing Your Cash Drawers](#).

While the above explanation is true, it isn't complete. In addition to the requirement that a tender must reference a tender control, the tender control must refer to a **Deposit Control**. Deposit controls give you administrative control over all of the tender controls whose contents will be deposited en masse. The following concepts will help explain the power of deposit controls:

- As explained above, when a cash drawer is started afresh, a new tender control must be created. The tender control "holds" all new tenders received by the cashier.
- Similarly, when a tender control is created, it must reference a deposit control. During the day, a deposit control's tender controls are constantly changing. You can view the total impact of a deposit control's tender controls at any time.
- At some point, you will want to deposit the tenders received during the day. To do this, you must indicate how much will be deposited at the bank. This deposit amount must equal the sum of the tender controls linked to the

cash drawer. When this deposit balancing starts, no additional tender controls may be associated with the deposit control.

- When the deposit total equals the sum of the tender controls, the deposit control becomes balanced and no changes may be made to it, its tender controls, or its tender controls' tenders.

Fastpath:

For more information, refer to [Managing Your Cash Drawers](#).

Note:

Background processes use the same concepts. Tenders that are interfaced from external sources (e.g., lockboxes and remittance processors) make use of the concepts describe above. For example, tenders interfaced from a remittance processor are linked to a tender control and this tender control is linked to a deposit control. The main difference is that the background processes require no human intervention; the system automatically creates tender and deposit controls and sets their states to balanced when the interface concludes successfully.

The ACH activation process also creates tender and deposit controls. Refer to [Activating Automatic Payments](#) for more information.

The topics in this section elaborate on the tender management concepts described above.

Managing Your Cash Drawers

Warning:

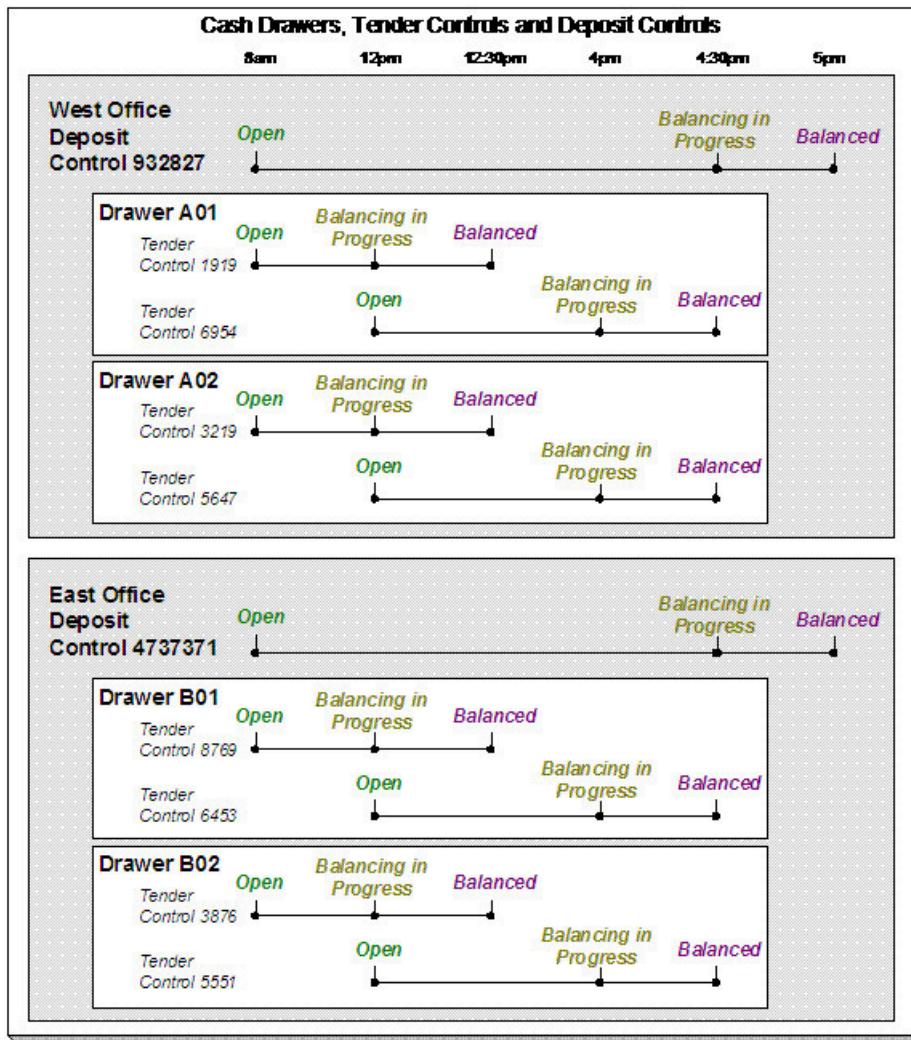

This section assumes you are familiar with the concepts described in [The Lifecycle Of A Deposit Control](#) and [The Lifecycle Of A Tender Control](#).

There are many ways to handle the daily management of tenders received via cash drawers. It really depends on how your organization works. To help you understand the potential of the system, we'll continue the example started above.

Assume that the cash drawers in your western office are balanced and deposited independently from those in your eastern office. We'll assume that both offices follows the same daily routine:

- Load fresh drawers first thing in the morning. Each drawer contains a starting balance of \$150.00. Note: the drawer's tender control's starting balance defaults from its tender source.
- At 10 am, the cashier turns in funds to the chief cashier and continues to receive additional tenders.
- At 12 noon, each drawer is pulled and balanced by a supervisor.
- By 12:30 pm, the tender controls are balanced.
- At 4 pm, the cashiering stations are closed. Each drawer is pulled and balanced by a supervisor.
- By 4:30 pm, the tender controls are balanced.
- At 5 pm, the deposit control is balanced and funds are ready to be deposited at the bank.

Given this, the following diagram illustrates the deposit controls and tender controls used by each office on a given day.

The following concepts are illustrated above:

- An Open deposit control must exist before you can create a tender control. And an Open tender control must exist before you can create a tender. From a business process standpoint, this means:
 - A supervisor would create a deposit control at the start of the day (8 am in the above illustration).
 - Each cashier would create a tender control when they start a drawer and reference the deposit control created by the supervisor.
 - During the day, the cashier can turn-in moneys to the chief cashier. These turn-in events are recorded in the system as they play a part in the ultimate balancing of the drawer. Refer to [Turn Ins](#) for more information.
 - At some point, the contents of a drawer can be pulled and balanced. If additional tenders can be received in a drawer, a new tender control must be created for the drawer. Refer to [Balancing By Tender Type](#) for more information.
 - At the end of the day, the supervisor checks to make certain that all tender controls linked to the deposit control are Balanced. After this has been done, the supervisor indicates the deposit amount on the deposit control and changes it to Balanced. Notice that in the above illustration each deposit control references four tender controls.

Note:

Alternate currency payments. If your organization accepts payments in alternate currencies, that is, a currency other than the account's currency; a supervisor would create a deposit control for each such currency. Likewise, the cashier would create a tender control for each such currency.

**Fastpath:**

Refer to [Alternate Currency Payments](#) for more information.

- Typically, a cash drawer has one tender control Open at any point in time (meaning that the tenders being received are being linked to a specific tender control). However, this is not a hard rule. If you want, you may have multiple tender controls Open at any point for a specific cash drawer (for example, if multiple cashiers can work the same drawer during the day but take their drawer with them).
- Typically, a specific cashier puts tenders into a specific tender control. However, this is not a hard rule. On a tender control, you can define if it's limited to a specific operator OR if any operator can link tenders to it.
- When you're ready to balance a drawer, you change the tender control to Balancing in Progress. This prevents new tenders from being added to the tender control. If the cashier can continue to receive tenders, they must create another tender control. In the above example, all drawers are balanced at 12 noon by a supervisor while the cashier continues to take payments.
- When the tender control is balanced, you change its state to Balanced. This prevents any changes to the tender control or its tenders.
- All tender controls exist in respect of a deposit control (in fact, the deposit control must be created before the tender control). This way, a supervisor can check the state of the related drawers throughout the day. Notice that the state transition of a deposit control is identical to that of the tender control (refer to [The Lifecycle Of A Deposit Control](#) and [The Lifecycle Of A Tender Control](#)). There is only a temporal difference. Notice that the deposit control stays open throughout the day while any number of tender controls are being opened and balanced.

**Note:**

Multiple deposits in a day. While the above example illustrates a single deposit per office per day, it is quite possible to have multiple deposit controls on any given day.

Turns ins. The above example did not illustrate the fact that a cashier can turn-in moneys during the day without having to balance the drawer. Refer to [Turn Ins](#) for more information.

Turn Ins

A cashier may optionally turn-in funds received into a cash drawer to a head cashier. The turn-in process requires two steps:

- Each time a cashier turns-in funds, they add a turn-in event on the [Tender Control - Turn Ins](#) page. Note that a separate turn-in event is required for each type of tender that's turned in. This is because the balancing of a tender control is performed for each tender type and therefore the system must know how much of each tender type has been removed from the drawer.

**Note:**

Turn in warning. If the amount of cash-like funds in a tender control exceeds the maximum balance defined on the tender control's tender source, a warning is issued to the cashier to remind them to turn in funds.

- The head cashier (the person responsible for the deposit control associated with the various tender controls) approves the turn in using the [Deposit Control - Turn Ins](#) page.

**Note:**

All turn-ins must be approved for balancing to complete. A tender control cannot be balanced until the head cashier has approved all turn-in events.

Balancing By Tender Type

It should be noted that when it's time to balance a tender control, the cashier must enter the amount of each tender type that is in the drawer in order to balance it. For example, assume the following takes place:

- A drawer is opened with a starting balance of \$150.50 (tender type is Cash).
- During the day, the cashier receives \$5,000 in Cash, and \$1,000 in Checks.

- During the day, the cashier turns in \$750 of the Checks and \$4,000 of Cash.

At the end of the day, the following operator would have to enter the balances shown in the Ending Balance column.

| Tender Type | Starting Balance | Tenders Received | Turn Ins | Ending Balance |
|-------------|------------------|------------------|----------|----------------|
| Cash | \$150.50 | \$5,000 | \$4,000 | \$1150.50 |
| Check | - | \$1,000 | \$750 | \$250 |

Note:

Time saver. The system assists in the balancing effort by amalgamating the amount of tenders by tender type when the tender control's status is changed from Open to Balancing In Progress. The cashier just needs to enter the Ending Balance. The system can then compare the cashier's Ending Balance against the Expected Ending Balance. When these values are equal for all tender types, the tender control's status can become Balanced.

Cash Back

When a [payment is added](#), the user defines the following:

- The amount of debt to be relieved (i.e., the payment amount)
- The amount remitted (i.e., the tender amount)
- The form of the remittance (i.e., the [tender type](#))

The payment amount typically equals the tender amount unless cash will be returned to the customer. For example, if a customer remits \$100, but only wants to pay off \$25 of debt, the tender amount will be \$100 and the payment amount will be \$25. The system will only allow a user to remit more than the payment amount if the tender type indicates "cash back" is allowed. For example, you may not allow cash to be returned if a check is remitted, but you may allow it to be returned if cash is remitted.

If cash back is allowed for the tender type, the system displays the amount of cash to be returned on the [Payment Event](#). In addition, because the system enforces [balancing the cash drawer by tender type](#), the system adjusts the payment event's tendered information as follows:

- When there is cash back, the payment event will have two tenders - one will be for the amount and type entered by the user, the other will be a negative amount with a tender type of cash (note, this tender type is retrieved from the Starting Balance Tender Type on the [installation record](#)). For example, if a customer remits \$100 in traveler's checks, but only wants to pay off \$25 of debt, there will be two tenders: one for the \$100 travelers check and the other for the -\$25 of cash.

Note:

Alternate currency payments. If your organization accepts payments in alternate currencies, that is, a currency other than the account's currency; the cash back tender is always created in the account's currency.

Note:

Multiple tenders and payment cancellation. If multiple tenders were created because of "cash back" processing, both tenders must be cancelled if the payment event needs to be cancelled.

When modifying an unfrozen payment on the [Payment Event](#), if the payment becomes unbalanced, a button is displayed allowing the user to **Recalculate Cash Back**. If the user clicks this button, the system reassesses the cash back tender as follows:

- If there is now cash back, a new tender is created for the credit amount
- If the cash back amount has changed, the tender for the cash back is adjusted to the new amount
- If there is no longer cash back due, the tender for the cash back is removed.

Managing Payments Interfaced From External Sources

Just like a payment recorded on-line via a cash drawer, a payment interfaced from an external source (e.g., lock box or remittance processor) must reference a tender control and the tender controls, in turn, must reference a deposit control. The only real differences between these two types of payments are highlighted below:

- Whilst an operator must create and balance the tender and deposit controls for real-time payments, the system creates the tender and deposit controls associated with interfaced payments.
- It's impossible for an invalid account to be referenced on a payment recorded real-time. However, it is quite possible for an interfaced payment to reference an unknown account. If an invalid account is referenced on an interfaced payment (using no distribution rules), the system links it to the suspense service agreement referenced on the tender source control table.

Fastpath:

Refer to [Interfacing Payments From External Sources](#) for more information.

Payment Financial Transaction Considerations

A payment segment exists for each service agreement that receives a portion of a payment. Linked to every frozen payment segment is a financial transaction. This financial transaction affects a service agreement's payoff balance and/or current balance. It also contains the journal details that debit cash and credit some other account.

The topics in this section provide information about the financial impact of a payment segment.

Fastpath:

Refer to [The Financial Big Picture](#) for more information about a payment's place in the financial big picture.

Payment - Current Balance versus Payoff Balance

Warning:

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

A payment segment financial transaction almost always affects payoff balance and current balance by the same amount (think of it like this - when a customer pays, the amount they think they owe goes down by the amount they really owe). The only exception is a payment segment for a charitable contribution. These payment segments only affect current balance because the customer was never billed for the contribution in the first place.

Fastpath:

Refer to [Setting Up Payment Segment Types](#) for more information about how payment segment type affects how a payment segment is produced and how its financial transaction is generated.

The Source Of GL Accounts On A Payment Financial Transaction

A payment segment's financial transaction also contains the double-sided accounting entry that defines how the payment segment affects the general ledger.

Fastpath:

Refer to [The Source Of GL Accounts On Financial Transactions](#) for a description of where the system extracts the distribution codes used to construct the GL accounts.

A Payment May Affect More Than Just Customer Balances

The topics in this section provide information about obscure things that may happen when a payment is distributed and frozen.

Open Item Accounting and Match Events

Fastpath:

Refer to [Payments and Match Events](#) for more information about how payments can create match events for open-item accounts.

FT Freeze Repercussions

Fastpath:

Refer to [Obscure Things That Can Happen](#) for more information about things that can happen when an FT is frozen (and FT's get frozen when a payment is frozen).

Automatic Payments

This section discusses how to set up and manage customers who pay their bills automatically (via direct debit or credit card debits)

How To Set Up A Customer To Pay Automatically

If a customer wants to pay automatically, transfer to [Account - Auto Pay](#) and define the source of the funds and the customer's account or credit card number.

What Are Automatic Payments?

An automatic payment is just like any other payment (refer to [A Payment Event Has Payments And Tenders](#) for more information about payments in general). However, automatic payments have one special trait - they cause funds to be transferred into your company's bank account. Refer to [Downloading Automatic Payments and Interfacing Them To The GL](#) for how this transference happens.

How And When Are Automatic Payments Created?

Automatic payments can be created in several ways:

- The system creates automatic payments for bills linked to accounts with an active auto pay option (note, the system uses the [account's autopay option](#) that's effective on the bill's due date). When the system does this is dependent on the value of the **Autopay Creation Option** on the [installation record](#):
 - If you've set this option to Create At Bill Completion, the automatic payment is created when the account's bill is completed. The payment is distributed and frozen at the same time. This means that the account's balance is almost always zero (or in credit if they have a deposit). You will see the automatic payments in the payment list immediately after the bill is completed (rather than waiting until the automatic payment's extraction date).
 - If you've set this option to Create On Extract Date, the automatic payment is NOT created when the bill is completed. Rather,
- At bill completion time, the bill is stamped with the automatic payment's extract date and amount. The date is the automatic payment source's extraction date (refer to [Automatic Payment Dates](#) for more information on how this date is calculated).
- The automatic payment background process ([APAYCRET](#)) creates the automatic payment on the extract date stamped on the bill. If the supplied Auto Pay Creation algorithm (APAY-CREATE) is used and is configured to override the automatic payment amount based on the account's current balance, the algorithm can either adjust the

auto pay amount (if the balance is less than the original auto pay amount) or skip automatic payment creation (if the balance is zero or a credit). Refer to the algorithm type description for more details.

- The automatic payment is NOT distributed and frozen when the automatic payment is initially created. A separate background process ([APAYDSFR](#)) distributes and freezes the automatic payment on the automatic payment GL distribution date (refer to [Automatic Payment Dates](#) for more information on how this date is calculated). This means that the customer's balance increases when the bill is completed and is only reduced when the automatic payment is marked for interface to the general ledger.

Note that it is possible for automatic payments to be distributed and frozen after being extracted and interfaced to a financial institution. Please refer to [Downloading Automatic Payments and Interfacing Them To The GL and The Nightly Processes](#).

An algorithm plugged in on the [Installation Record](#) calculates the payment amount whether the automatic payment is created at bill completion time or on the extract date. Please refer to APAM-DFLT for more information about how the algorithm that is supplied with the base package calculates this amount.

Note:

With balance forward accounting, automatic payments are not just for new charges. The base package algorithm includes prior balances when it creates a customer's first automatic payment. For example, if a customer has an existing balance of \$100 and then signs up for automatic payment, their next bill will cause an automatic payment of \$100 plus any new charges to be created (assuming the \$100 remains unpaid at the time the next bill is completed). Refer to [Open Item Versus Balance Forward Accounting](#) for information about balance forward accounting.

- If a customer with a pay plan indicates that the payment method is via "autopay", a background process ([PPAPAY](#)) creates an automatic payment on the scheduled payment dates. Please note, if the **Autopay Creation Option** on the [installation record](#) is set to Create On Extract Date, the automatic payment is NOT distributed and frozen when the automatic payment is initially created. Rather, a separate background process ([APAYDSFR](#)) distributes and freezes the automatic payment on the automatic payment GL distribution date (refer to [Automatic Payment Dates](#) for more information on how this date is calculated). Refer to [The Big Picture Of Pay Plans](#) for more information about pay plans.
- If a customer with an account that is set up for automatic payment has a Non-Billed Budget that is not excluded from automatic payment, a background process ([NBBAPAY](#)) creates an automatic payment on the scheduled payment dates. Please note, if the **Autopay Creation Option** on the [installation record](#) is set to Create On Extract Date, the automatic payment is NOT distributed and frozen when the automatic payment is initially created. Rather, a separate background process ([APAYDSFR](#)) distributes and freezes the automatic payment on the automatic payment GL distribution date (refer to [Automatic Payment Dates](#) for more information on how this date is calculated). Refer to [What is a Non-Billed Budget](#) for more information about Non-Billed Budgets.
- A user can create an automatic payment by simply adding a payment tender with a tender type that indicates it is for automatic payment purposes. This would be a rather unusual thing to do, but you might do this if you want to immediately debit a customer's bank account after a large adjustment is added to the system (e.g., if they suddenly owe you a lot of money and you don't want to wait until the next bill to collect it). Automatic payments created by this method must be distributed and frozen before they can be extracted.
- When a checking or savings account is used for the first-time on a self-service automatic payment enrollment, self-service one time payment or self-service payment option management, a payment event, payment tender and auto pay staging records are created for prenotification purposes. Refer to [Web Debit Account Validation](#) for more details.

Note:

An algorithm is used to create automatic payments. The logic used to create automatic payments is plugged in on the [Installation Record](#). This algorithm is **not** called when a user manually creates an automatic payment (by adding a payment tender with a tender type that indicates that it is for automatic payment purposes) and when the automatic payment is for prenotification purposes.

When an automatic payment is first created, it gets marked with a distribution date. The distribution date is the date on which the automatic payment's FT's GL details can be interfaced to the general ledger (via the standard GL interface). The distribution date is determined as follows:

- Every automatic payment references an auto-pay source.
- Every auto-pay source references an auto-pay route type.
- Every auto-pay route type contains an algorithm that is responsible for calculating the GL Distribution (Posting) date. On the GL distribution date, the automatic payment will be interfaced to the general ledger.

Automatic Payment Dates

As described in the previous section, an algorithm (that's plugged in on [Auto Pay Route Types](#)) controls the date on which the automatic payment is interfaced to your general ledger. We refer to this date as the GL distribution date.

This algorithm also populates the following dates:

- The payment date that is stored on the payment.
- The date on which the automatic payment is interfaced to the financial institution.

The algorithm that is supplied with the base package provides many parameters that allow you to dictate how these dates are calculated. Please refer to APAY-DTCALC for the details.

How To Implement Maximum Withdrawal Limits

In some locales, customers can define a "maximum withdrawal amount" to limit the amount of money that is automatically debited from their bank account. For example, a low-income customer may want to prevent direct debits of more than \$50 from being applied to their checking account.

You define a customer's maximum withdrawal amount when you setup their automatic payment information on [Account - Auto Pay](#).

The following points describe how the system implements maximum withdrawal limits:

- When a bill is completed for a customer who pays automatically the system calls the automatic payment creation algorithm that's plugged in on the [Installation Record](#). The base-package autopay creation algorithm (APAY-CREATE) checks if the amount of the automatic payment exceeds the customer's maximum withdrawal amount. If so, the autopay creation algorithm calls the automatic payment over limit algorithm that's plugged in on the account's [customer class](#). Algorithms of this type have the ability to reduce the amount of the autopay or to prevent the autopay from being created. Refer to APOL-RA for an example plug-in.
- When a user manually creates an automatic payment (by adding a tender with a tender type that indicates that it is for automatic payment purposes), the system issues a warning message when the tender amount exceeds the account's maximum withdrawal amount.

Note:

Pay plans and Non-Billed Budgets. Automatic payments that are created as a result of pay plans and Non-Billed Budgets are not subject to maximum withdrawal limits. This is because both of these options required customer approval and therefore the customer should be able to plan accordingly. Refer to [How And When Are Automatic Payments Created](#) for more information.

How Are Automatic Payments Cancelled?

There are two ways to cancel an automatic payment:

- The system will cancel an automatic payment behind-the-scenes if the related bill (if any) is reopened BEFORE the automatic payment is interfaced to the financial institution. When you recomplete the bill, the system will create a new automatic payment that reflects the new amount due (and the canceled automatic payment will net out the original automatic payment).
- An operator can cancel an automatic payment (refer to [How To Cancel A Tender](#)) at any time. You would do this if the automatic payment was rejected by the financial institution.

Fastpath:

Refer to [Credit / Correction Notes and Auto Pay](#) for information about how a credit note may cancel an automatic payment.

Match Events Are Created For Open-Item Customers When An Automatic Payment Is Created

The system creates a match event when a bill is completed for open-item customers that pay automatically (i.e., direct debit customers). The match event groups together the bill's new charges against the automatic payment's payment segments.

If the bill is subsequently re-opened, the match event will be cancelled when the automatic payment is cancelled.

Fastpath:

Refer to [Open Item Accounting](#) for more information.

Pay Plans and Automatic Payments

If a customer wants to pay their pay plan scheduled payments automatically, the account must be set up for automatic payment (as described under [How To Set Up A Customer To Pay Automatically](#)). In addition, the payment method defined on the pay plan must indicate automatic payment is being used.

When this is done, a background process (PPAPAY) creates automatic payments on the scheduled payment date by calling the automatic payment creation algorithm plugged in on the installation record.

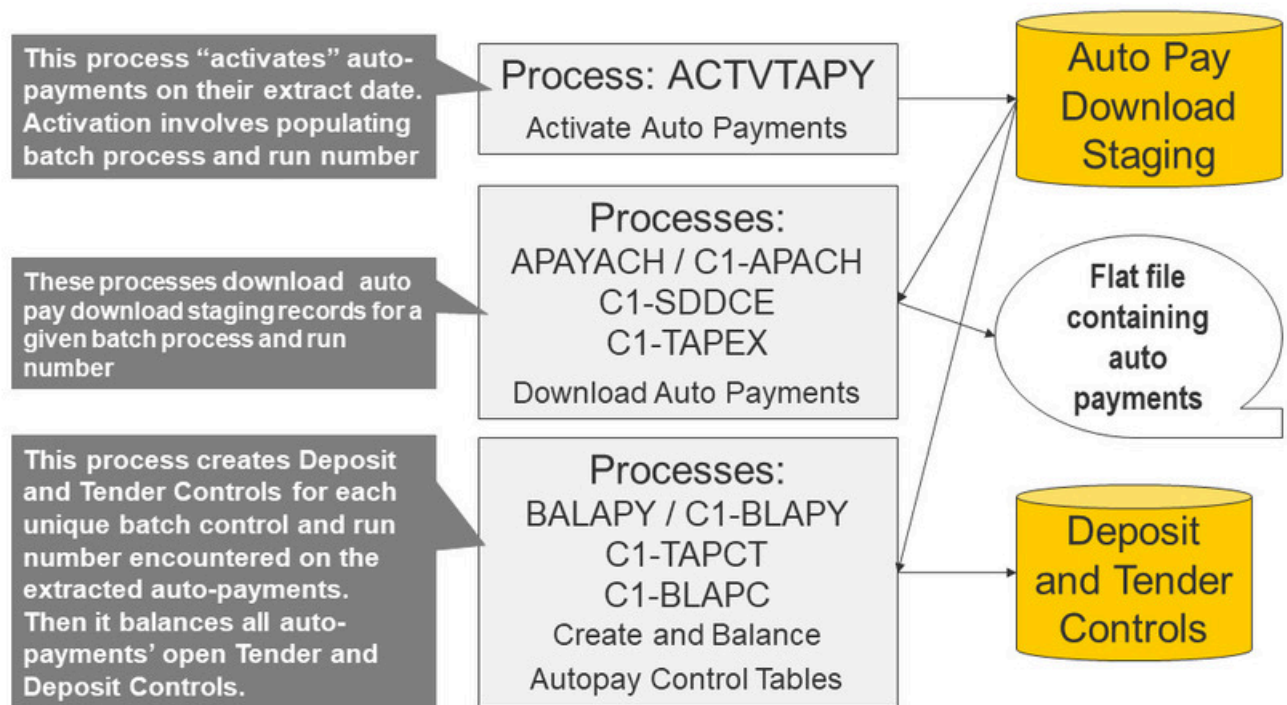

Non-Billed Budgets and Automatic Payment

If a customer wants to pay their Non-Billed Budget scheduled payments automatically, the account must be set up for automatic payment (as described under [How To Set Up A Customer To Pay Automatically](#)). In addition, the Non-Billed Budget must indicate that automatic payment is being used.

When this is done, a background process (NBBAPAY) creates automatic payments on the scheduled payment date by calling the automatic payment creation algorithm plugged in on the installation record.

Downloading Automatic Payments and Interfacing Them To The GL

The following diagram illustrates the background processes that interface automatic payment out of the system:

These processes are described in the following topics.

ACTVTAPY - Activating Automatic Payments

When an automatic payment is first created, it gets marked with an extract date. The extract date is the date the automatic payment will be downloaded to the respective financial institution. The extract date is determined as follows:

- Every automatic payment references an auto-pay source.
- Every auto-pay source references an auto-pay route type.
- Every auto-pay route type contains an algorithm that calculates this date.

On the extract date, the automatic payment is "activated". The automatic payment is activated is marked for download the next time its download process runs. An automatic payment's download process is defined on its auto-pay source's route type.

APAYACH - Download Automatic Payments To The ACH (Automated Clearing House)

This process reads all auto pay download staging records marked with a given batch control ID and run number, and creates the flat file that's passed to the ACH. Refer to [ACH Record Layouts](#) for the details of the record layouts.

The following outlines the differences between APAYACH and C1-APACH:

- APAYACH uses the Business Process Date as the draft date. C1-APACH populates the Effective Entry Date field on the Company Batch Header Record with a date (the actual draft date) as to when the payment should be withdrawn from the customer's account.
- APAYACH produces a file that has one File Header Record, a Company Batch Header Record per payment source (if multiple payment sources exist), and multiple detail lines. C1-APACH produces a file with multiple occurrences of the Company Batch Header Record differing on the Effective Entry Date field and the payment source (if multiple payment sources exist).

Note:

This process may be rerun. You can reproduce the flat file at any time. Simply request this job and specify the run number associated with the historic run.

If you require a different flat file format, you must create additional versions of this program. Refer to [Setting Up Automatic Payment Extracts](#) for instructions describing how to add another process.

C1-APACH - Download Automatic Payments To The ACH (Automated Clearing House)

This process is an alternative to using APAYACH. Similar to APAYACH, this process reads all auto pay download staging records marked with a given batch control ID and run number, and creates the flat file that's passed to the ACH. Refer to [ACH Record Layouts](#) for the details of the record layouts.

The following outlines the differences between APAYACH and C1-APACH:

- C1-APACH populates the Effective Entry Date field on the Company Batch Header Record with a date (the actual draft date) as to when the payment should be withdrawn from the customer's account. APAYACH uses the Business Process Date as the draft date.
- C1-APACH produces a file with multiple occurrences of the Company Batch Header Record differing on the Effective Entry Date field and payment source (if multiples payment sources exist). APAYACH produces a file that has one File Header Record, a Company Batch Header Record per payment source (if multiple payment sources exist), and multiple detail lines.

Note:

This process may be rerun. You can reproduce the flat file at any time. Request this job and specify the run number associated with the historic run.

If you require a different flat file format, you must create additional versions of this program. Refer to [Setting Up Automatic Payment Extracts](#) for instructions describing how to add another process.

C1-SDDCE - SEPA Direct Debit Payment Extract

This process reads all auto pay download staging records marked with a given batch control ID and run number to create an XML extract file that's passed to the financial institution. Refer to [SEPA Direct Debit Record Layouts](#) for the details of the record layouts.

Note:

This process may be rerun. You can reproduce the XML extract at any time. Simply request this job and specify the run number associated with the historic run.

C1-TAPEX - Third Party Auto Pay Extract

This process reads all auto pay download staging records marked with a given batch control ID and run number to create an extract file that is sent to the third party payment processing system.

This is a plugin-driven batch process that supports any of three file layouts (comma-separated values (CSV), fixed position and XML) specified in an input batch parameter.

The C1-TAPEX batch control is delivered with two algorithms plugged in:

- A Select Records algorithm is responsible for selecting the auto pay staging records to download.
- A Process Record algorithm is responsible for formatting and writing each extract record into the output flat file.

Your implementation can plug in your own Select Records and Process Record algorithms if your business rules for this extract differ.

This batch process is meant to be run after the Activate auto-pay (ACTVTAPY) runs and before Third Party Auto Pay Tender Controls (C1-TAPCT) runs.

Refer to [Third Party Auto Pay Record Layouts](#) on page 450 for the details of the record layouts.

Note:

This process may be rerun. You can reproduce the XML extract at any time. Simply request this job and specify the run number associated with the historic run.

BALAPY - Creating Automatic Payment Tender Controls

This process creates a new tender control (with an associated deposit control) for each unique batch control ID and run number encountered in the extracted automatic payments (where its payment tender is not yet linked to a tender control). The payment tender of each of these automatic payments is then linked to the corresponding tender control. This process also balances the open tender control records afterwards.

Note: A separate batch process ([C1-BLAPC](#)) must be scheduled after BALAPY to balance open tender and deposit control records.

C1-BLAPC - Balance Autopay Control Tables

This batch process is responsible for balancing tender and deposit control tables in the autopay extract process. This batch process is executed after [BALAPY](#) completes.

ACH Record Layouts

The topics in this section describe the layout of the records created by [APAYACH - Download Automatic Payments To The ACH \(automated clearing house\)](#) and [C1-APACH - Download Automatic Payments To The ACH \(automated clearing house\)](#).

Note:

APAYACH and C1-APACH share most of the same fields. The exceptions are documented in the following tables.

File Header Record

The ACH extract flat file must have one record of this type and it must be the first logical record on file.

| Field Name | Format | Source/Value/Description |
|-----------------------|--------|--|
| RECORD-TYPE | A1 | "1" |
| PRIORITY-CD | A2 | "01" |
| RESERVED-01 | A1 | Spaces |
| IMMEDIATE-DESTINATION | A9 | The auto pay route type's tender source's bank account's DFI ID. Note. Tender source may be overridden on CIS Division |
| COMPANY-ID | A10 | Auto Pay Route Type / Company Id Note. May be overridden on CIS Division |
| FILE-CRE-DT | A6 | YYMMDD. Current date |
| FILE-CRE-TM | A4 | HHMM. Current time |
| FILE-ID-MODIFIER | A1 | "A" |

| | | |
|-----------------------------------|-----|---|
| RECORD-SIZE-CONST | N3 | "094" The "FILLER" at the end of all but the Entry Detail Record serves to bring the total length of each record up to this constant. |
| BLOCKING-FACTOR | N2 | "10" |
| FORMAT-CD | A1 | "1" |
| DEST-FIN-INST-NAME | A23 | The auto pay route type's tender source's bank description. Note. Tender source may be overridden on CIS Division |
| COMPANY-NAME (ORIG-FIN-INST-NAME) | A23 | Auto Pay Route Type / Company Name Note. May be overridden on CIS Division |
| REFERENCE-CD | A8 | Spaces |

Company Batch Header Record

The ACH extract flat file can contain multiple company batch headers - one header per payment source as distinguished by STD-ENTRY-CLASS. This record must be the second logical record on file.

| Field Name | Format | Source/Value/Description |
|-----------------------|--------|--|
| RECORD-TYPE | A1 | "5" |
| SERVICE-CLASS-CD | A3 | "200" |
| COMPANY-NAME | A16 | Auto Pay Route Type / Company Name Note. May be overridden on CIS Division |
| COMPANY-DISCRETIONARY | A20 | Spaces |
| COMPANY-ID | A10 | Auto Pay Route Type / Company Id Note. May be overridden on CIS Division |

| | | |
|--------------------|-----|--|
| STD-ENTRY-CLASS | A3 | "PPD", unless the payment is a one-time payment. For one-time payments, the STD-ENTRY-CLASS can be populated using a One Time Payment Source characteristic on the associated tender. Base logic for self-service one-time payment processing adds a One Time Payment Source characteristic with a value of 'WEB' to the tender. Your implementation may define other characteristic values for any of your additional payment sources/triggers. Refer to the help for the One Time Payment Sources section of the Self-Service Integration Master Configuration for more details. |
| CO-ENTRY-DESCR | A10 | For standard Auto Pay Route Type: Company Entity Description Note. May be overridden on CIS Division |
| COMPANY-DESCR-DT | A6 | Business process date |
| EFF-ENTRY-DT | A6 | For APAYACH, the EFF-ENTRY-DT is the business process date. For C1-APACH, the EFF-ENTRY-DT is calculated from the ACH staging / Scheduled Extract Date + Number of Days batch parameter if specified greater than 0. A company batch is created for each value. |
| RESERVED-01 | A3 | Spaces |
| ORIGINATOR-STAT-CD | A1 | "1" |
| ORIGIN-DFI-ID | A8 | The auto pay route type's tender source's bank account's DFI ID. Note. Tender source may be overridden on CIS Division |
| BATCH-NBR | N7 | The batch number of this batch within the file. |

Entry Detail Record

The ACH extract flat file must have one record of this type for every direct debit record.

| Field Name | Format | Source/Value/Description |
|------------|--------|--------------------------|
|------------|--------|--------------------------|

| | | |
|--------------------|------|--|
| RECORD-TYPE | A1 | "6" |
| TRANSACTION-CD | A2 | Pay Tender's Tender Type / External Type Flag |
| TRANSIT-RTG-NBR | A9 | Auto pay source / External Source Id |
| DFI-ACCT-NBR | A17 | Auto pay staging / External Account Id |
| AMOUNT | N8.2 | Pay Tender / Tender Amount |
| INDIVIDUAL-ID | A15 | Pay Tender / Payor Account Id |
| INDIVIDUAL-NAME | A22 | Auto pay staging / Entity Name |
| DISCRETIONARY-DATA | A2 | Spaces |
| ADDENDA-REC-IND | A1 | "0" |
| DFI-ID | A8 | The auto pay route type's tender source's bank account's DFI ID. Note. Tender source may be overridden on CIS Division |
| ENTRY-DETAIL-CNT | N7 | Ascending counter starting at 1 and incremented by 1 for each entry detail record |

**Note:**

External Account ID. The EXT_ACCT_ID field supports up to 50 characters. If the value entered in the field is longer than that supported by the record layout (17 characters), the value will be truncated.

Company Batch Control Record

The ACH extract flat file must have one record of this type and it must follow the Entry Detail records.

| Field Name | Format | Source/Value/Description |
|---------------------|--------|---|
| RECORD-TYPE | A1 | "8" |
| SERVICE-CLASS-CD | A3 | "200" |
| ENTRY-ADDENDA-CNT | N6 | The total number of entry detail records in this batch. |
| ENTRY-HASH | N10 | The product of the first 8 digits of the external source id of the autopay source, multiplied by the number of entry detail records in the batch. |
| TOTAL-DR-DOLLAR-AMT | N10.2 | Total tender amounts of the entry detail records. |

| | | |
|---------------------|-------|--|
| TOTAL-CR-DOLLAR-AMT | N10.2 | Zero. |
| COMPANY-ID | A10 | Auto Pay Route Type / Company Id Note. May be overridden on CIS Division |
| RESERVED-01 | A19 | Spaces |
| RESERVED-02 | A6 | Spaces |
| ORIGIN-DFI-ID | A8 | The auto pay route type's tender source's bank account's DFI ID. Note. Tender source may be overridden on CIS Division |
| BATCH-NBR | N7 | The batch number of this batch within the file. |

File Control Record

The ACH extract flat file must have one record of this type and it must be the last logical record on file.

| Field Name | Format | Source/Value/Description |
|---------------------|--------|---|
| RECORD-TYPE | A1 | "9" |
| BATCH-CNT | N6 | The number of batches in this file. |
| BLOCK-CNT | N6 | Calculation of the total number of records in the file / 10.0 + 0.9 |
| ENTRY-ADDENDA-CNT | N8 | The total number of entry detail records in this file. |
| ENTRY-HASH | N10 | The sum of the entry hash values on all the batch control records in this file. |
| TOTAL-DR-DOLLAR-AMT | N10.2 | Sum of the total debit entry dollar amounts of all the batches in this file. |
| TOTAL-CR-DOLLAR-AMT | N10.2 | Sum of the total credit entry dollar amounts of all the batches in this file. |
| RESERVED-01 | A39 | Spaces |

SEPA Direct Debit Record Layouts

Group Header

A SEPA XML file must include a group header. The XML path for the group header is **CstmrDrctDbtInitm/GrpHdr** and the elements under the group header are as follows:

| Description | Element Name | Source/Value |
|------------------------|--------------|---|
| Message Identification | MsgId | Retrieved from the direct debit task type |
| Creation Date/Time | CreDtTm | Batch business date in the format YYYY-MM-DDThh:mm:ss |
| Number of Transactions | NbOfTxs | Calculated at extract time |
| Initiating Party Name | InitgPty/Nm | Retrieved from the direct debit task type |

Payment Information

Payment Information contains elements related to the credit side of the transaction, such as creditor and payment type. The XML path for payment information is **CstmrDrectDbtInitn/PmtInf** and the elements are as follows:

| Description | Element Name | Source/Value |
|--|--|--|
| Payment Information Identification | PmtInfId | Constructed at extract time by concatenating the following: Batch Code, Batch Run Number, Batch Business Date and a Sequence Number assigned to each Payment |
| Payment Method | PmtTpInf/PmtMtd | Defaulted to DD (Direct Debit) |
| Service Level Code | SvcLvl/Cd | Retrieved from the direct debit task type; defaulted to 'SEPA' |
| Local Instrument Code | PmtTpInf/LclInstrm/Cd | Retrieved from the direct debit task type; defaulted to 'CORE' |
| Sequence Type | PmtTpInf/SeqTp | Direct debit mandate task's Payment Type |
| Requested Collection Date | ReqdColltnDt | Payment event's pay date |
| Creditor Name | Cdtr/Nm | Direct debit mandate task's Creditor Name |
| Creditor Account Identification IBAN | CdtrAcct/Id/IBAN | CI_BANK_ACCOUNT.ACCOUNT_NBR |
| Creditor Agent Financial Institution Identification BIC | CdtrAgt/FinInstnId/BIC | CI_BANK_ACCOUNT.DFI_ID_NUM |
| Creditor Account Number | CdtrSchmeId/Id/PrvtId/Othr/Id | Direct debit task type's Creditor Identification |
| Creditor Party | CdtrSchmeId/Id/PrvtId/Othr/ SchmeNm/Prtry | Defaulted to 'SEPA' |

Direct Debit Transaction Information

Direct Debit Transaction Information contains elements related to the debit side of the transaction, such as debtor and remittance information rules. The XML path for direct debit transaction information is **CstmrDrctDbtInitn/PmtInf/DrctDbtTxInf** and the elements are as follows:

| Description | Element Name | Source/Value |
|---|------------------------------|--|
| Payment End to End Identification | PmtId/EndToEndId | CI_PAY_TNDR.PAY_TENDER_ID |
| Payment Instructed Amount | InstdAmt | CI_PAY_TNDR.TENDER_AMT |
| Mandate Related Information – Mandate Identification | DrctDbtTx/MndtRltdInf/MndtId | Direct debit mandate task's External Mandate Reference |
| Mandate Related Information – Date of Signature | MndtRltdInf/DtOfSgntr | Direct debit mandate task's Effective Date |
| Mandate Related Information – Electronic Signature | MndtRltdInf/ElectrncSgntr | Direct debit mandate task's Signature |
| Debtor Agent Financial Institution Identification BIC | DbtrAgt/FinInstnId/BIC | CI_APAY_SRC.EXT_SOURCE_ID |
| Debtor Name | Dbtr/Nm | CI_APAY_CLR_STG.ENTITY_NAME |
| Debtor Account Identification IBAN | DbtrAcct/Id/IBAN | CI_APAY_CLR_STG.EXT_ACCT_ID |

Third Party Auto Pay Record Layouts

The Third Party Auto Pay Extract file is a comma-separated (CSV) format file that contains one or more automatic payment detail records and a footer record.

Automatic Payment Detail Record

There must be at least one record of this type in the file.

| Field Name | Format | Source/Value/Description |
|---------------------------|--------|---|
| Account ID | A10 | Account Auto Pay Option / Account ID |
| Auto Pay Amount | N13.2 | Pay Tender linked to the Auto Pay Clearing Staging / Tender Amount |
| Due Date | A10 | Due Date of the Bill ID that is linked to the Auto Pay Clearing Staging |
| Maximum Withdrawal Amount | N13.2 | Account Auto Pay Option of the related Account ID / Maximum Withdrawal amount field |
| Auto Pay Staging ID | A12 | Auto Pay Clearing Staging / Auto Pay Staging ID |

Summary/Footer Record

There must be one record of this type at the end of the file.

| Field Name | Format | Source/Value/Description |
|-------------------------|--------|---|
| Total Number of Records | N13.2 | Total number of auto pay detail records in the file |
| Total Amount | N13.2 | Sum of auto pay amounts in the file |

Payment Information

The Third Party Auto Pay Extract file must have one record of this type for every direct debit record. The **C1-TAPEX-PR** Process Record algorithm uses the **C1-ThirdPartyAutoPayExtractRec** data area, which contains the following:

| Description | Element Name | Source/Value |
|---------------------------|----------------------------|--|
| Payor Account ID | payorAccountId | Payor account ID on the auto pay tender |
| Auto Pay Amount | autopayAmount | Tender amount on the auto pay tender |
| Due Date | billDueDate | Due date of the Bill ID linked to the auto pay |
| Maximum Withdrawal Amount | autopayMaxWithdrawalAmount | From the account's auto pay option |
| Auto Pay Clearing ID | autopayClearingId | From the auto pay staging record |

Footer Information

The Third Party Auto Pay Extract file must have one and only one record of this type. The **C1-TAPEX-PR** Process Record algorithm uses the **C1-ThirdPartyBatchRunVariables** data area, which contains the following:

| Description | Element Name | Source/Value |
|--------------|--------------|--------------------------------------|
| Record Count | recordCount | Total number of payments in the file |
| Total Amount | totalAmount | Total amount of payments in the file |

Third Party Payment Processing

A third party payment processing system is a service provider that can handle all aspects of electronic payments for a utility. When this service provider is integrated with *Oracle Utilities Customer Care & Billing*, every payment made through channels such as web self-service or integrated voice response (IVR) is accepted and processed within the service provider's fully hosted payment acceptance environment. Payment data (credit card number, bank account number, etc) is stored and processed outside of the utility's network.

The following sections describe the functions that are supported when this product is integrated with a third party payment processing system.

One Time Payments

A one time payment is a one-off, non-recurring payment option where the third party payment processing is authorized to collect a payment from a utility customer's credit card or bank account.

One time payments can be immediate or scheduled:

- Immediate one-time payments are processed on the same date that the payment is created/captured in the third party payment processing system.
- Scheduled one-time payments are processed at a future date that the customer designates.

The base product provides an inbound web service **C1-ThirdPartyOneTimePayNotification** that receives one time payment information from the third party payment processor, and, based on the required action, creates/updates the payment in the system. This web service supports the following functions:

- Creating an immediate or scheduled one time payment.
- Updating a scheduled one time payment
- Processing a scheduled one time payment
- Canceling a processed one time payment

The following sections describe these actions.

Creating One Time Payments

When the third party payment processing system processes a new one time payment, it will call the **C1-ThirdPartyOneTimePayNotification** inbound web service with an Add action. The payment details include the payment date/time, payment amount and basic details about the payment method (*i.e.*, bank account or credit card).

Note: Because bank account numbers and credit card numbers are captured outside of the system, the full account numbers are not sent. In most cases, only a partial value is sent, e.g. last four digits.

The inbound web service processes the payment as follows:

- If the Payment Date is the current date, it is processed as an immediate payment.
 - The system creates a Third Party One Time Payment Task, which in turn creates a frozen payment.
 - The payment date/time sent in by the third party payment processor is stored as a characteristic on the payment tender using the Processing Date/Time Characteristic Type in the Third Party One Time Payment Processing Integration master configuration. This is to capture the actual date/time when the payment was processed. This information is used in tender control processing.
 -  **Note:** The payment date/time is validated for XSD format. Any subsequent manual updates to this date/time will need to be in the correct XSD format. An adhoc characteristic validation algorithm type C1-VALIDATE exists for this purpose.
 - A reference to the Third Party One Time Payment Task's Service Task ID is stored as a characteristic on the payment tender using the Processing Reference Characteristic Type in the Third Party One Time Payment Processing Integration master configuration. This helps identify that the payment event/tender was created from third party payment processing.
 - The Payment Event ID is sent back to the third party payment processing system so that it has a way to identify the payment should there be a need to cancel the payment in the future.
- If the Payment Date is a future date, it is processed as a scheduled payment.
 - The system creates a pending Third Party One Time Payment Task. No further action is taken until the third party payment processing system sends another notification that the scheduled payment has been processed.
 - The Service Task ID is sent back to the third party payment processing system so that it has a way to identify the service task on subsequent requests to either update or process the pending one time payment.

Note: To prevent the creation of duplicate payments when the web service times out and the third party payment processing retries the web service call:

- The system checks if a frozen payment was already created from a previous web service call.
- The account is locked during payment event creation.

For more information about the lifecycle of the Third Party One Time Payment Notification service task, refer to the **C1-ThirdPartyOneTimePayTask** business object in the system.

For more information about master configuration settings, refer to the **Third Party Payment Processing Integration** master configuration in the system.

Updating Scheduled One Time Payments

If the third party payment processing system receives a request from the customer to update an existing one time payment, it will call the **C1-ThirdPartyOneTimePayNotification** inbound web service with an **Update** action, passing in the pending one time payment's Service Task ID and the updated payment details.

Note: Because bank account numbers and credit card numbers are captured outside of the system, the full account numbers are not sent. In most cases, only a partial value is sent, e.g. last four digits..

The inbound web service updates the existing Third Party One Time Payment Task with the new payment details sent in. The Third Party One Time Payment Task remains in the Pending state.

For more information about the lifecycle of the Third Party One Time Payment Notification service task, refer to the **C1-ThirdPartyOneTimePayTask** business object in the system.

Processing Scheduled One Time Payments

When it is time to process a scheduled one time payment, the third party payment processing will process the payment as it does an immediate one time payment. However, in this case, it will call the **C1-ThirdPartyOneTimePayNotification** inbound web service with a **Process** action, passing in the pending one time payment's Service Task ID and the payment details.

Note: Because bank account numbers and credit card numbers are captured outside of the system, the full account numbers are not sent. In most cases, only a partial value is sent, e.g. last four digits.

The inbound web service processes the one time payment as follows:

- The system transitions the existing Third Party One Time Payment Task so that it proceeds to create a frozen payment event.
- The payment date/time sent in by the third party payment processor is stored as a characteristic on the payment tender using the Processing Date/Time Characteristic Type in the Third Party One Time Payment Processing Integration master configuration. This is to capture the actual date/time when the payment was processed. This information is used in tender control processing.
- A reference to the Third Party One Time Payment Task's Service Task ID is stored as a characteristic on the payment tender using the Processing Reference Characteristic Type in the Third Party One Time Payment Processing Integration master configuration. This helps identify that the payment event/tender was created from third party payment processing.
- The Payment Event ID is sent back to the third party payment processing system so that it has a way to identify the payment should there be a need to cancel the payment in the future.

Note: To prevent the creation of duplicate payments when the web service times out and the third party payment processing retries the web service call:

- The system checks if a frozen payment was already created from a previous web service call.
- The account is locked during payment event creation.

For more information about the lifecycle of the Third Party One Time Payment Notification service task, refer to the **C1-ThirdPartyOneTimePayTask** business object in the system.

For more information about master configuration settings, refer to the **Third Party Payment Processing Integration** master configuration in the system.

Canceling One Time Payments

Scheduled or processed one time payments could get canceled for specific reasons. For instance, a processed payment could get canceled if a customer disputed a credit card charge or if the bank account has insufficient funds. When there is a need to cancel an existing scheduled or processed one time payment, the third party payment processor will cancel the one time payment in their system and call the **C1-ThirdPartyOneTimePayNotification** inbound web service with a **Cancel** action, passing in either a pending one time payment's Service Task ID (if canceling a scheduled payment) or a processed one time payment's Payment Event ID (if canceling a processed payment).

The inbound web service processes the one time payment cancellation as follows:

- For a scheduled on time payment, the existing Third Party One Time Payment Task is simply transitioned to the Discarded state.
- For a processed payment, the cancellation is processed as follows:
 - Since the original Third Party One Time Payment Task is already in the Completed state, a new Third Party One Time Payment Task is created to process the cancellation. Logic on the Process Payment state will cancel the existing Payment Tender using the Payment Event ID that is passed in from the web service.
 - The Tender Cancel Reason is taken from the **Third Party Payment Processing Integration** master configuration.
 - A reference to the cancellation Service Task ID is stored as a characteristic on the payment tender using the Cancellation Reference Characteristic Type that is defined in master configuration.
 - If master configuration is also set up with a Payment Auto-Cancel To Do Type, a To Do Entry is created.

For more information about the lifecycle of the Third Party One Time Payment Notification service task, refer to the **C1-ThirdPartyOneTimePayTask** business object in the system.

For more information about master configuration settings, refer to the **Third Party Payment Processing Integration** master configuration in the system.

Account Verification

A third party payment processing system can perform account verification prior to processing one time payments and automatic payment enrollments. This is to verify that the account exists, as well as to get specific information about the account such as the account balance, due date, past due amount, and existing auto pay information.

The base product provides an inbound web service **C1-ThirdPartyVerifyAccount** that receives an Account ID from the third party payment processor and creates a Third Party Account Verification Task that is responsible for verifying the account. Base-supplied logic on this service task checks that the account exists and returns the account's balance, due date, past due amount (if any) and existing auto pay information (if any). Refer to the **C1-ThirdPartyAcctVerifTask** business object for more details.

Automatic Payment Setup

When the system is integrated with a third party payment processing system, customers who opt for automatic bill payment enrol through the third party payment processing system, where payment information that includes credit card or bank account number are captured and stored.

The third party payment processing system sends a notification when it processes new or updated account auto pay information.

The base product provides an inbound web service **C1-ThirdPartyAutoPaySetup** that receives auto pay setup information and creates a Third Party Auto Pay Setup Task, which is responsible for creating or updating the account's auto pay information. Base-supplied logic on this service task adds an account auto pay option, updates an existing account auto pay option's details or cancels an existing account auto pay option by setting its end date to the designated date. Refer to the **C1-ThirdPartyAutoPayTask** business object for more details.

Interfacing Automatic Payments To A Third Party

For customers who are enrolled to automatically pay bills through a third party payment processing system, existing auto pay processing that occurs during bill completion applies. Refer to [How And When Are Automatic Payments Created?](#) on page 438 for more details.

The difference with automatic payment processing via third party payment processing system is that the auto pay staging records are not sent directly to the financial institution. Since the routing is different, a third party payment processing system is associated with a distinct Auto Pay Source and Auto Pay Route Type. Refer to [Define Auto Pay Sources and Auto Pay Route Types](#) for more details on this configuration.

Third party automatic payment transactions are extracted using the Third Party Auto Pay Extract (C1-TAPEX) batch process. Refer to [Downloading Automatic Payments and Interfacing Them To The GL](#) on page 441 for details on how this batch process fits into the auto pay batch process flows.

Highlighting Scheduled Payments

The Scheduled Payments Log zone in Control Central - Account Information displays the following:

- Pending third party one time payments
- Pending self-service one time payments
- Pending bill-related automatic payment records
- One time payments in error that have not been resolved, i.e. not succeeded by a Pending or Completed one time payment

Refer to the zone help for more information.

Automatic Payment Confirmations And Cancellations

A third party payment processing system can notify the system about whether or not the auto pay transactions sent to it for processing were processed successfully.

The base product provides two batch processes, one each for auto pay confirmation and auto pay cancellation. Refer to the following sections for more details.

C1-TAPDF - Third Party Auto Pay Confirmations

This batch process receives a comma-delimited (CSV) file containing information about auto pay transactions that were successfully processed at the third party payment processing system. Each record contains the following:

- Account ID
- Auto Pay Clearing ID (i.e. PK of the auto pay staging record)
- Payment Date/Time

A Process Record algorithm **C1-TAPDF-PR** is plugged in on this batch control. For each record in the file, it distributes and freezes the payment associated with the auto pay staging record. It also updates the payment event date if it differs from the payment date sent with the confirmation. The payment date/time on the confirmation is stored as a characteristic on the auto pay tender.

C1-TAPCN - Third Party Auto Pay Cancellations

This batch process receives a comma-delimited (CSV) file containing information about auto pay transactions that were not processed successfully at the third party payment processing system. Each record contains the following:

- Account ID
- Auto Pay Clearing ID (i.e. PK of the auto pay staging record)

A Process Record algorithm **C1-TAPCN-PR** is plugged in on this batch control. For each record in the file, it cancels the tender associated with the auto pay staging record, using the Tender Cancel Reason that is defined in the Third Party Payment Processing Integration master configuration.

Third Party Payment Tender Controls Processing

A third party payment processing system handles two types of payments: one time payments and recurring automatic bill payments.

The third party payment processing system sets the daily cutoff time for payment processing. For instance, a third party payment processor could set the default daily processing cutoff time to 8pm Eastern Time. But each implementation can override this processing cutoff time. The third party's processing cutoff time is defined in the Third Party Payment Processing Integration master configuration.

For recurring bill auto pays, the system will create the payment event, payment (non-frozen), tender and auto pay staging record. The Tender Control ID is not assigned until a batch process runs and creates the tender and deposit controls for the extracted auto pay transactions.

For one time payments, the assumption is that tender and deposit control processing will be handled in the same way as the recurring auto pays. The one time payment's tender will not be linked to a tender control at one time payment tender creation time. Instead, the tender control will be created in batch, similar to how recurring auto pay tender controls are created.

The base product provides two batch processes for Third Party Auto Pay Tender Controls (C1-TAPCT) and Third Party One Time Payment Tender Controls (C1-TOPCT). For a third party one time payment, a pre-processing batch

process C1–TOPPP takes the place of the usual auto pay extract process. This is because third party one time payment auto pays are used purely for tender controls processing and are not sent out to the third party payment processing.

The following sections describe these batch processes.

C1-TAPCT - Third Party Auto Pay Tender Controls

This process creates a tender control (with an associated deposit control) for each batch control and run number encountered for third party automatic payments that are not yet linked to a tender control.

This is a plugin-driven batch process. The C1–TAPCT batch control is delivered with two algorithms plugged in:

- A Select Records algorithm is responsible for selecting the auto pay staging records to process.
- A Process Record algorithm is responsible for linking each auto pay staging record's payment tender to the corresponding tender control.

Your implementation can plug in your own Select Records and Process Record algorithms if your business rules for this extract differ.

This batch process is meant to be run after the Third Party Auto Pay Extract (C1–TAPEX) runs and before Balance Autopay Control Tables (C1–BLAPC) runs.

C1-TOPPP - Third Party One Time Payment Controls Pre-Processing

This process reads all auto pay download staging records marked with a given batch control ID and run number, to verify that the associated one time payment was processed within the current processing cutoff time. Any one time payments that were processed after the cutoff will be updated with the next batch run number.

This is a plugin-driven batch process.

The C1–TOPPP batch control is delivered with two algorithms plugged in:

- A Select Records algorithm is responsible for selecting the auto pay staging records to retrieve, based on the input batch code and batch run number.
- A Process Record algorithm is responsible for verifying that each auto pay staging record selected was processed within the current cutoff time.

Your implementation can plug in your own Select Records and Process Record algorithms if your business rules for this extract differ.

This batch process is meant to be run after the Activate auto-pay (ACTVTAPY) runs and before Third Party One Time Payment Tender Controls (C1–TOPCT) runs. This batch control should be specified on your configured auto pay route type for third party one time payments.

C1-TOPCT - Third Party One Time Payment Tender Controls

This process creates a tender control (with an associated deposit control) for each batch control and run number encountered for third party one time payments that are not yet linked to a tender control.

This is a plugin-driven batch process. The C1–TOPCT batch control is delivered with two algorithms plugged in:

- A Select Records algorithm is responsible for selecting the auto pay staging records to process.
- A Process Record algorithm is responsible for linking each auto pay staging record's payment tender to the corresponding tender control.

Your implementation can plug in your own Select Records and Process Record algorithms if your business rules differ.

This batch process is meant to be run after the Third Party Auto Pay Extract (C1–TOPPP) runs and before Balance Autopay Control Tables (C1–BLAPC) runs.

Issuing A Payment Advice Instead Of Creating An Automatic Payment

If the system is configured to send the customer a payment advice (instead of initiating an electronic funds transfer) when a bill is completed, the automatic payment records - i.e. payment event, payment, tender and auto pay clearinghouse staging - are not created. Refer to [Payment Advices](#) for more information.

How To Set Up A Customer To Receive Payment Advices

Use [Account - Auto Pay](#) to capture the customer's bank details and indicate an auto pay method of Payment Advice.

Payment Advice Option Is For Bill-Related Automatic Payments Only

Payment advices can be printed for auto pays that result from completed bills.

An auto pay for a pay plan scheduled payment will not be created if the account's effective auto pay option is set to Payment Advice. The Pay Plan Auto Pay (PPAPAY) batch process will log an error in this case.

An auto pay for a Non-Billed Budget scheduled payment will not be created if the account's effective auto pay option is set to Payment Advice. The Non-Billed Budget Pay Plan Auto Pay (NBBAPAY) batch process will log an error in this case.

Manually created automatic payments (i.e. auto pays created via payment event UI) are always processed as direct debit.

Maintaining Payment Events

A payment event is used to record when moneys are remitted and how the moneys are allocated amongst accounts. The topics in this section describe how to maintain payment events.

Note:

The system creates most payment events behind-the-scenes. Most payment events are created by the system when it [uploads payments](#) and when it creates [automatic payments](#). You should only have to access the payment event transaction if you need to correct a payment event or add a payment event real-time. For information about how the system creates payment events, refer to [The Big Picture of Payments](#).

Payment Lifecycles

The topics in this section describe the lifecycle of the various payment objects.

Payment Event Lifecycle

The following diagram shows the possible lifecycle of a payment event.

Warning:

This diagram only makes sense in the context of the page used to maintain payment events. Refer to [Payment Event - Main Information](#) for the details.

The system, by default, distributes the sum of a payment event's tenders to the account that remits the tenders. After distribution the sum of the tenders equals the sum of the payments (remember, the term *payment* is used to refer to an allocation of some/all of a payment event's tenders to an account's debt) when the event is first created. We refer to such an event as being **Balanced**.

It is possible via any of the methods described in [Unbalanced Payment Events](#) to make a balanced payment event Unbalanced.

Click **Delete** to physically remove a balanced or unbalanced payment event from the database. You may not delete a payment event if: a) there are frozen or canceled payments linked to the event, or b) if there are canceled tenders linked to the event, or c) if a tender linked to the event is part of a balanced tender control. When the payment event is deleted, the system also deletes its tenders, payments, and payment segments.

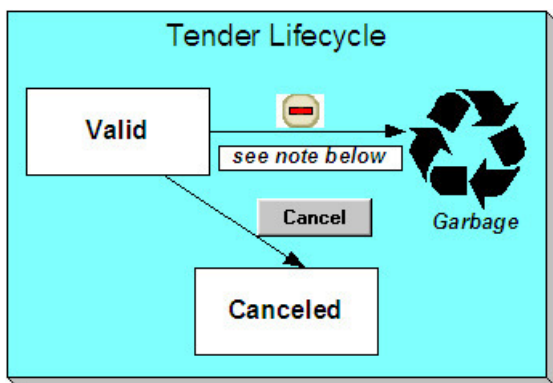

Tender Lifecycle

The following diagram shows the possible lifecycle of a payment event.

Warning:

This diagram only makes sense in the context of the page used to maintain tenders. Refer to [Payment Event - Tenders](#) for the details.

A tender is initially saved in the Valid state. It is possible via any of the methods described in [Unbalanced Payment Events](#) to make a balanced payment event Unbalanced.

If a tender is invalid, click **Cancel** to cancel the tender AND ALL PAYMENTS LINKED TO THE EVENT.

Click the delete button to physically remove a tender from the database. You may not delete a tender if it is part of a balanced tender control.

Payment Lifecycle

The following diagram shows the possible lifecycle of a payment.

**Warning:**

This diagram only makes sense in the context of the page used to maintain a payment. Refer to [Payment - Main](#) for the details.

Payments are initially created in the Incomplete state. Payments in this state don't have payment segments or financial transactions; they are simply a stub awaiting distribution.

Click **Distribute** to distribute a payment amongst an account's service agreements.

- If the system cannot distribute the payment (for whatever reason), the payment is moved to the Error state. You may delete such a payment.
- If the system successfully distributes a payment, the payment becomes Freezable.

Click the - button to physically remove an Incomplete, Error or Freezable payment from the database.

Click **Freeze** to freeze a payment and its financial transaction. Freezing the payment causes the following to occur:

- The system executes any payment freeze algorithms linked to the account's [customer class](#) and to the service agreement's [SA type](#).
- The payment's state becomes Frozen and the payment may now appear on a customer's bill.

You may not change a payment once it is frozen. However, you may reverse the payment's financial effect by clicking **Cancel**. Clicking this button will cause the following to occur:

- A new financial transaction is generated and linked to the payment. This financial transaction reverses the financial effects of the original payment.
- The system executes any payment cancellation algorithms linked to the account's [customer class](#).
- If the payment has a related adjustment, this adjustment is also cancelled. Refer to [Loan Overpayments](#) for an example of payments with adjustments.
- The payment becomes Canceled.

Payment Event - Add Dialog

The Payment Event transaction features an unusual dialog that simplifies the addition of new payment events. This page appears if you open the **Menu > Financial > Payment Event > Add** from either the Account context menu or from Menu (it also appears if you click the clear button when on the Payment Event page).

Note:

If you have opted to always use the payment event distribution rules method as your [default method](#), the [Payment Event Quick Add \(Single Payment Event\)](#) page appears instead.

There is an Add One-Time Payment dialog that behaves similarly to Payment Event - Add, but adds a number of capabilities related to automatic payment methods. Refer to [Add One-Time Payment](#) for more details.

To use the Add One-Time Payment popup instead of the Payment Event - Add popup, refer to [One-Time Payment Options](#) for details on enablement.

Description of Page

The **Payor Account ID** is the account that remitted the payment. We assume this account is both the tendering account and the account whose debt is being relieved by the payment. If this assumption is not correct, choose a **Distribute Action** of Do Not Distribute and then change the tendering or paying account when the Payment Event page appears (after you click **OK**).

Note:

Default note. If you have navigated to this page from account context menu, the Payor Account ID and Payment Amount are defaulted to this account.

The **Payment Amount** is the amount of the customer's debt to be relieved by the payment. Note, this amount is defaulted using an algorithm plugged in on the [Installation Record](#). Please refer to the Automatic Payment Amount Calculation algorithm, (C1-APAM-DFLT) for more information on the calculation.

The payment tenders grid allows you to enter multiple tender types and amounts. Click + to add a new tender. For each tender specify the following fields:

- The **Amount Tendered** is the amount of moneys remitted for the tender type.
- **Tender Type** describes what was remitted (e.g., cash, check, ...). **Tender Type** defaults from the Quick Add Tender Type that is defined on the [installation record](#).
- If a check was tendered, use **Check Number** to specify the identity of the check.

Note:

Cash back causes an additional tender to be created. If cash should be returned to the customer (because the customer overpaid and the tender type's cash back allowed switch is true and the tender type is not "like cash"), a negative tender for the cash back amount is created for the payment event. Refer to [Cash Back](#) for a description of how the system can recommend Cash Back amount if the customer tendered more than they are paying.

Match Type and **Match Value** are used if either of the following conditions is true:

- This **Payor Account** belongs to an [open item](#) customer class. In this situation, specify a **Match Type** to define how the payment should be matched to the customer's open-items and use **Match Value** to define the open-items covered by the payment. For example, if this payment is in respect of a bill, specify a match type of "bill ID" and a match value of the bill ID being paid.

Note:

Shortcut. If you enter a **Match Type** of "bill ID" and leave the **Match Value** blank, the system assumes the customer wants to pay the latest bill.

- The customer wants to restrict the distribution of the payment to a specific service agreement. In this situation, specify a **Match Type** of "service agreement ID" and a **Match Value** of the respective service agreement ID.

The **Payment Date** defaults to the current date.

If the **Payor Account ID's** [customer class](#) is designated as non-CIS (i.e., the person making the payment isn't a customer), the following information appears in the above window:

- **Non CIS Name** is the name of the person remitting the payment.
- **Reference Number** is the reference number of the item being paid (e.g., the property tax reference number).
- **Non CIS Comments** are used to describe anything unusual about the non-CIS payment.

Use **Distribute Action** to describe what you'd like to have happen when you click the **OK** button:

- Choose Distribute and Freeze if OK if this is a simple payment that should require no manual intervention. By "simple payment" we mean:
 - The account is both the tendering account and the account whose debt is being relieved by the payment
 - The payment date is the current date
 - The payment should be [distributed](#) amongst the account's service agreements using standard distribution logic
- If this option is selected, the system distributes the **Payment Amount** amongst the account's service agreements. If the distribution is successful, the system automatically freezes the payment. If the distribution is not successful, the payment will be in the Error or Incomplete state. When the Payment Event page appears, you can view the error and then correct it. After the cause of the error is corrected, you must distribute and freeze the payment manually (this can be done on several pages including [Payment Event - Main](#) and [Payment - Main](#)).
- Choose Manual Distribution if you need to manually distribute the payment amongst the account's service agreements. If this option is selected, the system creates a payment event, a tender and a payment and then transfers you to the [Payment - Manual Distribution](#) page where you can define the amount to be allocated to each of the account's service agreements. After you've distributed the payment, don't forget to freeze it.
- Choose Do Not Distribute if you want to process the payment event manually (e.g., if you need to define multiple accounts whose debt is relieved by the payment). If this option is selected, the [Payment Event - Main](#) page opens with the information you entered defaulted accordingly. You can make any changes you want and then distribute and freeze the payment. Refer to [How To Add A New Payment Event](#) for more information.

Note:

Cash-only warning. If the account has exceeded your [cash-only threshold](#) and the **Tender Type** isn't marked as "like cash", a warning appears advising of such. Note, a customer's cash-only points are maintained on [Account - Credit Rating](#).

Add One-Time Payment

The Add One-Time Payment user interface allows for quick add of one-time payment events using any of the following:

- Stored payment methods from self-service one-time payments and wallet maintenance
- A currently effective account auto pay option for recurring bill automatic payments
- New checking or savings payment methods - subject to web debit account validation, if the bank account is being used for the first time
- Cash
- Non-cash, non-auto pay tender types - e.g., check

Note: The Add One-Time Payment user interface is an alternative for the [Payment Event - Add Dialog](#). Refer to [One Time Payment Options](#) for information on how to enable it.

When enabled, the Add One-Time Payment dialog can be launched from any of the following:

- **Take A Payment** action from the Customer sidebar zone.
- Main Menu: **Menu > Financial > Payment Event > Add**
- Account context menu: **Payment Event > Add**

In addition, the Add One-Time Payment script can also be called from other places (zones, maps, etc) in the system where your implementation allows the capture of a one-time payment.

Note:

If you have opted to always use the payment event distribution rules method as your [default method](#), the [Payment Event Quick Add \(Single Payment Event\)](#) page appears instead.

The **Payment Date** defaults to the current date.

The **Payor Account ID** is the account that is tendering the payment. This is defaulted from the Account in context, if any.

Note:

Cash-only warning. If the account has exceeded your [cash-only threshold](#) a message appears advising of such. A customer's cash-only points are maintained on the [Account - Credit Rating](#) page.

The **Payment Amount** is the amount of the customer's debt to be relieved by the payment. Note, this amount is defaulted using an algorithm plugged in on the [Installation Record](#). Please refer to the Automatic Payment Amount Calculation algorithm, (C1-APAM-DFLT) for more information on the calculation.

The **Tenders - Existing Payment Options** grid is shown if the Payor Account has existing self-service payment methods and/or a currently effective recurring bill auto pay enrollment. Select a **Payment Option** and specify the **Tender Amount**.

The **Tenders - New Auto Pay Options and Other Tender Types** grid is used for new automatic payment methods, cash tender type(s) and other non-cash/non-auto pay tender types (e.g. check). Select a **Tender Type** and specify the applicable information. A new checking/savings payment method can be saved, to make it available for future one-time payments, including self-service payments. Specify the **Tender Amount**.

Note:

Cash back causes an additional tender to be created. If cash should be returned to the customer (because the customer overpaid and the tender type's cash back allowed switch is true and the tender type is not "like cash"), a negative tender for the cash back amount is created for the payment event. Refer to [Cash Back](#) for a description of how the system can recommend Cash Back amount if the customer tendered more than they are paying.

Credit card tender types are not supported. To ensure compliance with credit card processing rules, it is highly recommended that credit card payments be processed through a third-party payment processing system. If your implementation needs to support credit card tender types in this dialog, you can create a custom BPA script to override the base-owned BPA script. Refer to [One Time Payment Options](#) for details.

Match Type and **Match Value** are shown used if either of the following conditions is true:

- The **Payor Account** belongs to an [open item](#) customer class. In this situation, specify a **Match Type** to define how the payment should be matched to the customer's open-items and use **Match Value** to define the open-items covered by the payment. For example, if this payment is in respect of a bill, specify a match type of "bill ID" and a match value of the bill ID being paid.

Note:

Shortcut. If you enter a **Match Type** of "bill ID" and leave the **Match Value** blank, the system assumes the customer wants to pay the latest bill.

- The customer wants to restrict the distribution of the payment to a specific service agreement. In this situation, specify a **Match Type** of "service agreement ID" and a **Match Value** of the respective service agreement ID.

If the **Payor Account ID's** [customer class](#) is designated as non-CIS (i.e., the person making the payment isn't a customer), the following information appears in the above window:

- **Non CIS Name** is the name of the person remitting the payment.
- **Reference Number** is the reference number of the item being paid (e.g., the property tax reference number).
- **Non CIS Comments** are used to describe anything unusual about the non-CIS payment.

Use **Distribute Action** to describe what you'd like to have happen when you click the **OK** button:

- Choose **Distribute and Freeze if OK** if this is a simple payment that should require no manual intervention. "Simple payment" means:
 - The account is both the tendering account and the account whose debt is being relieved by the payment
 - The payment date is the current date
 - The payment should be [distributed](#) amongst the account's service agreements using standard distribution logic

If this option is selected, the system distributes the **Payment Amount** amongst the account's service agreements. If the distribution is successful, the system automatically freezes the payment. If the distribution is not successful or is on hold due to web debit account validation, the payment will be in the Error or Incomplete state, respectively. When the Payment Event page appears, you can view the error and then correct it. After the cause of the error is corrected, you must distribute and freeze the payment manually (this can be done on several pages including [Payment Event - Main](#) and [Payment - Main](#)). If any new auto pay methods are checking/savings bank accounts that have never been used on prior recurring auto pays and/or prior self-service one-time payments, the bank accounts will be subject to web debit account validation if the system is configured to do so. The One-Time Payment service task is created to manage bank account validation. The service task is linked to the payment event, which remains in Incomplete status until the validation is complete. The service task will either complete or delete the payment event, depending on the validation results. Refer to [Web Debit Account Validation](#) for more details.

- Choose **Manual Distribution** if you need to manually distribute the payment amongst the account's service agreements or if you want to process the payment event manually (e.g. if you need to define multiple payee accounts). If this option is selected, the system creates a payment event, a tender and a payment and then transfers you to the [Payment - Manual Distribution](#) page where you can define the amount to be allocated to each of the account's service agreements. After you've distributed the payment, don't forget to freeze it. If allocating the payment to multiple payee accounts, navigate to the [Payment Event - Main](#) page and make any changes before distributing and freezing the payment.

Payment Event - Main Information

The Main page contains core payment event information. Open this page using **Menu > Financial > Payment Event > Search**.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To](#) for a description of how to perform common payment event maintenance functions.

Description of Page

Note:

Cash-only customers. When you attempt to add a new payment event, the system warns you if the account remitting the tender is a cash-only customer and the tender's **tender type** is not cash. An account is considered cash-only if their current cash-only points exceed the cash-only threshold maintained on the Installation record or account's CIS Division. A customer's cash-only points are maintained on [Account - Credit Rating](#).

Pay Event Info contains a concatenation of the payment date, amount, and the name of the main customer on the account that remits the tender. If multiple tenders exist, the customer's name is not displayed. If the payment event is associated with a single distribution detail, the rule name and the description of the rule value are displayed as well. If multiple distribution details exist, Multiple Distribution Details Exist is displayed instead. If document numbering has been enabled, the assigned document number will appear. If the payment was made in an alternate currency, the message Alternate Currency Used is displayed. **Pay Event Info** is only displayed after the payment event has been added to the database.

Refer to [Alternate Currency Payments](#) and [Document Numbers](#) for more information. **Payment Event ID** is the system-assigned unique identifier of the payment event.

The area under **Pay Event Info** provides warnings about the payment event. Possible warnings are Unfrozen Payments and The Payment Event is Unbalanced. A warning is also issued to the cashier to remind them to turn in funds - see [Turn Ins](#).

If multiple distribution details are linked to the payment event, the distribution rule, value, and amount for each distribution detail displays.

Payment Date is the business date associated with the payment event.

**Warning:**

If you change the payment date and this event's tender(s) are automatic payments, the extract date (i.e., the date the automatic payment is sent to the financial institution) will be changed to equal the payment date. Refer to [Automatic Payments](#) for more information.

Payment(s) contains the total number and value of payments linked to the event.

Tender(s) contains the total number and value of tenders linked to the event.

Amount Tendered contains the amount that was tendered by the customer.

The system displays a **Cash Back Amount** if the customer tenders more than they are paying (refer to [Cash Back](#) for details).

If the payment event becomes unbalanced, a **Recalculate Cash Back** button appears. If this button is clicked, the system creates, deletes or recalculates the cash back tender. Refer to [Cash Back](#) for details.

While most payment events contain a single payment, the system allows many payments to exist under a payment event (when the payment event's tender(s) are distributed amongst multiple accounts). If a payment event has a large number of payments, you can use the **Account Filter** to limit the payments that appear in the **Payments** grid. The following options are available:

- **Account.** Use this option if you only want to see the payment linked to an **Account ID**.
- **All.** Use this option to view all payments linked to the payment event.
- **Person Name.** Use this option to restrict payments linked to accounts whose main customer has a primary name that matches **Person Name**.

The **Payments** grid contains the payment(s) linked to the payment event. The following points describe the attributes in this scroll; refer to [How To](#) for instructions describing how to perform common maintenance activities.

- **Account ID** references the payment's account. The name of the account's main customer is displayed adjacent.
- **Payment Amount** is the amount of the account's debt relieved by the payment. The adjacent context menu allows you to drill down to the details of the [payment](#) (this is where you can see the payment's payment segments and where you can override the distribution of the payment).
- **Payment Status** is the payment's status. If the payment's status is Error, the error message is displayed adjacent. Refer to [Payment Lifecycle](#) for the potential values and how to handle a payment when it exists in a given state.
- **Match Type** and **Match Value** should only be used if either of the following conditions is true:
 - This **Account ID** belongs to an [open item](#) customer class. In this situation, specify a **Match Type** to define how the payment should be matched to the customer's open-items and use **Match Value** to define the open-items covered by the payment. For example, if this payment is in respect of a bill, specify a match type of "bill id" and a match value of the bill id being paid.
 - The customer wants to restrict the distribution of the payment to a specific service agreement. In this situation, specify a **Match Type** of "service agreement ID" and a **Match Value** of the respective service agreement ID.
- The remaining columns are only used if the payment is linked to an **Account ID** that belongs to a customer class that is used for non-CIS payments. Refer to [Setting Up Customer Classes](#) for more information. If such an account exists, the following fields must be defined.
 - **Non CIS Name** is the name of the person remitting the payment.
 - **Reference Number** is the reference number of the item being paid (e.g., the property tax reference number).
 - **Non CIS Comments** are used to describe anything unusual about the non-CIS payment.
- Note, you can also define a comment for a non-CIS payment. To define a comment, use the context menu adjacent to **Payment Amount** to drill to [Payment - Main](#).
- **Payment ID** is the unique, system-assigned identifier of the payment. This value only appears after the payment has been added to the database.

Refer to [Payment Actions](#) and [Payment Event Actions](#) for information about the action buttons on this page. Refer to [How To](#) for a description of typical business processes that use these buttons.

Payment Event - Tenders

The Tenders page contains a scroll showing one row for every tender associated with the payment event. Open this page using **Menu > Financial > Payment Event > Search** and navigate to the **Tenders** page.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To](#) for instructions describing how to perform common maintenance functions.

Description of Page

Pay Event Info contains a concatenation of the payment date, amount, and the name of the main customer on the account that remits the tender. If multiple tenders exist, the customer's name is not displayed. If the payment event is associated with a single distribution detail, the rule name and the description of the rule value are displayed as well. If multiple distribution details exist, Multiple Distribution Details Exist is displayed instead. If document numbering has been enabled, the assigned document number will appear. If the payment was made in an alternate currency, the message Alternate Currency Used is displayed. **Pay Event Info** is only displayed after the payment event has been added to the database.

Payment Event ID is the system-assigned unique identifier of the payment event.

Payment Date is the business date associated with the payment event.

Payment(s) contains the total number and value of payments linked to the event.

Tender(s) contains the total number and value of tenders linked to the event.

Amount Tendered contains the amount that was tendered by the customer.

The system displays a **Cash Back Amount** if the customer tenders more than they are paying (refer to [Cash Back](#) for details).

If the payment event becomes unbalanced, a **Recalculate Cash Back** button appears. If this button is clicked, the system creates, deletes or recalculates the cash back tender. Refer to [Cash Back](#) for details.

The **Tenders** scroll controls the display of the tenders linked to the payment event. The following simply describes the fields in this scroll; refer to [How To](#) for instructions describing how to perform common tender maintenance activities.

- **Payor Account ID** references the tendering account. The name of the account's main customer is displayed adjacent. If the account has exceeded your cash-only threshold, the warning Cash-Only appears.

Warning:

If you change the Payor Account ID and the tender has an associated automatic payment request, the automatic payment request will be removed. A new automatic payment request will be created for the new Payor Account ID. Refer to [Automatic Payments for more information](#).

- **Tender Amount** is the amount of the tender. The amount is disabled if the payment was made in an alternate currency.
- If a check was used, the **Check Number** contains the identity of the check.
- **Pay Tender ID** is the system-assigned unique identifier of the tender. This value appears after the tender has been added to the database.
- **Tender Type** describes what was remitted (e.g., cash, check). If the **Tender Type** is associated with an automatic payment, the page displays a section that includes information about how and when the automatic payment was interfaced to the payment source.

Note:

Authorizing Tenders. The **Tender Type** dropdown list does not include tender types that require authorization (i.e. credit card payments).

**Fastpath:**

For information about tender types requiring authorization, refer to [Credit Card Payments](#).

- If the payment tender was remitted in an alternate currency, i.e. a currency other than the payor account's currency, **Alternate Currency** and **Exchange Rate** will display the formatted alternate amount ((includes the alternate amount and currency) and the exchange rate that was in effect on the payment date.

**Fastpath:**

For information about accepting payments in alternate currencies, refer to [Alternate Currency Payments](#).

- **Tender Status** is the tender's status. Refer to [Tender Lifecycle](#) for the potential values and how to handle a tender when it exists in a given state.
- If the **Tender Type** is associated with an [automatic payment](#), the system attempts to default automatic payment information from the [account's auto-pay](#) option if the tender type is the same as the tender type on the account's auto-pay source and if the auto pay option is effective on the payment date. If the system is unable to default information, you must specify the source of the funds and the customer's account number / credit card number at the financial institution. You can override automatic payment information as long as the automatic payment has not been sent to the financial institution or cancelled. The **Auto Pay Section** contains the following fields:
 - **Auto Pay Source** is the financial institution / credit card company that receives the automatic payment request.
 - **Scheduled Extract Date** is the date the automatic payment request was sent / is scheduled to be sent to the financial institution. This information is display-only.
 - **External Account ID** is the customer's account number at the financial institution.

Note: The system supports encryption for External Account ID. If your implementation has configured the system to encrypt External Account ID, the data will be displayed with a masked value; such as, *****.Refer to [Encrypting Sensitive Data](#) for more information.

- **Expires On** is only needed if the Tender Type indicates that an expiration date is necessary (e.g., for a credit card payment).
- **Name** is the customer's name in the financial institution's system.
- **Bill ID** is the ID of the bill whose completion caused the creation of the automatic payment. This information only appears if the automatic payment was created as a result of a bill. This information is display-only.
- If the payment was uploaded, the following fields MAY contain information (if they were populated in the interface file):
 - **MICR ID** is the value of the magnetic ink character recognition (MICR) line on the payment.
 - **Note:** The system supports encryption for MICR ID. If your implementation has configured the system to encrypt MICR ID, the data will be displayed with a masked value; such as, *****.Refer to [Encrypting Sensitive Data](#) for more information.
 - **Customer ID** is the customer's account ID that appeared on the interfaced payment.
 - **Ext. Reference ID** is the unique identifier of the payment upload interface record.
 - **Name** is the customer's name on the interfaced payment record.
- In the **Tender Control** area, the **Tender Control ID** is the identity of the remittance processor batch or cash drawer bundle in which the tender was remitted. Refer to [Tender Management and Workstation Cashiering](#) for more information about tender controls.
- Displayed adjacent to **Tender Control** is the date, tender source, and status of the tender control.

Every new tender must reference an open tender control. The system will attempt to default an appropriate tender control as follows:

- If the user has at least one open, user-specific Tender Control, the system will default one, at random.
- If the user has no open, user-specific Tender Controls; the system will default an open, "all users" tender control if it can find one whose tender source indicates it's used for online cashiering. If multiple exist, one will be selected at random.
- Turn off **Included in Tender Ctl Balance** if the tender should not be included in the tender amount in the tender control's tender balance. You would turn this switch off if you canceled a tender because it was mistakenly applied to the wrong account (or the amount was wrong). This switch is only enabled if:

- The tender control isn't balanced.
- The tender is canceled.
- **Deposit Control** contains a concatenation of the tender control's deposit control's creation date, tender source type, and status. Refer to [Tender Management and Workstation Cashiering](#) for more information about deposit controls.
- The **Tender Action** area contains a button that you use to cancel a tender. Refer to [Tender Actions](#) for information about this button. Refer to [How To Cancel A Tender](#) for more information.

The **Characteristics** collection on the Tenders page contains information that describes miscellaneous information about the tender. The following fields display:

Characteristic Type Indicate the type of characteristic.

Sequence Controls the order in which characteristics of the same type are displayed.

Characteristic Value Indicate the value of the characteristic.

Payment Event - Characteristics

To update payment event characteristics, open **Menu > Financial > Payment Event > Search** and navigate to the **Characteristics** page.

Description of Page

The **Characteristics** collection contains information that describes miscellaneous information about the payment event.

The following fields display:

Characteristic Type Indicate the type of characteristic.

Sequence Controls the order in which characteristics of the same type are displayed.

Characteristic Value Indicate the value of the characteristic.

Exception

The topics in this section describe exceptions that are detected when the system allocates a payment.

Payment Event Exception

It is possible for a payment event's tenders to not equal its payments. Such events are classified as unbalanced. For each unbalanced payment event, a record is written to the Payment Event Exception table (CI_PAY_EVT_EXCP). A To Do background process creates To Do entries for records in this table.

Unbalanced payment events cause a record to be written to the payment event exception table with a message indicating the nature of the error.

To view the messages associated with the exception records, schedule the [TD-UNBAL](#) background process. This process generates a To Do entry for every record in the payment event exception table.

Fastpath:

Refer to [Unbalanced Payment Events](#) for instructions describing how to correct an unbalanced payment event.

Payment Exception

When the system is unable to distribute a payment, a record to be written to the payment exception table with a message indicating the nature of the error. A common example of a payment exception is **no service agreement**

to hold a credit. This can occur when an account overpays their debt and the account doesn't have a single service agreement that is allowed to hold a credit, a payment error is generated.

The system saves payments that are in error just as it saves payments that are error-free. This is done because payments are nothing more than a snapshot of the data that was used to distribute the payment. By saving the snapshot, you can see the information the system used when it detected the error and therefore more effectively correct it.

Every payment in error is written to the Payment Exception table (CI_PAY_EXCP). A To Do background process creates To Do entries for records in this table.

To view the messages associated with the exception records, schedule the [TD-PYERR](#) background process. This process generates a To Do entry for every record in the payment exception table.

After correcting the cause of the error, drill into the [Payment](#) and attempt to redistribute it.

Resolving Exceptions Automatically

Some payment errors occur because master data was not fully set up prior to receiving a payment for the account. For these cases, the system will periodically check to see whether the master data problem has been resolved by attempting to distribute and freeze the payment in error.

A background process, Resolve Payments in Error - [PY-RPE](#), exists for this purpose. This background process works as follows:

- It looks for payments in error where the error was caused by the lack of active service agreements linked to the payment's account. Note, this may occur when a customer is verbally asked to pay a connection fee or deposit prior to starting service, and for some reason, the appropriate service agreement has not been set up yet, or is still pending.
- For each such payment, it attempts to re-distribute the payment. If service agreements have been created in the meantime, this payment will distribute and freeze successfully.

Payment Event Action Codes

The topics that follow describe each of the actions that appear on the payment event pages.

Payment Actions

The topics that follow describe payment-oriented actions. Refer to [How To](#) for a description of several business processes that use these buttons.

Distribute (Payments)

Clicking the **Distribute** button distributes all Incomplete, Error, or Freezable payments linked to the event. Refer to [Distribute \(A Payment\)](#) for information of how a single payment is distributed.

This button is enabled if at least one payment is Incomplete, Error, or Freezable.

Redistribute (Payments)

Clicking the **Redistribute** button redistributes all Incomplete, Error, or Freezable payments linked to the event. Refer to [Redistribute \(A Payment\)](#) for information of how a single payment is redistributed.

This button is enabled if at least one payment is Incomplete, Error, or Freezable.

Print

The Print button is enabled under the following conditions:

- The payment event must have at least one payment that is Frozen and no payments that are Incomplete, Error or Freezable.
- A processing script is configured in the Point Of Sale (POS) Printer Integration master configuration.
 - For the Payment Event page, a **POS Printing - Payment Event** BPA script should be configured.
 - For the Payment Event Quick Add page, a **POS Printing - Payment Event Quick Add** BPA script should be configured.
 - For the Payment Quick Add page, a **POS Printing - Payment Quick Add** BPA script should be configured.

Refer to [How To Print Receipts And Endorsements](#) for more information.

Freeze (Payments)

Clicking the **Freeze** button causes all Freezable payments linked to the event to become frozen. Refer to [Freeze \(A Payment\)](#) for information of how a single payment is frozen.

This button is enabled if at least one payment is Freezable.

Note:

If problems are detected after freezing. A payment may not be changed after it is frozen. All subsequent changes must occur by canceling the frozen payment and creating a new one. You can cancel and redistribute a payment on the next tab. Refer to [Canceling A Tender Versus Canceling a Payment](#) for more information.

Payment Event Actions

The topics that follow describe payment event-oriented actions. Refer to [How To](#) for a description of typical business processes that use these buttons.

Transfer

If the payment event was created using distribution rule(s), any transfer of its payments should also be done using the distribution rules method. Hence, a different dialog opens when you click **Transfer** based on whether the payment event is associated with at least one distribution detail or not.

Transfer (No Distribution Details Exist)

The **Transfer** button is enabled if:

- There is a single non-cancelled tender linked to the event AND
- There is a single frozen payment linked to the event AND
- The account on the tender is the same as the account on the payment.

When clicked, the **Payment Event Transfer** dialog opens.

You must specify the following parameters in the **Payment Event Transfer** dialog to transfer a payment:

- **Account ID** is the account to which the payment event should be transferred.
- **Cancel Reason** defines why you are performing the transfer.
- **Match Type** and **Match Value** are defaulted based on their values for the payment event that you are transferring. If necessary, modify the values appropriately for the account to which you are transferring the payment event. Match Type and Match Value are used for an account that belongs to an [open item](#) customer class or to restrict the distribution of the payment to a specific service agreement. Refer to [Payment Event - Main](#) for more information.
- Turn on **Freeze Payment** if the transferred payment should be frozen automatically. You may want to leave this turned off if you want to examine the payment distribution before freezing the payment.
- **Non CIS Name**, **Reference Number**, and **Non CIS Comments** appear if the **Account ID** belongs to a customer class that is used for non-CIS payments. Refer to [Setting Up Customer Classes](#) for more information.

Clicking **OK** causes the following to take place:

- The account on the tender is changed to reflect the transfer to account.
- The original payment and its segments are cancelled.
- A new payment is added for the transfer to account. The payment characteristics associated with the original payment are copied to the new payment.
- The new payment is distributed.
- If so designated, the new payment is frozen.

Transfer (Distribution Details Exist)

The **Transfer** button is enabled if:

- There is a single payor AND
- All existing payees before the transfer are the same as the payor AND
- There is at least a single non-cancelled tender linked to the event

When clicked, the **Payment Event Transfer** dialog opens.

You must specify the following parameters in this dialog to transfer payment(s):

- **Distribution Rule** is the account to which the payment event should be transferred.
- **Rule Value** is the value associated with the payment and expected by the distribution rule.
- **Amount** is the payment amount.
- **Cancel Reason** defines why you are performing the transfer.

Clicking **OK** causes the following to take place:

- The payment(s) associated with the original account are canceled.
- The new set of distribution details are processed, creating new payment(s) for the transfer to account. The payment characteristics associated with the original payment are copied to the new payment.
- If all new payments are for the same payee account (and the payee is different than the current payor) the account on the tender is changed to reflect the transfer to account.
- Original distribution details (only those with a non-zero amount) are deleted and replaced by the new set of details on the payment event.

Note:

Distribution rule entries can have a zero amount. Refer to [Rule Value Can Capture Additional Information](#) for more information about how to use distribution details to capture additional payment related information.

Determine Tender Account. This dialog does not call the Determine Tender Account algorithm defined on [distribution rule](#) as this action does not rebuild the payment tender collection.

Fastpath:

Refer to [Rule Value Can Capture Additional Information](#) for more information about how to use distribution details to capture additional payment related information.

Delete A Payment Event

The **Delete** button deletes a payment event and its tenders and payments.

This button is enabled if there are no frozen or canceled payments and no canceled tenders.

Tender Actions

The topics that follow describe tender-oriented actions. Refer to [How To](#) for a description of several business processes that use these buttons.

Cancel A Tender

Clicking **Cancel** causes the following to take place:

- All payments associated with the tender's payment event are canceled.
- The tender becomes canceled.
- If the cancellation reason indicates the cancellation is due to non-sufficient funds, other actions may occur. Refer to [NSF Cancellations](#) for more information.

The **Cancel** button is enabled if the tender is not canceled

When clicked, the **Tender Cancel** window opens.

You must specify the following parameters to cancel a tender:

- Select a **Cancel Reason** to describe why the tender is being canceled.
- The system also needs to know which **Bank Account To Charge** the cancellation against. The system will default the **Bank** and **Bank Account Key** from the original bank information used when the tender was deposited. You can override them here.

When you click the **OK** button, the system cancels the tender and ALL payments linked to the event.

Note:

When non-canceled tenders are still linked to the event. If there are multiple tenders linked to the payment event, you must either add new payment(s) that equal the sum of the event's non-canceled tenders or cancel the remaining tenders.

Cancellation after cash back. If a customer tenders a check for \$100, but only owes \$80, the system will recommend returning \$20 in cash to the customer (assuming the tender type for checks allows overpayment). If the tender type for checks is not "like cash", a second tender is created for -\$20 (the first tender is for \$100). If the check subsequently bounces, both tenders must be cancelled.

Payment Event Quick Add

The Payment Event Quick Add page is used to quickly add, distribute and freeze one or more payment events using [distribution rules](#). Open this page using **Menu > Financial > Payment Event Quick Add > Search**.

Description of Page

Specify the **Tender Control ID** in which the tenders will be recorded. Every new tender must reference an open tender control. The system will attempt to default an appropriate tender control as follows:

- If the user has at least one open, user-specific Tender Control whose type is online cashiering or ad hoc, the system will default one, at random.
- If the user has no open, user-specific Tender Controls; the system will default an open, "all users" tender control if it can find one whose tender source has a tender source type of online cashiering or ad hoc. If multiple exist, one will be selected at random.

Specify the **Payment Date**. The current date defaults.

Use **Number of Payment Events** to indicate whether you intend to add a single payment event or multiple payment events.

Choose the multiple payment events option if you intend to add "simple" payment events. By "simple" we mean:

- A single account is both the payor account and the account whose debt is being relieved by the payment.
- The payment tender is not an auto-pay tender.

For all other cases choose the single payment event dialogue as it is designed to handle more complex payment event configurations such as when:

- The payor account is different than the payee account.
- Multiple payors cover payments for one or more payees.
- The payment tender is an auto-pay tender.

Once you have made your selection the page is adjusted to support the corresponding dialog.

Note:

Cash-Only customers. When you attempt to add a new payment event, the system warns you if the account remitting the tender is a cash-only customer. An account is considered cash-only if their current cash-only points exceed the cash-only threshold maintained on the Installation record or the account's CIS Division. A customer's cash-only points are maintained on [Account - Credit Rating](#).

Multiple Payment Events Dialog

This section describes the default dialog setup when navigating from **Menu > Financial > Payment Event Quick Add**

Description of Page

Using the multiple payment events option, each row in the payment detail grid typically represents a unique distribution detail. However, more than one row in the grid can belong to a single payment event. All distribution details for identical tender account will be grouped under a single pay event.

The following columns appear in the **Payments** grid:

- Select a **Distribution Rule** by which the payment detail is to be processed. If you have set up a [default distribution rule](#), it is defaulted in the first row.
- Specify the **Rule Value** associated with the payment and expected by the distribution rule.
- Use **Payment Amount** to define the amount of the payment.
- Use **Tender Type** to define the form or remittance (e.g., cash, check, etc.). Note that the **Tender Type** defaults from the [installation record](#).

Note:

Authorizing Tenders. The **Tender Type** dropdown list does not include tender types that require authorization (i.e. credit card payments).

Fastpath:

For information about tender types requiring authorization, refer to [Credit Card Payments](#).

Note:

Automatic Payments. The multiple payment events dialog does not support automatic payments. Switch to the single payment event dialog to enter automatic payments.

- Use **Check Number** if a check is remitted.
- **MICR ID** is the value of the magnetic ink character recognition (MICR) line on the payment.

Note: The system supports encryption for MICR ID. If your implementation has configured the system to encrypt MICR ID, the data will be displayed with a masked value; such as, *****. Refer to [Encrypting Sensitive Data](#) for more information.

- You may use **Customer ID** to record additional customer information.
- You may use **External Reference ID** to record external information associated with the payment tender.
- You may use **Name** to record additional payment tender information.
- **MICR ID** is the MICR ID associated with the tender.
- **Payor Account ID** is the tender account as determined by the Determine Tender Account algorithm defined on the [distribution rule](#). This information is only populated after the distribution detail has been processed.

After specifying the various payment distribution details in the grid, click **Create**. The system attempts to create payment event(s) as follows:

- As mentioned earlier, all distribution details for identical tender accounts are grouped under a single pay event. The first step in identifying common tenders is to determine the tender account. To do that the system calls the Determine Tender Account algorithm defined on the [distribution rule](#).
- A payment event is created for each unique tender account.
- All rows having all attributes of the tender identical except for the amount are grouped together where each group represents a single tender.
- A single payment tender is created for each unique tender and linked to the payment event.
- The total payment amount for each distinct group of distribution details (for the payment event) having the same rule and value is summarized. For each distinct group, the system calls the Create Payment algorithm defined on the [distribution rule](#) providing it with the rule value and total payment amount. It is the responsibility of this algorithm to create the payments for this payment event.
- Add the distinct payment event distribution detail and its total amount beneath the payment event.
- If your implementation is configured for printing at a cashier station, the [Print](#) dialog appears. Refer to [How To Print Receipts and Endorsements](#) for more details.

The **Payment Event ID** column appears in the grid after the distribution details have been processed. It shows the payment event ID created for the distribution detail record and a short description as to the status of the payment(s) created for the payment event. You can use this field to navigate to the payment event.

After you've added a group of payment events, you should press the [clear](#) button (or Alt-C), to ready the page for the next group of payment event details.

Single Payment Event Dialog

If you have opted to always use the payment event distribution rules method as your [default method](#), this section describes the default dialog setup when you navigate to the **Payment Event** page in **Add** mode.

Adding a single payment event at a time, allows for more complex payment event information to be captured.

Enter one row in the **Tenders** grid for every unique tender associated with the payment event.

- **Payor Account ID** references the tendering account. The name of the account's main customer is displayed adjacent. If the account has exceeded your cash-only threshold, the warning Cash-Only appears.

Warning:

If you change the Payor Account ID and the tender has an associated automatic payment request, the automatic payment request will be removed. A new automatic payment request will be created for the new Payor Account ID. Refer to [Automatic Payments for more information](#).

- **Tender Amount** is the amount of the tender.
- Use **Tender Type** to define the form or remittance (e.g., cash, check, etc.). Note, the **Tender Type** defaults from the [installation record](#).
- Use **Check Number** if a check is remitted.
- **MICR ID** is the value of the magnetic ink character recognition (MICR) line on the payment.

Note: The system supports encryption for MICR ID. If your implementation has configured the system to encrypt MICR ID, the data will be displayed with a masked value; such as, *****. Refer to [Encrypting Sensitive Data](#) for more information.

- You may use **Customer ID** to record additional customer information.
- You may use **External Reference ID** to record external information associated with the payment tender.
- You may use **Name** to record additional payment tender information.
- If the **Tender Type** is associated with an automatic payment, the page displays a section that includes information about how and when the automatic payment was interfaced to the payment source.
- If the **Tender Type** is associated with an [automatic payment](#), the system attempts to default automatic payment information from the [account's auto-pay](#) option if the tender type is the same as the tender type on the account's auto-pay source and if the auto pay option is effective on the payment date. If the system is unable to default

information, you must specify the source of the funds and the customer's account number / credit card number at the financial institution.

- **Auto Pay Source** is the financial institution / credit card company that receives the automatic payment request.
- **External Account ID** is the customer's account number at the financial institution.
- **Expires On** is only needed if the **Tender Type** indicates that an expiration date is necessary (e.g., for a credit card payment).
- **Name** is the customer's name in the financial institution's system.

The following columns appear in the **Payments** grid:

- Select a **Distribution Rule** by which the payment detail is to be processed. If you have set up a [default distribution rule](#), it is defaulted in the first row.
- Specify the **Rule Value** associated with the payment and expected by the distribution rule.
- Use **Payment Amount** to define the amount of the payment.

After specifying the various payment distribution details in the grid, click **Create**.

Note:

Go To Payment Event. If you wish to be transferred to the payment event page once processing is complete, remember to check the Go To Payment Event check box before you click **Create**. This field does not appear when this page is used as the default Payment Event - Add Dialog and you are automatically transferred to the payment event page once the payment event is created.

After distribution details have been processed, a short description of the payment event that has been created is displayed to the right of the **Go To Payment Event** field. The description provides information as to the status of the payment(s) created for the payment event. You can use this field to navigate to the payment event.

The system attempts to create the payment event as follows:

- Validate that the sum of the tenders is not less than the sum of the payments.
- Create the payment event with a separate payment tender for each row in the Tenders grid.
- Summarize the total payment amount for each distinct group of distribution details having the same rule and value. For each distinct group, call the Create Payment algorithm defined on the [distribution rule](#) providing it with the rule value and total payment amount. It is the responsibility of this algorithm to create the payments for the payment event.
- Add the distinct payment event distribution detail summary beneath the payment event.
- If your implementation is configured for printing at a cashier station, the [Print](#) dialog appears. Refer to [How To Print Receipts and Endorsements](#) for more details.

Note:

Determine Tender Account. Having an explicit collection of tenders eliminate the need to determine the tender account. Therefore this dialog does not call the Determine Tender Account algorithm.

Payment Quick Add

The Payment Quick Add page is used to quickly add, distribute and freeze payment events for up to fifteen accounts. Open this page using **Menu > Financial > Payment Quick Add**.

Description of Page

Specify the **Tender Control ID** in which the tenders will be recorded. Every new tender must reference an open tender control. The system will attempt to default an appropriate tender control as follows:

- If the user has at least one open, user-specific Tender Control whose type is online cashiering or ad hoc, the system will default one, at random.
- If the user has no open, user-specific Tender Controls; the system will default an open, "all users" tender control if it can find one whose tender source has a tender source type of online cashiering or ad hoc. If multiple exist, one will be selected at random.

Specify the **Payment Date**. The current date defaults.

Enter one row in the grid for every payment event to be added. The following information is entered for each payment event:

- Use **Account ID** to define the customer who tendered the payment. It's important to note that this transaction assumes that the tendering account is the same as the account whose balance is relieved by the payment. Refer to [How To Allocate The Tender Amount To Multiple Accounts](#) if you need to distribute the payment to an account (or accounts) other than the tendering account.

Note:

Cash-Only customers. You cannot use this transaction to add a payment for a "cash-only" account if the tender type is not "like cash". An account is considered cash-only if its cash-only points exceed the cash-only threshold maintained on the Installation record. A customer's cash-only points are maintained on [Account - Credit Rating](#). You must use the [Payment Event transaction](#) to add such a payment (note, if you use the Account context menu to transfer to the Payment Event page in add mode, you won't have to retype the Account ID when you add the payment event).

- Use **Payment Amount** to define the amount of the payment.
- Use **Tender Type** to define the form or remittance (e.g., cash, check, etc.). Note, the **Tender Type** defaults from the [installation record](#).

Note:

Authorizing Tenders. The **Tender Type** dropdown list does not include tender types that require authorization (i.e. credit card payments).

Fastpath:

For information about tender types requiring authorization, refer to [Credit Card Payments](#).

- Use **Check Number** if a check is remitted.
- **Match Type** and **Match Value** are only used if either of the following conditions is true:
 - This **Account ID** belongs to an [open item](#) customer class. In this situation, specify a **Match Type** to define how the payment should be matched to the customer's open-items and use **Match Value** to define the open-items covered by the payment. For example, if this payment is in respect of a bill, specify a match type of "bill id" and a match value of the bill id being paid.

Note:

Shortcut. If you enter a **Match Type** of "bill id" and leave the **Match Value** blank, we assume the customer wants to pay the latest bill.

- The customer wants to restrict the distribution of the payment to a specific service agreement. In this situation, specify a **Match Type** of "service agreement ID" and a **Match Value** of the respective service agreement ID.

After specifying the various accounts and amounts in the grid, click the **Distribute and Freeze** button. When you click this button, the system attempts to create a payment event for each row in the grid. Four potential outcomes are possible for each row:

- If the data you entered for a payment event isn't complete (e.g., you don't specify a valid account or amount):
 - No payment event is created.
 - A **Message** describing the problem is displayed.
 - All fields on the row remain modifiable.
- You should correct each such line and then press the **Distribute and Freeze** button.
- If the data you entered is complete, but the system issues a warning (e.g., the account is considered "cash-only" and a tender type other than cash is remitted, or if the account already has a payment for this amount on this date):
 - No payment event is created.
 - A **Message** containing the warning is displayed.
 - All fields on the row remain modifiable.

- You must clear the line and add a payment using the [Payment Event transaction](#) (note, if you use the Account context menu to transfer to the Payment Event page in add mode, you won't have to retype the Account ID when you add the payment event).
- If the data you entered is complete, but the system is not successful in distributing the payment:
 - The system creates a payment event, a payment and a tender.
 - A **Message** describing the problem is displayed.
 - The payment's **Status** is displayed
 - All fields on the row are disabled.
- You must press the adjacent go to button to drill to the payment event where the error can be corrected.
- If the data you entered is complete and the system is successful in distributing the payment:
 - The system creates a payment event, a payment, and a tender.
 - The system distributes the payment amongst the account's service agreements and then freezes the payment.
 - The payment's **Status** is displayed.
 - All fields on the row are disabled.
 - If your implementation is configured for printing at a cashier station, the [Print](#) dialog appears. Refer to [How To Print Receipts and Endorsements](#) for more details.
- You can press the adjacent go to button to view a payment event.

Note:

Separate Commits. This page is unusual in that each payment event is committed to the database independently. For example, if you enter seven payment events and one is invalid, six payment events will be added to the database when you press **Distribute and Freeze**. When the page is redisplayed, the rows containing the valid payments are protected and an indication of their validity is displayed. The row containing the invalid payment remains unprotected. You can correct the erroneous payment and then press the **Distribute and Freeze** button again.

After you've added a group of payments, you should press the [clear button](#) (or Alt-C), to ready the page for the next group of payment events.

Maintaining Payments

Payments and payment segments are automatically created by the system when [payment events](#) are created. You should only need to access this transaction as follows:

- To view a payment's payment segments (i.e., to view how a payment was distributed amongst its account's service agreements).
- To override the distribution of a payment amongst its account's service agreements. Refer to [Distributing A Payment Amongst An Account's Service Agreements](#) for information describing how payments are typically distributed.

The topics in this section describe how to maintain a payment.

Payment - Main

This page contains basic information about a payment. Open this page using **Menu > Financial > Payment > Search**.

Warning:

Most payments are maintained using the [Payment Event](#) page. The transaction described below is typically only used to view a payment's payment segments and to manually distribute a payment amongst an account's service agreements.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To](#) for instructions on how to perform common maintenance functions.

Description of Page

Payment Info contains a concatenation of the payment date, amount, status, and the name of the main customer on the account.

Payment ID is the system-assigned unique identifier of the payment.

Payment Event ID is the system-assigned unique identifier of the payment event. The adjacent info contains a concatenation of the payment date, amount, and the name of the main customer on the account that remits the event's tender. If multiple tenders exist, the customer's name is not displayed. A warning may also be displayed. The possible warnings are Unfrozen Payments and The Payment Event is unbalanced.

Payment(s) contains the total number and value of payments linked to the payment event.

Tender(s) contains the total number and value of tenders linked to the payment event.

Account ID is the account whose debt is reduced by the payment. The name of the account's main customer is displayed adjacent. This field is gray after the payment is frozen.

Payment Amount is the amount of the payment. This field is gray after the payment is frozen. If the account has exceeded your [cash-only threshold](#), a warning (in red) appears adjacent to **Payment Amount**. Note, a customer's cash-only points are maintained on [Account - Credit Rating](#).

Payment Status is the payment's status. Refer to [Payment Lifecycle](#) for the potential values and how to handle a payment when it exists in a given state. If the payment is in Error, the error message is displayed adjacent. If the payment is canceled, the **Cancel Reason** is displayed adjacent.

Match Type and **Match Value** will only be used if either of the following conditions is true:

- This **Account ID** belongs to an [open item](#) customer class. In this situation, specify a **Match Type** to define how the payment should be matched to the customer's open-items and use **Match Value** to define the open-items covered by the payment. For example, if this payment is in respect of a bill, specify a match type of "bill id" and a match value of the bill id being paid.
- The customer wants to restrict the distribution of the payment to a specific service agreement. In this situation, specify a **Match Type** of "service agreement ID" and a **Match Value** of the respective service agreement ID.

Match Type and **Match Value** are gray after the payment is frozen.

If the payment is linked to an **Account ID** that belongs to a [customer class](#) that is used for non-CIS payments, the following fields appear (note, these fields are gray after the payment is frozen):

- **Name** is the name of the person remitting the payment.
- **Reference Number** is the reference number of the item being paid (e.g., the property tax reference number).
- **Comments** are used to describe anything unusual about the non-CIS payment.

The contents of the **Payment Segments** section depends on the number of payment segments linked to the payment. If more than 25 payment segments exist, a message appears that allows you to navigate to [Payment - Payment Segments](#) where you can view the payment segments (this page has special functionality that allows you to defined which payment segments should be displayed). If 25 or fewer payment segments exist, the grid contains information about each payment segment:

- **Premise** is the address of the service agreement's main premise.
- **SA Information** contains basic information about the service agreement.
- **Distributed Amt** is the amount of the service agreement's debt relieved by the payment.

The following information appears at the bottom of the page:

- **Payment Amount** is the amount of the payment.
- **Distributed Amount** is the sum of the payment segments linked to the payment.
- The **Difference** between the **Payment Amount** and the **Distributed Amount** appears if it is non-zero.
- **Billed Amount** is the amount of the bill preceding the payment date.

- **Delinquent Amount** is the amount of the customer's debt that was due on / before the prior bill's due date.
- **Current Balance** is the account's current balance.

Refer to [Payment Action Codes](#) for information about the action buttons on this page.

Payment - Pay Segments

You can use this page to view all or selected payment segments linked to a payment.

Open **Menu** > **Financial** > **Payment** > **Search** and navigate to the **Payment Segments** page to view this information.

Warning:

Most payments are maintained using the [Payment Event](#) page. The transaction described below is typically only used to view a payment's payment segments.

Note:

If the payment has more than 25 payment segments, the search criteria are intentionally left blank in order to avoid retrieving all payment segments (with the resultant slow response times). You must therefore use the **SA Filter** to define the type of payment segments that should be retrieved. See the Description of page below for more information about this page's search criteria.

Description of page

Payment Info contains a concatenation of important information about the payment.

Payment ID is the system-assigned unique identifier of the payment.

Payment Event ID is the system-assigned unique identifier of the payment event. The adjacent info contains a concatenation of the payment date, amount, and the name of the main customer on the account that remits the event's tender. If multiple tenders exist, the customer's name is not displayed. A warning may also be displayed. The possible warnings are Unfrozen Payments and The Payment Event is unbalanced.

Payment(s) contains the total number and value of payments linked to the payment event.

Tender(s) contains the total number and value of tenders linked to the payment event.

Note:

If the payment has more than 25 payment segments, the search criteria are intentionally left blank in order to avoid retrieving all payment segments (with the resultant slow response times). You must therefore use the **SA Filter** to define the type of payment segments that should be retrieved.

Use the **SA Filter** to define the types of service agreements whose payment segments appear in the grid. The following options are available:

- **Address.** Use this option to restrict payment segments to those whose service agreements are linked to service points associated with a given **Address**, **City** and/or **Postal** code. Note, you can specify any combination of these fields.
- **All.** Use this option if you do not wish to restrict payment segments based on service agreement attributes.
- **Geographic Type.** Use this option to restrict payment segments to those whose service agreements are linked to service points associated with a given **Geographic Type** and **Geographic Value**.
- **SA Type.** Use this option to restrict payment segments to those whose service agreements are linked to a given **CIS Division** and **SA Type**.

Don't forget to click the search button after changing the **SA Filter**.

The grid that follows contains the payment segments that match your search criteria. The following information appears in the grid:

- The **Premise** column contains the characteristic premise associated with the payment segment's service agreement. Refer to [Maintaining Premises](#) for more information about this premise.

- Click the go to button to transfer to view the financial transaction related to the payment segment. This is only available after the payment has been frozen.
- **SA Information** contains summary information about the service agreement.
- **Distributed Amt** is the amount of the service agreement's debt relieved by the distribution.
- **Adjustment ID** is displayed if there is an adjustment associated with the payment. Refer to [Loan Overpayments](#) for an example of when an adjustment is associated with a payment.

The following information appears at the bottom of the page:

- **Payment Amount** is the amount of the payment.
- **Distributed Amount** is the sum of the payment segments linked to the payment.
- The **Difference** between the **Payment Amount** and the **Distributed Amount** appears if it is non-zero.
- **Billed Amount** is the amount of the bill preceding the payment date.
- **Delinquent Amount** is the amount of the customer's debt that was due on / before the prior bill's due date.
- **Current Balance** is the account's current balance.

Payment - Manual Distribution

You can use this page to view service agreements linked to the payment's account and to manually distribute a payment amongst specific service agreements.

Open this page using **Menu > Financial > Payment > Search** and navigate to the **Manual Distribution** page.

Warning:

Most payments are maintained using the [Payment Event](#) page. The transaction described below is typically only used to view a payment's payment segments and to manually distribute a payment amongst an account's service agreements.

Note:

If the payment's account has more than 25 service agreements, the search criteria are intentionally left blank in order to avoid retrieving all service agreements (with the resultant slow response times). You must therefore use the **SA Filter** to define the type of service agreements that should be retrieved. See the Description of page below for more information about this page's search criteria.

Description of page

Payment Info contains a concatenation of important information about the payment.

Payment ID is the system-assigned unique identifier of the payment.

Note:

If the payment's account has more than 25 service agreements, the search criteria are intentionally left blank in order to avoid retrieving all service agreements (with the resultant slow response times). You must therefore use the **SA Filter** to define the type of service agreements that should be retrieved.

Use the **SA Filter** to define the types of service agreements that appear in the grid. The following options are available:

- **Address.** Use this option to restrict service agreements to those linked to service points associated with a given **Address, City** and/or **Postal** code. Note, you can specify any combination of these fields.
- **All.** Use this option if you want to view all service agreements.
- **Geographic Type.** Use this option to restrict service agreements to those linked to service points associated with a given **Geographic Type** and **Geographic Value**.
- **SA Type.** Use this option to restrict service agreements to those linked to a given **CIS Division** and **SA Type**.

Don't forget to click the search button after changing the **SA Filter**.

The grid that follows contains the service agreements that match your search criteria. The following information appears in the grid:

- **Premise** contains the characteristic premise associated with the service agreement.
- **SA Information** contains summary information about the service agreement.
- **Distributed Amt** is the amount of the service agreement's debt relieved by the payment. This field is gray after the payment is frozen.
- **Billed Amt** is the amount that was billed for the service agreement on the bill preceding the payment date.
- **Delinquent Amt** is the amount of debt associated with financial transactions that appear on overdue bills.
- **Current Balance** is the amount currently owing for this service agreement.

Note:

If the account being paid is an **open item** account, then an alternate grid is displayed. The alternate grid is designed to break down payable balances by individual bill and service agreement. Both unpaid bill balances and new charges are displayed. After distribution, a separate match event will be created for each bill paid or partially paid.

that an implementation can override the type of grid displayed for open item accounts by setting up a Financial Transaction Options [Feature Configuration](#) with an Always Use Manual Payment Distribution By SA option set to Y. With this in place, the system will always display the manual distribution by service agreement grid.

The open item manual distribution grid contains the following columns:

- **Bill Date**
 - Shows bill date if the row contains an account's unpaid bill.
 - Shows '**New Charges**' if the row contains an account's unbilled new charges.
 - Shows '**Payment Segment**' for the following conditions:
 - Row is a pay segment of a cancelled payment.
 - Row is a pay segment of an overpayment to the highest priority SA or an excess credit SA.
 - Row is a pay segment of a balance forward payment distribution.
 - **Premise Information** contains the characteristic premise associated with the service agreement.
 - **SA Information** contains summary information about the service agreement.
 - **Distributed Amount**
 - You can enter an amount to distribute if the payment is non-frozen and non-cancelled, otherwise, this field is protected.
 - **Billed Amount**
 - The amount that was billed for the service agreement on the row's bill. If the row does not represent a bill amount then this will be zero.
 - **Unpaid Amount**
 - This is determined by the "determine open-item bill amount" algorithm as defined on the installation option.
 - This column will contain zero if:
 - The row is linked to an open non-disputed match event with other bills' FTs on it. In this case, it is not possible to determine the bill amount.
 - The row is linked to an open disputed match event.

For either grid, the following information appears at the bottom of the page:

- **Payment Amount** is the amount of the payment.
- **Distributed Amount** is the sum of the payment segments linked to the payment.
- The **Difference** between the **Payment Amount** and the **Distributed Amount** appears if it is non-zero.
- **Billed Amount** is the amount of the bill preceding the payment date.
- **Delinquent Amount** is the amount of the customer's debt that was due on / before the prior bill's due date.
- **Current Balance** is the account's current balance.

Payment - Characteristics

To update payment characteristics, open **Menu > Financial > Payment > Search** and navigate to the **Characteristics** page.

Description of Page

The **Characteristics** collection contains information that describes miscellaneous information about the payment. The following fields display:

Characteristic Type Indicate the type of characteristic.

Sequence Controls the order in which characteristics of the same type are displayed.

Characteristic Value Indicate the value of the characteristic.

Payment Action Codes

The topics in this section describe each of the actions that appear on the payment pages.

Distribute (A Payment)

Clicking the **Distribute** button causes a payment to be distributed amongst the account's service agreements. Refer to [Distributing A Payment Amongst An Account's Service Agreements](#) for a description of how this is achieved.

This button is enabled if a payment is Incomplete, Error, or Freezable. Refer to [Payment Lifecycle](#) for more information about these status values.

If the payment is distributed appropriately, click the [Freeze](#) button to freeze the payment and its payment segments.

Redistribute (A Payment)

Clicking the **Redistribute** button causes a payment to be redistributed amongst the account's service agreements. Refer to [Distributing A Payment Amongst An Account's Service Agreements](#) for a description of how this is achieved.

This button is enabled if a payment is Incomplete, Error, or Freezable. Refer to [Payment Lifecycle](#) for more information about these status values.

If the payment is distributed appropriately, click the [Freeze](#) button to freeze the payment and its payment segments.

Note:

This button is only available on the [Payment - Main](#) and [Payment - Manual Distribution](#) pages.

Confirm (A Payment)

Clicking the **Confirm** button confirms that manually entered amounts associated to certain SAs will relieve their balances. This is the same process that is triggered by clicking **Save**.

This button is enabled if a value is manually entered in a Distributed Amount field.

Freeze (A Payment)

Clicking the **Freeze** button causes a payment and its payment segments to become frozen. Refer to [Payment Lifecycle](#) for more information about freezing.

This button is enabled if the payment is Freezable.

Note:

If problems are detected after freezing. A payment may not be changed after it is frozen. All subsequent changes must occur by canceling the frozen payment and creating a new one.

Cancel (A Payment)

Clicking the **Cancel** button causes the payment and its payment segments to be canceled. Canceling a payment (as opposed to canceling a tender) is typically only done if the original distribution was frozen and it's incorrect.

This button is enabled if the payment is Frozen. Refer to [Payment Lifecycle](#) for more information about these status values.

Transfer (A Payment)

The **Transfer** button is enabled if the payment is Frozen. Refer to [Payment Lifecycle](#) for more information about these status values.

If the payment being transferred was created using payment event distribution rule(s), the payment transfer should also be done using the distribution rules method. Hence, a different dialog opens when you click **Transfer** based on whether the payment's payment event is associated with at least one distribution detail or not.

Transfer Payment (No Distribution Details Exist)

Payment transfer causes the payment and its payment segments to be canceled and a new payment to be created. Transferring a payment is typically only done if the original distribution was targeted at the wrong account but all tender information for the pay event is correct. Unlike the [payment event transfer](#), transferring a single payment does not affect the pay event's tender information.

You must specify the following parameters in the **Payment Transfer** window to transfer a payment:

- **Account ID** is the account to which the payment should be transferred.
- **Cancel Reason** defines why you are performing the transfer.
- **Match Type** and **Match Value** are defaulted based on their values for the payment event that you are transferring. If necessary, modify the values appropriately for the account to which you are transferring the payment event. Match Type and Match Value are used for an account that belongs to an [open item](#) customer class or to restrict the distribution of the payment to a specific service agreement. Refer to [Payment Event - Main](#) for more information.
- Turn on **Freeze Payment** if the transferred payment should be frozen automatically. You may want to leave this turned off if you want to examine the payment distribution before freezing the payment.
- **Non CIS Name**, **Reference Number**, and **Non CIS Comments** appear if the **Account ID** belongs to a customer class that is used for non-CIS payments. Refer to [Setting Up Customer Classes](#) for more information.

Clicking **OK** causes the following to take place:

- The original payment and its segments are cancelled.
- A new payment is added for the transfer to account. The payment characteristics associated with the original payment are copied to the new payment.
- The payment is distributed amongst the new account's service agreements.
- If so designated, the new payment is frozen.

Transfer Payment (Distribution Details Exist)

Payment transfer causes the payment to be canceled and new payment(s) to be created using new payment event distribution rule(s). Transferring a payment is typically done when a payment event has multiple payments and one or more payments have been assigned to the wrong SA. Each of the incorrectly directed payments can be transferred to the correct SA(s) using the **Transfer via Distribution Rules** dialog.

Total Amount is the total payment amount to transfer from.

You must specify the following parameters in order to transfer a payment:

- **Distribution Rule** is the service agreement to which the payment should be transferred.
- **Rule Value** is the value associated with the payment and expected by the distribution rule.
- **Amount** is the payment amount.
- **Cancel Reason** defines why you are performing the transfer.

Clicking **OK** causes the following to take place:

- The payment associated with the original account is canceled.
- The new set of distribution details is processed, creating new payment(s) for the transfer-to service agreement(s). The payment characteristics associated with the original payment are copied to the new payment.
- The new set of distribution details is added to the payment event. The original distribution details are kept.

Note:

Distribution rule entries can have a zero amount. Refer to [Rule Value Can Capture Additional Information](#) for more information about how to use distribution details to capture additional payment related information.

Determine Tender Account. This dialog does not call the Determine Tender Account algorithm defined on [distribution rule](#) as this action does not rebuild the payment tender collection.

Delete (A Payment)

The **Delete** button deletes a payment. This button is enabled if the payment is Incomplete, Error, or Freezable.

Payment Portal

The base package is shipped with a configured payment portal that can be used for payment processing. The portal supports the following functionality that is not supported in the base [Payment Event - Add Dialog](#):

- Processing of payments that require authorization (i.e. credit card payments)
- Creating non CIS payments based on payment templates
- Processing payment tenders in alternate currencies

Fastpath:

Refer to [The Big Picture of Portals and Zones](#) in the *Oracle Utilities Application Framework Administration Guide* for a description of portal and zone functionality.

Credit Card Payments

The payment portal provides the functionality needed for posting and authorizing customers' credit card charges in real-time. If the credit card authorization is successful, the payment will be added automatically (assuming you selected the appropriate payment freeze action via the portal).

Fastpath:

Refer to [How To](#) for instructions describing how to add a payment that requires authorization.

Non CIS Payments

The payment portal allows you to add non-CIS payments using a payment template. Payment Templates can be configured for common types of payment allocations to pre-populate the payment distribution, allowing non-CIS payments to be directly allocated against the appropriate distribution codes.

Fastpath:

Refer to [How To](#) for instructions describing how to add a non-CIS payment using a payment template.

Alternate Currency Payments

The payment portal allows you to process a payment tender remitted in an alternate currency. The system enables conversion of the tendered amount into the account's currency.

Fastpath:

Refer to [How To](#) for instructions describing how to process a payment in an alternate currency.

How To

The topics in this section describe how to perform common payment maintenance functions.

How To Add A New Payment Event

There are several ways to add a new event:

- You can use [Payment Quick Add](#) to quickly add one or more payment events. You'd use this approach to add simple payments where no manual intervention is required. By "simple payment" we mean:
 - The account is both the tendering account and the account whose debt is being relieved by the payment
 - The payment date is the current date
 - The payment should be [distributed](#) amongst the account's service agreements using standard distribution logic
- If applicable to your business practice, you can use [Payment Event Quick Add](#) to quickly add one or more payment events using [distribution rules](#).
- You can use [Payment Event Maintenance](#) to add a payment event. You would use this approach if multiple forms of payment are remitted (e.g., cash and a check) or if there are multiple payors and/or payees linked to the payment event.

Note:

By default the system opens the [Payment Event - Add Dialog](#) when you navigate to this page in add mode. If you have opted to always use the payment event distribution rules method as your [default method](#), the [Payment Event Quick Add \(Single Payment Event\)](#) page appears instead. Refer to these pages for more information.

How To Cash A Check

If you allow customers to cash checks, you'll have a payment event with two tenders:

- The first tender contains information about the check.
- The second tender contains information about the cash refund (the tender amount is a negative amount equal to the amount of the check).

The interesting aspect of this payment event is that it has no payments because the sum of the tenders is zero.

We start this explanation in the middle of [How To Add A New Payment Event](#).

In the **Payment Event Add** dialog, be sure to select Do Not Distribute before clicking **OK**.

- On the **Main** page, click - to remove the payment (cashing a check is a payment event with no payments).
- Transfer to the **Payment Event, Tenders** page.
- **Insert** a row in the tender scroll (click the + button) for the cash refund tender. In this row enter a tender type of "cash" and a tender amount of negative the check amount.
- Save the event (note there is nothing to distribute or freeze).

How To Allocate The Tender Amount To Multiple Accounts

When you add a payment event, the system automatically creates a single payment for the account that remitted the funds. If someone is remitting funds for someone other than themselves, you must change/add payments. This section describes how to do this.

Note:

This section assumes you chose to add the payment event using the [Payment Event - Add Dialog](#). Refer to [How To Add A New Payment Event](#) for the complete list of options.

In the [Payment Event - Add Dialog](#), be sure to select Do Not Distribute before clicking **OK**.

On the payment event Main page, do the following:

- If the remitting account shouldn't have received any part of the payment, **Remove** it from the payments grid by clicking the - button. Alternatively, you can just change the account id to reflect the recipient.
- If multiple accounts receive the remitted funds, **Insert** one row in the payments grid (click the + button) for each additional account.
- When the payment event is balanced, **Save** it. Then **Distribute** and **Freeze** the payment(s). Refer to [Payment Event Actions](#) for more information on these action buttons.

How To Print Receipts And Endorsements

The system can be configured to allow you to endorse checks and print receipts using special cashiering station printers. This section describes the print options available.

Note:

These options are only available if they have been installed in your system. Installing these options are a delivery and installation issue and are not within the domain of this document. Refer to the Receipt Printing section of the Optional Products Installation Guide for information on how to enable these print options.

The print functions are available from the [Payment Event](#), [Payment Quick Add](#) and [Payment Event Quick Add](#) transactions. Refer to those sections for more information.

The print dialog functions are described below.

Description of Page

Use the **Endorse** button to endorse checks using the cashier station printer. This is only enabled if at least one tender type is not like cash and does not generate an automatic payment. If there are multiple checks, use the scroll buttons to select them. Feed the appropriate check in the printer and an endorsement message is printed on the back.

Use the **Receipt** button to print a receipt using the cashier station printer. Choose a **Short** or **Long** option. Use the **Duplicate** button to print a duplicate receipt. This prints the receipt with a "Duplicate" label.

Use the **Stub** button to print special information in bill stub format (e.g. account, name, amount). Feed a slip of paper into the printer and the special stub information will be printed.

Note:

The various text strings that are printed on the receipt and the endorsement are defined on the Payment Receipt Message and Endorse Message messages on the Point Of Sale (POS) Printer Integration master configuration. Refer to the master configuration's embedded help for more details.

The Stub function is available only on the Payment Event page.

Refer to the Optional Products Installation Guide for details on the print BPA script samples provided in base and for sample printouts using these scripts.

How To Cancel A Tender

If a tender is no longer valid (e.g., a check bounces), the tender must be canceled. The following steps explain how to do this.

Warning:

These steps only make sense in the context of the page used to maintain tenders. Refer to [Payment Event - Tenders](#) for the details.

You navigate through the pages as follows:

1. Open the payment event - tenders page for the tender in question. Proceed to step 2.
2. Click **Cancel**. Proceed to step 3.
3. Before the system cancels the tender, you must specify the cancel reason. The tender cancel window opens.

In the tender cancel window, select a **Cancel Reason** to describe why the tender is being canceled. The system also needs to know which **Bank Account To Charge** the cancellation against. The system will default the **Bank** and **Bank Account Key** from the original bank information used when the tender was deposited. You can override them here.

When you click the **OK** button, the system cancels the tender and ALL payments linked to the event.

If the cancellation reason you supply is indicated as being "non-sufficient funds", the system will generate an adjustment to levy a NSF charge. Refer to [SA Type - Main Information](#) for more information.

Note:

When non-canceled tenders are still linked to the event. If there are multiple tenders linked to the payment event, you must either add new payment(s) that equal the sum of the event's non-canceled tenders or cancel the remaining tenders.

Cancellation after cash back. If a customer tenders a check for \$100, but only owes \$80, the system will recommend returning \$20 in cash to the customer (assuming the tender type for checks allows overpayment). If the tender type for checks is not "like cash", a second tender is created for -\$20 (the first tender is for \$100). If the check subsequently bounces, both tenders must be cancelled.

How To Transfer A Payment From One Account To Another

If you need to transfer a payment amount from one account to another, you can use the **Transfer** button either on the payment event page or the payment page.

Fastpath:

Refer to [Transferring A Payment](#) for a description of when to use each option.

How To Distribute A Payment To A Specific Service Agreement

When you click **Distribute**, the system uses the payment distribution algorithm defined on the account's customer class to allocate the payment amongst the account's service agreements. In this section, we describe how to override this distribution (e.g., when you need to allocate a payment to specific service agreement(s)).

We start this explanation in the middle of [How To Add A New Payment Event](#).

In the **Payment Event Add** dialog, be sure to select Do Not Distribute before clicking **OK**.

- **Save** the payment event (this also saves the payment and tender information).
- Use the **Payment Amount** context menu to transfer to the **Manual Distribution** page.
- Fill in the desired **Distributed Amt** for each service agreement and save the payment.
- Click **Freeze** to freeze the payment when the amount distributed is equal to the payment amount.

How To Get An Unbalanced Tender Control In Balance (Fixing Over/Under)

In order to balance a tender control that is out-of-balance, you must create a tender for an account associated with your company.

Note:

The over / under account. Your organization must set up a company-use account with a service agreement whose SA type references the over/under distribution code. This account should be linked to the person ID associated with company usage.

- If you have more money in the drawer than you have tenders, then you're "over". In this situation, you need to record a payment for the "over" amount and the tender type configured for cash drawer over/under amounts. This will cause cash to be debited by the over amount, and the expense account associated with the account's service agreement to be credited.
- If you have less money in the drawer than you have tenders, then you're "under". In this situation, you need to record a negative payment for the "under" amount and the tender type configured for cash drawer over/under amounts. This will cause cash to be credited by the over amount, and the expense account associated with the account's service agreement to be debited.

Important:

A separate tender type is used for recording cash drawer over/under amounts. Once the over/under amount has been determined, you must enter a new tender using your over/under tender type for the company-use account. Check out the following table for an example:

| Tender Type | Starting Balance | Tenders Received | Turn Ins | Actual Ending Balance (Entered by Cashier) | Expected Ending Balance | Over/Under Amount |
|-------------|------------------|------------------|----------|--|-------------------------|-------------------|
| Cash | \$150.50 | \$5,000 | \$4,000 | \$1151 | \$1150.50 | Over \$0.50 |
| Check | - | \$1,000 | \$750 | \$249 | \$250 | Under \$1 |
| Over/Under | - | -\$0.50 | - | - | -\$0.50 | Over \$0.50 |

In this example, you'd have to create a new tender for the company-use account for the amount that will be distributed to the company-use account's service agreement (debit over/under expense, credit cash):

- Tender type: Over/Under, Tender amount: -\$0.50

Note:

You must reopen the tender control. Before you can add an over/under tender to a tender control, you must re open the tender control (tenders may only be added to open tender controls).

How To Add A Non-CIS Payment Using A Template

The payment portal allows you to add non-CIS payments using a payment template. Payment Templates can be configured for common types of payment allocations to pre-populate the payment distribution and allowing non-CIS payments to be directly allocated against distribution codes. The following steps explain how to do this.

You navigate through the pages as follows:

- Open **Menu > Financial > Payment Portal**.
- The **Add Non CIS Payment Zone** shows a list of all active payment templates. Use the **Add** button to add a non-CIS payment for a specific payment template.

- Enter the payment and tender details (**Payment Amount**, **Payment Date** defaults to the current date, **Tender Source** is used to find an open tender control when adding the tender).

Note:

Authorizing Tenders. If the **Tender Type** selected requires authorization (i.e. credit card payments), additional authorization details are required (e.g. credit card type, credit card number, etc.). Only one tender that requires authorization can exist for a single payment event.

Fastpath:

For information about tender types requiring authorization, refer to [How To Authorize A Credit Card Tender](#).

- Enter the non-CIS information for the customer remitting the payment (**Customer Name**, **Agreement Number** and **Comments** to describe anything unusual about the non CIS payment).

Note:

Payor Account ID. The Non CIS Account Id specified on the payment template is used as the tendering account. If the account has exceeded your [cash-only threshold](#) and the **Tender Type** isn't marked as "like cash", a warning appears advising of such.

Including a CIS payment. If a portion of the tender is for a CIS payment, ensure that the **Add CIS Payment** checkbox is selected. The system will process the non-CIS payment, and then navigate the user to the Payment Event page where the CIS payment can be included.

- The distribution details are defaulted from the payment template but may be overridden. You can add additional distribution lines. Enter the payment amount and Reference Number for each applicable distribution line.
- When you click the **OK** button, the system creates the payment event and tender(s). A single payment is created for each non-zero amount entry in the distribution details list. The payment template is captured as a characteristic on the tender. The corresponding distribution code, GL account and reference number are captured as characteristics on each payment. When the financial transactions are created for these payments, the distribution code (and GL account) is retrieved from the payment characteristic collection.

How To Authorize A Credit Card Tender

You can use the Payment Portal to add a payment event for a tender that requires authorization. The following steps explain how to do this.

If your organization is using the base tender authorization functionality, you can navigate through the pages as follows:

- Open **Menu > Financial > Payment Portal**.
- The **Add CIS Payment** zone only expands if there's an account in context. To expand this zone, either search for an account using Control Central or use the Tender Search available on the **Payment Portal**.
- Use the **Add Payment** button to add a payment for the account displayed in the zone.
- The information displayed is the same as that on the [Payment Event - Add Dialog](#), except for the following:
 - Use **Distribute Action** to describe what you'd like to have happen when you click the **OK** button. The dropdown contains the following values - Distribute and Freeze if OK, Manual Distribution and Manual Distribution - Multiple Payments

Note:

The **Distribute and Freeze if OK** and **Manual Distribution** options are also present on the **Distribute Action** on the payment event add dialog screen. The third option, **Manual Distribution - Multiple Payments**, is special for credit card authorization processing. This option is similar to the **Manual Distribution** option except that the user is navigated to the **Payment Event** maintenance page after authorization has taken place.

- If the **Tender Type** selected requires authorization (e.g., credit card payments), additional authorization details are required (e.g. credit card type, credit card number, etc.). This information is displayed in the **Credit Card Information** section.

Note:

Authorizing Tenders. Only one tender that requires authorization can exist for a single payment event.

- The **Authorization Override** checkbox is only displayed if the tender type selected requires authorization. Use the **Authorization Override** checkbox to indicate whether or not tender authorization should take place. If **Authorization Override** is checked, an authorization code must be entered and the system bypasses the authorization web service call.
- Click **OK to save the payment and navigate to the appropriate page.**
- Assuming the credit card is accepted, the authorization code returned by the credit card authorization provider is captured as a tender characteristic.
- If the credit card is declined, the tender will not be added.

How To Reverse A Credit Card Tender

The steps required to reverse a credit card tender are the same as the steps for [How To Cancel A Tender](#).

The reversal code from the credit card authorization service is stored as a tender characteristic.

Fastpath:

For more information on authorizing credit card payments, refer to the following business objects: Tender Type - Credit Card with Authorization, CyberSource - Credit Card Authorization and CyberSource - Credit Card Reversal.

How To Process An Alternate Currency Payment

You can use the Payment Portal to add a payment event for a tender(s) in an alternate currency, i.e. a currency that differs from the account's currency. The following steps explain how to do this.

- Open **Menu > Financial > Payment Portal**.
- The **Add CIS Payment Zone** only expands if there's an account in context. To expand this zone, either search for an account using Control Central or use the Tender Search available on the **Payment Portal**.
- Use the **Add Payment** button to add a payment for the account displayed in the zone.
- The information displayed is the same as that on the [Payment Event - Add Dialog](#), except for the following:
 - If your organization accepts payment tenders in alternate currencies, the **Currency Converter** button appears in the tender list
- Use the **Currency Converter** button to enter the **Tendered Amount** and **Tendered Currency** in the alternate currency and click **OK**. The system will convert the alternate currency amount to the account's currency.
- Click **OK to save the payment and navigate to the appropriate page.**
- When you click the **OK** button, the system creates the payment event and tender(s). Each tender is linked to an appropriate tender control based on the currency of the tender.

Fastpath:

Refer to [Alternate Currency Payments](#) for more information.

Financial Transactions On A Payment

Open **Menu > Financial Query > Financial Transactions On A Payment** to view the financial transactions on a payment.

**Note:**

You can also open this page using the go to buttons that prefix the financial transaction summaries on [Payment - Main](#).

Description of page

Payment ID is the system-assigned unique identifier of the payment.

Account ID is the payment's account.

The area beneath **Account ID** provides you with options that control which financial transactions appear in the grid. The following points describe the various options:

- Use the **SA Filter** to define the types of service agreements whose financial transactions appear in the grid. The following options are available:
 - Address. Use this option to restrict financial transactions to those whose service agreements are linked to service points associated with a given **Address, City** and/or **Postal** code.
 - All. Use this option if you do not wish to restrict financial transactions based on service agreement attributes.
 - Geographic Type. Use this option to restrict financial transactions to those whose service agreements are linked to service points associated with a given **Geo Type** and **Value**.
 - SA ID. Use this option to restrict financial transactions to those of a specific service agreement.
 - SA Type. Use this option to restrict financial transactions to those whose service agreements are linked to a given **CIS Division** and **SA Type**.
- Use **Match Event Status Filter** to restrict the financial transactions based on the status of their [match event](#). This filter only appears if the payment's account is an [open-item](#) customer. The following options are available:
 - All. This option shows all financial transactions.
 - Balanced. This option shows all financial transactions whose match event is balanced.
 - Disputed. This option shows all financial transactions whose match event is disputed.
 - Unbalanced. This option shows all financial transactions whose match event is unbalanced.
 - Unmatched. This option shows all financial transactions that are not linked to a match event.

**Warning:**

Don't forget to click the search button after changing the filters or after selecting a new Payment Id.

The grid that follows contains the financial transactions that match your search criteria. The following information is displayed:

- **Match Event Status** shows the status of the financial transaction's [match event](#). This column only appears if the account is an [open-item](#) customer.
- **FT Type** displays the type of financial transaction. Click on the hyperlink to transfer to [Financial Transaction - Main](#). On this page, you can change certain aspects of the FT in question.
- **Accounting Date** is the date the system uses to determine the financial transaction's accounting period in your general ledger.
- **Current Amount** contains the financial transaction's effect on the service agreement's current balance.
- **Payoff Amount** contains the financial transaction's effect on the service agreement's payoff balance. The **Payoff Amount** will be dim if it equals the **Current Amount**.
- **Show on Bill** indicates if information about the financial transaction appears on the customer's bill.
- **SA Information** contains a summary of the respective service agreement.
- **Financial Transaction ID** is the system-assigned unique identifier of the financial transaction.

At the bottom of the page is a summary of the financial transactions that match the search criteria.

Payment History

The payment history page shows all payments that have been distributed to an account's service agreements. Open this page using **Menu > Financial Query > Account Payment History**.

Description of Page

One row is displayed for every payment that has been distributed to an account's service agreements. The payment date, amount, payment status and the tender source associated with the tender's tender control are displayed for each payment.

Note:

Tender Source typically contains the description of the cash drawer in which the payment was made or the remittance processor that processed the payment. **Tender source** will be blank for automatic payments until they are interfaced to the financial institution. Refer to [Downloading Automatic Payments](#) for more information about interfacing automatic payments.

If you need to see more detailed information about the payment, click the Go To button to transfer to the payment event page.

Payment Tender History

The **Payment Tender History** page shows a list of all tenders linked to an open tender control for the current user. Open this page using **Menu > Financial Query > Payment Tender History**.

Description of Page

One row is displayed for every tender that is linked to an open tender control to which the current user has access. The freeze date/time, payment date, pay tender ID, payor account, tender amount, tender type and tender status are displayed for each tender.

Payment / Tender Search

This page allows you to look for payments and/or tenders using a combination of search criteria. Open this page using **Menu > Financial Query > Payment / Tender Search**.

Description of Page

The top half of the page is where you enter the criteria used to search for payments and tenders.

Note:

Multiple search criteria may be specified. You can search for payments and tenders using a combination of search criteria. For example, if you enter both a **Payment Account** name of Brandon and a **Payment Amount** between 150 and 170; only those payments for customers named Brandon whose amount is between 150 and 170 will be displayed.

Warning:

Try to be as specific as possible when entering search criteria. Why? Because entering open-ended search criteria may have a severe impact on response times. For example, if you know the payments you're looking for have a payment date sometime in January 2003 and the customer's name is Brazil, John, then enter both of these criteria. If you also know the payment amount is between 150 and 170, enter these values too.

The following table describes each of the different search methods.

| Search Method | Description |
|---------------|-------------|
|---------------|-------------|

| | |
|-------------------|---|
| Search for | <p>Use this field to define if you're searching for Payments, Tenders or both Payments and Tenders. The value entered in this field controls which of the remaining search methods are enabled.</p> |
| Distribution Rule | <p>Use this field if you're searching for a tender or a payment and know the distribution rule and value used to created it.</p> <p>Note. This section appears only if you have configured your system to allow the payment event distribution rules method to be used.</p> |
| Payment Account | <p>Use this field if you're searching for a payment and know the account ID or the name of any person linked to the account whose debt is relieved by the payment.</p> <ul style="list-style-type: none"> - If you know the payment's account ID, first choose Account in the adjacent dropdown and then and enter the account's ID. You must enter all of the account ID. - If you know the name of any person linked to the account, first choose Person Name in the adjacent dropdown and then enter the person's name. You can enter all or part of the person's name (the more you enter, the faster the search will be). The name search is not case sensitive. <p>A search method of Person Name defaults.</p> <p>If you leave the person name or ID blank, the system ignores this search method.</p> <p>These fields are protected if you've selected a Search for of Tender.</p> |
| Payment Amount | <p>Use this field if you're searching for a payment and know its amount.</p> <ul style="list-style-type: none"> - If you know the exact amount, first choose Equal To in the adjacent dropdown and then enter the amount. - If you know the payment amount is between a given range of values, first choose Between and then enter the range of values. <p>A search method of Between defaults.</p> <p>If you leave the amount(s) blank, the system ignores this search method.</p> <p>These fields are protected if you've selected a Search for of Tender.</p> |

Payor Account

Use this field if you're searching for a tender and know the account ID or the name of any person linked to the tendering account.

- If you know the tender's account ID, first choose Account in the adjacent dropdown and then enter the account's ID. You must enter all of the account ID.

- If you know the name of any person linked to the tendering account, first choose Person Name in the adjacent dropdown and then enter the person's name. You can enter all or part of the person's name (the more you enter, the faster the search will be). The name search is not case sensitive.

A search method of Person Name defaults.

If you leave the person name or ID blank, the system ignores this search method.

These fields are protected if you've selected a **Search for** of Payment.

Tender Amount

Use this field if you're searching for a tender and know its amount.

- If you know the exact amount, first choose Equal To in the adjacent dropdown and then enter the amount.

- If you know the tender amount is between a given range of values, first choose Between and then enter the range of values.

A search method of Between defaults.

If you leave the amount(s) blank, the system ignores this search method.

These fields are protected if you've selected a **Search for** of Payment.

Tender Source

If you're searching for a tender and you know the source of the tender (e.g., the lockbox, cashier, etc.), enter the tender source code.

A search method of Equal To defaults.

If you leave the tender source blank, the system ignores this search method.

These fields are protected if you've selected a **Search for** of Payment.

| | |
|--------------|---|
| MICR ID | <p>Use this field if you're searching for a tender and know its MICR (magnetic ink character recognition) ID.</p> <ul style="list-style-type: none"> - If you know the entire MICR ID, first choose Equal To in the adjacent dropdown and then and enter the entire MICR ID. - If you know the first X characters of the MICR ID, first choose Like in the adjacent dropdown and then and enter the entire MICR ID. <p>A search method of Like defaults.</p> <p>If you leave the MICR ID blank, the system ignores this search method.</p> <p>These fields are protected if you've selected a Search for of Payment.</p> |
| Payment Date | <p>Use this field if you're searching for a tender or a payment and know its date.</p> <ul style="list-style-type: none"> - If you know the exact date, first choose Equal To in the adjacent dropdown and then enter the date. - If you know the date is between a given range of values, first choose Between and then enter the date range. <p>A search method of Between defaults.</p> <p>If you leave the date(s) blank, the system ignores this search method.</p> |

The system shows the total number of payments / tenders that satisfy your search results immediately below the grid.

The first group of payments / tenders is displayed in the grid at the bottom of the page. Different columns appear in the grid depending on the value of **Search for**.

- If you use a **Search for** of Payment, only payment-oriented columns appear in the grid.
- If you use a **Search for** of Tender, only tender-oriented columns appear in the grid.
- If you use a **Search for** of Payment and Tender, both payment-oriented and tender-oriented columns appear in the grid.

Warning:

If you use the Payment and Tender search method, and the resultant tenders / payments are linked to payment events that have multiple payments or tenders, multiple rows may be displayed for the payment event's tenders and payments. For example, if a tender with multiple payments is selected, a separate row will be displayed for every payment that matches your payment search criteria. If you don't specify any payment search criteria, a row will be displayed for every payment linked to the tender.

Payment Date This contains the date of the payment event associated with the payment / tender. This column appears regardless of the value of **Search for**.

Payment Account Info This contains a concatenation of important information about the account whose debt was relieved by the payment. This column does not appear if you use a **Search for** of Tender .

Payment Amount This contains the amount of the payment. This column does not appear if you use a **Search for** of Tender.

Payment Status This contains the status of the payment. Refer to [Payment Lifecycle](#) for more information. This column does not appear if you use a **Search for** of Tender.

Payment ID This contains the unique identifier of the payment. This column does not appear if you use a **Search for** of Tender.

Payor Account Info This contains a concatenation of important information about the account who tendered the payment. This column does not appear if you use a **Search for** of Payment .

Tender Amount This contains the amount of the tender. This column does not appear if you use a **Search for** of Payment.

Tender Source This contains the source of the tender of the tender. This column does not appear if you use a **Search for** of Payment.

MICR ID This contains the MICR (magnetic ink character recognition) ID of the tender. This column does not appear if you use a **Search for** of Payment .

Note: The system supports encryption for MICR ID. If your implementation has configured the system to encrypt MICR ID, the data will be displayed with a masked value; such as, *****. Refer to [Encrypting Sensitive Data](#) for more information.

Tender Status This contains the status of the tender. Refer to [Tender Lifecycle](#) for more information. This column does not appear if you use a **Search for** of Payment.

Pay Tender ID This contains the unique identifier of the tender. This column does not appear if you use a **Search for** of Payment.

Pay Event ID This contains the unique identifier of the payment event.

Payment Exception

When the system is unable to distribute a payment, a record is written to the payment exception table with a message indicating the nature of the error. A common example of a payment exception is **no service agreement to hold a credit**. This can occur when an account overpays their debt and the account doesn't have a single service agreement that is allowed to hold a credit, a payment error is generated.

The system saves payments that are in error just as it saves payments that are error-free. This is done because payments are nothing more than a snapshot of the data that was used to distribute the payment. By saving the snapshot, you can see the information the system used when it detected the error and therefore more effectively correct it.

Every payment in error is written to the Payment Exception table (CI_PAY_EXCP). A To Do background process creates To Do entries for records in this table.

To view the messages associated with the exception records, schedule the [TD-PYERR](#) background process. This process generates a To Do entry for every record in the payment exception table.

After correcting the cause of the error, drill into the [Payment](#) and attempt to redistribute it.

Maintaining Deposit Controls

Deposit controls exist to give you administrative control over your cash drawers (and all other tender sources) and the subsequent deposit of funds at banks.

Fastpath:

Refer to [Tender Management and Workstation Cashiering](#) for background information.

Note:

The system creates most deposit controls behind-the-scenes. Most deposit controls are created by the system when it processes tenders from your remittance processor and lock boxes. You should only have to access the deposit control pages if you record payments in cash drawers. For information about how the system creates deposit controls, refer to [Managing Payments Interfaced From External Sources](#). Also note

that the automatic payment activation process also creates tender and deposit controls. Refer to [Activating Automatic Payments](#) for more information.

The Lifecycle Of A Deposit Control

The following diagram shows the possible lifecycle of a deposit control.

Open A deposit control is initially created in the Open state. While in this state, you may add new deposits to it, change the deposit amount on its deposits, and transfer tender controls into and out of it.

Balancing In Progress You change a deposit control's status to Balancing In Progress when you're ready to balance its contents. While in this state, you can change the deposit amount on its deposits and transfer tender controls out of it. If you need to add new deposits to it or transfer tender controls into it you must return it to the Open state.

Balanced You change a deposit control's status to Balanced when the sum of its tender controls is consistent with the total of its deposits. While in this state, you cannot modify its deposits or its tender controls. If you need to make modifications, you must return it to the Open or Balancing In Progress state.

Note:

Background processes and state transition. When payments are interfaced from external sources, the system automatically creates a deposit control and links a tender control to it. When all payments have been successfully loaded, the system changes the state of the respective deposit control to Balanced.

Deposit Control - Main

The Main page contains core deposit control information. Open this page using **Menu > Financial > Deposit Control > Search**.

Description of Page

Deposit Control contains a concatenation of the deposit control's creation date, tender source type, and status.

Deposit Control ID is the system-assigned, unique identifier of the deposit control.

User is the person who created the deposit control.

Create Date/Time is the date and time the deposit control was created.

Tender Source Type is the type of tender control that has been linked to the deposit control. Valid values are: Ad hoc, Auto Pay, Online Cashiering and Lockbox. The system uses this information to prevent tender controls from different

sources from being included under the same deposit control. In other words, you can't mix automatic payment, cashiering and lockbox tenders under the same deposit control.

Currency Code is the currency in which the deposit control's tenders are denominated.

Note:

Default note. The currency code defaults from the installation record.

The summary information that follows contains a summary of the starting balance and the tenders that are linked to the tender control.

- **Starting Balance** is the sum of the starting balances from all tender controls linked to the deposit control.
- **Total Tenders Amount** is the sum of tenders from all tender controls linked to the deposit control.
- **Total Tender Controls** is the number and amount of tender controls linked to the deposit control.
- **Total Tender Deposits** is the number and amount of tender deposits linked to the deposit control.
- **Expected Ending Balance** is the **Total Tender Control** minus **Total Tender Deposits**.
- **Ending Balance** is the actual amount of money in the tender control minus the deposit tender amount. This amount must equal the **Expected Ending Balance** before the tender control can be marked as Balanced.
- **Outstanding Over/Under** is **Ending Balance** minus **Expected Ending Balance**.

Deposit Control Status shows the status of the deposit control. Valid values are Open, Balanced, and Balancing In Progress.

Fastpath:

For more information, refer to [The Lifecycle Of A Deposit Control](#).

The **Balanced User ID** and **Balanced Date/Time** are populated when the status is changed to Balanced.

Use **Comments** to describing anything unusual about the deposit control.

Deposit Control - Tender Control

The Tender Control page contains a row for every tender control linked to the deposit control. Open this page using **Menu > Financial > Deposit Control > Search** and navigate to the **Tender Control** page.

Description of Page

Deposit Control contains a concatenation of the deposit control's creation date, tender source type, and status.

Deposit Control ID is the system-assigned, unique identifier of the deposit control.

The grid that follows contains a row for every tender control linked to the deposit control. No information about the tender controls may be modified on this page. To view or modify tender control information, click the Go To button.

Deposit Control - Tender Deposit

The Tender Deposit page contains a row for every tender deposit linked to the deposit control. Open this page using **Menu > Financial > Deposit Control > Search** and navigate to the **Tender Deposit** page.

Description of Page

Deposit Control contains a concatenation of the deposit control's creation date, tender source type, and status.

Deposit Control ID is the system-assigned, unique identifier of the deposit control.

The **Tender Deposit** scroll that follows contains one row for every financial institution into which the tenders will be deposited. To insert a new row, click the + button and fill in the following fields:

- **Tender Deposit ID** is maintained by the system. When a deposit is being created, there is no ID number displayed. Once a deposit is entered and saved, the system generates an ID and displays it here.

- **Deposit Amount** contains the amount to be deposited at the bank. **Currency Code** is the currency in which the deposit is denominated.
- **Reference ID** contains the ID of the deposit (if any).
- Use **Bank** and **Bank Account** to define where the tenders will be deposited.

Deposit Control - Turn Ins

The Turn Ins page contains a row for every turn-in event linked to the deposit control. Open this page using **Menu > Financial > Deposit Control > Search** and navigate to the **Turn Ins** page.

Fastpath:

Refer to [Turn Ins](#) for background information.

Description of Page

Deposit Control contains a concatenation of the deposit control's creation date, tender source type, and status.

Deposit Control ID is the system-assigned, unique identifier of the deposit control.

The turn-ins grid contains one row for every turn-in event associated with the deposit control. A turn-in event is created when moneys originally deposited in respect of a tender control are turned in to the tender control's deposit control. Turn-in events are created and maintained on the [Tender Control - Turn Ins](#) page. Refer to [Turn Ins](#) for background information. The following information is displayed in the grid:

- **Turn In Status** defines if it is a new turn in Awaiting approval or has been Approved by the operator who is responsible for the Deposit Control. Once the turn-in is Approved, this field becomes display-only.
- **Tender Type** is the type of tender that has been turned in. This is a display-only field.
- **Turn In Amount** is the amount of the **Tender Type** that has been turned in. This is a display-only field.
- **Receipt Number** is the ID of the receipt given to the person who turn-in the funds. This is a display-only field.
- **Create Date/Time** contains when the turn-in event was created. This is a display-only field.

Deposit Control - Characteristics

To update deposit control characteristics, open **Menu > Financial > Deposit Control > Search** and navigate to the **Characteristics** page.

Description of Page

Deposit Control contains a concatenation of the deposit control's creation date, tender source type, and status.

Deposit Control ID is the system-assigned, unique identifier of the deposit control.

The **Characteristics** collection contains information that describes miscellaneous information about the deposit control.

The following fields display:

Characteristic Type Indicate the type of characteristic.

Sequence Controls the order in which characteristics of the same type are displayed.

Characteristic Value Indicate the value of the characteristic.

Maintaining Tender Controls

Tender controls exist to give you administrative control over your cash drawers (and all other tender sources).

Fastpath:

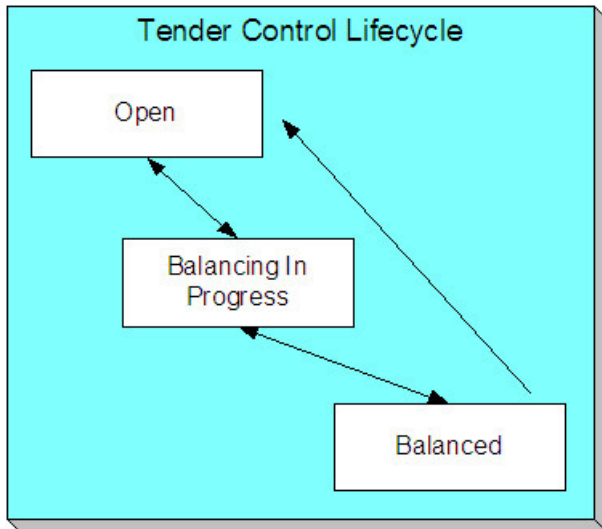

Refer to [Managing Your Cash Drawers](#) for more information.

**Note:**

The system creates most tender controls behind-the-scenes. Most tender controls are created by the system when it processes tenders from the remittance processors and lock boxes. You should only have to access the tender control pages if you record payments in cash drawers. For information about how the system creates tender controls, refer to [Managing Payments Interfaced From External Sources](#). Also note that the automatic payment activation process also creates tender and deposit controls. Refer to [Activating Automatic Payments](#) for more information.

The Lifecycle Of A Tender Control

The following diagram shows the possible lifecycle of a tender control.

Open A tender control is initially created in the Open state. While in this state, you may add new tenders to it, change the tender amount on its tenders, and transfer tenders into and out of it.

Balancing In Progress You change a tender control's status to Balancing In Progress when you're ready to balance its contents. While in this state, you can change the tender amount on its tenders and transfer tenders out of it. If you need to add new tenders to it or transfer tenders into it, you must return it to the Open state.

Balanced You change a tender control's status to Balanced when the sum of its tenders is consistent with the ending balance in the drawer. While in this state, you cannot modify it or its tenders. If you need to make modifications, you must return it to the Open or Balancing In Progress state.

If the tender control is part of a Balanced deposit control, you may not change its status.

**Note:**

Background processes and state transition. When payments are interfaced from external sources, the system automatically creates a tender control and links tenders to it (one for each payment interfaced). When all payments have been successfully loaded, the system changes the state of the respective tender control to Balanced.

Tender Control - Main

The Main page contains core tender control information. This page is used to balance the tender control.

Open this page using **Menu > Financial > Tender Control > Search**.

**Note:**

Searching For Tender Controls. When you use the **Creation Date** to search for tender controls, the system returns tender controls that are created on or before the date you specify. If the number of records returned exceeds the search limit (i.e. 300 records), only the records that do not exceed search limit are displayed. Therefore, you may need to specify an earlier creation date to find the record you are looking for. If you do not specify a creation date and search based on other criteria, the system uses the most recent date.

Fastpath:

Refer to [Managing Your Cash Drawers, Turn Ins](#) and [Balancing By Tender Type](#) for more information.

Description of Page

Tender Control contains a concatenation of the tender control's creation date, tender source, and status.

Tender Control ID is the system-assigned, unique identifier of the tender control.

Tender Source is the source of the tenders (e.g., cash drawer 22, lockbox 1 at Bank of America).

Deposit Control ID is the system-assigned, unique identifier of the deposit control that the tender control is part of. The deposit control's **Currency Code** is displayed below.

Fastpath:

For more information about deposit controls and tender controls, refer to [Managing Your Cash Drawers](#).

Turn on **All Users** if any user may insert tenders into this tender control. Turn this switch off and specify the appropriate **User ID** if only a single user may insert tenders into this tender control.

Create Date/Time is the date and time the tender control was created.

The **Starting Balance** of the tender control is defaulted from the tender source. This may be overridden while the **Tender Control Status** is Open or Balancing in Progress.

The **Tender Control Status** shows the status of the tender control. The **Balanced User ID** and **Balanced Date/Time** are populated when the status is changed to Balanced.

Fastpath:

For more information, refer to [The Lifecycle Of A Tender Control](#).

The **Balance** button is enabled when the **Tender Control Status** is Balancing in Progress. When this button is clicked, the system checks the following:

- All Turn-Ins have been Approved.
- The sum of all **Ending Balances** equals the sum of all **Expected Ending Balances**.

If the above conditions are true, the status of the tender control is changed to Balanced and all modifiable fields become protected.

The tenders grid contains a summary of the tenders linked to the tender control. One row is displayed for each tender type. Each row contains the number of tenders of this type and their total amount. In order to Balance the tender control, you must enter an appropriate **Ending Balance** for each **Tender Type**. Refer to [Balancing By Tender Type](#) for more information. The following information appears in the grid:

- **Tender Type** represents the type of tender (e.g., cash, credit card). This is a display-only field.
- **Nbr of Tenders** contains the total number of tenders of this type in the tender control. This is a display-only field and is calculated by the system by accumulating the tenders linked to the tender control.
- **Total Tenders** contains the total amount of tenders of this type in the tender control. This is a display-only field and is calculated by the system by accumulating the tenders linked to the tender control. Navigate to the **Tenders** page to see the individual tenders.
- **Turn In Amount** contains the total amount of turn-ins of this type. This is a display-only field and is calculated by the system by accumulating the turn-ins linked to the tender control. Navigate to the **Turn Ins** pages to see the individual turn ins.

- **Starting Balance** contains the starting balance of this type of turn in. This field is only populated on the row defined as the Starting Balance tender type on the Installation Record. This is a display-only field and is equal to the tender control's **Starting Balance**.
- **Expected Ending Bal** is the **Starting Balance** plus **Total Tenders** minus **Turn In Amount** for this type of tender.
- **Ending Bal** is the actual amount of money of this tender type. The cashier must enter this field in order to balance the tender control. This field is protected unless the **Status** of the tender control is **Balancing In Progress**. This amount must equal the Expected Ending Balance before the tender control can be marked as **Balanced**. Refer to [How To Get An Unbalanced Tender Control In Balance \(Fixing Over/Under\)](#) for more information.
- **Outstanding Over/Under** is the difference between **Expected Ending Bal** and **Ending Bal**. This is a display-only field.

The summary information beneath the tender type grid contains a summary of the tenders that are linked to the tender control.

- **Total Tender Amount** is the total amount of all tenders linked to the tender control.
- **Ending Balance** is the actual amount of money in the tender control (as defined in the above grid).
- **Expected Ending Balance** is the expected amount of money in the tender control (as defined in the above grid).
- **Outstanding Over/Under** is Ending Balance minus Expected Ending Balance. If this amount is zero, the field is not displayed.

If the tender controls were created for a background process, such as the automatic payment extract, the following information is displayed:

- **Batch Code** is the batch code for which the tender control was created. This field only appears if it contains a value.
- **Batch Number** is the batch number for which the tender control was created. This field only appears if it contains a value.

Use **Comments** to describe anything unusual about the tender control (e.g., to explain why a large over/under amount was created).

Tender Control - Tenders

The Tenders page contains a row for every tender linked to the tender control. Open this page using **Menu > Financial > Tender Control > Search** and navigate to the **Tenders** page.

Description of Page

Tender Control contains a concatenation of the tender control's creation date, tender source, and status.

Tender Control ID is the system-assigned, unique identifier of the tender control.

This grid at the top of the page contains a row for every tender linked to the tender control. When first displayed, the grid is ordered by the Create Date/Time column. No information about the tenders may be modified. To view or modify tender information, click the Go To button.

The grid at the bottom of the page contains a summary by tender type of all tenders linked to the tender control.

Tender Control - Turn Ins

Every time you turn in funds to the deposit control that is associated with your tender control, you create a turn-in event using this page. Open this page using **Menu > Financial > Tender Control > Search** and navigate to the **Turn Ins** page.

Fastpath:

Refer to [Managing Your Cash Drawers](#) and [Turn Ins](#) for more information.

Description of Page

Tender Control contains a concatenation of the tender control's creation date, tender source, and status.

Tender Control ID is the system-assigned, unique identifier of the tender control.

The turn-ins grid contains one row for every turn-in event associated with the tender control. A turn-in event is created when moneys are physically transferred to the deposit control associated with the tender control. Turn-in events are approved on the [Deposit Control - Turn Ins](#) page. The following information is displayed in the grid:

- **Turn In Status** defines if the turn-in is Awaiting Approval or has been Approved by the operator who is responsible for the Deposit Control. When a turn-in is first created, its status is Awaiting Approval and the following fields should be defined. Once the turn-in is Approved by the user responsible for the deposit control associated with the tender control, all of the following fields become display-only and the turn-in event cannot be deleted.
- **Tender Type** is the type of tender that has been turned in. This field may only be modified when the **Turn In Status** is Awaiting Approval.
- **Turn In Amount** is the amount of the **Tender Type** that has been turned in. This field may only be modified when the **Turn In Status** is Awaiting Approval.
- **Receipt Number** is the ID of the receipt given to the person who turn-in the funds. This field may only be modified when the **Turn In Status** is Awaiting Approval.
- **Create Date/Time** contains when the turn-in event was created. This is a display-only field.

Tender Control - Exceptions

This page contains an entry for every exception (i.e., error) associated with the tender control's payments and payment events. Open this page using **Menu > Financial > Tender Control > Search** and navigate to the **Exceptions** page.

Fastpath:

Refer to [Exceptions](#) for more information.

Description of Page

This page contains an entry for every exception (i.e., error) associated with the tender control's payments and payment events.

Tender Control - Characteristics

To update tender control characteristics, open **Menu > Financial > Tender Control > Search** and navigate to the **Characteristics** page.

Note:

If your tender control is balanced, you cannot update tender control characteristics.

Description of Page

The **Characteristics** collection contains information that describes miscellaneous information about the tender control.

The following fields display:

Characteristic Type Indicate the type of characteristic.

Sequence Controls the order in which characteristics of the same type are displayed.

Characteristic Value Indicate the value of the characteristic.

Interfacing Payments From External Sources

Most payments are NOT added by an operator using the Payment Event page. Rather, they are interfaced from an external source (e.g., a lock box or a remittance processor).

The base-package provides two interfaces to upload payments, each based on a different method of creating payment events.

Fastpath:

Refer to [Distributing A Payment Event](#) for more information about how payment event distribution is handled in the system.

The topics in this section describe how these payment interfaces work.

Interfacing Payments

The topics in this section describe how the payment interface using the system default method of creating payment events works.

Populating The Payment Upload Staging Records

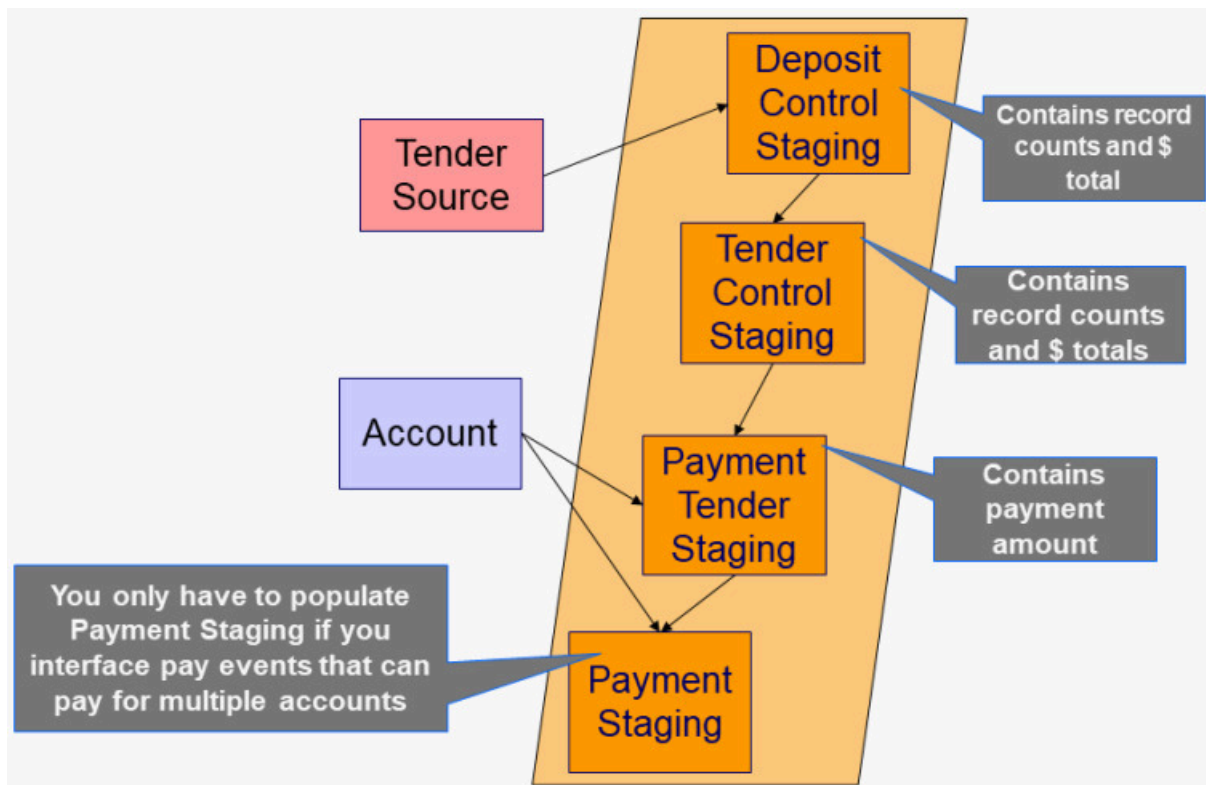

The following diagram illustrates the processes involved in the uploading of payment into the system.

The topics in this section describe each background process referenced above.

Process X - Populate Payment Upload Staging

Process X refers to the mechanism used by your organization to populate the various staging tables (shown in the orange section of the following ERD).

The following topics in this section describe each of these tables:

- [Deposit Control Staging](#)
- [Tender Control Staging](#)
- [Payment Tender Staging](#)
- [Payment Staging](#)

Deposit Control Staging

You must create a deposit control staging record for each batch of payments to be uploaded into the system. The name of this table is CI_DEP_CTL_ST. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-----------------|--------|-------|-----------|--|
| EXT_SOURCE_ID | 30 | Y | A/N | This must correspond with an external source ID on one of the defined tender sources. Refer to Setting Up Tender Sources for more information. |
| EXT_TRANSMIT_ID | 50 | Y | A/N | This is the unique identifier of the transmission from the external source. This must be a unique value for each transmission from the source. |

| | | | | |
|--------------------|------|---|----------|---|
| DEP_CTL_STG_ST_FLG | 2 | Y | A/N | This must be set to 20 (20 is the lookup value that corresponds with the Pending state) |
| DEP_CTL_ID | 10 | N | N | Leave this column blank. It will be assigned by the system when it creates a deposit control record. |
| TRANSMIT_DTTM | 15 | Y | DateTime | Date and time that the file was transmitted. |
| CURRENCY_CD | 3 | Y | A/N | This must be a valid currency code (this would be USD for United States dollars). |
| TOT_TNDR_CTL_AMT | 13.2 | Y | N | This column must equal the sum of the payment amounts on the tender control staging records associated with this deposit control staging. |
| TOT_TNDR_CTL_CNT | 10 | Y | N | This column must equal the number of tender control staging records associated with this deposit control staging. |
| LAST_UPDATE_INST | 10 | N | N | This field is populated during the upload. It is the process scheduler instance ID of the process performing the upload. |

You must create one or more [Tender Control Staging](#) for this deposit control staging record.

[Top of Page](#)

Tender Control Staging

You must create at least one tender control staging record for each batch of payments to be uploaded into the system. The name of this table is CI_TNDR_CTL_ST. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|----------|
|-------------|--------|-------|-----------|----------|

| | | | | |
|---------------------|------|---|-----|--|
| EXT_SOURCE_ID | 30 | Y | A/N | This must correspond with the external source ID on the parent deposit control staging record. |
| EXT_TRANSMIT_ID | 50 | Y | A/N | This must correspond with the external transmission ID on the parent deposit control staging record. |
| EXT_BATCH_ID | 30 | Y | A/N | This is the unique identifier of the batch of payments in respect of the external transmission ID. |
| TNDR_CTL_STG_ST_FLG | 2 | Y | A/N | This must be set to 20 (20 is the translate value that corresponds with the Pending state) |
| TNDR_CTL_ID | 10 | N | N | Leave this column blank. It will be assigned by the system when it creates a tender control record. |
| TOT_TNDR_AMT | 13.2 | Y | N | This column must equal the sum of the payment amounts on the payment tender staging records associated with this tender control staging. |
| TOT_TNDR_CNT | 10 | Y | N | This column must equal the number of payment tender staging records associated with this tender control staging. |

You must create one or more [Payment Tender Staging](#) records for this tender control staging record.

[Top of Page](#)

Payment Tender Staging

You must create at least one payment tender staging record for each payment associated with the tender control staging record. The name of this table is CI_PAY_TNDR_ST. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|--------------------|--------|-------|-----------|--|
| EXT_SOURCE_ID | 30 | Y | A/N | This must correspond with the external source ID on the parent deposit control staging record. |
| EXT_TRANSMIT_ID | 50 | Y | A/N | This must correspond with the external transmission ID on the parent tender control staging record. |
| EXT_BATCH_ID | 30 | Y | A/N | This must correspond with the external batch ID on the parent tender control staging record. |
| EXT_REFERENCE_ID | 30 | Y | A/N | This is the unique identifier of the payment in respect of the external batch ID. |
| PAY_TND_STG_ST_FLG | 2 | Y | A/N | This must be set to 10 (10 is the translate value that corresponds with the Pending state) |
| PAY_TENDER_ID | 12 | N | N | Leave this column blank. It will be assigned by the system when it creates a tender record. |
| TENDER_AMT | 13.2 | Y | N | The amount tendered (i.e., the payment amount). |
| ACCOUNTING_DT | 10 | Y | Date | This is the date that should be used for accounting purposes. This should correspond with an open accounting period. |

| | | | | |
|----------------|----|---|-----|--|
| TENDER_TYPE_CD | 4 | Y | A/N | This must correspond with the prime key of one of your tender types. Refer to Setting Up Tender Types for more information. |
| CUST_ID | 15 | Y | A/N | This is the account ID or old account number of the customer tendering the payment. If the system cannot find an account ID or old account number that matches this value, the account ID of the tender source's suspense SA will be used on the corresponding tender and payment. |
| MICR_ID | 30 | N | A/N | This is the MICR ID associated with the payment. |
| NAME1 | 40 | N | A/N | This is the customer name on the payment. |
| CHECK_NBR | 10 | N | A/N | This is the check number on the payment. |

[Top of Page](#)

Payment Staging

You need only populate rows on this table if any of the following conditions apply:

- If you need to distribute a payment tender to an account other than that defined with the CUST_ID on the payment tender staging record, you must create a payment staging record. You may distribute a tender to multiple accounts by creating multiple payment staging records. Note, if you want to distribute the payment tender to the same account, you do NOT need a payment staging record.
- If you want to restrict a payment to a specific service agreement, you must insert a row on this table to indicate the specific the service agreement in question. You do this by populating MATCH_TYPE_CD with a value that indicates that you are paying for a specific service agreement and MATCH_VALUE with the unique ID of the service agreement.
- If you practice [open-item accounting](#), you must insert a row on this table for each to indicate the open-item to which the payment should be matched. Note, because open-item customer typically match payments to bills, you would populate MATCH_TYPE_CD with a value to indicate that you are matching by bill ID and MATCH_VALUE with the unique ID of the bill.

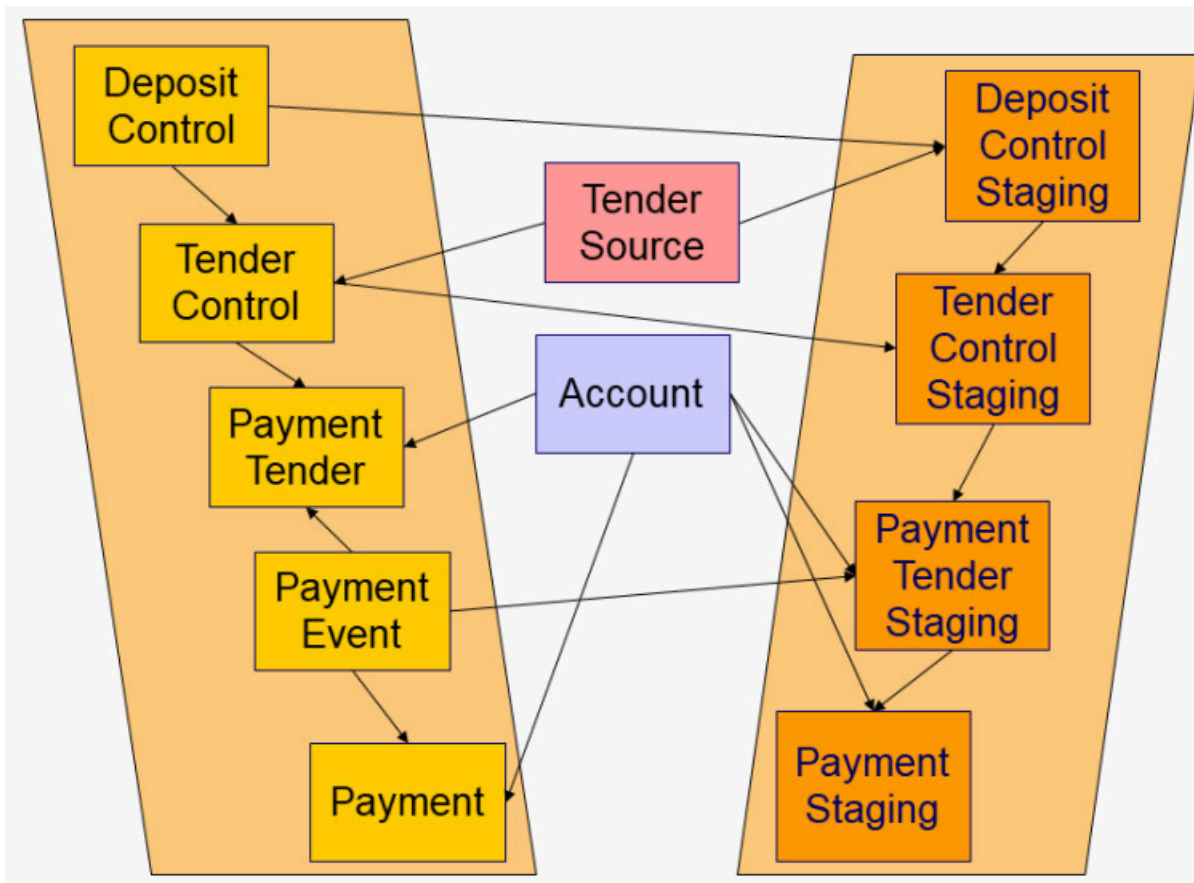

The name of this table is CI_PAY_ST. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|------------------|--------|-------|-----------|--|
| EXT_SOURCE_ID | 30 | Y | A/N | This must correspond with the external source ID on the parent payment tender staging record. |
| EXT_TRANSMIT_ID | 50 | Y | A/N | This must correspond with the external transmission ID on the parent payment tender staging record. |
| EXT_BATCH_ID | 30 | Y | A/N | This must correspond with the external batch ID on the parent payment tender staging record. |
| EXT_REFERENCE_ID | 30 | Y | A/N | This must correspond with the external reference ID on the parent payment tender staging record. |
| CUST_ID | 15 | Y | A/N | This is the account ID or old account number of the customer to which the payment should be distributed. If the system cannot find an account ID or old account number that matches this value, the account ID of the payor is used on the corresponding payment. If the payor's account ID is invalid, the tender source's suspense SA is used. |
| PAY_AMT | 13.2 | Y | N | The amount tendered (i.e., the payment amount). |

| | | | | |
|---------------|----|---|-----|---|
| MATCH_TYPE_CD | 8 | N | A/N | See the description of the MATCH_VALUE field below. Refer to Payments And Match Events for more information about the significance of this field. |
| MATCH_VALUE | 30 | N | A/N | MATCH_VALUE and MATCH_TYPE_CD are used in conjunction to indicate that the distribution of the payment should be restricted in some way (i.e., the standard payment distribution algorithm should not be used). MATCH_TYPE_CD indicates how the payment should be distributed (e.g., only distribute to a specific service agreement), MATCH_VALUE contains the ID of the restriction (e.g., the SA ID). If MATCH_TYPE_CD is specified, it must reference a valid Match Type . |

Process PUPL - Upload Payments

The background process (PUPL) loads the contents of the various payment staging records into the various payment event tables. The tables that are populated by this process are shown in the left orange section of the following ERD (the right orange section are the staging tables populated by the process described above)

The topics in this section describe how these tables are populated.

[Phase 1 - Create Deposit Control](#)

[Phase 2 - Create Tender Control](#)

[Phase 3 - Create Payment Events, Tenders, Payments, and Payment Segments](#)

Phase 1 - Create Deposit Control

The following points describe, at a high level, the first phase of the payment upload process:

- PUPPL checks that the record counts and money totals of tender control stagings add up to the expected amount on deposit control staging. If not,
 - PUPPL sets the status of the deposit control staging to be Error . None of the tender controls within the deposit control will be processed until everything adds up. You can fix these on the [Deposit Control Staging](#) page.
 - When PUPPL runs next, it will recheck the totals on deposit control stagings that are in Error or Pending
- If the record and dollar amounts are clean,
 - PUPPL creates the corresponding deposit control
 - PUPPL sets the status of the deposit control staging to be In Progress

[Top of Page](#)

Phase 2 - Create Tender Control

The following points describe, at a high level, the second phase of the payment upload process:

- PUPPL checks that record counts and money totals of payment tender staging(s) adds up to expected amount on tender control staging. If not,

- PUPL sets the status of the tender control staging to be Error . None of the tender controls within the deposit control will be processed until everything adds up for ALL tender controls. You can fix these on the [Tender Control Staging](#) page.

Note:

that the Deposit Control Staging record is **not** updated - its status is unchanged. Neither is the Pay Tender Staging record updated - its status also remains unchanged. Only the Tender Control Staging record is updated to be in Error .

- When PUPL runs next, it will recheck the totals of tender control stagings that are in Error or Pending.
- If the record and dollar amounts are clean,
 - PUPL creates the corresponding tender control.
 - PUPL sets the status of the tender control staging to be In Progress .

[Top of Page](#)

Phase 3 - Create Payment Events, Tenders, Payments, and Payment Segments

At this point, all deposit control stagings and tender control stagings are in the state of In Progress. Next, PUPL starts the upload of payment tender staging and payment staging. The following points describe, at a high level, this phase of the payment upload process:

- If the payment tender staging record has a future accounting date, the processing for the record is skipped. This prevents uploaded payments from being created and subsequently frozen until their accounting date is reached. (Some external sources may provide advance notification of payments to be made in the future.) A skipped staging record remains in the Pending state until its accounting date is reached.
- PUPL checks money totals of payment advices (if any) adds up to expected amount on payment tender staging.
 - If not, PUPL sets the payment tender staging's status to Error .
 - Any errors are written to the [Payment Upload Exception](#) table. You can fix these errors on the [Payment Upload Staging](#) page and change the record's status back to Pending.
 - When PUPL runs next, it will recheck the totals of the payment tender staging
- If payment tender staging record is clean:
 - PUPL creates a corresponding payment event, tender, and payment.
 - If the account on payment tender staging is wrong, the account on the corresponding tender will be the tender source's suspense SA's account. Refer to [Setting Up Tender Sources](#) for more information. Refer to [How To Transfer A Payment From One Account To Another](#) for how to transfer to payment to the correct account.
 - If the account on payment advice is wrong, the account on the corresponding payment will be the account on the payment tender.
 - PUPL distributes the payment(s) amongst the account's service agreements, and payment segments are created. Note, the payment could be in error if there are no SAs for the account (as well as other reasons). Payments in error are written to the payment exception (CI_PAY_EXCP).
 - PUPL changes the payment tender staging's status to Complete.
- If all payment tender stagings are Complete:
 - PUPL changes the tender control staging's status to Complete.
 - PUPL changes the deposit control staging's status to Complete .
- If there are payment tender staging that are not Complete
 - The status of the tender control staging will still be In progress .
 - The status of the deposit control staging will still be In progress .
- PUPL will attempt to upload the offending payment tender staging records when it next runs.

Note: Balancing Control Tables. The balancing of the deposit and tender control tables during payment upload can either be done by PUPL, or after PUPL successfully completes. The latter might be useful for high volume payment uploads that could result in deadlocks on these control tables. If your implementation wishes to execute control table balancing after PUPL completes, ensure that the necessary batch parameter is

set to exclude balancing when PUPL runs and also that the separate balancing batch process (C1-PUBAL) is scheduled after PUPL.

PYUP-PRG - Purge Payment Upload Objects

Completed payment upload staging objects should be periodically purged from the system by executing the [PYUP-PRG](#) background process. This background process allows you to purge all Completed payment upload staging objects older than a given number of days.

We want to stress that there is no system constraint as to the number of Completed payment upload objects that may exist. You can retain these objects for as long as you desire. However we recommend that you periodically purge Completed payment upload objects as they exist only to satisfy auditing and reporting needs.

Maintaining Deposit Control Staging

The Deposit Control Staging page has three purposes:

- You can view historical deposit and tender control staging records associated with uploaded payments.
- You can correct deposit and tender control records that are in error.
- You can add deposit and tender control records to be uploaded by the payment upload background process.

The topics in this section describe this page.

Deposit Control Staging - Main

This page shows the details of a deposit control staging record.

Fastpath:

Refer to [Populating The Payment Upload Staging Records](#) for more information about this record.

Open this page using **Menu > Financial > Deposit Control Staging > Search.**

Description of Page

External Source ID corresponds with an external source ID on one of the your tender sources. This should be the unique ID of the source of the interfaced payments. Refer to [Setting Up Tender Sources](#) for more information.

External Transmit ID is the unique identifier of the transmission of payments from the external source. This must be a unique value for each transmission from the source.

Status shows the state of the deposit control staging records. Potential values are: Incomplete , Pending, In Progress, Partial Load, Complete, Error.

Deposit Control ID is the system-assigned, unique identifier of the related deposit control. This value is populated after the system creates a deposit control for the upload staging record.

Transmission Date/ Time are when the information was interfaced into the system.

Total Tender Controls must equal the number of tender control staging records associated with this deposit control staging.

Total Tender Control Amount must equal the sum of the payment amounts on the tender control staging records associated with this deposit control staging. The **Currency Code** related to the amount is adjacent.

Deposit Control Staging - Tender Control Staging

This page shows the details of a tender control staging record.

Fastpath:

Refer to [Populating The Payment Upload Staging Records](#) for more information about this record.

Open this page using **Menu > Financial > Deposit Control Staging > Search** and navigate to the **Tender Control Staging** page.

Description of Page

External Source ID is the external source ID on the parent deposit control staging record.

External Transmit ID is the external transmission ID on the parent deposit control staging record.

The grid that follows contains a row for every tender control staging record linked to the deposit control staging record. The following information is displayed.

External Batch ID This is the unique identifier of the batch of payments in respect of the external transmission ID.

Status This is the state of the tender control staging records. Potential values are: Pending, In Progress, Complete, Error.

Tender Control ID This is the system-assigned, unique identifier of the related tender control. This value is populated after the system creates a tender control for the upload staging record.

Total Tenders Amount This is the sum of the payment amounts on the payment staging records associated with this tender control staging.

Total Number Of Tenders This is the number payment tender staging records associated with this tender control staging.

Payment Upload Staging

The Payment Upload Staging page has three purposes:

- You can view historical payment tender and payment staging records associated with uploaded payments.
- You can correct payment tender records that are in error.
- You can add new payment tender and payment staging records to be uploaded by the payment upload process.

The topics in this section describe this page.

Payment Upload Staging - Tender Detail

This page shows the details of a payment tender staging record.

Fastpath:

Refer to [Populating The Payment Upload Staging Records](#) for more information about this record.

Open this page using **Menu > Financial > Payment Upload Staging > Search** to open the **Tender Detail** page.

Description of Page

External Source ID this is the external source ID on the parent tender control staging record.

External Transmission ID is the external transmission ID on the parent tender control staging record.

External Batch ID is the external batch ID on the parent tender control staging record.

Ext. Reference ID is the external source's unique identifier of the payment tender.

Customer ID is the account ID or old account number of the customer tendering the payment. If the system cannot find an account ID or old account number that matches this value, the account ID of the tender source's suspense SA will be used on the corresponding tender and payment.

The **Tender Amount** is the amount tendered (i.e., the payment amount).

Tender Type defines the type of tender. Refer to [Setting Up Tender Types](#) for more information.

**Note:**

Authorizing Tenders. The **Tender Type** dropdown list does not include tender types that require authorization (i.e. credit card payments).

**Fastpath:**

For information about tender types requiring authorization, refer to [Credit Card Payments](#).

MICR ID is the MICR ID associated with the tender.

Check Number is the check number on the payment.

Name is the customer's name (as it appeared on the uploaded tender).

Accounting Date is the date that should be used for accounting purposes.

Pay Tender Staging Status shows the state of the tender control staging records. Potential values are: Pending, Complete, Error.

Payment Event ID is the system-assigned, unique identifier of the related payment event. This value is populated after the system creates a payment event for the upload staging record.

Payment Upload Staging - Payment Advice

If a tender was distributed to customers other than that defined on the Tender Detail page, the customers that the tender was distributed to are defined on this page. This page will not contain information if the tender is distributed to the tender detail's customer.

**Fastpath:**

Refer to [Populating The Payment Upload Staging Records](#) for more information about this record.

Open this page using **Menu > Financial > Payment Upload Staging > Search** and navigate to the **Payment Advice** page.

Description of Page

External Source ID this is the external source ID on the parent tender control staging record.

External Transmission ID is the external transmission ID on the parent tender control staging record.

External Batch ID is the external batch ID on the parent tender control staging record.

External Reference ID is the external reference ID of the payment tender.

The grid that follows is only populated if the tender is distributed to customer(s) other than the tendering customer. The following information is displayed.

Customer ID This is the account ID or the old account number of the customer to which the payment should be distributed.

Customer Info If the **Customer ID** is an account ID that exists in the system, the name of the primary person and the customer class of the account are displayed here.

Payment Amount This is the amount of the tender to be distributed to the customer.

Match Type and **Match Value** These fields are only used if the distribution of the payment should be restricted in some way (i.e., the standard payment distribution algorithm should not be used). **Match Type** indicates how the payment should be distributed (e.g., only distribute to a specific service agreement), **Match Value** indicates the ID of the restriction (e.g., the service agreement ID). Valid values of **Match Type** are Service Agreement.

Payment Upload Staging- Characteristics

Select **Menu > Financial > Payment Upload Staging > Search** and navigate to the **Characteristics** page.

Description of Page

External Source ID this is the external source ID on the parent tender control staging record.

External Transmission ID is the external transmission ID on the parent tender control staging record.

External Batch ID is the external batch ID on the parent tender control staging record.

Ext. Reference ID is the external source's unique identifier of the payment tender.

Use the characteristics grid to capture additional information about the payment tender staging record.

- Use **Payment Characteristics Entity** to define where each characteristic will be populated on upload. Valid values are: **Payment**, **Payment Event** or **Payment Tender**
- Select a **Characteristic Type** for each payment characteristic entity. You can only choose Characteristic Types defined as permissible for the applicable entity. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.
- Enter a valid **Characteristic Value** for the selected characteristic type. You may enter more than one characteristic row for the same characteristic type, each associated with a unique Sequence number. If not specified, the system defaults it to the next **sequence** number for the characteristic type.

Payment Upload Exception

If errors are detected during the payment upload process, a record is written to the payment upload exception table with a message indicating the nature of the severe error.

To view the messages associated with the exception records, schedule the [TD-PYUPL](#) background process. This process generates a To Do entry for every record in the payment upload exception table.

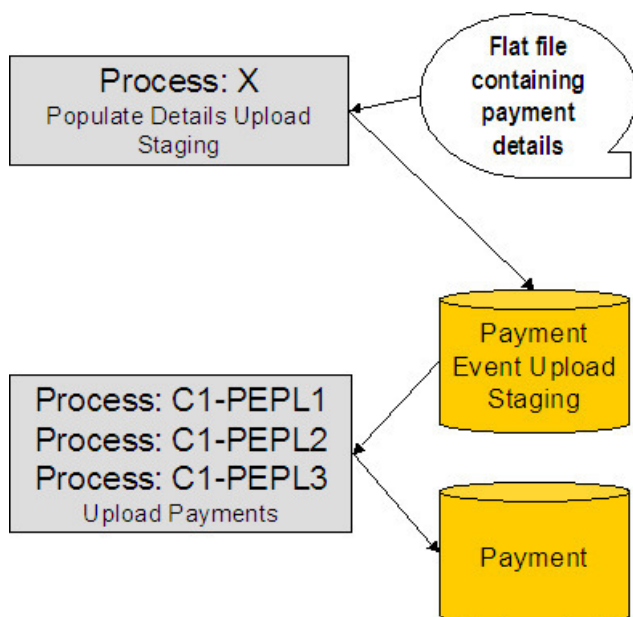

You can fix this error using the [Payment Upload Staging](#) page and change the status of the record from Error to Pending. When the payment upload process next runs, it attempts to upload this record again.

Interfacing Payments Using Distribution Rules

The topics in this section describe how the payment interface using distribution rules works.

Populating The Payment Event Upload Staging Records

The following diagram illustrates the processes involved in the uploading of payment event distribution details into the system.

The topics in this section describe each background process referenced above.

Process X - Populate Payment Event Upload Staging

Process X refers to the mechanism used by your organization to populate the payment event upload staging table.

payment Event Upload Staging Table

You must create a payment event upload staging record for each payment distribution detail to be uploaded into the system. The name of this table is CI_PEVT_DTL_ST. The following table describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-----------------|--------|-------|-----------|--|
| EXT_SOURCE_ID | 30 | Y | A/N | This must correspond with an external source ID on one of the defined tender sources. Refer to Setting Up Tender Sources for more information. |
| EXT_TRANSMIT_ID | 50 | Y | A/N | This is the unique identifier of the transmission from the external source. This must be a unique value for each transmission from the source. |
| PEVT_DTL_SEQ | 12 | Y | N | Unique identifier of the detail record within the transmission. The C1-PEPL1 process uses this field to organize the parallel threads. |
| PEVT_STG_ST_FLG | 4 | Y | A/N | This must be set to 10 (10 is the lookup value that corresponds with the Incomplete state) |
| DST_RULE_CD | 12 | Y | A/N | This must be a valid distribution rule . The distribution rule contains the set of algorithms designed to process the staging detail. |

| | | | | |
|------------------|------|---|------|--|
| DST_RULE_VALUE | 254 | Y | A/N | This must be a valid value for the characteristic type defined on the distribution rule. |
| CURRENCY_CD | 3 | Y | A/N | This must be a valid currency code (this would be USD for United States dollars). |
| TENDER_AMT | 13.2 | Y | N | The amount tendered (i.e., the payment amount). |
| ACCOUNTING_DT | 10 | Y | Date | This is the payment date that should be used for accounting purposes. This should correspond with an open accounting period. |
| TENDER_TYPE_CD | 4 | Y | A/N | This must be a valid tender type. Refer to Setting Up Tender Types for more information. |
| CHECK_NBR | 10 | N | A/N | This is the check number on the payment. |
| MICR_ID | 30 | N | A/N | This is the MICR ID associated with the payment tender. |
| CUST_ID | 15 | N | A/N | This field may be used to record customer information. |
| NAME1 | 30 | N | A/N | This field may be used to capture additional payment tender information. |
| EXT_REFERENCE_ID | 30 | N | A/N | This field may be used to capture external information associated with the payment tender. |

| | | | | |
|---------------|----|---|-----|---|
| MATCH_TYPE_CD | 8 | N | A/N | See the description of the MATCH_VALUE field below. Refer to Payments And Match Events for more information about the significance of this field. |
| MATCH_VALUE | 30 | N | A/N | MATCH_VALUE and MATCH_TYPE_CD are used in conjunction to indicate that the distribution of the payment should be restricted in some way (i.e., the standard payment distribution algorithm should not be used). MATCH_TYPE_CD indicates how the payment should be distributed (e.g., only distribute to a specific service agreement), MATCH_VALUE contains the ID of the restriction (e.g., the SA ID). If MATCH_TYPE_CD is specified, it must reference a valid Match Type . |
| TNDR_CTL_ID | 10 | N | A/N | Leave this column blank. It will be assigned by the system when it creates a tender control record. |

| | | | | |
|-----------------|----|---|-----|---|
| ACCT_ID | 10 | N | A/N | <p>This is the tender account. If left blank, the C1-PEPL1 process will populate this field by calling the Determine Tender Account algorithm defined on the distribution rule.</p> <p>Note that this Account ID is not necessarily unique as multiple staging details can reference the same tender account.</p> |
| PAY_EVENT_ID | 12 | N | A/N | <p>Leave this column blank. It will be assigned by the system when it creates a payment event record.</p> |
| PEVT_PROCESS_ID | 10 | N | A/N | <p>If left blank, the C1-PEPL1 process will set this field equal to the Tender Account ID.</p> <p>This field is used for grouping staging records and for organizing parallel threads (in the C1-PEPL2 process). Therefore, it is strongly encouraged that it bears a relationship to the tender account ID.</p> |
| APAY_SRC_CD | 12 | N | A/N | <p>This must be a valid auto-pay source code.</p> |
| EXT_ACCT_ID | 50 | N | A/N | <p>This is the customer's account number at the financial institution</p> |

| | | | | |
|-------------|----|---|------|---|
| EXPIRE_DT | 10 | N | Date | This field is only needed if the Tender Type indicates that an expiration date is necessary (e.g., for a credit card payment) |
| ENTITY_NAME | 64 | N | A/N | This is the customer's name in the financial institution's system |

Data Setup Examples of Payment Distribution Details

Typically, each staging record will represent a single payment event - with a corresponding payment tender and payment. However, it is possible to specify complex relationships within a set of staging records. For example, it will be straightforward to define a set of staging records that represent a single tender but multiple payments (to model the single payment tender of a welfare agency which covers payments for multiple accounts). Similarly, it is equally possible to define a set of staging records that represent a single payment but multiple tenders (although not a common requirement).

Each staging record can represent:

- Zero or one new payment events. Typically, each detail staging record will represent a single payment event. However, it is possible to define multiple records for a single payment event. All details for a single payment event are identified by a common value on the staging record: **Pay Event Process ID**.

Note:

Pay Event Process ID. This field is used for grouping staging records **and** for organizing parallel threads (in the C1-PEPL2 process). Therefore, it is **strongly encouraged** that it bears a relationship to the tender account ID.

- A partial or one new payment tenders. Typically, each detail staging record will represent a single payment tender. However, it is possible to define multiple staging records for a single pay tender. All details for a single tender are identified by a common payment event ID as well as common tender information (tender type, tender account ID, check number, external reference, etc.).
- A partial or many new payments. Typically, each detail staging record will represent a set of one or many new payments. However, it is possible to define multiple staging records for a single payment. All details for a single payment are identified by a common payment event ID as well as common distribution rule and characteristic value information.

The sections below provide examples of a few of these complex payment event configurations. Note that these examples assume the same distribution rule is referenced in all staging records.

- [Staging Entry Example 1: One Payment Event, Two Tenders, Two Payments](#)
- [Staging Entry Example 2: One Payment Event, One Tender, Two Payments](#)
- [Staging Entry Example 3: One Payment Event, Two Tenders, One Payment](#)

Staging Entry Example 1: One Payment Event, Two Tenders, Two Payments

| Seq. | Pay Event Process ID | Tender Account ID | Tender Ref. | Date | Rule Value | Amount | Tender Type | Check No |
|------|----------------------|-------------------|-------------|----------|-------------|--------|-------------|----------|
| 1 | 1234567890 | 1234567890 | 112A | 1/1/2006 | 113-54-8978 | 30.00 | Check | 101 |
| 2 | 1234567890 | 1234567890 | 112B | 1/1/2006 | 575-40-3030 | 40.00 | Check | 102 |

[Top of Page](#)

Staging Entry Example 2: One Payment Event, One Tender, Two Payments

| Seq. | Pay Event Process ID | Tender Account ID | Tender Ref. | Date | Rule Value | Amount | Tender Type | Check No |
|------|----------------------|-------------------|-------------|----------|-------------|--------|-------------|----------|
| 1 | 1234567890 | 1234567890 | 112A | 1/1/2006 | 113-54-8978 | 30.00 | Check | 101 |
| 2 | 1234567890 | 1234567890 | 112A | 1/1/2006 | 575-40-3030 | 40.00 | Check | 101 |

[Top of Page](#)

Staging Entry Example 3: One Payment Event, Two Tenders, One Payment

| Seq. | Pay Event Process ID | Tender Account ID | Tender Ref. | Date | Rule Value | Amount | Tender Type | Check No |
|------|----------------------|-------------------|-------------|----------|-------------|--------|-------------|----------|
| 1 | 1234567890 | 1234567890 | 112A | 1/1/2006 | 575-40-3030 | 30.00 | Check | 101 |
| 2 | 1234567890 | 7878787870 | 888Q | 1/1/2006 | 575-40-3030 | 40.00 | Check | 9872 |

The Lifecycle of a Payment Event Upload Staging Record

The following diagram shows the possible lifecycle of a payment event upload staging record.

- **Incomplete.** A payment event staging record is initially created in incomplete state. The C1-PEPL1 process sets it to pending once it links it to a tender control and determines its tender account.
- **Pending.** The C1-PEPL2 process sets a pending record to complete once all processing logic is executed and a payment event is linked to it.
- **Complete.** When processing of the staging record is complete the record is in the complete state. This is a final state.
- **Error.** A payment event staging record may be set to Error from Incomplete or Pending states by the C1-PEPL1 and C1-PEPL2 processes respectively.

Fastpath:

Refer to [To Do Entries Instead of Exceptions](#) for more information on how To Do entries are used to capture processing errors.

To Do Entries Instead of Exception Records

Instead of creating an exception record for staging records in the Error state the C1-PEPL1 and C1-PEPL2 background processes create To Do entries and link them to the offending staging records.

Each process determines the [To Do type](#) to use for reporting errors by looking for the To Do Type defined with this process as its creation process.

Process C1-PEPL1 - Upload Payments (Step 1)

The batch process C1-PEPL1 refers to the first of three background processes that load the contents of the payment event upload staging records into the various payment tables.

The responsibility of this process is to transition the status of the staging records from Incomplete to Pending. The status of a staging record must remain Incomplete until:

- It is linked to a tender control. This process creates a new deposit control record. It creates a new tender control record if the staging record is not currently linked to one. It then updates the payment event upload staging records with the corresponding **Tender Control ID**.
- The **Tender Account ID** field is populated. The Determine Tender Account algorithm defined on the [distribution rule](#) is called and the returned account ID is posted on the staging record.
- The **Pay Event Process ID** field is populated. If left blank this field is set equal to the **Tender Account ID**.

The following diagram and the sections below describe at a high level the processing phases of the C1-PEPL1 background process.

- [Phase 1 - Create Tender Control](#)
- [Phase 2 - Determine Tender Account](#)

Phase 1 - Create Tender Control

Note:

This step cannot be bounded by thread range but must execute across the entire population of staging details. Therefore this step in the process is designed so that all parallel threads attempt to execute it at the same time but only one thread succeeds to avoid creating duplicate tender controls.

This step creates all tender controls required by the upload records as follows:

- For each distinct tender source transmissions represented within the incomplete set of upload staging details a deposit control and a tender control are created in an open state. (If the upload record is already linked to a tender control, then that tender control is used and a new one is not created.)
- If an error occurs at this stage

- A designated staging record for the transmission group (one is picked at random) is set to Error and a To Do entry is created and linked to it to capture the error message that applies for the whole transmission group. Other records in the group remain incomplete .
- The process stops.

Note:

Group Error. This technique allows for an easier recovery from a setup error that may affect a large volume of records in a single transmission. Capturing the error only on a single designated record requires only this record to be set back to Incomplete once the setup issue is corrected. It is important to note that the transmission group is not processed if at least one of the records in the group is in Error status.

- Once a transmission group of records is fully processed, a To Do cleanup processing takes place to complete To Do entries previously raised for its designated staging record.

Fastpath:

Refer to [To Do Entries Instead of Exceptions](#) for more information on how To Do entries are used to capture processing errors.

[Top of Page](#)

Phase 2 - Determine Tender Account

After all tender controls have been created the second step attempts to transition all incomplete records to the pending state.

Each incomplete staging record is processed as follows:

- If not yet associated with a tender control ID, the process looks for an Open tender control that matches the batch code, batch number and external source ID and links it to the staging record. An error is raised if a matching tender control is not found.
- Execute the Determine Tender Account algorithm defined on the distribution rule and populate the record with the returned account ID. Note that the algorithm is called even when the tender account is populated to provide for a potential override of the initial value when necessary. An error is raised if a tender account may not be determined.
- If not already populated, the **Pay Event Process ID** is set equal to the Tender Account ID. The C1-PEPL2 process uses this field to organize the parallel threads and to group multiple staging details into a single payment event.
- The staging record is moved to pending state.
- If any errors occur set the record to Error and create a To Do entry for the error message.
- If no error occurred, a To Do cleanup processing takes place to complete To Do entries previously raised for the staging record.

Fastpath:

Refer to [To Do Entries Instead of Exceptions](#) for more information on how To Do entries are used to capture processing errors.

Note:

This step is designed to support execution in parallel threads based upon the sequence number portion of the staging table prime key.

Process C1-PEPL2 - Upload Payments (Step 2)

The batch process C1-PEPL2 refers to the second of three background processes that load the contents of the payment event upload staging records into the various payment tables.

The responsibility of the C1-PEPL2 process is to create payment events, payment tenders and payments and transition the corresponding staging records from Pending to Complete.

The following diagram and the section below describe at a high level the processing phases of the C1-PEPL2 background process.

Each distinct group of pending staging records associated with the same external source ID, external transmit ID, accounting date, and pay event process ID is processed as follows:

- A payment event is created for the group and stamped on each of its records.
- A payment tender is created for each distinct set of staging records having the same tender account, tender type and other tender information fields, except for the tender amount.
- The Create Payment algorithm is then called for each distinct group of staging records having the same tender account, [distribution rule](#) and rule value providing it with the total amount for the group.
- The staging record is moved to the complete state.
- If any error occurs a designated staging record for the payment event group (one is picked at random) is set to Error and a To Do entry is created and linked to it to capture the error message that applies for the whole group. Other records in the group remain incomplete .

Note:

Group Error. This technique allows for an easier recovery from an error that affects all staging records for a single payment event. Capturing the error only on a single designated record requires only this record to be set back to pending once the issue is corrected. It is important to note that the whole set of records is not processed if at least one of the records in the group is in Error status.

- If no error occurred, a To Do cleanup processing takes place to complete To Do entries previously raised for the designated staging record.

Fastpath:

Refer to [To Do Entries Instead of Exceptions](#) for more information on how To Do entries are used to capture processing errors.

Note:

This process is designed to support execution in parallel threads based upon the payment event process ID field.

Process C1-PEPL3 - Upload Payments (Step 3)

The batch process C1-PEPL3 refers to the last of three background processes that load the contents of the payment event upload staging records into the various payment tables.

The responsibility of the C1-PEPL3 process is to update the status of the related deposit and tender controls from open to balanced.

Each distinct tender control for which all associated staging records are in complete status is processed as follows:

- The tender deposit is created.
- The tender control is set to balanced.
- The deposit control is set to balanced.

Note:

This process is designed to support execution in parallel threads based upon the Tender Control ID field.

Payment Event Upload Staging

The Payment Event Upload Staging page has three purposes:

- You can view historical payment event upload staging records associated with uploaded payments.
- You can correct payment event upload staging records that are in error.
- You can add new payment event upload staging records to be uploaded by the payment event upload processes.

The topics in this section describe this page.

Payment Event Upload Staging - Main

This page shows the details of a payment event upload staging record.

Fastpath:

Refer to [Populating The Payment Event Upload Staging Records](#) for more information about this record.

Open this page using **Menu > Financial > Payment Event Upload Staging > Search.**

Description of Page

External Source ID corresponds with an external source ID on one of the your tender sources. This should be the unique ID of the source of the interfaced payments. Refer to [Setting Up Tender Sources](#) for more information.

External Transmission ID is the unique identifier of the transmission of payments from the external source. This must be a unique value for each transmission from the source.

Sequence is the identifier of the record within the transmission. The C1-PEPL1 process uses this field to organize the parallel threads.

Accounting Date is the payment date that should be used for accounting purposes.

Distribution Rule is the rule by which the payment detail is to be processed. A [default distribution rule](#) is displayed if you have set one.

Rule Value is a value associated with the payment and expected by the distribution rule.

Match Type and **Match Value** are only used if the distribution of the payment should be restricted in some way (i.e., the standard payment distribution algorithm should not be used). **Match Type** indicates how the payment should be distributed (e.g., only distribute to a specific service agreement), **Match Value** indicates the ID of the restriction (e.g., the service agreement ID).

Payor Account ID is the tender account. If not populated the C1-PEPL1 process populates this field by calling the Determine Tender Account algorithm defined on the [distribution rule](#).

Tender Amount is the amount tendered (i.e., the payment amount).

Currency Code is the currency of the tendered amount. This should be the same as currency defined on the tender source.

Tender Type defines the form or remittance (e.g., cash, check, etc.). Note that the **Tender Type** defaults from the [installation record](#).

Note:

Authorizing Tenders. The **Tender Type** dropdown list does not include tender types that require authorization (i.e. credit card payments).

Fastpath:

For information about tender types requiring authorization, refer to [Credit Card Payments](#).

Check Number is the check number on the payment.

MICR ID is the value of the magnetic ink character recognition (MICR) line on the payment.

External Reference ID may be used to record external information associated with the payment tender.

Customer ID may be used to record additional customer information.

Name may be used to record additional payment tender information.

Tender Control ID is the tender control associated with the payment. This field is should typically be left for the C1-PEPL1 process to populate.

If the **Tender Type** is associated with an [automatic payment](#), the **Auto Pay** section displays. The system attempts to default automatic payment information from the [account's auto-pay](#) option if the tender type is the same as the tender type on the account's auto-pay source and if the auto pay option is effective on the payment date. If the system is unable to default information, you must specify the source of the funds and the customer's account number / credit card number at the financial institution.

- **Auto Pay Source** is the financial institution / credit card company that receives the automatic payment request.
- **External Account ID** is the customer's account number at the financial institution.
- **Expires On** is only needed if the **Tender Type** indicates that an expiration date is necessary (e.g., for a credit card payment).
- **Name** is the customer's name in the financial institution's system.

Pay Event Process ID is used to group multiple staging records into a single payment event. If not populated, the C1-PEPL1 process sets this field equal to the **Payor Account ID**.

Pay Event Staging Status shows the state of the staging record. Refer to [The Lifecycle of a Payment Event Upload Staging](#) for a state transition overview.

Payment Event ID is the system-assigned, unique identifier of the related payment event. The C1-PEPL2 process populates this field when it creates a payment event for the upload staging record. You can use this field to navigate to the payment event page.

If a staging record is in Error state then the error message associated with the [corresponding To Do entry](#) is displayed.

Adjustments

In this section, we describe when and how to adjust a service agreement's balance.

The Big Picture Of Adjustments

The topics in this section provide background information about a variety of adjustment issues.

Fastpath:

We strongly recommend familiarizing yourself with the topics described in [The Financial Big Picture](#) to fully appreciate the place of an adjustment in the system's financial architecture. In particular, refer to [Setting Up Adjustment Types](#) and [Setting Up Adjustment Type Profiles](#).

Adjustments - Current Balance versus Payoff Balance

Adjusting how much a customer owes involves changing a service agreement's payoff balance and/or current balance by creating an adjustment. In this section we describe these two balances.

Warning:

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

When Current Balance Equals Payoff Balance

For most service agreements, payoff balance and current balance are always the same (or in colloquial speech - the amount the customer thinks they owe equals what they really owe). In this situation, an adjustment is easy: both payoff balance and current balance are adjusted by the same value.

Let's run through a typical example. The values in the payoff balance and current balance columns reflect the amount due after the financial transaction has been applied (i.e., the running balance):

| Date | Financial Transaction | Payoff Balance | Current Balance |
|-----------|----------------------------------|----------------|-----------------|
| 1-Jan-99 | Bill: \$125 | 125 | 125 |
| 15-Jan-99 | Payment: \$150 | -25 | -25 |
| 2-Feb-99 | Bill: \$175 | 150 | 150 |
| 14-Feb-99 | Payment: \$150 | 0 | 0 |
| 3-Mar-99 | Bill: \$200 | 200 | 200 |
| 15-Mar-99 | Payment: \$150 | 50 | 50 |
| 2-Apr-99 | Bill: \$225 | 275 | 275 |
| 27-Apr-99 | Adj: Late Payment Charge \$10 | 285 | 285 |

As you can see, payoff balance and current balance are always in sync.

When Current Balance Differs From Payoff Balance

For some service agreements, payoff balance and current balance differ (or in colloquial speech - the amount the customer thinks they owe differs from what they would owe if they wanted to payoff their account).

Let's run through an example of a customer on a budget to illustrate a classic service agreement where these two balances are not the same. The values in the payoff balance and current balance columns reflect the amount due after the financial transaction has been applied:

| Date | Financial Transaction | Payoff Balance | Current Balance |
|------|-----------------------|----------------|-----------------|
|------|-----------------------|----------------|-----------------|

| | | | |
|-----------|---|-----|-----|
| 1-Jan-99 | Bill: \$125, Budget \$150 | 125 | 150 |
| 15-Jan-99 | Payment: \$150 | -25 | 0 |
| 2-Feb-99 | Bill: \$175, Budget \$150 | 150 | 150 |
| 14-Feb-99 | Payment: \$150 | 0 | 0 |
| 3-Mar-99 | Bill: \$200, Budget \$150 | 200 | 150 |
| 15-Mar-99 | Payment: \$150 | 50 | 0 |
| 2-Apr-99 | Adj: Mar 3, 97 bill incorrect due to meter exchange discrepancies; manual correction of -\$33. | 17 | 0 |

Notice the adjustment of -\$33 affects only payoff amount. This is because the customer is on a budget. The adjustment will not affect their monthly payment and therefore it doesn't affect how much they think they owe.

The following table describes the various types of service agreements where these balances may differ.

| Type Of Service Agreement | What Payoff Balance Holds | What Current Balance Holds |
|-------------------------------------|---|---|
| Deposit | Payoff balance holds the amount of deposit you are holding on behalf of the customer's debt. This amount is showed as a credit (with a negative sign) because you truly owe the customer this money. | Current balance holds the amount the customer owes for a deposit. |
| Charitable contribution | N/A - charitable contribution service agreements never have a payoff balance. | Current balance holds the amount the customer owes for a charitable contribution. |
| Payment arrangements | Payoff balance holds the total amount of delinquent debt that remains unpaid. When a payment arrangement is started, you transfer the payoff balance from the utility service agreement to the payment arrangement service agreement. Each billing period, the customer pays down this balance. | Current balance holds the amount the customer owes in respect of the billed payment arrangement amounts. |
| Utility agreements on a budget plan | Payoff balance holds the actual amount owed (actual bills minus payments). | Current balance holds the amount the customer owes in respect of the billed budget amount. |
| Loans | Payoff balance holds the payoff amount for the loan, which is the current balance (the billed loan amount) plus the principal balance (the unbilled loan amount) and any accrued interest charges. | Current balance holds the amount the customer owes in respect of the billed amount (the periodic payment amount). |

Adjustment Type And Balances

When you create an adjustment, you must define its adjustment type. The adjustment type controls how payoff balance and current balance are affected by the adjustment amount.

You can only pick adjustment types that make sense for the service agreement. For example, if your organization doesn't allow budget billing, all adjustments for a utility service agreement will affect payoff balance and current balance the same (you can't get the balances out-of-sync).

The various types of adjustments that may be linked to a service agreement are controlled by the adjustment profiles defined on the service agreement's SA type.

Fastpath:

Refer to [Adjustment Type Controls Everything](#) for more information.

Canceling Adjustments

You may cancel any frozen adjustment. Canceling the adjustment creates another financial transaction that reverses the financial effects of the original adjustment. The impact of the cancellation appears on the customer's next bill. You may view both the original financial transaction and its cancellation on the Adjustment page.

Transfer Adjustments

A convenient mechanism exists to transfer moneys between two service agreements. The net effect of such a request is the creation of two adjustments, each of which is linked to the other. Both adjustments are created together, frozen together, and posted to the GL together. This is useful because you can't create one side of the transfer and without the other. Refer to [How To Create A Transfer Adjustment](#) for more information.

Note:

Inter or Intra Account. It's important to be aware that the transfer can be inter or intra account (i.e., the accounts on the two adjustments may be different).

Calculated Adjustments

An adjustment can calculate the adjustment amount using an algorithm. A calculated adjustment can be used to calculate:

- Sales or other taxes for a base amount
- Any charge amount based on a user-supplied quantity, such as feet, miles, hours, etc.
- Others.... Any calculation that can be made by a rate can be applied to an adjustment.

When you create a calculated adjustment, you may be asked to supply a base amount. The user may supply the base amount or the amount could be **defaulted** from the adjustment type and possibly overridden by the user prior to calculating the adjustment amount.

When the adjustment is generated, the calculation algorithm may use the base amount and calculation date. The base package algorithm calls the rate application and returns the calculated amount with calculation lines and GL distribution codes.

An adjustment's adjustment type controls whether the adjustment is calculated and the algorithm that performs the calculation.

Fastpath:

For more information, refer to [Adjustment Type Controls Everything](#) and [Setting Up Calculated Adjustment Types](#).

Adjustment Amount May Be Positive, Negative, Or Zero

An adjustment's amount may be positive, negative or zero:

- A positive amount causes the customer's balance(s) to increase.
- A negative amount causes the customer's balance(s) to decrease.
- A zero amount will not affect the customer's balance(s). A zero amount is odd, but necessary when you need to use an adjustment to correct the GL distribution. Refer to [How To Use An Adjustment To Change Amounts Booked In Your GL](#) for more information.

Adjustment Type Controls Everything

When you create an adjustment, you must define its adjustment type. The topics in this section describe how adjustment type controls the behavior of an adjustment.

Controls Which Balance(s) Are Affected

The adjustment type's financial transaction (FT) algorithm controls how payoff balance and current balance are affected by the adjustment amount.

Defines The GL Account Affected By The Adjustment

Most adjustments affect the general ledger (GL) in some way. The following points describe the source of these GL accounts.

- For normal adjustments (i.e., non-calculated adjustments that affect a single service agreement), there is a single accounting entry generated:
 - One side of the accounting entry is taken from the distribution code on the SA type of the service agreement affected by the adjustment. For example, if you are adjusting the payoff balance on a normal service agreement, the A/R account is constructed from the distribution code on the service agreement's SA type.
 - The other side of the accounting entry is taken from the distribution code on the adjustment's adjustment type. For example, if a late payment charge is created, the "late payment charge" adjustment type references this fee's revenue account.
- For transfer adjustments (i.e., adjustments used to transfer moneys between two service agreements), there are two accounting entries generated - one for the "from" side and one for the "to" side. Each adjustment carries its own set of balanced GL accounting details.
 - For each adjustment, one side of the entry is taken from the distribution code on the SA type of the service agreement affected by the adjustment (just like for normal adjustments).
 - The other sides of both accounting entries have the same GL account. This account should be the intermediate clearing GL account that is to be used for the transfer. The source of this clearing GL account is the distribution code on the adjustment type used to transfer the funds.
- For calculated adjustments (i.e., adjustments where rates may be applied to calculate the adjustment amount), there is a single accounting entry:
 - For each adjustment, one side of the entry is taken from the distribution code on the SA type of the service agreement affected by the adjustment (just like for normal adjustments).
 - The other side of the entry is taken from the distribution codes that resulted from the rate calculation if the adjustment financial transaction algorithm is set up to use the calculation lines as the distribution code source. If the adjustment financial transaction algorithm is set up to use the adjustment type as the distribution code source, the other side of the accounting entry is taken from the distribution code on the adjustment type.

Note:

Not all adjustments affect the GL. As a general rule of thumb, only those adjustments that affect a service agreement's payoff balance affect the GL. So, if you adjust a budget customer's current balance, but don't adjust their payoff balance, the GL is not affected.

Defaults The Adjustment Amount

The adjustment type may default the adjustment amount in one of the following ways:

- The adjustment type may specify a default amount. This would be used for those adjustment types that have a standard charge for all customers that receive this adjustment, for example a non-sufficient funds charge.
- The adjustment type may specify a default adjustment amount algorithm. This would be used for those adjustment types that have a charge that varies based on other factors. For example, a non-sufficient funds charge may be based on a customer's credit rating.

When an amount is defaulted onto a new adjustment it may be overridden by a user.

Calculates The Adjustment Amount

Some adjustment types [calculate the adjustment](#) amount. If the adjustment type uses a calculated amount, a base amount is passed to the rate application, which then returns the calculated amount with calculation lines and GL distribution codes.

The adjustment type's generate adjustment algorithm controls which rate is applied to the base amount. A user supplied calculation date controls which version of the rate is used. The user may supply the base amount or it may be [defaulted](#) from the adjustment type and possibly overridden by the user prior to calculating the adjustment amount.

Controls The Interface To A/P & 1099 Reporting

If the adjustment type is associated with a payment (e.g. a refund or a loan disbursement) of money to a customer, the adjustment type indicates such with a reference to an A/P request type.

When an adjustment that references an A/P request type is frozen, an A/P download request record is created. This record is the interface request to ask your A/P system to cut a check. This interface record is marked with a batch process ID and run number.

- The batch process ID is the background process responsible for creating the flat file that contains check request that is interfaced to your account's payable system. The batch process ID is defined on [Installation Options - Financial](#). The base package is supplied with a skeletal background process (APDL) that must be populated with logic to format the records in the format compatible with your accounts payable system.
- The run number is the batch process ID's current run number.

Fastpath:

Refer to [Accounts Payable Check Request](#) for more information.

If the resultant check needs to be reported for income tax purposes under a specific 1099 category, the category is also specified on the adjustment type. The 1099 category is in turn interfaced to the A/P system (the system does NOT manage 1099 reporting).

Controls Information Printed On The Bill

If the adjustment appears on the customer's next bill, the verbiage is specified on the adjustment type (and may NOT be overridden on the adjustment).

Controls If The Adjustment Can Be Frozen Prior To Bill Completion

Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) for how adjustment type can control whether adjustments of a given type can be frozen prior to bill completion.

Controls If The Adjustment Requires Approval

If an adjustment's adjustment type references an approval profile, the system will not allow the initiating user to freeze the adjustment. Rather, the initiating user can submit the adjustment for approval. When an adjustment is submitted for approval, the system determines the necessary approval levels and notifies the first approver. The system will freeze the adjustment when last approver approves the adjustment (if the adjustment's adjustment type allows it to be frozen prior to the completion of the next bill).

Note:

Only online adjustments are subject to approval. The system assumes that no approval is necessary for adjustments created by batch processes even those whose adjustment type references an approval profile.

Fastpath:

Refer to [The Big Picture of Adjustment Approvals](#) for more information.

Unbilled Adjustments And Aged Debt

A Frozen adjustment waits in limbo until the customer's next bill is produced. This limbo period could be several weeks if the customer is billed infrequently. When the customer's next bill is completed, all limbo adjustments are linked to the bill. A brief description (as defined on the adjustment type) appears on the printed bill.

It is important to stress the following in respect of these limbo adjustments:

- If the adjustment decreases the amount of debt, the customer's aged debt is affected immediately regardless of whether the adjustment appears on a bill.
- If the adjustment increases the amount of debt, the amount the customer owes from an aged debt perspective may or may not be affected by the adjustment. There is a switch on the financial transaction created for the adjustment called New Charge that controls the arrears behavior. When the FT for this type of adjustment is created, the switch is set to on and the customer's aged debt will not reflect the adjustment amount until the adjustment is swept onto a bill. The moment the adjustment is swept onto the customer's bill, the debt starts aging. A user may turn the switch off to cause the debt to start aging sooner. For this case, the date on which the adjustment starts aging must be defined in the Arrears Date field.
- The amount a customer owes in total is immediately affected by the adjustment regardless of whether the adjustment appears on a bill. This means that amount of aged debt may not be in sync with the total amount owed. This seems odd but is useful from a credit and collections perspective. You see, you probably don't want to start aging an adjustment until the customer has actually seen it.

An Adjustment May Affect More Than Just Customer Balances

Fastpath:

When an adjustment is frozen or cancelled, a customer's current and payoff balances are affected. However, several other objects may be affected when such events occur. Refer to [Obscure Things That Can Happen](#) for more information.

Maintaining Adjustments

An adjustment is used to change the amount of debt stored on a service agreement. The topics in this section describe the pages on which adjustments are maintained.

Fastpath:

For more information about adjustments, refer to [The Big Picture Of Adjustments](#).

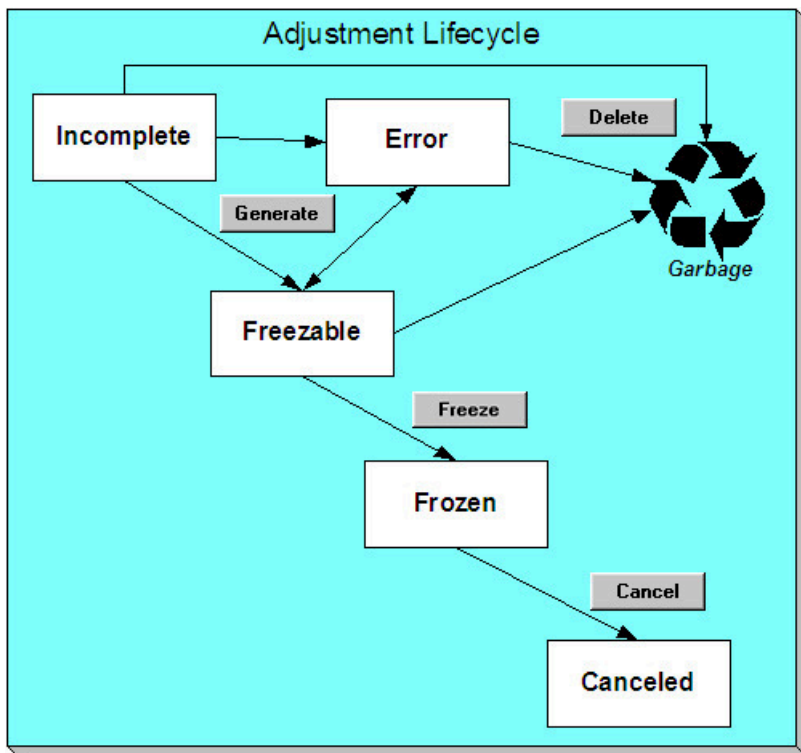

The Lifecycle Of An Adjustment

The following diagram shows the possible lifecycle of an adjustment.

Warning:

This diagram only makes sense in the context of the page used to maintain Adjustments. Refer to [Adjustment - Main Information](#) for the details.

Note: Even though New is considered a valid adjustment state, this is only used as default when adding an adjustment. Once the adjustment is saved, it is assigned the appropriate state in the adjustment life cycle. An adjustment will never exist in the New state.

Adjustments are initially created in the Incomplete state. Adjustments in this state don't have a financial transaction. This means, you can change the adjustment type and amount at will.

Click **Generate** to generate a financial transaction for the adjustment. The financial transaction contains the adjustment's effect on the general ledger and on the customer's payoff and current balances. If the adjustment is calculated, the algorithm on the adjustment type's Generate Adjustment event controls how the adjustment is calculated. If the adjustment is calculated, you must specify the calculation date, which is passed as a parameter to the calculation algorithm and is used for calculations that are effective dated (e.g., rate version or bill factor value). The financial transaction (FT) algorithm defined on the adjustment type Adj. Financial Transaction event controls how the financial transaction is constructed. For calculated adjustments, the distribution code may be taken from the adjustment type or the calculation lines.

After generating the financial transaction, the adjustment becomes Freezable. While in this state, you may change the service agreement, adjustment type and amount at will. However, if you change this information, you will have to regenerate the financial transaction (by clicking the Generate button).

In the very rare situation when the system cannot generate the financial transaction because of inconsistent setup data, the adjustment is moved to the Error state. You may regenerate the financial transaction after correcting the source of the error. You may also delete such an adjustment.

Click the delete button to physically remove an Incomplete, Error or Freezable adjustment from the database.

Warning:

Please be aware that you can prevent specific types of adjustments from being frozen until the account's next bill is completed. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) for how to enable this feature on your adjustment types.

Click **Freeze** to freeze the adjustment and its financial transaction. After doing this, the adjustment's state becomes Frozen. While in this state, you cannot change the adjustment's type or amount, but you may change:

- When the adjustment starts aging.
- Whether the adjustment appears on a customer's bill.
- The accounting date used to derive the general ledger accounting period(s) to which the financial transaction is booked.

Note:

Adjustments may require approval. If the adjustment type referenced on the adjustment has an approval profile, the Freeze button is replaced with a Submit for Approval button. If an adjustment is currently being approved, all action buttons are disabled because the adjustment must be either approved or rejected using the [Adjustment - Approval](#) page.

However, the Delete button is enabled for an adjustment in a freezable state and linked to an approval request that is in a “no approval necessary” state. If the adjustment is deleted a log entry is created on the associated approval request.

Refer to [The Big Picture of Adjustment Approvals](#) for more information.

If you need to remove the financial effects of an adjustment, click **Cancel**. Canceling an adjustment causes the generation of another financial transaction. This new financial transaction reverses the financial impact of the original adjustment.

Adjustment - Main Information

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How and When To Use An Adjustment](#) for instructions describing how to perform common maintenance functions.

The Main page contains core adjustment information. Open this page using **Menu > Financial > Adjustment > Search**.

Warning:

All adjustments reference a very important field that controls much validation and processing; this field is called Adjustment Type. Take special care when adding a new adjustment to specify the appropriate Adjustment Type as it affects how the adjustment appears on the customer's bill, how the adjustment is reflected in your general ledger, and much more. After the adjustment is frozen, you may not change its Adjustment Type.

Description of Page

Adjustment Info contains a concatenation of the adjustment amount, adjustment type and status.

Note:

Formatting may be performed by a plug-in. The contents of **Adjustment Info** may be formatted by a plug-in algorithm on the [Adjustment Type](#). Refer to the base package's C1-ADT-INFO for an example. If such an algorithm is not plugged-in on the Adjustment Type, the system looks for a corresponding algorithm on the [installation record](#). Refer to the base package's C1-ADI-INFO for examples. If you prefer different formatting logic, your system administrator should configure the system appropriately.

Adjustment ID is the system-assigned, unique identifier of the adjustment.

Account ID is the account to which the adjustment is linked. The name of the main person on the account appears next to the account ID.

Use **Service Agreement ID** to define the service agreement whose value needs to be adjusted. Basic information about the service agreement appears adjacent.

Premise is a display-only field that shows the **Service Agreement's** characteristic premise (i.e., the primary premise associated with the service agreement).

Indicate the **Adjustment Type**. This field is very important as it controls numerous aspects of the adjustment's impact on the customer's balance and your general ledger. This field is gray after the adjustment is frozen.

Note:

You can only choose certain adjustment types. The service agreement's SA type has a collection of valid adjustment profiles. You may only reference adjustment types that are listed in one of the adjustment type profiles linked to the SA type.

The list of adjustment types is also restricted to those without a CIS Division and those with a CIS Division that matches the service agreement's CIS Division.

Enter the **Amount** of the adjustment. If the adjustment type is a calculated adjustment, the **Calculated Amount** and **Calculation Date** are displayed. The values of the calculated amount and calculation date are displayed after the adjustment is generated. The calculated amount shows the result of the generate adjustment algorithm. The calculation date is specified when you click Generate for a calculated adjustment type. It is used by the generate adjustment algorithm for any calculations that are effective dated (e.g., rate version calculation group or bill factor value).

Note:

Default note. The adjustment amount defaults based on the adjustment type. When you change the adjustment type, the amount changes accordingly. You may change the adjustment amount after it is defaulted.

On Behalf SA ID is a display-only field that is only populated on system-generated adjustments instigated by one customer, but attributed to another customer. For example, if chargeable field work is performed for a customer, but is payable by the customer's meter maintenance service provider, the adjustment will be linked to the service provider and will reference the customer's SA as its **On Behalf SA ID**. This field is only visible if it is populated on the adjustment.

You may not change an adjustment's **Adjustment Status** directly. Rather, you use the buttons in the **Adjustment Actions** area. Refer to [The Lifecycle Of An Adjustment](#) for the details.

If the status is canceled, the **Cancel Reason** is displayed.

Use the **Comments** to describe anything unusual about the adjustment.

The **Creation Date** defines the date on which the adjustment was created.

If the adjustment is subject to approval, a message indicating such appears. Clicking this message navigates the user to the **Approvals** tab. Refer to [The Big Picture of Adjustment Approvals](#) for more information.

The financial transaction (FT) grid contains the financial transactions associated with the adjustment. It only contains information after the adjustment is frozen. If the adjustment is canceled, a second row appears showing the details of the cancellation FT.

- **Financial Transaction ID** is the system-assigned unique identifier of the FT. Click the go to button to transfer to the financial transaction. On this page you can change certain aspects of the FT in question.
- **Arrears Date** is the date the FT starts aging.
- **Accounting Date** is the date the system uses to determine the FT's accounting period in your general ledger.
- **Current Amount** contains the FT's effect on the service agreement's current balance.
- **Payoff Amount** contains the FT's effect on the service agreement's payoff balance.
- **Bill ID** is the bill on which the FT appears (if it has been swept onto a bill). Click the adjacent go to button to transfer to the bill on which the FT appears. Note: an FT is linked to a bill the next time a bill is completed for the service agreement's account.

The **Calculation Lines** grid contains the details of the calculations associated with a [calculated adjustment](#). It only appears if the rate that calculated the adjustment amount created at least one calculation line. One row exists for every calculation involved in the process. This information is for audit purposes only and cannot be modified. The following information displays in the grid:

- If at least one of the calculation lines has characteristics, **Calc Line Char** displays go to buttons, allowing you to go to characteristics that are linked to a specific adjustment calculation line. This column is only displayed if at least one of the calculation lines has characteristics.
- **Sequence** is the system-assigned unique identifier of the calculation detail row.
- **Description on Bill** is the information about the calculation line that appears on the customer's bill.
- **Calculated Amount** is the calculated amount associated with the calculation line.
- The **Print** switch controls whether information about this line will print on the customer's bill.
- The **Appears in Summary** switch defines if this line's amount also appears on a summary line. This switch plays a part at bill print time - those lines that appear in a summary print in the left dollar column, those that don't appear in a summary print in the right dollar column.
- **Unit of Measure (UOM)** is the unit of measure of the service quantity priced on the calculation line.
- **Time of Use (TOU)** is the time-of-use code of the service quantity priced on the calculation line.
- **SQI** is the service quantity identifier of the service quantity priced on the calculation line.
- **Billable Service Quantity** is the service quantity priced on the calculation line. This quantity differs from the measured consumption if there are pre-processing calculation groups in effect.
- **Base Amount** is used by calculation lines (e.g. taxes) that are cross-referenced to other calculation lines and whose value(s), therefore, depend on the amounts calculated by those other lines. The Base Amount shows the total amount derived from the cross-referenced line(s) that the current line then used to calculate its billed amount.
- **Rate Component Sequence** refers to the sequence number of the rate component on the applicable rate version calculation group that was used to calculate the line. This is only populated if the original rate engine calculated the charges.
- **Calculation Rule** is the rule that calculated the line. This is only populated if the new rate engine calculated the charges.
- **Measures Peak Qty** is checked if the UOM priced on the calculation line is used to measure a peak quantity.
- **Exempt Amount** is the amount of the calculated charge that the customer doesn't have to pay because they are tax exempt.
- **Distribution Code** is the distribution code associated with the calculation line. This distribution code is used to build the general ledger details on the bill segment's financial transaction.
- **Description** describes the characteristic value that was used when the line's amount was calculated. This information is only displayed if the line was calculated using a bill factor (because only bill factors use characteristic values). Refer to [An Illustration Of A Bill Factor And Its Characteristics](#) for more information.

Fastpath:

For more information, refer to [Calculated Adjustments](#).

The **Adjustment Actions** area contains buttons that you use to commit and cancel the adjustment's financial impact. The adjustment's status controls the button you can see and select. Refer to [The Lifecycle Of An Adjustment](#) for the details.

Warning:

Please be aware that you can prevent specific types of adjustments from being frozen until the account's next bill is completed. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) for how to enable this feature on your adjustment types.

Cancel may not be enabled. The cancel button is not enabled if the adjustment is linked to a bill that is written off.

Note:

Canceling An Accounts Payable (A/P) Adjustment. If you need to cancel an A/P adjustment (i.e. an adjustment of an adjustment type that has an A/P request type) that has already been extracted by A/P, refer to [How To Cancel An A/P Adjustment After It's Been Selected By A/P](#).

Adjustment - Characteristics

You use this page to link additional information to the adjustment. Open using **Menu > Financial > Adjustment > Search** and navigate to the **Characteristics** page.

Description of Page

The characteristics collection contains information that describes miscellaneous information about the adjustment.

Note:

Characteristic Types. You can only choose characteristic types defined on the adjustment's [adjustment type](#).

The following fields display:

Characteristic Type Indicate the type of characteristic.

Characteristic Value Indicate the value of the characteristic.

Note:

Default Note. An adjustment's characteristics default from the [adjustment type](#).

Adjustment - Transfer Adjustment

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How and When To Use An Adjustment](#) for instructions describing how to perform common maintenance functions.

The Transfer Adjustment is used to define the reciprocal adjustment associated with a transfer adjustment (there are always two adjustments associated with a transfer). Open using **Menu > Financial > Adjustment > Search**.

The Main page describes one side of the transfer adjustment; for example, the “transfer from” adjustment. As well, the Transfer Adjustment page describes the reciprocal adjustment; for example, the “transfer to” adjustment.

Description of Page

Adjustment Info contains a concatenation of the adjustment amount, adjustment type and status.

Adjustment ID is the system-assigned, unique identifier of the adjustment.

Account ID is the account to which the adjustment is linked. The name of the main person on the account appears next to the account ID.

Use **Service Agreement ID** to define the transfer to service agreement. Basic information about the service agreement appears adjacent.

Premise is a display-only field that shows the **Service Agreement's** characteristic premise (i.e., the primary premise associated with the service agreement).

The **Adjustment Type** and adjustment **Amount** from the first page are displayed. If you need to change either value, return to the first page.

Adjustment Status shows the status of the transfer to adjustment. If you need to change the adjustment's status, use the action buttons.

Use the **Comments** to describe anything unusual about the adjustment.

Transfer Adj ID is the system-assigned, unique identifier of the adjustment.

The **Creation Date** defines the date on which the adjustment was created.

The financial transaction grid contains the financial transactions associated with the adjustment. It only contains information after the adjustment is frozen. If the adjustment is canceled, a second row appears showing the details of the cancellation FT.

- **Financial Transaction ID** is the system-assigned unique identifier of the FT. Click the go to button to transfer to the financial transaction. On this page you can change certain aspects of the FT in question.
- **Arrears Date** is the date the FT starts aging.
- **Accounting Date** is the date the system uses to determine the FT's accounting period in your general ledger.
- **Current Amount** contains the FT's effect on the service agreement's current balance.
- **Payoff Amount** contains the FT's effect on the service agreement's payoff balance.
- **Bill ID** is the bill on which the FT appears (if it has been swept onto a bill). Click the adjacent go to button to transfer to the bill on which the FT appears. Note: an FT is linked to a bill the next time a bill is completed for the account.

Adjustment - A/P Request

Fastpath:

The **Description of Page** below describes the fields on this page. Refer to [How and When To Use An Adjustment](#) for instructions describing how to perform common maintenance functions.

The A/P Request page contains information about adjustments used to refund money via an A/P check request. This page is only relevant if:

- The adjustment's adjustment type references an A/P Request Type (i.e., it will be interfaced to your accounts payable system which will cut the check), AND
- The adjustment is frozen.

Open this page using **Menu > Financial > Adjustment > Search** and navigate to the **A/P Request** page.

Description of Page

Adjustment Info contains a concatenation of the adjustment amount, adjustment type and status.

Adjustment ID is the system-assigned, unique identifier of the adjustment.

Account ID is the account to which the adjustment is linked.

Note:

Adjustment type controls A/P check requests. The A/P Request information is populated when an adjustment used to refund money via an A/P check request is frozen. Whether or not an adjustment is interfaced to A/P is controlled by the adjustment's adjustment type. The adjustment type's A/P Request Type controls the payment date and the bank.

Name is the name printed on the check. This name is derived from the account's main person:

- If this person has an override mailing name, the first line of the override mailing name is used.
- If this person does not have an override mailing name, the person's primary name is used.

Payment Selection Status is the status of the check request. The values are:

- Not Selected for Payment before it's selected by A/P for payment
- Requested for Payment after it's selected by A/P
- Paid after it's paid by A/P
- Canceled if it's been canceled in A/P
- Hold if it's been held in A/P

Scheduled to Pay is the date on which the check is scheduled to be cut. This is equal to the adjustment date plus the Due Days on the adjustment type's A/P request type.

The following fields are provided in order to support a two-way interface with an A/P system. The system provides the inbound web service C1-UpdateAPCheckRequest that can be used to update these fields.

- **Payment Date** is the date on which the check was cut in A/P. This field is only populated after A/P cuts the check.
- **Paid Amount** is the amount of the check. This field is only populated after A/P cuts the check.
- **A/P Request ID** is the system-assigned, unique identifier of the A/P check request.
- **Payment Number** is the system-assigned number of the payment in A/P (this number typically appears on the printed check). This field is only populated after A/P cuts the check.

The address information in the bottom frame is the address to which the check is mailed. This is the billing address of the main customer linked to the account. After the adjustment is frozen, this information is automatically populated based on the address information for the account. This information is only modifiable when the Payment Selection Status is Not Selected for Payment.

Adjustment - Adjustment Portal

Select **Menu > Financial > Adjustment > Search** and navigate to the **Adjustment Portal** page to view additional information associated with an Adjustment.

Depending on your implementations requirements, you may define additional zones to appear on this Portal.

The contents of this section describe the zones that are available on this portal page.

General Information

Adjustment ID, **Adjustment Info** are displayed.

Adjustment - Approval

This page only appears after an adjustment has started the approval process. Open this page using **Menu > Financial > Adjustment > Search** and navigate to the **Approval** page.

Fastpath:

Refer to [The Big Picture of Adjustment Approvals](#) for more information about the approval process.

The topics in this section describe the base-package zones that appear on the Approval Profile portal.

Adjustment Information

The Adjustment Information zone contains display-only information about the adjustment.

Approval Request

The Approval Request zone shows the current and future approvers of an adjustment. This zone only appears if the adjustment is in the approval process.

If the current user has approval authority, the following functions are available:

- **Approve:** to approve the adjustment.
- **Reject:** to reject the adjustment.

Approval Request Log

The Approval Request Log zone contains the history of the adjustment's approval.

Financial - Adjustment Calculation Line Characteristics

This page displays the characteristics that are linked to a specific adjustment calculation line. The information on this page is for audit purposes only and cannot be changed.

Open this page by clicking on the characteristics go to button on the calculation lines grid of the [Adjustment - Main](#) page.

Description of Page

Account is the account to which the adjustment is linked. The name of the main person on the account appears next to the account ID.

The **SA** is the service agreement whose value needs to be adjusted. Basic information about the service agreement appears adjacent.

Premise shows the service agreement's characteristic premise (i.e., the primary premise associated with the service agreement).

The **Adjustment Info** displays information to identify the adjustment, including amount, type, and status.

Adjustment ID displays the identification of the adjustment, and **Calc Line** displays the calculation line with which the characteristics are associated.

The **Description on Bill** displays the description of the calculation line that appears on the customer's bill.

The characteristics grid displays the **Characteristic Types** and the **Characteristic Values** associated with the calculation line.

Fastpath:

For more information about characteristics, refer to [Setting Up Characteristic Types and Their Values](#).

How and When To Use An Adjustment

Note:

A last resort. Adjustments should be viewed as a last resort because you should correct the cause of errors, rather than the effect. For example, if a customer's bill is incorrect, you should fix the customer's rate / meter reads / contract terms and then perform a cancel / rebill. Issuing an adjustment to fudge the balance is really just that - a fudge.

The topics in this section describe how to perform common adjustment maintenance functions.

How To Create A Transfer Adjustment

The following steps describe how to create a transfer adjustment on the Adjustment page.

Note:

You cannot use an adjustment type with a calculated amount for transfer adjustments.

Warning:

These steps only make sense in the context of the page used to maintain Adjustments. Refer to [Adjustment - Main Information](#) for the details.

To create a transfer adjustment:

- Specify the "transfer from" account and service agreement on the Adjustment - Main page.
- Specify the adjustment type and the amount and transfer to the Transfer Adjustment page.
- Specify the "transfer to" service agreement and click the **Generate** and **Freeze** buttons to generate and freeze the adjustments' financial transactions. Please be aware that the **Freeze** button may be disabled for certain types of adjustments. This is because you can prevent specific types of adjustments from being frozen until the account's

next bill is completed. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) for how to enable this feature on your adjustment types.

How To Create A Calculated Adjustment

The following steps describe how to create a [calculated adjustment](#) on the Adjustment page.

Warning:

These steps only make sense in the context of the page used to maintain Adjustments. Refer to [Adjustment - Main Information](#) for the details.

To create a calculated adjustment:

1. Open **Menu > Financial > Adjustment > Add** and specify the **Service Agreement** that will receive the adjustment.
2. Specify the **Adjustment Type** that calculates the amount, and enter a base **Amount**.
3. Click **Generate**. The **Generate** dialog box opens.
4. In the resulting dialog box, specify an **Accounting Date** and **Generation Reference Date**. Click **Calculate**.
5. Click **Freeze** to freeze the calculated transactions.

The **Calculation Date** that you supply is used by the generate adjustment algorithm for any calculations that are effective dated (e.g., rate version calculation group or bill factor value).

Please be aware that the **Freeze** button may be disabled for certain types of adjustments. This is because you can prevent specific types of adjustments from being frozen until the account's next bill is completed. Refer to [Preventing SA Balances And The GL From Being Impacted Until Bill Completion](#) for how to enable this feature on your adjustment types.

How To Cancel An A/P Adjustment After It Has Been Selected By A/P

Adjustments that are interfaced to A/P (because A/P needs to cut a refund check) sometimes need to be canceled. You may cancel an A/P adjustment in the CIS system while its A/P request is Not Selected. If the A/P request is Requested for Payment or Paid you must first cancel the payment in A/P. Canceling the payment in A/P changes the A/P request in CIS to Canceled. At this point, you can cancel the adjustment in CIS.

How To Correct Normal Service Agreement Debt

If a customer is unhappy with the balance on a "normal" service agreement and you cannot fix the source of their unhappiness (i.e., the bills and payments), create an adjustment. Simply select an adjustment type that describes why you are adjusting the balance and enter the amount of the adjustment (a negative number if you are crediting the customer).

Note:

What's normal? There really is no such thing as a "normal" service agreement. We use this term to reference service agreements used to bill for services like utility service, land leases, home warranties, security monitoring, etc. where the current amount is the same as the payoff amount.

Warning:

A service agreement that is part of a budget plan is NOT normal. Refer to [How To Adjust A Service Agreement On A Budget for more information](#).

How To Apply Ad Hoc Fees To A Service Agreement

If you need to apply a fee (e.g., late payment charge, connection charge, NSF charge) to a "normal" service agreement, issue an adjustment using the appropriate adjustment type. The adjustment amount should be a positive number so that the customer's balance increases.

Warning:

Take care if you apply a fee to a service agreement that's on a budget. The adjustment affects current balance and payoff balance by the amount of the fee. If you didn't mean to affect the customer's current balance, you'll have to issue another adjustment to change it.

How To Apply Interest To A Deposit

Fastpath:

You should only have to issue adjustments to calculate and refund interest if you need to override the system's automated procedures. Refer to [Controls Interest Calculation](#) for the details.

If you need to manually apply interest to a deposit, issue an adjustment using the appropriate adjustment type. The adjustment amount should be a negative number (you are crediting the customer's deposit balance).

If you want to apply the interest to the customer's outstanding balance, refer to [How To Apply A Deposit To Outstanding Debt](#).

If you want to cut a check for the deposit, refer to [How To Refund A Deposit With A Check](#).

How To Apply A Deposit To Outstanding Debt

Fastpath:

You should only have to issue adjustments to apply a deposit to outstanding debt if you need to override the system's automated procedures. Refer to [Refunding Deposits](#) for the details.

Applying a deposit is a two-step process:

- The deposit service agreement's payoff balance contains the amount of deposit you are holding on behalf of the customer's debt. Its current balance should be zero (i.e., the customer doesn't owe any additional deposit). Before you apply the deposit balance, we recommend making the deposit's current balance equal to the amount to be transferred. You do this by issuing an adjustment that just affects the deposit's current balance. The amount of this adjustment should be a negative number.
- After the deposit's current balance reflects an appropriate credit amount (equal to the amount to be applied to the customer's debt), use the Transfer Adjustment process to apply the deposit's credit balance to another service agreement's debit balance. The deposit service agreement is the transfer from service agreement; the delinquent service agreement is the transfer to service agreement. The adjustment amount should be a positive number. Refer to [How To Create A Transfer Adjustment](#) for more information.

Warning:

Take care if you apply a deposit to a service agreement that's on a budget. The transfer adjustment affects current balance and payoff balance by the same amount. If you didn't mean to affect the customer's current balance, you'll have to issue another adjustment to change it.

How To Refund A Deposit With A Check

Fastpath:

You should only have to issue adjustments to apply a deposit to outstanding debt if you need to override the system's automated procedures. Refer to [Refunding Deposits](#) for the details.

Refunding a deposit with a check (cut by your A/P system) is a two step process:

- The deposit service agreement's payoff balance contains the amount of deposit you are holding on behalf of the customer's debt. Its current balance should be zero (i.e., the customer doesn't owe any additional deposit). Before you refund the deposit balance, we recommend making the deposit's current balance equal to the amount to be refunded. You do this by issuing an adjustment that just affects the deposit's current balance. The amount of this adjustment should be a negative number.
- After the deposit's current balance reflects an appropriate credit amount (equal to the amount to be refunded), issue a refund adjustment. The adjustment amount should be a positive number. This adjustment causes a check request to be interfaced to your A/P system.

How To Write-Down Deposit Due

If a customer doesn't pay their deposit and you don't expect them to, create an adjustment to write-down the current balance. Simply select an adjustment type that describes why you are adjusting the balance and enter the amount of the adjustment (a negative number).

How To Refund A Credit Balance With A Check

If you need to refund a credit balance on a "normal" service agreement, issue a refund adjustment using the appropriate adjustment type. The adjustment amount should be a positive number. This adjustment causes a check request to be interfaced to your A/P system.

Warning:

Take care if you refund a credit balance from a service agreement that's on a budget. The adjustment affects current balance and payoff balance by the amount of the refund. If you didn't mean to affect the customer's current balance, you'll have to issue another adjustment to change it.

How To Transfer A Credit Balance To A Service Agreement In Arrears

Use the Transfer Adjustment process to apply a "normal" service agreement's credit balance to another service agreement's debit balance. The credit service agreement is the transfer from service agreement; the delinquent service agreement is the transfer to service agreement. The adjustment amount should be a positive number. Refer to [How To Create A Transfer Adjustment](#) for more information.

Warning:

Take care if you apply a credit to a service agreement that's on a budget. The transfer adjustment affects current balance and payoff balance by the transfer amount. If you didn't mean to affect the customer's current balance, you'll have to issue another adjustment to change it.

How To Change The Age Of Debt

If a service agreement's debt is older (or younger) than what it should be (for whatever reason), you should do the following.

- Use the Transfer Adjustment process to re-age the debt. The transfer from and transfer to service agreements will be the same. The adjustment amount should be a negative number. Refer to [How To Create A Transfer Adjustment](#) for more information.
- After creating the transfer adjustment, drill into the transfer to adjustment and populate the arrears date with the day on which the debt should start aging (e.g., if the debt should be 7 days old, the arrears date should be the current date minus 7 days).

Warning:

Be careful if you transfer debt from a service agreement that's on a budget. Before doing the transfer, you should make the customer's current balance equal their payoff balance.

How To Write-Down A Charitable Contribution Service Agreement Debt

If a customer doesn't want to contribute as much to the charity as the agreed to, create an adjustment to fix the current balance (charity service agreements shouldn't have a payoff balance as the "debt" is voluntary). Simply select an adjustment type that describes why you are adjusting the balance and enter the amount of the adjustment (a negative number).

How To Write-Off Debt

To write-off debt:

Warning:

You don't have to do the tasks outlined below if you use the [Write Off - Main](#) page. This page does these tasks for you.

- Create a write-off service agreement using the Start Service page (you could also use the Service Agreement page to do this).
- Use the Transfer Adjustment process to transfer the delinquent debt to the to the write-off service agreement. The original service agreement is the transfer from service agreement; the write-off service agreement is the transfer to service agreement. The adjustment amount should be a negative number. Refer to [Transfer Adjustments](#) for more information.

Warning:

Take care if you transfer debt from a service agreement that's on a budget. Before doing the transfer, you should make the service agreement's current balance equal their payoff balance.

How To Cancel A Service Agreement's Budget

Warning:

You don't have to do the tasks outlined below if you use the [Account - Budget](#) panel. This panel does these tasks for you.

Canceling a service agreement's budget involves the following steps:

- Update the service agreement to indicate the service agreement is no longer on a budget.
- Issue an adjustment to make the service agreement's current balance equal the payoff balance.

Note:

Credit and collections (C&C). You can change the arrears date on the adjustment that synchronizes current and payoff balance to reflect the true age of the debt. You do this on the financial transaction associated with the adjustment. If you do this, C&C will monitor the old debt accordingly.

How To Adjust A Service Agreement On A Budget

If you need to adjust the debt on a service agreement that's on a budget plan, you have to ask yourself why you're adjusting the balance:

- If you're adjusting the balance to correct the payoff balance (for whatever reason), choose an adjustment type that just affects this balance.
- If you're adjusting the balance to correct the current balance (for whatever reason), choose an adjustment type that just affects this balance.
- If you need to adjust both balances equally, choose an adjustment type that affects both.

How To Adjust An Installment Plan Service Agreement

If you need to adjust the debt on a service agreement that's used to bill a total amount in installments, you have to ask yourself why you're adjusting the balance:

- If you're adjusting the balance to correct the payoff balance (for whatever reason), choose an adjustment type that just affects this balance.
- If you're adjusting the balance to correct the current balance (for whatever reason), choose an adjustment type that just affects this balance.

If you need to adjust both balances equally, choose an adjustment type that affects both.

How To Use An Adjustment To Change The GL Distribution

Assume you have a frozen bill segment that affected an incorrect GL distribution code (e.g., it booked revenue to commercial - time-of-use - revenue and it should have booked it to industrial - time-of-use - revenue. You have two ways to correct such a situation:

- You could correct the cause of the incorrect distribution code (probably incorrect GL information on a calculation rule/pricing rule) and cancel / rebill the bill segment. Refer to [Cancel / Rebill](#) for more information about this method.
- You could create an adjustment that does not impact the customer's balance but does have a GL entry. This GL entry would reverse the effect of the original distribution code and have an offsetting entry to the correct distribution code. The following points explain how to do this:
 - Choose an adjustment type that only impacts the GL (i.e., the adjustment's adjustment type has an FT algorithm that doesn't impact the customer's current or payoff balance, it only impacts the GL).
 - Enter an adjustment amount of zero.
 - Generate the adjustment.
 - Drill into the adjustment's [financial transaction](#) and enter two (or more) GL distribution rows that reflect the redistribution of the amounts.
 - Return to the adjustment and freeze it.

Note:

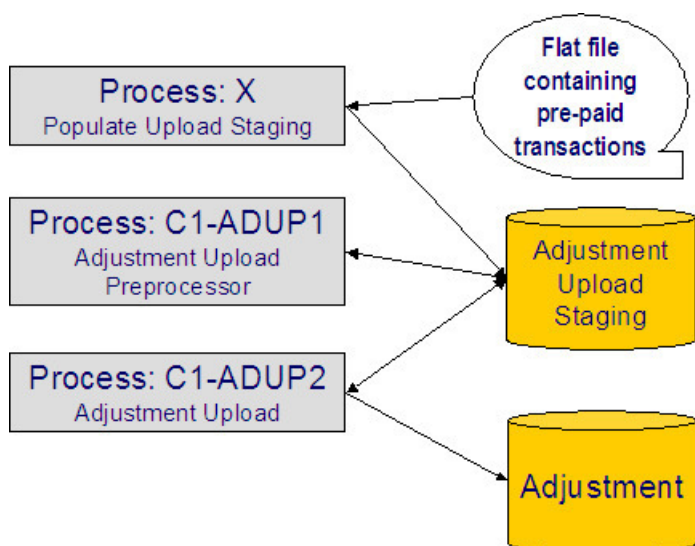

Adjusting statistical amounts. You can use the above approach to change the statistical amount that is interfaced to the general ledger. The statistical amount is simply another column on the financial transaction's GL distribution rows.

Interfacing Adjustments From External Sources

The topics in this section describe how adjustments are uploaded from an external source.

Interfacing Adjustments

The following diagram illustrates the processes involved in the uploading of adjustments into the system.

The topics in this section describe how these processes work.

Process X - Populate Adjustment Upload Records

Process X refers to the mechanism used by your organization to populate the various staging tables (shown in the orange section of the following ERD).

The topics in this section describe each of these tables.

Adjustment Staging Control

You must create an adjustment staging control record for each batch of adjustments to be uploaded into the system. The name of this table is CI_ADJ_STG_CTL. The following describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|-------------|--------|-------|-----------|----------|
|-------------|--------|-------|-----------|----------|

| | | | | |
|-------------------------------|------|---|----------|---|
| ADJ_STG_CTL_ID | 12 | Y | N | This is the unique identifier of the adjustment staging control record. This key is a sequential number so you can use a database function to assign the value when populating the table. |
| CRE_DTTM | 15 | Y | DateTime | This is the date / time on which the adjustment staging control record was created. This must be populated with the current date / time. |
| ADJ_STG_CTL_STATUS_FLG | 4 | Y | A/N | This must be set to P for Pending. |
| ADJ_STG_UP_REC_CNT | 10 | Y | N | This is the total number of adjustment upload staging records that are linked to this adjustment staging control. |
| TOT_ADJ_AMT | 13.2 | Y | N | This column must equal the sum of adjustment amounts on the adjustment upload staging records that are linked to this adjustment staging control. |
| CURRENCY_CD | 3 | Y | A/N | This must be a valid currency code in the system. Refer to Defining Currency Codes for more information. |
| MESSAGE_CATEGORY | 5 | N | N | Leave this blank. The adjustment upload preprocessor populates this when an error occurs during upload. |

| | | | | |
|--------------------|---|---|---|--|
| MESSAGE_NBR | 5 | N | N | Leave this blank. The adjustment upload preprocessor populates this when an error occurs during upload. |
|--------------------|---|---|---|--|

Adjustment Staging Control Characteristic

You must create an adjustment staging control characteristic record for each characteristic that you would like to link to the adjustment staging control. The name of this table is CI_ADJ_STG_CTL_CHAR. The following describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|--|---------|-------|-----------|---|
| ADJ_STG_CTL_ID | 12 | Y | N | This must correspond with the prime key of the related CI_ADJ_STG_CTL record. |
| CHAR_TYPE_CD | 8 | Y | A/N | This must correspond with a characteristic type that is defined as valid for adjustment staging control. Refer to Setting Up Characteristic Types & Their Values for more information. |
| SEQ_NUM | 3 | Y | N | This should be set to 10 unless you have multiple values for a given adjustment staging control and characteristic type. |
| CHAR_VAL | 16 | N | A/N | Populate this field if your characteristic type is predefined. |
| ADHOC_CHAR_VAL | 254 | N | A/N | Populate this field if your characteristic type is ad-hoc or file location. |
| CHAR_VAL_FK1 - CHAR_VAL_FK5 | 50 each | N | A/N | Populate these fields if your characteristic type is foreign key reference. Up to five columns of 50 bytes each are provided to accommodate compound keys. |

Adjustment Upload Staging

You must create an adjustment upload staging record for each adjustment you want to upload. The name of this table is CI_ADJ_STG_UP. The following describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|------------------------------|--------|-------|-----------|--|
| ADJ_STG_UP_ID | 12 | Y | N | This is the unique identifier of the adjustment upload staging record. This key is a sequential number so you can use a database function to assign the value when populating the table. |
| ADJ_STG_CTL_ID | 12 | Y | N | The ID of the adjustment staging control that is linked to this adjustment upload staging record. |
| ADJ_TYPE_CD | 8 | Y | A/N | This must correspond to the prime key of one of your adjustment types. Refer to Setting up Adjustment Types for more information. |
| ADJ_STG_UP_STATUS_FLG | 4 | Y | A/N | This must be set to P for Pending. |
| CREATE_DT | 10 | Y | Date | The date when the adjustment occurred. |
| ADJ_AMT | 13.2 | Y | N | The amount of the adjustment. |
| ADJ_SUSPENSE_FLG | 4 | Y | N | This must be set to NSUS for Not In Suspense. |

| | | | | |
|-------------------------|----|---|-----|--|
| SA_ID | 10 | N | A/N | This must correspond to a valid service agreement in the system. If you leave this blank and opt to let the system find the SA during adjustment upload preprocessing, a Determine SA algorithm must be plugged in on the associated adjustment type. This plug-in is meant to derive the SA ID based on supplied miscellaneous information - e.g. information supplied via adjustment characteristic upload staging. |
| ADJ_ID | 10 | N | A/N | Leave this blank. The adjustment upload process populates this. |
| SUSPENSE_ADJ_ID | 10 | N | A/N | Leave this blank. The adjustment upload process populates this. |
| MESSAGE_CATEGORY | 5 | N | N | Leave this blank. The adjustment upload background processes populate this when an error occurs during upload. |
| MESSAGE_NBR | 5 | N | N | Leave this blank. The adjustment upload background processes populate this when an error occurs during upload. |

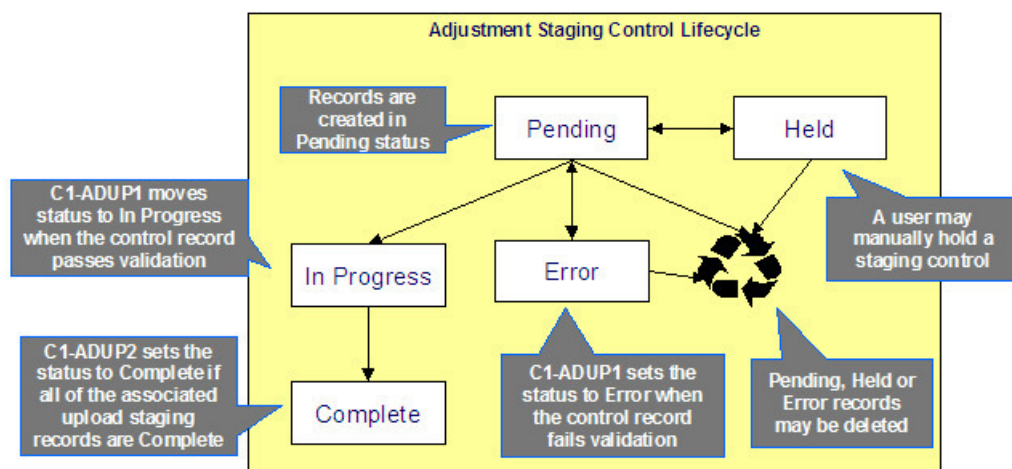

Adjustment Characteristic Upload Staging

You must create an adjustment characteristic upload staging record for each characteristic that you would like to link to the adjustment upload staging. The name of this table is CI_ADJ_STG_UP_CHAR. The following describes each column on this table.

| Column Name | Length | Req'd | Data Type | Comments |
|------------------------------------|---------|-------|-----------|--|
| ADJ_STG_UP_ID | 12 | Y | N | This must correspond with the prime key of the related CI_ADJ_STG_UP record. |
| CHAR_TYPE_CD | 8 | Y | A/N | This must correspond with a characteristic type that is defined as valid for adjustment. Refer to Setting Up Characteristic Types & Their Values for more information. |
| SEQ_NUM | 3 | Y | N | This should be set to 10 unless you have multiple values for a given adjustment upload staging and characteristic type. |
| CHAR_VAL | 16 | N | A/N | Populate this field if your characteristic type is predefined. |
| ADHOC_CHAR_VAL | 254 | N | A/N | Populate this field if your characteristic type is ad-hoc or file location. |
| CHAR_VAL_FK1 - CHAR_VAL_FK5 | 50 each | N | A/N | Populate these fields if your characteristic type is foreign key reference. Up to five columns of 50 bytes each are provided to accommodate compound keys. |

The Lifecycle of an Adjustment Staging Control Record

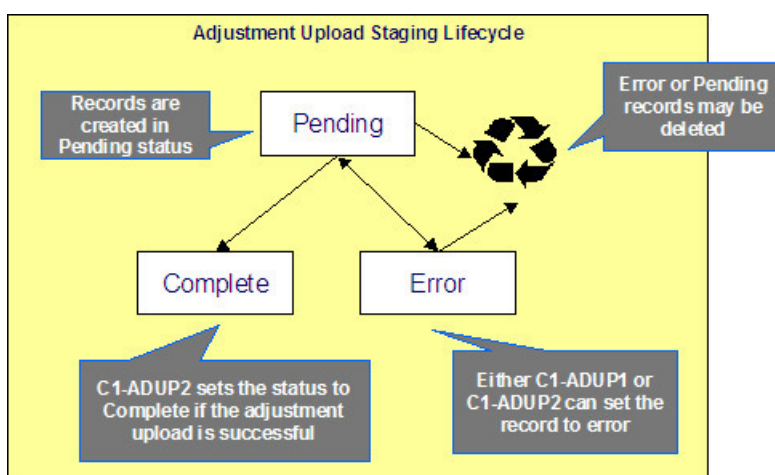

The following diagram shows the possible lifecycle of an adjustment staging control record.

- Pending. An adjustment staging control record is created in this state. The C1-ADUP1 process selects pending adjustment staging control records for validation.
- In Progress. The C1-ADUP1 process sets a pending record to in progress when the totals on the adjustment staging control are successfully validated against the totals from the associated adjustment upload staging records.
- Complete. The C1-ADUP2 process sets the adjustment staging control's status to complete when all adjustment upload staging records linked to the adjustment staging control are complete.
- Error. The C1-ADUP1 process sets a pending record to error if the adjustment staging control fails validation. The status may be set back to pending after the error is fixed.
- Held. The held status is available for situations where you want to prevent or delay the upload of a batch of adjustment staging records. The status may be set back to pending when the batch of records is ready for upload.
- Pending, error and held records may be deleted.

The Lifecycle of an Adjustment Upload Staging Record

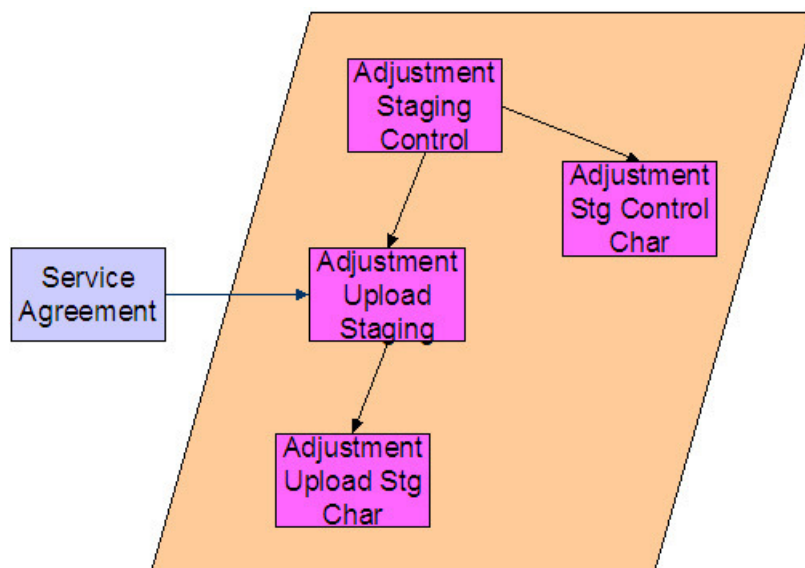

The following diagram shows the possible lifecycle of an adjustment upload staging record.

- Pending. Adjustment upload records are created in this state. The C1-ADUP2 process selects pending adjustment upload records and creates adjustments for each of them.
- Complete. The C1-ADUP2 process sets a pending record to complete if an adjustment is successfully created.
- Error. Either C1-ADUP1 or C1-ADUP2 process sets pending record to error when it encounters an error during the upload process. The status may be set back to pending after the error is fixed.
- Pending and error records may be deleted.

Process C1-ADUP1 - Preprocess Adjustment Uploads

The background process (C1-ADUP1) validates adjustment staging control records and populates service agreement IDs on adjustment upload staging records that do not specify an SA ID.

Phase 1 - Validate Adjustment Staging Controls

The following points describe, at a high level, the first phase of the adjustment upload pre-process:

- For each Pending adjustment staging control,
- Check that the record count on the adjustment staging control record equals the number of adjustment upload staging records that are linked to the adjustment staging control.
- Check that the total adjustment amount on the adjustment staging control record equals the sum of the adjustment amounts from the adjustment upload staging records that are linked to the adjustment staging control.
- If the adjustment staging control passes validation, set its status to In Progress. Otherwise, set the status to Error. Create a To Do entry using the inputs To Do type and To Do role (if supplied) for adjustment staging control errors. (Complete any outstanding To Do entries for the adjustment staging control before creating a new To Do entry.)
- If no errors occur, perform To Do cleanup by completing any outstanding To Do entries that were previously created for the adjustment staging control.

Note:

You can fix errors by going to the To Do entry and drilling into the adjustment staging control page. Don't forget to change the adjustment staging control's status back to Pending after fixing the error.

Phase 2 - Populate SA ID

The following points describe, at a high level, the second phase of the adjustment upload pre-process:

- For each Pending adjustment upload staging that is linked to an In Progress adjustment staging control AND does not have the SA ID,
- Execute the Determine SA algorithm that is plugged in on the [adjustment type](#).
- If the algorithm returns a valid SA ID, stamp that SA ID onto the adjustment upload staging. If the algorithm also returns an indication that the adjustment is to be put into suspense, set the suspense flag on the adjustment upload staging to In Suspense. Refer to [Suspense Adjustments](#) for more information on how suspense adjustments are handled.

- If the algorithm returns an error, set the adjustment upload staging record's status to Error. Create a To Do entry using the inputs To Do type and To Do role (if supplied) for adjustment upload staging errors. (Complete any outstanding To Do entries for the adjustment upload staging before creating a new To Do entry.)
- If no errors occur, perform To Do cleanup by completing any outstanding To Do entries that were previously created for the adjustment upload staging.

Note:

You can fix errors by going to the To Do entry and drilling into the adjustment upload staging page. Don't forget to change the adjustment upload staging's status back to Pending after fixing the error.

Process C1-ADUP2 - Upload Adjustments

The background process (C1-ADUP2) creates adjustments for all adjustment upload staging records that are stamped with an SA ID.

The following diagram and section describe, at a high level, the processing done in the C1-ADUP2 background process.

- For each Pending adjustment upload staging that has an SA ID,
- Add a frozen adjustment using the amount, creation date and adjustment type on the staging record.

Note:

If the type of adjustment being uploaded is one that is calculated, the algorithm that's plugged in on the adjustment type will calculate the adjustment amount and generate associated calculation lines (if applicable). See [Calculated Adjustments](#) for more information.

- If adjustment creation is successful, update the adjustment ID on the staging record and set the staging record's status to Complete.
- If adjustment creation results in an error, set the staging record's status to Error. Create a To Do entry using the To Do type on which this batch process (C1-ADUP2) is defined as creation process. (Complete any outstanding To Do entries for the adjustment upload staging before creating a new To Do entry.)
- If no errors occur, perform To Do cleanup by completing any outstanding To Do entries that were previously created for the adjustment upload staging.

Suspense Adjustments

What Are Suspense Adjustments?

When the adjustment upload preprocessor is unable to identify a valid SA ID, it can post the adjustment to a suspense SA. This is similar to how a payment is posted to a suspense account when a valid account ID could not be identified during payment upload.

Putting adjustments in suspense is optional. Therefore, this logic sits in a plug-in spot. If suspense adjustments are applicable to you, you must plug in your suspense logic in a Determine SA algorithm on [Adjustment Type](#).

How Are Suspense Adjustments Resolved?

A background process can be run periodically to automatically resolve suspense adjustments. Since rules for resolving suspense may vary, this logic sits in a plug-in spot. You must plug in your resolve logic in a Resolve Suspense algorithm on [Adjustment Type](#).

Process C1-ADURS - Resolve Suspense Adjustments

The batch process refers to the background process (C1-ADURS) that resolves suspense adjustments.

For each adjustment upload staging that is In Suspense, execute the Resolve Suspense algorithm that is plugged in on the [adjustment type](#).

Maintaining Adjustment Staging Control

Use this page to add, view or modify an adjustment staging control record. Open this page using **Menu > Financial > Adjustment Staging Control > Search**

Description of Page

Adjustment Staging Control ID is the unique identifier of the adjustment staging control record.

Create Date/Time is when the adjustment staging control was created. This field is protected after the record is saved.

Number of Staging Records is the number of adjustment upload staging records that are linked to this adjustment staging control record.

Total Adjustment Amount is the total of adjustment amounts from the adjustment upload staging records that are linked to this adjustment staging control record.

Enter the **Currency** for the total adjustment amount on the adjustment staging control. This is also the currency of the adjustment amounts on the associated adjustment upload staging records.

Status shows the state of the adjustment staging control. Possible values are: Pending, In Progress, Complete, Error, and Held.

A **Hold** button appears adjacent to the status description if **Status** is Pending. Click this button to set the status to Held. The adjustment upload process will ignore staging controls in this state.

A **Pend** button appears adjacent to the status description if **Status** is either Held or Error . Click this button to set the status to Pending. An error message box also appears below the status description if **Status** is Error.

Use the **Characteristics** collection to capture miscellaneous information about an adjustment staging control.

- **Characteristic Type** The type of characteristic.
- **Characteristics Value** The value of the characteristic.

Note:

You can only choose characteristic types defined as permissible on an adjustment staging control. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Maintaining Adjustment Upload Staging

Use this page to add, view, or modify an adjustment upload staging record. Open this page using **Menu > Financial > Adjustment Upload Staging > Search**.

Description of Page

Adjustment Upload ID is the unique identifier of the adjustment upload staging record.

Adjustment Staging Control ID is the identifier of the adjustment staging control to which the adjustment upload staging is linked.

Indicate the **Adjustment Type**. This field is very important as it controls numerous aspects of the adjustment's impact on the customer's balance and your general ledger.

Note:

You can only choose certain adjustment types. The service agreement's SA type has a collection of valid adjustment profiles. You may only reference adjustment types that are listed in one of the adjustment type profiles linked to the SA type.

Enter an **Adjustment Amount**.

Creation Date is the date when the adjustment occurred. This will be the creation date on the uploaded adjustment. This field is protected after the record is saved.

Service Agreement indicates the SA to which the adjustment was posted. If the adjustment is in suspense, the label shows **Suspense SA** instead.

Adjustment is a reference to the adjustment that got created from the upload.

Status shows the state of the adjustment upload staging. Possible values are: Pending, Complete, and Error.

If **Status** is Error, a **Pend** button appears adjacent to the status description. In addition, an error message box displays below the status description.

If the adjustment is in suspense, a message appears to indicate the condition and the **Suspense Adjustment** is shown. A different message appears when the suspense is resolved.

Use the **Characteristics** collection to keep miscellaneous information about an adjustment upload staging.

- **Characteristic Type** The type of characteristic.
- **Characteristics Value** The value of the characteristic.

Note:

Default Note. An adjustment upload staging's characteristics default from the [adjustment type](#).

Credit & Collection

The system periodically monitors how much your customers owe to ensure they haven't violated your collection criteria. When a violation is detected, the system generates the appropriate events (e.g., letters, disconnect field activities, To Do entries, write-off outstanding debt, etc.). This section describes how to manage your credit & collections processing.

Note:

In the section, [The Big Picture Of Credit & Collection \(C&C\)](#), we describe how to set up the control tables that automate most of your credit & collections processing. If you set these tables up properly, the system will manage most of your collection, severance and write-off processes; little or no user intervention should be necessary. You will only access the C&C pages when you need to override what the system does.

The Big Picture Of Credit & Collection

The topics in this section provide background information about a variety of credit & collections issues.

Automating Your C&C Activities

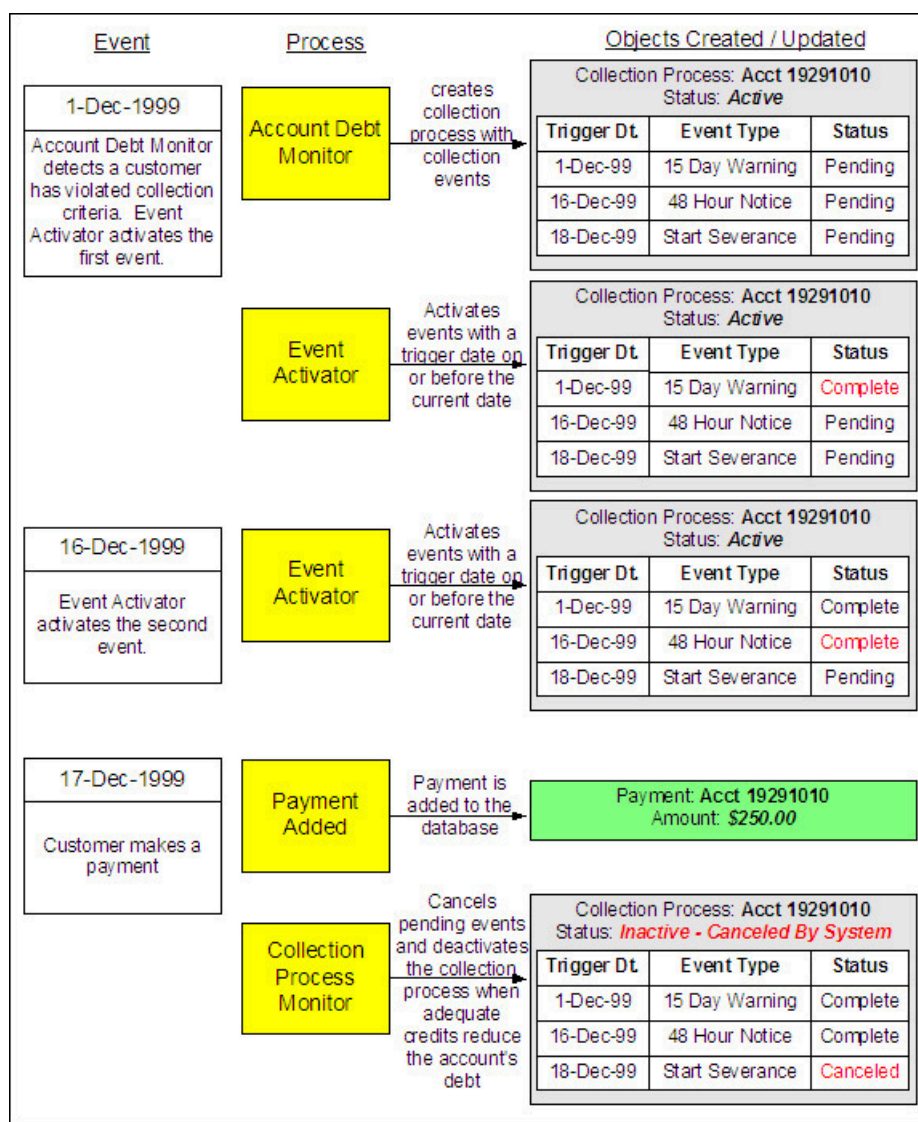

Fastpath:

Refer to [The Big Picture Of Credit & Collections \(C&C\)](#) to understand how the system monitors overdue debt and initiates the appropriate collection, severance and write-off events when a customer exceeds your debt tolerances.

The Lifecycle Of A Collection Process And Its Events

The following diagram illustrates the lifecycle of a typical collection process and its collection events:

The preceding diagram is referenced in the following topics.

What Is A Collection Process?

A collection process is a series of events (e.g., letters, To Do entries) meant to encourage an account to pay its delinquent debt. Linked to the collection process are the specific service agreements that contributed to the delinquent debt.

How Are Collection Processes Created?

A collection process and its events may be created as follows:

- The Account Debt Monitor is a background process that creates a collection process when an account violates your collection criteria. The collection process has one or more collection event(s). The collection process template associated with the collection process controls the number and type of events.
- A user may create an ad hoc collection process at will. The collection process template controls the number and type of events linked to the collection process.

In the above diagram, the event on 1-Dec-99 shows the creation of a collection process with three collection events. Notice that the events all exist in the Pending state. The events will exist in this state until their trigger date is on or before the current date.

Fastpath:

Refer to [How Does The Account Debt Monitor Work?](#) to understand how the system monitors overdue debt and initiates the appropriate collection process when a customer exceeds your debt tolerances. Refer to [The Big Picture Of Collection Events](#) for more information about a collection process' events.

When you enable the Control Central alert algorithm, C1-COLLPR-AC, an alert displays when an account has an active collection process. This algorithm is plugged-in on the [installation record](#).

How Are Collection Events Completed?

The event activator runs periodically (at least daily). It looks for collection events with a trigger date on or before the current date. For each such event, the system executes its activity and then completes it.

In the above diagram, the event activator activates pending events on 1-Dec-99 and 16-Dec-99. Notice that the events are moved to the Complete state.

Fastpath:

Refer to [The Big Picture Of Collection Events](#) for more information about the various types of collection events and what happens when they are completed.

How Are Collection Processes (and their Events) Canceled?

Fastpath:

Refer to [How Are Collection Processes Cancelled](#) for a description of how and when collection processes are automatically cancelled by the system.

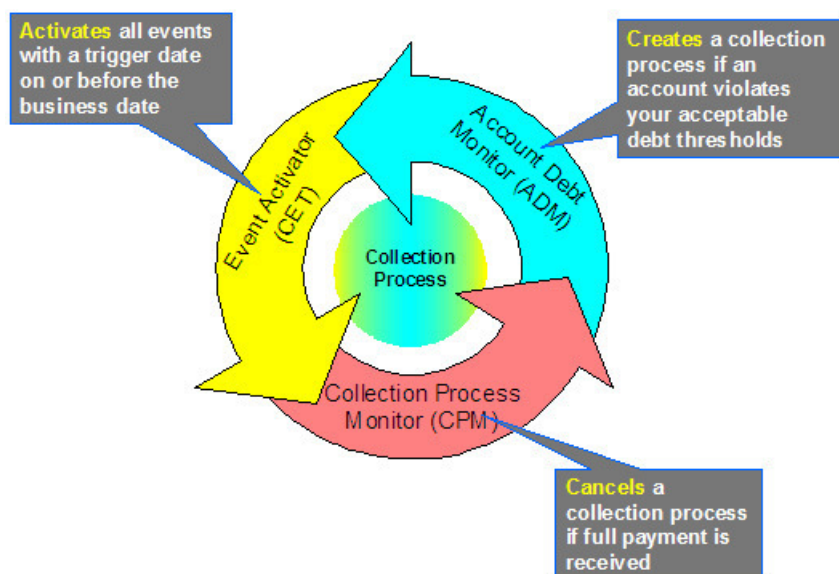

Besides the automated cancellation process, a user may cancel a collection process at will. Refer to [How To Cancel A Collection Process](#) for more information.

What Happens If A Payment Is Not Received?

If a payment (or some other type of credit) is not received by the trigger date of the last event in the process, a severance process is initiated for one or more service agreements. Refer to [The Last Collection Event Should Sever Service Agreement\(s\)](#) for more information.

The Collection Process Background Processes

There are three background processes that automate the creation, activation, and cancellation of collection processes:

Account Debt Monitor

The Account Debt Monitor (ADM) creates a collection process when an account violates your collection criteria. The collection process has one or more collection event(s). The number and type of events is defined on the collection process's template.

This process has an optional input parameter for CIS Division. It can be used if your implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

Note:

Monitoring account debt is usually done based on a schedule triggered by system events such as a bill or canceled payment. If too much time has gone by since the last debt review, the account can be selected for debt monitoring as well. ADM has an optional input parameter **Include Minimum Days Review**. When set, accounts that have gone too long since their last review are selected along with those scheduled to be reviewed. The minimum days between review is defined on the [customer class](#)

A separate background process (ADM2) only selects accounts based on the minimum days. This process can be used when the option to include minimum days on ADM has not been set.

ADM2 does not have an option to be run by CIS Division.

In the above [diagram](#), the account debt monitor creates a collection process (with 3 events) on 1-Dec-99. Notice that the events all exist in the Pending state. The events will exist in this state until their trigger date is on or before the current date.

Fastpath:

Refer to [How Does The Account Debt Monitor Work](#) for more information.

Collection Event Activator

The Collection Event Activator (CET) runs periodically (at least daily). It looks for collection events with a trigger date on or before the current date. For each such event, the system executes its activity and then completes it.

This process has an optional input parameter for CIS Division. It can be used if your implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

In the above [diagram](#), the collection event activator activates pending events on 1-Dec-99 and 16-Dec-99. Notice that the events are moved to the Complete state after they are activated.

Collection Process Monitor

The Collection Process Monitor (CPM) runs periodically (at least daily). This process reviews a collection process whenever one of its service agreements' debt is reduced.

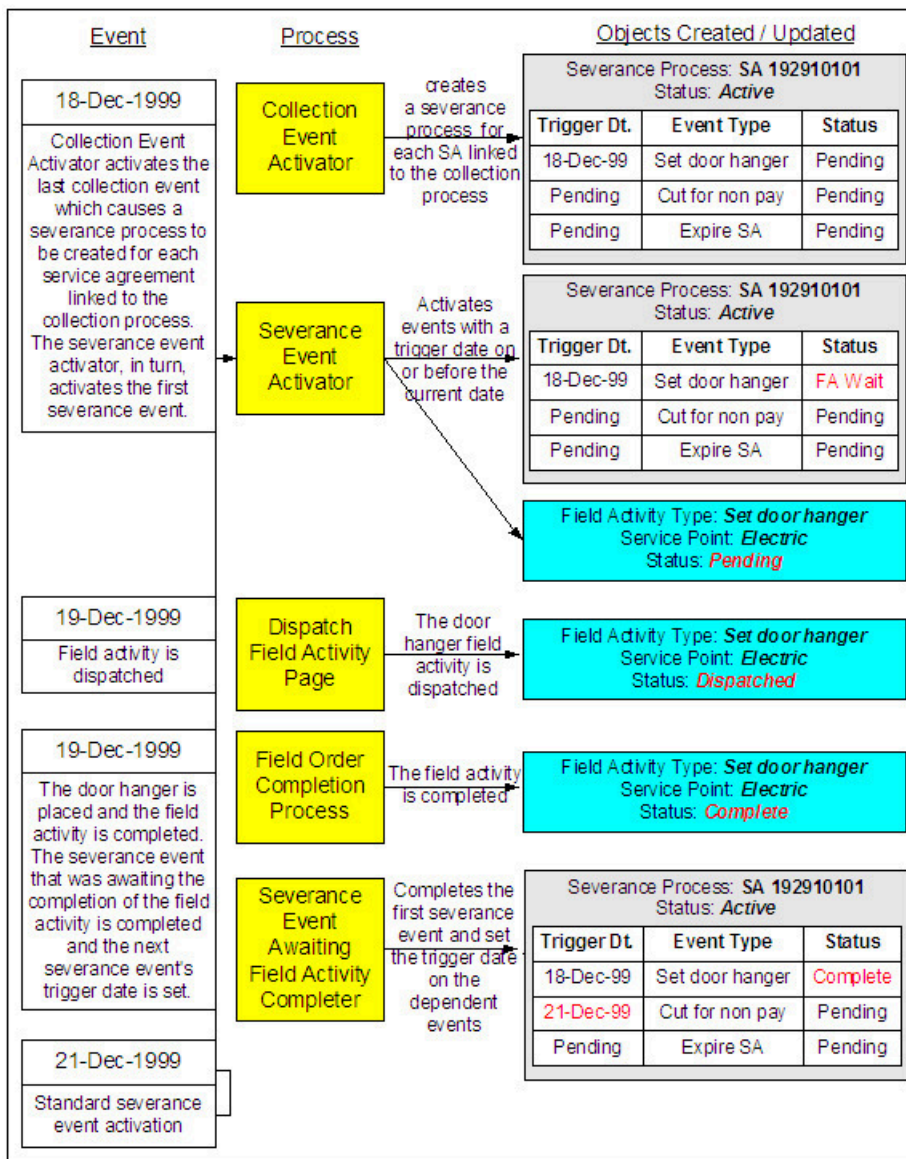

This process has an optional input parameter for CIS Division. It can be used if your implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

At review time, the Collection Process Monitor determines if it can cancel the collection process (because the customer's debt is no longer in a bad state). Refer to [How Does The Collection Process Monitor Work](#) for details describing how this process works.

In the above [diagram](#), the collection process monitor cancels the process on 17-Dec-99. Notice that the events are moved to the Cancelled state and the process becomes Inactive.

The Lifecycle Of A Severance Process And Its Events

The following diagram illustrates the first part of the lifecycle of a typical severance process and its events:

The preceding diagram is referenced in the following topics.

What Is A Severance Process?

A severance process is a series of events (e.g., letters, To Do entries, field activities) that lead to the severance of a service agreement. A separate severance process is required for each service agreement to be severed.

How Are Severance Processes Created?

Severance processes may be created as follows:

- The Collection Event Activator creates a severance process when it completes a "start severance process" collection event. The severance process has one or more severance event(s). The severance process template associated with the severance process controls the number and type of events.
- A user may create an ad hoc severance process at will. The severance process template defined when the severance process is created controls the number and type of events linked to the severance process.

Note:

Manual Creation. A user can create a severance process for an account that does not qualify to be on severance according to the cancel criteria algorithm. For example, perhaps your cancel criteria algorithm cancels a severance process when the account's debt falls below a threshold amount. A user can create a severance process for an account whose debt is already below this threshold. Because cancellation is real time, there is no action that will cause this severance process to be canceled. When a manual severance process is created, the system executes the appropriate cancellation criteria algorithm. If the algorithm indicates that the system would have canceled this severance process, a warning is issued. Refer to [How Are Severance Processes Cancelled](#) for more information about cancellation algorithms.

In the above diagram, the event on 18-Dec-99 shows the creation of a severance process with three collection events. Notice that only the first event has a trigger date, this is because the later events' trigger date can only be determined after the first event is completed. Also, notice that the events all exist in the Pending state. The events will exist in this state until their trigger date is on or before the current date.

Fastpath:

Refer to [How Are Collection Events Completed?](#) for more information about the completion of collection events.

When you enable the Control Central Alert installation algorithm, C1-SEVPR-ACT, an alert displays when an account has an active severance process. This algorithm is plugged-in on the [installation record](#).

How Are Severance Events Completed?

The Severance Event Activator runs periodically (at least daily). It looks for severance events with a trigger date on or before the current date. For each such event, the system executes its activity. The type of severance event dictates what happens to the severance event's state. Refer to [Field Events Versus Office Events](#) for the details.

In the above diagram, the event activator activates a pending event on 18-Dec-99. Take note of the state of the severance event (it becomes Awaiting Field Activity Completion).

Fastpath:

Refer to [The Big Picture Of Severance Events](#) for more information about the various types of severance events and what happens when they are completed.

How Are Severance Processes (and their Events) Canceled?

Fastpath:

Refer to [How Are Severance Processes Cancelled](#) for a description of how the system automatically cancels a severance process.

Note:

Real time cancellation. Unlike collection processes, the system cancels severance processes real time (i.e., there is no equivalent of the collection process monitor for severance processes). Why are severance processes canceled real time? Because a severance process may have events that create field activities to sever service. These events need to be canceled the moment the FT is frozen, we can't wait until a background process runs. This means that if a customer pays in person for a service agreement that is pending severance, the system will cancel the process and its field activities (if any) the moment the payment is entered. The logic to cancel the field activities is in an algorithm plugged in on the [installation record](#).

Fastpath:

Refer to [Setting Up Severance Process Templates](#) for more information about severance process templates. Refer to [Designing Your Reconnection Procedures](#) for more information about how severance processes are used to reconnect services.

Besides the automated cancellation process, a user may cancel a severance process at will.

What Happens If The Customer Does Not Pay?

If a payment (or some other type of credit) is not received by the trigger date of the last event in the severance process, the service agreement is stopped (as long as you've setup your severance process to include an Expire Service Agreement event as the last event). The expiration of the last service agreement will, in turn, trigger a final bill. If the account doesn't pay the final bill, a write-off process will be started.

Note:

Final bills. The account will be setup for final billing when the LAST service agreement linked to the account is stopped. Refer to [Finalizing Pending Stops](#) for more information about how the system changes the account's bill cycle when the last service agreement is stopped.

Fastpath:

Refer to [The Big Picture Of Write Off Processing](#) for more information about the write off process.

The Severance Process Background Processes

The Collection Event Activator creates a severance process when it completes a "start severance process" collection event. The severance process has one or more severance event(s). The severance process template associated with the severance process controls the number and type of events. There are 3 background processes that automate the activation and cancellation of severance events:

Severance Event Activator

The Severance Event Activator (SET) runs periodically (at least daily). It looks for severance events with a trigger date on or before the current date. For each such event, the system executes its activity. The type of severance event dictates what happens to the severance event's state.

This process has an optional input parameter for CIS Division. It can be used if your implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

In the above [diagram](#), the event activator activates a pending event on 18-Dec-99. Take note of the state of the severance event (it becomes Awaiting Field Activity Completion).

Completing Severance Events That Are Dependent On The Completion Of A Field Activity

The Complete Field Events (SEC) process runs periodically (at least daily). It looks for severance events that are dependent on the completion of field activities before they can be completed. The system completes each such event when the field activities linked to the event are complete.

This process has an optional input parameter for CIS Division. It can be used if you implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

In the above [diagram](#), this process completes the event that was Awaiting Field Activity Completion on 19-Dec-99. Take note of the state of the severance event (it becomes Complete).

Set Trigger Date

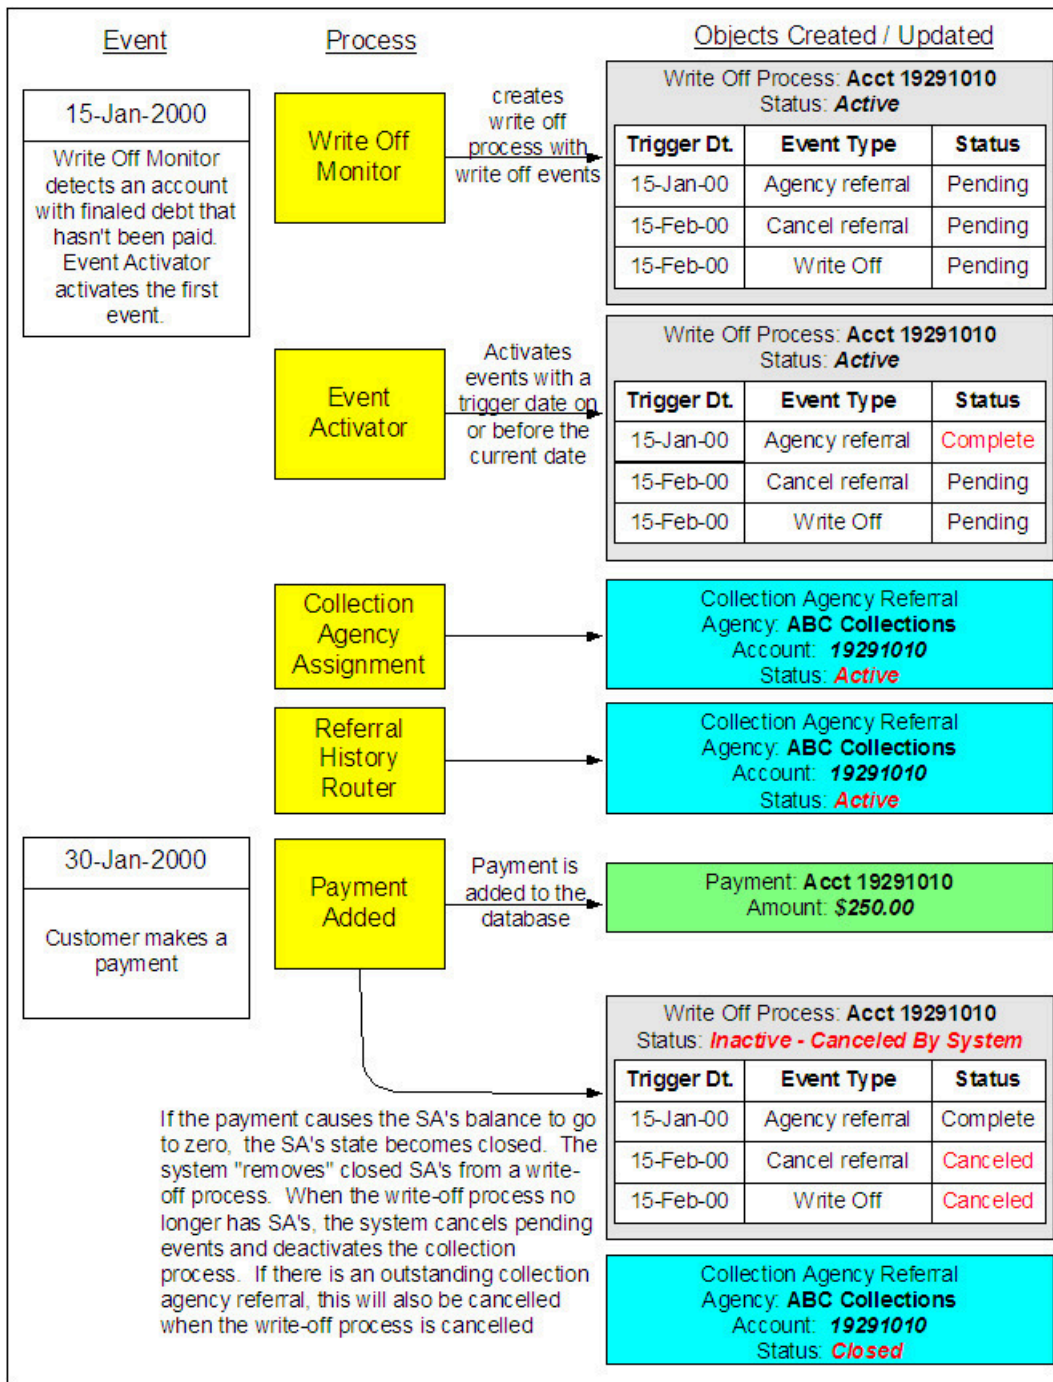

The Set Trigger Date (SED) process runs periodically (at least daily). It looks for severance events that are dependent on the completion of other events before their trigger date can be set. The system sets the trigger date of each such event when all of its dependent events are complete.

This process has an optional input parameter for CIS Division. It can be used if you implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

In the above [diagram](#), this process sets the trigger date of the second event on 19-Dec-99.

The Lifecycle Of A Write-Off Process And Its Events

The following diagram illustrates the lifecycle of a typical write-off process and its write-off events:

The above diagram is referenced in the following topics.

What Is A Write-Off Process?

A write-off process is a series of events (e.g., letters, collection agency referrals) meant to encourage an account to pay its delinquent debt. Linked to the write-off process are the specific service agreements that contributed to the delinquent debt.

How Are Write-Off Processes Created?

A write-off process and its events may be created as follows:

- The Write Off Monitor is a background process (WPM) that creates a write-off process when an account has finalized, unpaid service agreements. The write-off process has one or more write-off event(s). The write-off process template associated with the write-off process controls the number and type of events.
- A user may create an ad hoc write-off process at will. The write-off process template controls the number and type of events linked to the write-off process.

In the above diagram, the event on 15-Jan-00 shows the creation of a write-off process with three write-off events. Notice that the events all exist in the Pending state. The events will exist in this state until their trigger date is on or before the current date.

Fastpath:

Refer to [How Does The Write-Off Monitor Work?](#) to understand how the system monitors overdue debt and initiates the appropriate write-off process when a customer has unpaid, finalized service agreements. Refer to [The Big Picture Of Write-off Events](#) for more information about a write-off process' events.

How Are Write-Off Events Completed?

The event activator runs periodically (at least daily). It looks for write-off events with a trigger date on or before the current date. For each such event, the system executes its activity and then completes it.

In the above diagram, the event activator activates a pending event on 15-Jan-00. Notice that the events are moved to the Complete state.

Fastpath:

Refer to [The Big Picture Of Write-off Events](#) for more information about the various types of write-off events and what happens when they are completed.

How Are Write-Off Processes (and their Events) Canceled?

When a stopped service agreement's balance is reduced to zero (i.e., it closes), the system checks if there is an ongoing write-off process associated with the service agreement. If so:

- The system "removes" the service agreement from the write-off process.
- When the last service agreement is removed from a write-off process, the system cancels all pending write-off events and deactivates the write-off process.
- If the canceled process has collection agency referrals, the system cancels the referrals.

Note:

Real time cancellation. Unlike collection processes, the system cancels write-off processes real time (i.e., there is no equivalent of the collection process monitor for write-off processes). This means that if a customer (or collection agency) pays for a service agreement that is linked to write-off process, the system will cancel the process and its collection agency referrals (if any) the moment the payment is entered.

Fastpath:

Refer to [Setting Up Write Off Process Templates](#) for more information about write off process templates.

Besides the automated cancellation process, a user may cancel a write-off process at will.

What Happens If The Debt Is Not Paid?

If a payment (or some other type of credit) is not received by the trigger date of the last event in the process, the debt will be written off (assuming you designed your write off process template to do such).

Note:

The last write-off event should cause debt to be written off. Debt will only be written off if the last write-off event is the type that writes off debt. If the write-off process template contains no such event, nothing

further will transpire until the next time the write-off monitor runs (when it will create another write-off process for the unpaid, finalized debt).

Fastpath:

Refer to [How Is Debt Financially Written-Off?](#) for a description of exactly how debt is written off.

How Is Debt Referred To Collection Agencies

Fastpath:

Refer to [How Do Collection Agency Referrals Work?](#) for more information about how the system refers debt to a collection agency.

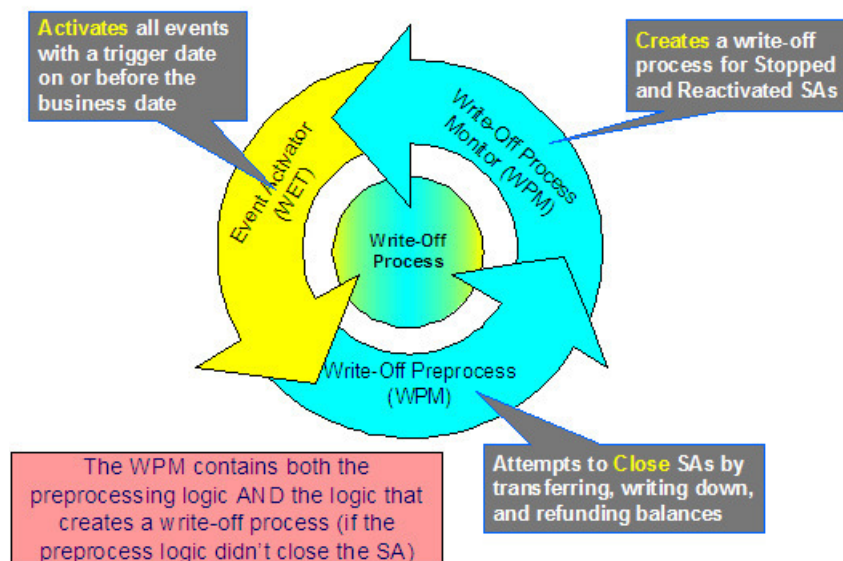

The Write-Off Process Background Processes

There are 2 background processes that automate the creation, activation, and cancellation of write-off processes:

Note:

If necessary, you can write-off debt outside of the automated write-off process by simply transferring bad debt to a write-off service agreement using the Write Off transaction.

Write-Off Monitor

The Write-Off Monitor (WPM) is a background process that has two functions:

- It attempts to close Stopped and Reactivated service agreements using several methods as described under [Attempt To Close The SA Before Creating A Write Off Process](#).
- If it is unsuccessful at closing a SA, it creates a write-off process. The write-off process has one or more write-off event(s). The write-off process template associated with the write-off process controls the number and type of events.

This process has an optional input parameter for CIS Division. It can be used if your implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

In the above [diagram](#), the event on 15-Jan-2000 shows the creation of a write-off process with three write-off events. Notice that the events all exist in the Pending state. The events will exist in this state until their trigger date is on or before the current date.

Write-Off Event Activator

The Write-Off Event Activator (WET) runs periodically (at least daily). It looks for write-off events with a trigger date on or before the current date. For each such event, the system executes its activity and then completes it.

This process has an optional input parameter for CIS Division. It can be used if your implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

In the above [diagram](#), the write-off event activator activates a pending event on 15-Jan-2000. Notice that the event is moved to the Complete state.

Collection Process Maintenance

A collection process is a series of events (e.g., letters, To Do entries) meant to encourage an account to pay its delinquent debt. Linked to the collection process are the specific service agreements that contributed to the delinquent debt. The topics in this section describe the pages on which collection process-related information is maintained.

Fastpath:

For more information about collection processes, refer to [The Lifecycle Of A Collection Process And Its Events](#).

Collection Process - Main Information

The Main page contains core collection process information. Open this page using **Menu > Credit & Collection > Collection Process > Search**.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Perform Common Collection Process Functions](#) for more instructions describing how to use this transaction.

Description of Page

Collection Process is a concatenation of summary information about this collection process. It is composed of the name of the main customer on the account, the collection status, the reason code for the collection status, the collection class control name, and the creation date of the process.

Collection Process ID is the unique system-generated identifier for this collection process.

Account ID is the system-generated account number. The name of the main customer on the account and its customer class are displayed next to the ID number.

Collection Status defines the state of the collection process. The following values may exist:

Active The system creates a collection process in the Active state. A collection process remains in this state until the last event linked to the process is complete OR the customer pays the collection amount on the service agreements linked to the process OR you want to stop the process for whatever reason.

Inactive A collection process becomes Inactive when the last event linked to the process is completed OR the customer pays the collection amount on all service agreements linked to the process OR you want to stop the process for whatever reason. The **Reason** field tells you how a collection process became inactive.

Fastpath:

To completely understand the significance of a collection process' status, refer to [The Lifecycle Of A Collection Process And Its Events](#).

Reason defines how a collection process became Inactive or why a collection process is Active. The following values may exist:

Canceled by User This reason should be used when a user manually inactivates a collection process (for whatever reason).

Canceled by System This reason is populated by the system when it cancels a collection process. The system automatically cancels a collection process when sufficient credits have been posted to the process' service agreements since the process was started.

Events Pending This reason is populated by the system when a process has pending events.

Completed This reason is populated by the system when it completes the last event linked to the collection process.

Collection Class Control defines the debt class (i.e., the type of debt) associated with the collection process. This is important as it controls which service agreements can be linked to the collection process (every service agreement is associated with a specific debt class). This field is gray when there are service agreements linked to the collection process.

Note:

Multiple collection processes may be linked to an account. It's important to be aware that if an account's service agreements reference multiple debt classes, a collection process must be created for each debt class that you want to collect.

One collection process per debt class. A given debt class for an account may only have one ongoing collection process at any point in time.

Beneath **Collection Class Control** is displayed a message showing why the system generated the collection process. This information is only displayed for collection processes created by the Account Debt Monitor. If you have plugged in a Collection Process Additional Information algorithm on the [Installation](#) record, the results of the algorithm, if any, is displayed on a separate line.

The following line displays the minimum value payment to the collection process debt class that will cause cancellation of the collection process.

Fastpath:

For more information, refer to [How Does The Account Debt Monitor Work?](#).

Collection Process Template defines the collection events in the process. You can override these events on the **Events** page.

Note:

Changing the template. If you change the template when all events are pending, the system will remove the pending events and replace them with the new template's events.

Fastpath:

For more information, refer to [Setting Up Collection Process Templates](#).

Creation Date/Time defines the start date/time of the collection process. This is important as it affects the trigger dates of the process' collection events. This field becomes protected after the collection process exists on the database. If you need to change the trigger date on the events you can navigate to the **Events** tab and change the dates manually. Alternatively, you can perform the following "trick":

- Change the **Collection Process Template** to something (anything). Doing this causes the **Create Date/Time** to become unprotected.
- Specify the date of the first collection event in the newly unprotected **Create Date/Time**.
- Change the **Collection Process Template** back to the desired value. When you change the template, the system removes the events and creates new ones using the **Create Date/Time**.

The collection process cancellation logic will cancel a collection process when its account's debt no longer exceeds a given amount (you define this threshold amount when you set up the system). Rather than compare an account's total debt to the threshold amount, the cancellation logic compares the account's debt that is older than X days to the threshold amount. X is the date specified in **Collection Amount Base Date**. You can have the system calculate this date for you by entering the age of the arrears in the field embedded in **Calculate Date Using ___ Days In Arrears**.

Fastpath:

For more information, refer to [How Are Collection Processes \(and their Events\) Canceled?](#)

Enter any **Comments** about the collection process.

The [tree](#) at the bottom of the page shows a variety of information about the **account** and the collection process including:

- The service agreements linked to the collection process.
- The events linked to the collection process.
- The amount of debt currently associated with the account's debt classes.
- Whether a pay plan exists for the account, or existed at the time the collection process was created.
- The balance for any service agreements linked to the collection process in Inactive status but that have credit balances contributing to the overall debt class arrears for the account.
- A summary of other active collection activities (i.e., collection, severance and write-off processes) associated with the **account**.

Collection Process - SAs (Service Agreements)

The SA page contains the service agreements whose debt is being collected by the collection process. Open this page using **Menu > Credit & Collection > Collection Process > Search** and navigate to the **SAs** page.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Perform Common Collection Process Functions](#) for more instructions describing how to use this transaction.

Description of Page

The top portion of every page in this page contains the following information:

Collection Process is a concatenation of summary information about this collection process. It is composed of the name of the main customer on the account, the collection status, the reason code for the collection status, the collection class control name, and the creation date of the process.

ID is the unique system-generated identifier for this collection process.

The **Collection SAs** scroll contains the service agreement being collected under this collection process. To modify a service agreement linked to the collection process, simply move to a field and change its value. To add a new service agreement, press the + button to insert a row, then fill in the information for each field. The following fields display:

Service Agreement ID identifies the service agreement being collected. Information about the service agreement is displayed beneath the SA ID.

Status defines the state of the service agreement in respect of the collection process. The following values may exist:

Active An Active service agreement is one currently being collected by the collection process. The service agreement will remain in this state until the last event linked to the process is complete OR the customer pays the collection amount on the service agreement OR you want to remove the service agreement from the collection process for whatever reason.

Inactive A service agreement becomes Inactive within the collection process when the last event linked to the process is completed OR the customer pays the collection amount on the service agreement OR you want to remove the service agreement from the collection process for whatever reason.

The **Collection Amount** is the amount of debt that initially triggered the collection process. This will be zero for collection processes that were created manually.

The **Amount Still Owing** is the amount of debt older than the **Collection Amount Base Date** defined on the Main page.

The **Credit Amount** is displayed if the Amount Still Owing is less than zero.

The **SA Balances** area displays how much is owed for the service agreement. The **Days Old** and **Arrears Amount** information shows how old the current balance is. This information will be blank if the current balance is a credit.

Note:

Information about debt balances by age is not applicable to [open-item accounts](#).

Current Balance indicates the amount the customer currently owes for the service. **Payoff Balance** indicates the amount the customer would owe if they wanted to close the service agreement. This value is only displayed when it differs from the current balance.

Fastpath:

Refer to [Current Amount versus Payoff Amount](#) for more information.

Collection Process - Events

The events page contains the activities that will be performed to persuade the customer to pay the outstanding debt. Open this page using **Menu > Credit & Collection > Collection Process > Search** and navigate to the **Events** page.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Perform Common Collection Process Functions](#) for more instructions describing how to use this transaction.

Note:

We strongly recommend that you understand the information described in [How Are Collection Events Completed?](#) before using this page.

Fastpath:

The number and type of events associated with a collection process are defined by the process's collection process template (which is defined on the first page). Refer to [Setting Up Collection Process Templates](#) for more information.

Description of Page

The top portion of every page in this page contains the following information:

Collection Process is a concatenation of summary information about this collection process. It is composed of the name of the main customer on the account, the collection status, the reason code for the collection status, the collection class control name, and the creation date of the process.

ID is the unique system-generated identifier for this collection process.

The **Collection Events** scroll contains the collection events that comprise the collection process. Only one event is displayed at a time. The inner scroll controls the display of the customer contacts that were created by the system when a particular collection event was triggered.

Event Sequence is the unique identifier of the event.

Collection Event Status defines the state of the event. The following diagram shows the possible lifecycle of a collection event:

Collection events are initially created in the pending state.

When the system sees a pending event with a **Trigger Date** on or before the current date, the system executes the event's activity and completes the event.

You can cancel an individual collection event by setting the status to cancelled.

The **Collection Event Type** defines the event's activity (e.g., Email sent, a To Do entry is generated, a letter is sent).

Fastpath:

For more information, refer to [Setting Up Collection Process Templates](#).

The **Trigger Date** defines the date when the system completes (i.e., executes) the event.

Fastpath:

For more information about a collection event's trigger date, see [Collection Event Trigger Date](#).

If the status of the event is complete, the **Completion Date** is displayed with the date on which the system completes the event. If the status of the event is cancelled, the **Canceled Date** is displayed with the date on which the event was system canceled.

The **Customer Contact** information contains information when the event template causes a letter to be generated (because letters are created by customer contacts).

How To Perform Common Collection Process Functions

The topics in this section describe how to perform common collection process maintenance functions. Refer to [The Lifecycle Of A Collection Process](#) for more information about collection processes. Refer to [The Big Picture Of Collection Processing](#) for high-level information about collection processing.

How To Create A Collection Process

99.9% of all collection processes are created by the [Account Debt Monitor](#) and require no human intervention before they are executed (refer to [How Are Collection Processes Created](#) for information about how the account debt monitor creates collection processes). The other 0.1% are created by users on-line / real time. The following points describe how to create the 0.1%.

- Use **Control Central** to choose the account that requires a new collection process.
- After the account is populated on Control Central, choose the **Collection Process > Add** option on the account context menu to transfer to the collection process transaction in add mode.
- After the Collection Process - Main page appears, specify the appropriate **Collection Class Control**. **Collection Class Control** defines the debt class (i.e., the type of debt) associated with the collection process. This is important as it controls which service agreements can be linked to the collection process (every service agreement is associated with a specific debt class). It's important to be aware that if an account's service agreements reference

multiple debt classes, a collection process must be created for each debt class that you want to collect. Also be aware that a given debt class for an account may only have one ongoing collection process at any point in time.

- Choose a **Collection Process Template**. **Collection Process Template** defines the collection events in the process. You can override these events on the Events page. For more information, refer to [Setting Up Collection Process Templates](#).
- Use **Collection Amount Base Date** to define the arrears cutoff date that the system uses when it "removes" a SA from a collection process. The system removes a SA from a collection process when its debt older than X is less than or equal to zero. X is the date specified in **Collection Amount Base Date**. You can have the system calculate this date for you by entering the age of the arrears in the field embedded in **Calculate Date Using ___ Days In Arrears**.
- Navigate to the **SAs** page to define the specific service agreement's whose debt is covered by this collection process. You must define at least one service agreement.
- Save the collection process.

How To Change Collection Events

When a collection process is first created, it has one or more collection events. The events are the activities that will be performed to persuade the customer to pay the outstanding debt.

The number and type of events that are created when a collection process is initiated are defined on the collection process's collection process template. The following points describe how to add / change / delete events on a collection process if the defaulted events are not satisfactory.

- Use **Control Central** to choose the account with the collection process whose events need to be changed.

After the account is populated on Control Central, choose the **Collection Process > Search** option on the account context menu to transfer to the collection process transaction in update mode.

To add a new event, transfer to the **Events** tab and press the + button in the **Collection Events** scroll to add a new event. At this point, the event has not been added to the database; rather, it just exists in memory. Before you add the event to the database, you must specify the following information:

- Choose an **Event Sequence** so that the new event will be positioned properly in respect of the other events.
- Choose a **Collection Event Status** of Pending.
- Choose the desired **Collection Event Type**.
- Use **Trigger Date** to define the date on which the event should be activated (i.e., completed).

To delete an existing event, transfer to the **Events** tab and use the scroll arrows to toggle to the desired collection event. When the desired collection event appears, press the - button to remove the event. At this point, the event has not been removed from the database; rather, it's been removed in memory.

To change an existing event, transfer to the **Events** tab and use the scroll arrows to toggle to the desired collection event. When the desired collection event appears, make the desired changes.

After all desired changes have been made, save the collection process.

How To Cancel A Collection Process

The [Collection Process Monitor](#) will automatically "remove" service agreements from a collection process when their debt has been reduced sufficiently. When all service agreements are "removed" from a collection process, the collection process is canceled. The following points describe how to manually cancel a collection process.

- Use **Control Central** to choose the account with the collection process to be cancelled.
- After the account is populated on Control Central, choose the **Collection Process > Search** option on the account context menu to transfer to the collection process transaction in update mode. A list of all collection processes associated with the account appears. If only one collection process exists, it is automatically selected for you.
- On the **Main** tab, click Cancel.
- When the warning dialog appears, click OK to continue. The collection process and its pending events are canceled.

Severance Process Maintenance

A severance process is a series of events (e.g., field orders, letters, To Do entries) meant to encourage an account to pay its delinquent debt. Linked to the severance process is the specific service agreement being severed. The topics in this section describe the pages on which severance process-related information is maintained.

Fastpath:

For more information about severance processes, refer to [The Lifecycle Of A Severance Process And Its Events](#).

Severance Process - Main Information

The Main page contains core severance process information. Open this page using **Menu > Credit & Collection > Severance Process > Search**.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Perform Common Severance Process Functions](#) for more instructions describing how to use this transaction.

Description of Page

The top portion of every page in this page contains the following information:

Severance Process is a concatenation of summary information about this severance process. It is composed of the name of the main customer on the account, the division and SA type, and severance process template code, the process status, the reason code for the process status and the creation date of the process.

Severance Process ID is the unique system-generated identifier for this severance process.

The remaining fields are maintained on the main severance process page.

Service Agreement ID is the system-generated identifier of the service agreement to which the severance process is linked. Adjacent to the ID number is summary information about the SA.

Severance Status defines the state of the severance process. The following values may exist:

Active The system creates a severance process in the Active state. A severance process remains in this state until the last event linked to the process is complete OR the customer pays the collection amount associated with the severance process OR you want to stop the process for whatever reason. The **Reason** field tells you why a severance process is still in the active state.

Inactive A severance process becomes Inactive when the last event linked to the process is completed OR the customer pays the collection amount on the severance process OR you want to stop the process for whatever reason. The **Reason** field tells you how a severance process became inactive.

Fastpath:

To completely understand the significance of a severance process' status, refer to [The Lifecycle Of A Severance Process And Its Events](#).

Reason defines how a severance process became Inactive or why a severance process is Active. The following values may exist:

Canceled by User This reason should be used when a user manually inactivates a severance process (for whatever reason).

Canceled by System This reason is specified by the system when it cancels a severance process. The system automatically cancels a severance process when sufficient credits have been posted to the process' service agreement since the process was started.

Events Pending This reason is specified by the system when a process has pending events.

Completed This reason is specified by the system when it completes the last event linked to the severance process.

Severance Process Template defines the severance events in the process. You can override these events on the **Severance Events** page. If you change the template after events exist, the system will remove the existing events and replace them with the new template's events.

Fastpath:

For more information, refer to [Setting Up Severance Process Templates](#).

Create Date/Time defines the start date/time of the severance process. This is important as it affects the trigger dates of the process' severance events. This field becomes protected after the severance process exists on the database. If you need to change the trigger date on the events you can navigate to the **Events** tab and change the dates manually. Alternatively, you can perform the following "trick":

- Change the **Severance Process Template** to something (anything). Doing this causes the **Create Date/Time** to become unprotected.
- Specify the date of the first severance event in the newly unprotected **Create Date/Time**.
- Change the **Severance Process Template** back to the desired value. When you change the template, the system removes the events and creates new ones using the **Create Date/Time**.

The **Collection Amount** is the amount of debt that initially triggered the severance process.

The **Amount Still Owing** is the amount of debt older than the **Severance Amount Base Date**.

The severance process cancellation logic will cancel a severance process when its SA's debt no longer exceeds a given amount (you define this threshold amount when you set up the system). Rather than compare a SA's total debt to the threshold amount, the cancellation logic compares the SA's debt that is older than X days to the threshold amount. X is the date specified in **Severance Amount Base Date**. You can have the system calculate this date for you by entering the age of the arrears in the field embedded in **Calculate Date Using __ Days In Arrears**.

Fastpath:

For more information, refer to [How Are Severance Processes \(and their Events\) Canceled?](#)

Enter any **Comments** about the severance process.

The [tree](#) at the bottom of the page shows a variety of information about the **service agreement's** account and the severance process including:

- The events linked to the severance process.
- The amount of debt associated with the account's debt classes.
- A summary of other active severance activities (i.e., severance, severance and write-off processes) associated with the **service agreement's** account.

Severance Process - Severance Events

The events page contains the activities that will be performed to persuade the customer to pay the outstanding debt. Open this page using **Menu > Credit & Collection > Severance Process > Search** and navigate to the **Events** page.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Perform Common Severance Process Functions](#) for more instructions describing how to use this transaction.

Note:

We strongly recommend that you understand the information described in [How Are Severance Events Completed?](#) before using this page.

Fastpath:

The number and type of events associated with a severance process are defined by the process's severance process template (which is defined on the first page). Refer to [Setting Up Severance Process Templates](#) for more information.

Description of Page

The top portion of every page in this page contains the following information:

Severance Process is a concatenation of summary information about this severance process. It is composed of the name of the main customer on the account, the SA business unit and SA type, set ID and severance process template name, the process status, the reason code for the process status and the creation date of the process.

ID is the unique system-generated identifier for this severance process.

The **Severance Events** scroll contains the severance events that comprise the severance process. The grid at the bottom (when visible) shows the events that must be completed before the severance event is triggered. Only one severance event is displayed at a time.

Event Sequence is the unique identifier of the event.

Severance Event Status defines the state of the event.

Fastpath:

For more information, refer to [Severance Event Lifecycle](#).

The **Severance Event Type** defines the event's activity (e.g., a field order is generated, a To Do entry is generated, a letter is sent).

Fastpath:

For more information, refer to [Setting Up Severance Event Templates](#).

If **Dependent on Other Events** is turned on, then the event's trigger date is only determined after the event(s) on which it depends are completed. When this switch is on, a grid appears at the bottom of the page in which you define the event(s) on which this event depends.

Fastpath:

For more information about dependent events, see [Severance Event Dependencies & Trigger Date](#).

The **Trigger Date** defines the date when the system completes (i.e., executes) the event. This field is gray when the event is dependent on the completion of other events.

Fastpath:

For more information about a severance event's trigger date, see [Severance Event Dependencies & Trigger Date](#).

Days After Prev Response defines how a dependent event's trigger date is calculated. The trigger date is set equal to X days after the last dependent event is completed, where X is the number in this field. This field is gray when the event is not dependent on other events.

Fastpath:

For more information about dependent events, see [Severance Event Dependencies & Trigger Date](#).

If the status of the event is complete, the **Completion Date** is displayed with the date on which the system completes the event. If the status of the event is cancelled, the **Canceled Date** is displayed with the date on which the event was canceled.

The grid at the bottom of the page contains the events on which this event depends. This grid is only visible when the event is dependent on other events (as defined by the Dependent on Other Events switch). To add additional sequences press the + button (insert row), and define the sequence of the event on which this event depends.

Severance Process - Field Activity/Customer Contact

The Field Activity/Customer Contact page contains information about the objects created when the system completes the event. Open this page using **Menu > Credit & Collection > Severance Process > Search** and navigate to the FA/CC page.

Fastpath:

What happens when a severance event is completed (i.e., executed) is dictated by the severance event's template. Refer to [Types Of Severance Events](#) for more information.

Description of Page

The top portion of every page in this page contains the following information:

Severance Process is a concatenation of summary information about this severance process. It is composed of the name of the main customer on the account, the SA business unit and SA type, set ID and severance process template name, the process status, the reason code for the process status and the creation date of the process.

ID is the unique system-generated identifier for this severance process.

The **Severance Events** scroll contains the severance events that comprise the severance process. The grids show the objects created when the system completes each event.

The **Field Activity/SP** grid contains information about the field activities that were created when the event was activated. This information will only be populated with the event's event type causes a field activity to be generated.

The **Customer Contact** area contains information about the customer contacts that were created when the event was activated. This information will only be populated with the event's event type causes a customer contact to be created (note, letters are generated via the creation of a customer contact).

How To Perform Common Severance Process Functions

The topics in this section describe how to perform common severance process maintenance functions. Refer to [The Lifecycle Of A Severance Process](#) for more information about severance processes. Refer to [The Big Picture Of Severance Processing](#) for high level information about severance processing.

How To Create A Severance Process

99.9% of all severance processes are created when a "start severance" collection event is activated by the [Collection Event Activator](#) and require no human intervention before they are executed (refer to [How Are Severance Processes Created](#) for information about how the account debt monitor creates severance processes). The other 0.1% are created by users on-line / real time. The following points describe how to create the 0.1%.

- Use **Control Central** to choose the account that requires a new severance process.
- After the account is populated on Control Central, choose the **Severance Process > Add** option on the account context menu to transfer to the severance process transaction in add mode. If the account has multiple service agreements, you must select the service agreement to be severed.
- After the Severance Process - Main page appears, specify a **Severance Process Template**. **Severance Process Template** defines the severance events in the process. You can override these events on the Events page. For more information, refer to [Setting Up Severance Process Templates](#).
- Use **Severance Amount Base Date** to define the arrears cutoff date that the system uses when it determines if a severance process can be cancelled. The system cancels a severance process when its SA's debt that is older than X is less than or equal to zero. X is the date specified in **Severance Amount Base Date**. You can have the system calculate this date for you by entering the age of the arrears in the field embedded in **Calculate Date Using ___ Days In Arrears**.
- Save the severance process.

How To Change Severance Events

When a severance process is first created, it has one or more severance events. The events are the activities that will be performed to persuade the customer to pay the outstanding debt.

The number and type of events that are created when a severance process is initiated are defined on the severance process's severance process template. The following points describe how to add / change / delete events on a severance process if the defaulted events are not satisfactory.

- Use **Control Central** to choose the account with the severance process whose events need to be changed.

After the account is populated on Control Central, choose the **Severance Process > Search** option on the account context menu to transfer to the severance process transaction in update mode.

- To add a new event, transfer to the **Events** tab and press the + button in the **Severance Events** scroll to add a new event. At this point, the event has not been added to the database; rather, it just exists in memory. Before you add the event to the database, you must specify the following information:
 - Choose an **Event Sequence** so that the new event will be positioned properly in respect of the other events.
 - Choose a **Severance Event Status** of Pending.
 - Choose the desired **Severance Event Type**.
 - If the activation of the new event is dependent on the successful completion of earlier events, turn on **Dep on Other Event** and then a) specify the sequences of the dependent events in **Event Dependencies** and b) specify the number of days after the completion of the last dependent event when the new event should be activated.
 - If the activation of the new event is NOT dependent on the successful completion of earlier events, turn off **Dep on Other Event** and use **Trigger Date** to define the date on which the event should be activated (i.e., completed).

To delete an existing event, transfer to the **Events** tab and use the scroll arrows to toggle to the desired severance event. When the desired severance event appears, press the - button to remove the event. At this point, the event has not been removed from the database; rather, it's been removed in memory.

To change an existing event, transfer to the **Events** tab and use the scroll arrows to toggle to the desired severance event. When the desired severance event appears, make the desired changes.

After all desired changes have been made, save the severance process.

How To Cancel A Severance Process

The system will automatically cancel a severance process when its service agreement's debt has been reduced sufficiently. Refer to [How Are Severance Processes and Events Cancelled](#) for more information.

The following points describe how to manually cancel a severance process.

- Use **Control Central** to choose the account with the severance process to be cancelled.
- After the account is populated on Control Central, choose the **Severance Process > Search** option on the account context menu to transfer to the severance process transaction in update mode. A list of all severance processes associated with the account appears. If only one severance process exists, it is automatically selected for you.
- On the **Main** tab, click Cancel.
- When the warning dialog appears, click OK to continue. The severance process and its events are canceled.

Write-Off Process Maintenance

A write-off process is a series of events (e.g., letters, collection agency referrals) meant to encourage an account to pay its unpaid, finaled debt. Linked to the write-off process are the specific service agreements that contributed to the delinquent debt. The topics in this section describe the pages on which write-off process-related information is maintained.

Fastpath:

For more information about write-off processes, refer to [The Lifecycle Of A Write Off Process And Its Events](#).

Write Off Process - Main Information

The Main page contains core write-off process information. Open this page using **Menu > Credit & Collection > Write Off Process > Search**.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Perform Common Write-Off Process Functions](#) for more instructions describing how to use this transaction.

Description of Page

The top portion of every page contains the following information:

Write Off Process is a concatenation of summary information about this write-off process. It is composed of the name of the main customer on the account, the write-off status, the reason code for the write-off status, the write-off class control name, and the creation date of the process.

Write Off Process ID is the unique system-generated identifier for this write-off process.

The remaining fields are maintained on the main write-off process page.

Account ID is the system-generated account number. The name of the main customer on the account and its customer class are displayed adjacent.

Write-off Status defines the state of the write-off process. The following values may exist:

Active The system creates a write-off process in the Active state. A write-off process remains in this state until the last event linked to the process is complete OR the finalized debt is paid off OR you want to stop the process for whatever reason.

Inactive A write-off process becomes Inactive when the last event linked to the process is completed OR the finalized debt is paid off OR you want to stop the process for whatever reason. The **Reason** field tells you how a write-off process became inactive.

Fastpath:

To completely understand the significance of a write-off process' status, refer to [The Lifecycle Of A Write Off Process And Its Events](#).

Reason defines how a write-off process became Inactive or why a write-off process is Active. The following values may exist:

Canceled by User This reason should be used when a user manually inactivates a write-off process (for whatever reason).

Canceled by System This reason is populated by the system when it cancels a write-off process. The system automatically cancels a write-off process when all finalized debt associated with the process' service agreements is paid.

Events Pending This reason is populated by the system when a process has pending events.

Completed This reason is populated by the system when it completes the last event linked to the write-off process.

Write Off Control defines the write-off debt class (i.e., the type of debt) associated with the write-off process. This is important as it controls which service agreements can be linked to the write-off process (every service agreement is associated with a specific write-off debt class). This field is gray when there are service agreements linked to the write-off process.

Note:

Multiple write-off processes may be linked to an account. It's important to be aware that if an account's service agreements reference multiple write-off debt classes, a write-off process is created for each write-off debt class that you want to write-off.

Multiple write-off processes per write-off debt class. A given write-off debt class for an account may have multiple ongoing write-off processes at any point in time. However, a given service agreement may only be on one active write-off process at any point in time.

Write Off Process Template defines the write-off events in the process. You can override these events on the **Events** page.

Note:

Changing the template. If you change the template when all events are pending, the system will remove the pending events and replace them with the new template's events.

Fastpath:

For more information, refer to [Setting Up Write Off Process Templates](#).

Create Date/Time defines the start date/time of the write-off process. This is important as it affects the trigger dates of the process' write-off events. This field becomes protected after the write-off process exists on the database. If you need to change the trigger date on the events you can navigate to the **Events** tab and change the dates manually. Alternatively, you can perform the following "trick":

- Change the Write-off Process Template to something (anything). Doing this causes the **Create Date/Time** to become unprotected.
- Specify the date of the first write-off event in the newly unprotected **Create Date/Time**.
- Change the **Write-off Process Template** back to the desired value. When you change the template, the system removes the events and creates new ones using the **Create Date/Time**.

Enter any **Comments** about the write-off process.

The [tree](#) at the bottom of the page shows a variety of information about the **account** and the write-off process including:

- The service agreements linked to the write-off process.
- The events linked to the write-off process.
- The amount of debt associated with the account's debt classes.
- A summary of other active collection activities (i.e., collection, severance and write-off processes) associated with the **account**.

Write Off Process - SAs (Service Agreements)

The SA page contains the service agreements whose unpaid, finalized debt is being managed by the write-off process. Open this page using **Menu > Credit & Collections > Write Off Process > Search** and navigate to the **SAs** page.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Perform Common Write-Off Process Functions](#) for more instructions describing how to use this transaction.

Description of Page

The top portion of every page in this page contains the following information:

Write Off Process is a concatenation of summary information about this write-off process. It is composed of the name of the main customer on the account, the write-off status, the reason code for the write-off status, the write-off control name, and the creation date of the process.

ID is the unique system-generated identifier for this write-off process.

To modify a service agreement linked to the write-off process, simply move to a field and change its value. To add a new service agreement, press + to insert a row, then fill in the information for each field. The following fields display:

Service Agreement identifies the service agreement being collected. Information about the service agreement is displayed adjacent.

Write Off SA Status defines the state of the service agreement in respect of the write-off process. The following values may exist:

Active An Active service agreement is one currently being collected by the write-off process. The service agreement will remain in this state until the last event linked to the process is complete OR the service agreement is closed (due to payment in full) OR you want to remove the service agreement from the write-off process for whatever reason.

Inactive A service agreement becomes Inactive when the last event linked to the process is completed OR the service agreement is closed (due to payment in full) OR you want to remove the service agreement from the write-off process for whatever reason

The **Write Off Amount** is the amount of debt that initially triggered the write-off process.

The **SA Balances** area displays how much is owed for the service agreement. The **Days Old** and **Amount** information shows how old the current balance is. This information will be blank if the current balance is a credit.

Current Balance indicates the amount the customer currently owes for the service. **Payoff Balance** indicates the amount the customer would owe if they wanted to close the service agreement. This value is only displayed when it differs from the current balance.

Fastpath:

Refer to [Current Amount versus Payoff Amount](#) for more information.

Write Off Process - Events

The events page contains the activities that will be performed to persuade the customer to pay the outstanding debt. Open this page using **Menu > Credit & Collection > Write Off Process > Search** and navigate to the **Events** page.

Fastpath:

The **Description of Page** section below describes the fields on this page. Refer to [How To Perform Common Write-Off Process Functions](#) for more instructions describing how to use this transaction.

Note:

We strongly recommend that you understand the information described in [How Are Write-off Events Completed?](#) before using this page.

Fastpath:

The number and type of events associated with a write-off process are defined by the process's write-off process template (which is defined on the first page). Refer to [Setting Up Write Off Process Templates](#) for more information.

Description of Page

The top portion of every page in this page contains the following information:

Write Off Process is a concatenation of summary information about this write-off process. It is composed of the name of the main customer on the account, the write-off status, the reason code for the write-off status, the write-off class control name, and the creation date of the process.

ID is the unique system-generated identifier for this write-off process.

The **Write Off Events** scroll contains individual write-off events that comprise the write-off process. Only one event is displayed at a time. The grid contains the customer contacts that were created by the system when a particular write-off event was triggered (if any).

Event Sequence is the unique identifier of the event.

Write Off Event Status defines the state of the event. The following diagram shows the possible lifecycle of a write-off event:

Write-off events are initially created in the pending state.

When the system sees a pending event with a **Trigger Date** on or before the current date, the system executes the event's activity and completes the event.

You can cancel an individual write off event by setting the status to cancelled.

The **Write Off Event Type** defines the event's activity (e.g., the related debt is referred to a collection agency, a To Do entry is generated, a letter is sent).

Fastpath:

For more information refer to [Setting Up Write Off Process Templates](#).

The **Trigger Date** defines the date when the system completes (i.e., executes) the event.

Fastpath:

For more information about a write-off event's trigger date, see [Write-off Event Trigger Date](#).

If the status of the event is complete, the **Completion Date** is displayed with the date on which the system completed the event. If the status of the event is cancelled, the **Canceled Date** is displayed with the date on which the event was cancelled.

The **Customer Contact** information contains information when the event template causes a letter to be generated (because letters are created by customer contacts).

How To Perform Common Write-Off Process Functions

The topics in this section describe how to perform common write-off process maintenance functions. Refer to [The Lifecycle Of A Write-off Process](#) for more information about write-off processes. Refer to [The Big Picture Of Write-off Processing](#) for high level information about write-off processing.

How To Create A Write-Off Process

99.9% of all write-off processes are created by the [Write-Off Monitor](#) and require no human intervention before they are executed (refer to [How Are Write-off Processes Created](#) for information about how the account debt monitor creates write-off processes). The other 0.1% are created by users on-line / real time. The following points describe how to create the 0.1%.

- Use **Control Central** to choose the account that requires a new write-off process.
- After the account is populated on Control Central, choose the **Write Off Process > Add** option on the **account context menu** to transfer to the write-off process transaction in add mode.
- After the Write-off Process - Main page appears, specify the appropriate **Write Off Control**. **Write Off Control** defines the debt class (i.e., the type of debt) associated with the write-off process. This is important as it controls which service agreements can be linked to the write-off process (every service agreement is associated with a

specific debt class). It's important to be aware that if an account's service agreements reference multiple write-off debt classes, a write-off process must be created for each write-off debt class that you want to collect.

- Choose a **Write Off Process Template**. **Write Off Process Template** defines the write-off events in the process. You can override these events on the Events page. For more information, refer to [Setting Up Write-off Process Templates](#).
- Navigate to the **SAs** page to define the specific service agreement's whose debt is covered by this write-off process. You must define at least one service agreement.
- Save the write-off process.

How To Change Write Off Events

When a write-off process is first created, it has one or more write-off events. The events are the activities that will be performed in the course of the write-off process.

The number and type of events that are created when a write-off process is initiated are defined on the write-off process's write-off process template. The following points describe how to add / change / delete events on a write-off process if the defaulted events are not satisfactory.

- Use **Control Central** to choose the account with the write-off process whose events need to be changed.

After the account is populated on Control Central, choose the **Write Off Process** > **Search** option on the account context menu to transfer to the write-off process transaction in update mode.

To add a new event, transfer to the **Events** tab and press the + button in the **Write Off Events** scroll to add a new event. At this point, the event has not been added to the database; rather, it just exists in memory. Before you add the event to the database, you must specify the following information:

- Choose an **Event Sequence** so that the new event will be positioned properly in respect of the other events.
- Choose a **Write Off Event Status** of Pending.
- Choose the desired **Write Off Type Code**.
- Use **Trigger Date** to define the date on which the event should be activated (i.e., completed).

To delete an existing event, transfer to the **Events** tab and use the scroll arrows to toggle to the desired write-off event. When the desired write-off event appears, press the - button to remove the event. At this point, the event has not been removed from the database; rather, it's been removed in memory.

To change an existing event, transfer to the **Events** tab and use the scroll arrows to toggle to the desired write-off event. When the desired write-off event appears, make the desired changes.

After all desired changes have been made, save the write-off process.

How To Cancel A Write-Off Process

The system will automatically "remove" service agreements from a write-off process when the close (i.e., when their balance becomes zero). When all service agreements are "removed" from a write-off process, the write-off process is cancelled. Refer to [How Are Write off Processes and Events Cancelled](#) for more information.

The following points describe how to manually cancel a write-off process.

- Use **Control Central** to choose the account with the write-off process to be cancelled.
- After the account is populated on Control Central, choose the **Write Off Process** > **Search** option on the **account** context menu to transfer to the write-off process transaction in update mode. A list of all write-off processes associated with the account appears. If only one write-off process exists, it is automatically selected for you.
- On the **Main** tab, click Cancel.
- When the warning dialog appears, click OK to continue. The write off process and its pending events are canceled.

Writing Off Uncollectable Debt

The Write-off pages described in this section describe the transaction used to manually transfer bad debt to a write-off service agreement.

Write Off - Main

Most write-offs happen behind-the-scenes as part of the automated write-off processing. If you need to perform a partial write-off or cannot wait for the automated process, open **Menu > Credit & Collection > Write Off > Search**.

Fastpath:

Refer to [The Big Picture of Write Off Processing](#) for background information about the write-off process.

Description of Page

Account contains the name of the main customer on the account. The **Account ID** is the account whose debt is being written off.

The **Candidate SAs** scroll contains one row for each of the account's service agreements that is eligible for write-off. The system displays the respective age and amount of each SA's debt. The accumulated total of all such debt appears in **Write Off Amount**. The checkbox adjacent to this field is used to confirm that you want to write-off the adjacent debt.

When you click the **Create** button, the system writes off the selected debt by executing the write-off algorithm that's plugged in on the account's [customer class](#). Refer to [The Ramifications of Write Offs in the General Ledger](#) for an explanation of how the base-package algorithm (CCWO-DST) works.

How To Manually Write-Off Debt

To manually write-off debt:

- Select the **Account** in question on [Write Off - Main](#).
- Select the debt to be written off for each **Candidate SA**. You do this by turning on the checkbox adjacent to **Write Off Amount**. You can also vary the amount of the **Write Off Amount**.
- Click the **Create** button.

Write Off - Write Off SAs

The Write Off SAs page shows all write-off service agreements linked to the account along with their respective current and payoff balance. Use **Menu > Credit & Collection > Write Off > Search** and navigate to the **Write Off SAs** page.

Description of Page

Account contains the name of the main customer on the account. The **Account ID** is the account associated with the WO SAs displayed below.

The grid contains an entry for every write-off service agreement linked to the account. The following information is displayed for each write-off service agreement:

- The service agreement's **SA Information** is displayed.
- **Current Balance** contains the WO SA's current balance (i.e., the amount written off).
- **Payoff Amount** contains the WO SA's payoff balance (i.e., the amount written off).

Note:

Write off SA. There is a field on SA type called [Special Role](#). Only those SA types with a role of Write Off are displayed.

Collection Referral

The Collection Referrals page contains information about an account's debt that has been referred to a collection agency.

Fastpath:

Refer to [How Do Collection Agency Referrals Work?](#) for more information about how the system creates and maintains collection agency referrals as part of the automated write off processing. In theory, you need only access this page if you need to override the automated processing.

Open **Menu > Credit & Collection > Collection Agency Referral > Search** to maintain this information.

Description of Page

The **Agency Referrals** scroll contains one entry for every collection agency referral associated with the account. The following information is defined for each referral.

Use **Collection Agency** to define the agency to which the referral is being sent.

Start Date is the date on which the referral was initially created.

Referral Status defines if the referral is Active or Closed.

Use **Comments** to describe anything unusual about the referral.

The grid contains the history of interactions with the collection agency. Each time an account's debt is referred to a collection agency, the system creates a referral history record.

You can communicate changes about the referral by inserting a new row in the collection. For example,

- If you need to change the referral amount, insert a row and indicate the **Creation Date** and a **Referral History Reason** of Change Referral.
- If you need to cancel the referral, insert a row and indicate a **Referral History Reason** of Referral Cancellation.
- If the customer pays, insert a row and indicate a **Referral History Reason** of Referral Paid.
- If you need to add a new referral, insert a row and indicate a **Referral History Reason** of Initial Referral.

Collection agency referral records are interfaced to the respective collection agency using the batch process defined on the collection agency control record (refer to [Setting Up Collection Agencies](#)). The **Batch Control** process and the respective **Batch Number** in which the records were interfaced to the collection agency are displayed adjacent.

The **System Generated** switch is on for those collection agency referrals created as part of the automated write-off processing. Refer to [How Do Collection Agency Referrals Work?](#) for more information.

Downloading Collection Agency Referrals

Collection referral records need to be periodically extracted and sent to collection agencies.

C1-CAGYX - Collection Agency Referral Extract

This batch was developed using the plug-in driven extract template. It contains a select record and process record algorithm. The records can be extended to include custom fields that your implementation needs. The process records algorithm type delivered with the system, C1-CAGYX-PR, contains instruction for extending the record.

Collection Agency Referral Record

This section describes the layout of the record created by C1-CAGYX.

| Field | Format | Source/Value/Description |
|------------|--------|--------------------------------------|
| Account ID | A10 | Collection Agency Referral's Account |
| Name | A254 | Account's Main Person Primary Name |

| | | |
|--------------------------------------|-------|---|
| Person Type | A2 | Person or Business Indicator (Main Person) |
| Person Type Description | A60 | Description of Person Type |
| ID Type | A8 | Primary ID Type (Main Person) |
| ID Value | A100 | Primary ID Value (Main Person) |
| Primary Phone Type | A30 | Person Contact Type (Main Person) |
| Primary Phone Number | A254 | Primary Phone Person Contact Number (Main Person) |
| Primary Phone Number Extension | A6 | Primary Phone Person Contact Extension (Main Person) |
| Email Address | A254 | Primary Email Person Contact (Main Person) |
| Mailing Address | A1241 | Mailing Address (Main Person). See below for the fields. See Address Subrecord for the fields. |
| Service Address | A1241 | Service Address of Premise linked to SA being written off. One chosen. Stopped SAs given priority. See below for the fields. See Address Subrecord for the fields. |
| Customer Class | A8 | Account's Customer Class |
| Customer Class Description | A60 | Customer Class Description |
| Currency | A3 | Account's Currency |
| Referral Activity Date | D10 | Collection Referral History Create Date |
| Referral Activity Reason | A4 | Collection Referral History Reason |
| Referral Activity Reason Description | A60 | Collection Referral History Reason Description |
| Referral Activity Amount | N13.2 | Collection Referral History Referral Amount |
| Initial Referral Date | D10 | Collection Agency Referral Initial Referral Date |
| Initial Referral Amount | N13.2 | This is the amount on the record marked with a referral reason of initial. If more than one initial record is found the newest one is chosen by default. A parameter on the process record algorithm allows provides the option of choosing the oldest, newest or some of all initial records. Note: additional initial records can be created manually. The system only creates the first one. |
| Initial Referral Comments | A254 | Collection Agency Referral Comments |

| | | |
|---|-------|--|
| Connect Date | D10 | If the collection agency referral is linked to a write off process, this is the oldest start date for SAs associated with the write off process. If the collection agency referral is not linked to a write off process this is the oldest start date for SAs on the account, giving preference to stopped SAs. |
| Disconnect Date | D10 | If the collection agency referral is linked to a write off process, this is the latest end date for SAs associated with the write off process. If the collection agency referral is not linked to a write off process this is the latest end date for SAs on the account, giving preference to stopped SAs. |
| Write Off Date | D10 | If the collection agency referral is linked to a write off process, this is the creation date for the write off process. If the collection agency referral is not linked to a write off process, the initial referral date is noted here. |
| Payments Since Last Activity | N13.2 | If the collection agency referral is linked to a write off process, this is the sum of pay segment transactions since the last agency referral history record up to the current record. If the collection agency referral is not linked to a write off process, the sum reflects all SAs. |
| Canceled Payments Since Last Activity | N13.2 | If the collection agency referral is linked to a write off process, this is the sum of canceled pay segment transactions since the last agency referral history record up to the current record. If the collection agency referral is not linked to a write off process, the sum reflects all SAs. |
| Adjustments Since Last Activity | N13.2 | If the collection agency referral is linked to a write off process, this is the sum of adjustment and canceled adjustment transactions since the last agency referral history record up to the current record. If the collection agency referral is not linked to a write off process, the sum reflects all SAs. |
| Fin Resp - Name | A254 | Primary Name of Financially Responsible Person on Account |
| Fin Resp - Person Type | A2 | Person or Business Indicator (Financially Responsible Person) |
| Fin Resp - Person Type Description | A60 | Description of Person or Business Indicator (Financially Responsible Person) |
| Fin Resp - ID Type | A8 | Person's Primary ID Type (Financially Responsible Person) |
| Fin Resp - ID Value | A100 | Person's Primary ID Value (Financially Responsible Person) |
| Fin Resp - Primary Phone Type | A30 | Primary Phone Person Contact Type (Financially Responsible Person) |
| Fin Resp - Primary Phone Number | A254 | Primary Phone Person Contact Number (Financially Responsible Person) |
| Fin Resp - Primary Phone Number Extension | A6 | Primary Phone Person Contact Extension (Financially Responsible Person) |

| | | |
|----------------------------|-------|--|
| Fin Resp - Mailing Address | A1241 | Mailing Address (Financially Responsible Person). See Address Subrecord for the fields. |
|----------------------------|-------|--|

End of File Footer Record

Payment Arrangements and Pay Plans

Payment arrangements and pay plans are very similar concepts in that they are both used to payoff debt. This section describes each method.

Note:

To distinguish between payment arrangements and pay plans, it is helpful to understand some terminology: 1) an agreement with a customer to pay off their debt as part of their future bills (sometimes referred to as "current bill plus") is a **payment arrangement**, 2) an agreement with specifically scheduled payments is called a **pay plan**.

Setting Up Payment Arrangement Requests

A payment arrangement request is used to manage the step-by-step process of starting a payment arrangement. These steps can include: checking the account's eligibility for a payment arrangement, capturing the terms of the payment arrangement (i.e. amount of the outstanding debt to include in the payment arrangement, down payment amount, installment details, etc.), performing required approvals, monitoring the payment of an applicable down payment, and the actual creation of the payment arrangement service agreement. Refer to [The Big Picture Of Payment Arrangement Requests](#) for more information

The topics in this section describe how to set up a payment arrangement request.

Starting A Payment Arrangement Request

There are multiple ways start a payment arrangement request:

- From Control Central:
 - Select the Account.
 - Navigate to the **Payment Arrangements** tab page
 - On the [Payment Arrangement Requests](#) zone, click on the **New Payment Arrangement** button.
- From the Main Menu: Navigate using **Menu > Credit & Collection > Payment Arrangement Request > Add**.
- From the **Payment Arrangement Request Search** portal, click on the **Add** button on the page header.
- From a page/zone that displays the Account: On the Account context menu, navigate using **Go To Payment Arrangement Request > Add**.

All navigation options launch the [Payment Arrangement Request Process Flow](#), which will take you through each of the steps needed to set up a payment arrangement request.

Maintaining Payment Arrangement Requests

A payment arrangement request is used to start a payment arrangement. Aside from capturing the agreed upon terms of the payment arrangement (such as the service agreements and debts to include, number of installments and installment amount), it can also manage any applicable prerequisites for starting the payment arrangement, e.g. down payments, approvals, etc.

Refer to [The Big Picture Of Payment Arrangement Requests](#) for an overview of payment arrangement request functionality.

This section describes how to view and maintain payment arrangement requests.

Navigate using **Menu > Credit & Collection > Payment Arrangement Request > Search**. You are brought to a query portal with options for searching for payment arrangement requests.

Once a payment arrangement request record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Payment Arrangement Request** zone shows the details of the payment arrangement request. Refer to the zone's embedded help for more information.

The **Notes** zone allows users to capture additional notes on the payment arrangement request.

Payment Arrangement Request Process Flow

The base product provides a **Payment Arrangement Request** process flow type that includes three steps:

- Execution of one or more eligibility criteria, to determine whether or not the account is eligible for a payment arrangement. The results of each eligibility criteria and the overall eligibility result are displayed on the first panel of the process flow
- Setting up the terms of the payment arrangement:
 - The service agreements and debt to include in the payment arrangement
 - If a down payment must be paid prior to starting the payment arrangement, the down payment amount can be a percentage or a fixed-amount portion of the total payment arrangement amount
 - The remaining payment arrangement amount (after down payment, if applicable)
 - The number of installments
 - The installment amount
- Review of the eligibility results and the agreed upon payment arrangement terms before submitting the payment arrangement request

Refer to the **Payment Arrangement Request** process flow panels for more details. Also refer to [Understanding Process Flows](#) for information about how process flows work, in general.

Viewing Payment Arrangement Request History

An account's payment arrangement request history can be viewed on the [Payment Arrangement Requests](#) zone of the [Control Central – Payment Agreements](#) page. Refer to this zone's embedded help for more details.

Setting Up Payment Arrangements

A payment arrangement is an agreement with a customer to payoff severely overdue debt in installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount. Refer to [The Big Picture Of Payment Arrangements](#) for information about the financial ramifications of payment arrangements and for a description of how the system monitors payment arrangements.

The topics in this section describe how to set up a payment arrangement and how to break a payment arrangement (if a customer doesn't fulfill their obligations).

Pay Arrangement - Main

Note: This page is used to create the payment arrangement service agreement. If you require eligibility checking and other prerequisites for starting a payment arrangement, set up a [Payment Arrangement Request](#) instead.

This page allows you to set up a payment arrangement. When you create a payment arrangement, the system performs the following functions:

- It creates a payment arrangement service agreement (PA SA). It sets the installment amount on this service agreement equal to the installment amount specified on this page.
- It transfers delinquent debt from each delinquent service agreement(s) to the new PA SA.
- As it transfers the debt to the PA SA, it creates synchronizing adjustments to reduce the PA SA's current balance by the amount transferred. Why? Because when delinquent debt is transferred to the PA SA, its current balance increases. Because current balance contains the amount the customer currently owes, this balance must be reduced because the customer is going to payoff the debt in installments (and therefore they don't currently owe anything on the PA SA).

Note:

Payment Arrangement Algorithm. The system only performs the above steps if the new PA SA's SA Type does not reference a Payment Arrangement algorithm. If your implementation uses a Payment Arrangement algorithm, then the logic performed when a payment arrangement SA is created will depend on this algorithm.

You could do the above functions by adding a new service agreement (using the service agreement page) and creating transfer adjustments (using the adjustment page). However, this is tedious. Rather, open **Menu > Credit & Collection > Payment Arrangement > Add** to set up a payment arrangement.

Description of Page

SA (service agreement) **Info** and **SA ID** are displayed on every page. These values only appear after the payment arrangement service agreement (PA SA) exists on the database. The **ID** is a system assigned random number that stays with the payment arrangement service agreement for life. The **SA Info** is a concatenation of important details about the payment arrangement service agreement and its account.

The **Current Balance** that appears beneath **SA Info** contains the PA SA's current balance. When you initially set up a PA SA this balance will be zero. It is only non-zero if the customer has not paid a billed installment.

Payoff Balance beneath **SA Info** contains the PA SA's payoff balance. The payoff balance is the total amount to be paid off over the PA SA's life. It is only non-zero after delinquent funds have been transferred to the PA SA. This balance is only displayed when it differs from the **Current Balance**.

Fastpath:

Refer to [Current Amount versus Payoff Amount](#) for more information.

Account contains the name of the main customer on the account. **Account ID** is the account associated with the PA SA.

The occurrences of **Current** and **Payoff Balance** below **Account** are the account's respective balances. These values are displayed to help you confirm exactly how much the customer currently owes versus how much they will have to payoff over time (remember, after you transfer funds to a payment arrangement, the amount transferred is reduced from the account's current balance).

The **Candidate SAs** scroll contains one row for each of the account's service agreements with aged debt. The system displays the respective age and amount of each SA's debt. All debt that is checked will be transferred to the PA SA when you click **Create**.

Warning:

The system automatically indicates that all debt that isn't "new" (i.e., debt that the customer has seen on their bills) should be transferred to the payment arrangement. It does this by checking each parcel of aged debt.

Total is the sum of ALL current balances (not just the checked amounts) from all candidate SAs.

The next two fields are used to populate the arrangement amount (i.e., the amount the customer will be billed on each bill).

- The **Installments** field exists to calculate the **Arrange Amount** (the next field) when a time period has been stipulated. Simply enter the number of installments and tab out. When you tab out of the field, the system sets the **Arrange Amount** equal to **New Payoff Balance / Installments**.

Note:

Arrange Amount may not add up. The **Arrange Amount** is rounded up so that if you multiply the number of installments by the calculated installment amount, the result will be greater than the PA SA's payoff amount. Don't worry - only the actual dollar amount of the PA SA's total debt will be billed by the system. The last installment will be slightly lower than the other installments.

- Use the **Arrange Amount** field to define the payment arrangement's installment amount if a specific dollar amount has been stipulated. For example, if the customer agrees to pay off their delinquent debt by paying an additional \$50 on each bill, you'd enter "50" in this field. Note - If you enter a dollar amount in this field and tab out, the system will calculate the number of installments and display the number in the **Installments** field.

New Payoff Balance contains the PA SA's payoff balance. This is the total amount of debt that will be paid off over the lifetime of the PA SA. This value equals the current payoff balance on the PA SA plus all selected debt from the **Candidate SAs** scroll.

Define the **CIS Division** and **SA Type** of the payment arrangement service agreement.

Note:

Payment arrangement SA types. There is a field on SA type called Special Role. Only those SA types with a role of Payment Arrangement may be selected.

Clicking **Create** (or **Change**) causes the system to perform the following:

- It adds / updates a payment arrangement service agreement (PA SA). It sets the installment amount on this service agreement equal to the installment amount specified on the page.
- It transfers delinquent debt from the delinquent service agreement(s) to the PA SA. The adjustment type used to transfer these funds is defined on the PA SA's SA type.
- It reduces the current balance on the PA SA by the amount of debt transferred to the PA SA. Why? Because when delinquent debt is transferred to the PA SA, its current balance increases. Because current balance contains the amount the customer currently owes, this balance must be reduced because the customer is going to pay off the debt in installments (and therefore they don't currently owe anything). The adjustment type used to transfer these funds is defined on the PA SA's SA type.

Note:

Payment Arrangement Algorithm. The system only performs the above steps if the new PA SA's SA Type does not reference a Payment Arrangement algorithm. If your implementation uses a Payment Arrangement algorithm, then the logic performed when a payment arrangement SA is created will depend on this algorithm.

You can transfer to the **History** page to view the transfer adjustments that were created by the system when it transferred the selected debt to the PA SA.

Clicking **Break** causes the PA SA to become broken. Please refer to the note below for what transpires when a PA is broken.

Note:

Break logic is in a plug-in. Please be aware that the logic that is executed when a payment arrangement is broken exists in a plug-in algorithm (plugged-in on the PA SA's SA type). An implementation can use either a Break Payment Arrangement algorithm which the system calls when a payment arrangement is broken, or the Payment Arrangement algorithm which the system calls when a payment arrangement is created, canceled or broken. These two algorithms are mutually exclusive on the SA Type.

Break Payment Arrangement Algorithm. The base package algorithm (SAT BREAK PA) expires the PA SA and cancels all related frozen adjustments, returning the debt to the original service agreements. Because this logic is in a plug-in, you can develop alternative logic and plug it in if the base package logic is not satisfactory.

How To Set Up A Payment Arrangement

Note: The following steps only apply to setting up payments using the [Payment Arrangement – Main](#) page.

To set up a new payment arrangement:

- Select the **Account** in question.
- Select the debt to be transferred to the payment arrangement (by turning on/off the checkbox adjacent to the **Candidate SAs** amounts).
- Enter the number of **Installments** and the total **Arrange Amount**.
- Define the **CIS Division** and **SA Type** of the new payment arrangement service agreement.

Note: If the service agreement's account's CIS Division's **Restrict to Account CIS Division** flag is set to *Restricted*, the CIS Division is set to the account's CIS Division and cannot be changed

- Click the **Create** button.

How To Add Additional Debt To A Payment Arrangement

To transfer additional debt to an existing payment arrangement:

- Select the **SA ID** of the existing payment arrangement.

- Select the debt to be transferred to the payment arrangement (by turning on/off the checkbox adjacent to the **Candidate SAs** amounts).
- Enter the number of **Installments** and the total **Arrange Amount**.
- Click the **Create** button.

Note:

After transfer. After transferring the funds to the payment arrangement service agreement, confirm the account's payoff and current balances make sense (the payoff balance is the total amount of debt that the account will eventually have to payoff, the current balance is how much they currently owe, i.e., the amount that credit and collections monitors). The account's payoff and current balances are displayed in the page's second section. If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

How To Break A Payment Arrangement

You would break a payment arrangement when a customer doesn't make the agreed payments. Typically, your credit and collections processes will break a payment arrangement behind-the-scenes. Refer to [The Big Picture Of Payment Arrangements](#) for information about how the system monitors payment arrangements.

If you want to manually break a payment arrangement simply select the **SA ID** of the existing payment arrangement and click the **Break** button.

How To Cancel A Payment Arrangement

You would cancel a payment arrangement if you made a mistake and never intended to set up the payment arrangement in the first place. To cancel a payment arrangement

- Select the **SA ID** of the existing payment arrangement and navigate to the **History** tab.
- Click the **Cancel** button to cancel the transfer adjustments that were used to transfer debt to the payment arrangement from the customer's regular service agreements.
- Next, navigate to the payment arrangement SA's (PA SA) financial history page (using the service agreement context menu). You will see that there are a few non-canceled adjustments (these were used to change the PA SA's current balance after debt was transferred to the PA SA). Cancel these adjustments by drilling down on these adjustments and then click the **Cancel** button on the adjustment maintenance transaction.
- Finally, display the PA SA on the service agreement maintenance transaction and cancel the payment arrangement.

Note:

Payment Arrangement Algorithm. If the payment arrangement SA's SA Type references a Payment Arrangement algorithm, then the logic performed when the PA SA is canceled will depend on this algorithm.

Pay Arrangement - History

Open **Menu > Credit & Collection > Payment Arrangement > Search** and navigate to the **History** page to view the transfer adjustments that were created by the system when it transferred the selected debt to the PA SA.

Description of Page

SA (service agreement) **Info** and **ID** are displayed on every page in this page. These values only appear after the payment arrangement service agreement (PA SA) exists on the database. The ID is a system-assigned random number that stays with the service agreement for life. The SA Info is a concatenation of important details about the service agreement and its account.

Current Balance beneath **SA Info** contains the PA SA's current balance. When you initially set up a PA SA this balance will be zero. It is only non-zero if the customer has not paid a billed installment.

Payoff Balance beneath **SA Info** contains the PA SA's payoff balance. The payoff balance is the total amount to be paid off over the PA SA's life. It is only non-zero after delinquent funds have been transferred to the PA SA. This balance is only displayed when it differs from the Current Balance.

Fastpath:

Refer to [Current Amount versus Payoff Amount](#) for more information.

Account contains the name of the main customer on the account. **Account ID** is the account associated with the PA SA.

The occurrences of **Current** and **Payoff Balance** below **Account** are the account's respective balances. These values are displayed to help you confirm exactly how much the customer currently owes versus how much they will have to payoff over time (remember, after you transfer funds to a payment arrangement, the amount transferred is reduced from the account's current balance).

The **Adjustment Details** area contains one row for each transfer adjustment used to transfer delinquent debt to the PA SA. Click the Go To button to transfer to the adjustment page to view the details of an adjustment (or to cancel the adjustment if you want to reinstate the debt on the originating service agreement).

Total Frozen Adj is the total amount of debt transferred to the payment arrangement that has not been canceled.

Clicking **Cancel** causes the system to cancel all related frozen adjustments, returning the debt to the original service agreements. You must specify the cancel reason by selecting it from the drop down list when Payment Arrangement Cancellation window is displayed.

Total Canceled Adj is the total amount of debt transferred to the payment arrangement that has been canceled.

Setting Up Pay Plans

A pay plan (PP) is an agreement with a customer to make specific payments on specific dates (as opposed to payment arrangements where the customer makes fixed payments as part of their regular bills).

Consider the following situations that would require a pay plan:

- A customer makes a request to payoff severely overdue debt in one or more installments. The existence of the pay plan insulates the portion of the debt covered by the plan from C&C processing (specifically, from the account debt monitor).
- A commercial or industrial customer cannot or will not post a deposit. This type of pay plan is not specifically paying off past debt; rather, it can be viewed as an installment plan to prepay a regular service agreement.

The topics in the following section describe how to set up a pay plan.

Pay Plan - Main

The pay plan transaction allows you to set up a pay plan. When you create a pay plan, the system performs the following functions:

- It creates an active pay plan using the pay plan type entered.
- It defaults the customer as the payor if no third party is defined.

Fastpath:

Refer to [The Big Picture Of Pay Plans](#) for information about the financial ramifications of pay plans and for a description of how the system monitors pay plans.

Open **Menu > Credit & Collection > Pay Plan > Search** to maintain a customer's pay plan.

Description of Page

Pay Plan and **Pay Plan ID** only appear after the pay plan is added to the database. **Pay Plan ID** is a system-assigned random number that stays with the pay plan for life. **Pay Plan** is a concatenation of important details about the pay plan.

Account ID identifies the account of the customer for which the pay plan exists. This field is protected once the pay plan is Active.

The **Status** displays the status of the pay plan. Refer to [The Lifecycle Of A Pay Plan](#) for more information about a pay plan's status.

Created by displays the id of the user who created the pay plan and the date and time on which it was created.

Clicking the **Cancel** button causes the pay plan's status to become cancelled.

Last Updated by displays the id of the user who last modified the pay plan and the date and time on which it was changed.

Select a Pay Plan **Type**. The Pay Plan Type defines the **Debt Class** whose debt is insulated by the pay plan. The account's **Current Balance** in this debt class appears beneath as well as the portion that is considered **Delinquent Debt**.

If a 3rd party is responsible for the pay plan's payment, **Third Party Payor** must be checked, and the associated 3rd party selected.

The **Payor Account Id** contains the account ID and name of the person responsible for making the pay plan's payments. If a **Third Party Payor** is responsible, the payor's account appears; otherwise the account whose debt is insulated by the pay plan appears.

The **Start Date** defines the first day on which the pay plan is tracked; it defaults to the current date.

Pay Method defines the manner in which the customer intends to fulfill payments under this pay plan.

Note:

Significance of payment method. A pay method can have a grace period associated with it. This period controls when a scheduled payment is considered to be missed. For example, a pay method of "postal" might have a grace period of 3 days. This would give the customer 3 extra days to make the scheduled payments before the pay plan is broken.

In addition to grace period, pay method also control if the system will automatically create an automatic payment on the scheduled payment date. If the pay method so indicates AND the account has been set up for automatic payment, the PPAPAY background process will create [Automatic Payments](#) on the scheduled payment date.

The **Scheduled Payments** grid contains the pay plan's scheduled payments. The **Scheduled Date** and **Scheduled Amount** must be entered for each scheduled payment. The **Total Amount** of the scheduled payments is displayed at the bottom.

Free format **Comments** can be entered to describe any special notes about the pay plan.

How To Set Up A Pay Plan

To set up a new pay plan:

- Select the **Account** in question on [Pay Plan - Main](#).
- Select the **Pay Plan Type** for the type.
- Identify a **Third Party Payor** if there is one.
- Select a **Pay Method**.
- Enter one or more **Scheduled Payments**. The **Total Amount** of the scheduled payments should cover the customer's **Delinquent Debt** if you want the pay plan to protect the customer from additional credit and collection activity.
- Click the **Save** button.

Reviewing Pay Plans

In addition to using this maintenance page for reviewing pay plans, Control Central has a pay plan tree that can be used to view pay plan history, including current status. Refer to [Pay Plan Tree](#) for more information.

Financial Transactions

In this section, we describe the financial transactions generated as a result of your bills, payments and adjustments.

The Big Picture Of Financial Transactions

The topics in this section provide background information about a variety of financial transaction issues.

**Fastpath:**

We strongly recommend familiarizing yourself with the topics described in [The Financial Big Picture](#) to fully appreciate the system's financial architecture.

Bill Segment Financial Transactions

A bill segment has a related financial transaction. The financial transaction contains the financial effects of the bill segment on the service agreement's current and payoff balances and on the general ledger.

If a bill segment is cancelled, another financial transaction is created to reverse the original financial transaction. The cancellation financial transaction appears on the next bill produced for the account as a bill correction.

**Fastpath:**

For more information about bill segment financial transactions, refer to [Bill Details](#).

Payment Segment Financial Transactions

A payment segment has a related financial transaction. The financial transaction contains the financial effects of the payment segment on the service agreement's current and payoff balances and on the general ledger.

If a payment segment is cancelled, another financial transaction is created to reverse the original financial transaction. The cancellation financial transaction appears on the next bill produced for the account as a negative payment.

**Fastpath:**

For more information about payment segment financial transactions, refer to [Payment Details](#).

Adjustment Financial Transactions

An adjustment has a related financial transaction. The financial transaction contains the financial effects of the adjustment on the service agreement's debt and on the general ledger.

If the adjustment is eventually cancelled, another financial transaction will be linked to the adjustment to reverse its financial effect. The cancellation financial transaction appears on the next bill produced for the account as an adjustment.

**Fastpath:**

For more information about adjustment financial transactions, refer to [Adjustment Details](#).

Financial Transactions And Aged Debt

When a financial transaction's related bill segment / payment segment / adjustment is frozen, the financial transaction (FT) is also frozen. When an FT is frozen, its service agreement's debt is impacted. It is important to stress the following in respect of this impact:

- The FT's GL details will be interfaced to the GL when the GL interface next executes.
- If the FT decreases the amount of debt, the customer's aged debt is affected immediately regardless of whether the FT appears on a bill.
- If the FT increases the amount of debt, the amount the customer owes from an aged debt perspective may or may not be affected by the FT. There is a switch on an FT called New Charge that controls the arrears behavior. If this switch is on, the customer's aged debt will not reflect the FT amount until the FT is swept onto a bill. The moment the FT is swept onto the customer's bill, the debt starts aging. If this switch is off, the date on which the FT starts aging must be defined in the Arrears Date field.
- The amount a customer owes in total is immediately affected by the FT regardless of whether the FT appears on a bill. This means that the amount of aged debt may not be in sync with the total amount owed. This seems odd, but is useful from a credit and collections perspective. You see, you probably don't want to start aging a FT until the customer has actually seen it.

Fastpath:

For more information, refer to [Financial Transactions Created Between Bills](#).

Current Balance versus Payoff Balance

Fastpath:

For information about current and payoff balance in general, refer to [Current Amount versus Payoff Amount](#).

The topics in this section describe when payoff amount differs from current amount for the various types of financial transactions.

Adjustments - Current Balance versus Payoff Balance

Fastpath:

For information about current and payoff balance for adjustments, refer to [Adjustments - Current Balance versus Payoff Balance](#).

Billing - Current Balance versus Payoff Balance

Fastpath:

For information about current and payoff balance for bill segments, refer to [Billing - Current Balance versus Payoff Balance](#).

Payment - Current Balance versus Payoff Balance

Fastpath:

For information about current and payoff balance for payment segments, refer to [Payment - Current Balance versus Payoff Balance](#).

The Source Of GL Accounts On Financial Transactions

Fastpath:

For information about the source of the distribution codes used to generate the GL accounts on the financial transactions, refer to [The Source Of GL Accounts On Financial Transactions](#).

Obscure Things That Can Happen

The topics in this section provide information about obscure things that can happen when a financial transaction (FT) is frozen.

A Stopped Service Agreement May Be Closed

If an FT causes a Stopped SA's current and payoff balances to become zero, the system closes the service agreement (i.e., the service agreement's status becomes Closed).

A Closed Service Agreement May Be Reactivated

After a service agreement is closed (i.e., after it's stopped and paid-in-full), it's possible for some types of financial transactions to be linked to the service agreement. These financial transactions could cause the current and/or payoff balances to become non-zero. If this happens, the system reactivates the service agreement (i.e., the service agreement's status becomes reactivated).

When a service agreement becomes reactivated, it becomes eligible for review by the write-off process monitor (when it next runs). The write-off process monitor will, in all likelihood, start a write-off process for the reactivated service agreement.

Financial events that can be linked to a closed service agreement are:

- The cancellation of a bill segment
- The freezing of a payment segment
- The cancellation of a payment segment
- The freezing of an adjustment
- The cancellation of an adjustment

A Write-Off Process May Be Deactivated If The SA Is Closed

When a service agreement becomes Closed, it will be removed from any ongoing write-off processes. This removal could cause the write-off process to become Inactive (if this is the last service agreement linked to the write-off process). The inactivation of the write-off process, could, in turn, cause collection agency referrals associated with the write-off process to be cancelled.

A Reactivated Service Agreement May Be Closed

After a service agreement has been reactivated (refer to the previous section for how this happens), a financial transaction (or transactions) may be linked to it that will cause the current and payoff balance to return to zero. If this happens, the system closes the service agreement (i.e., the service agreement's status becomes Closed).

All types of financial transactions can be posted to a Reactivated service agreement.

A Collection Process May Be Canceled When A Credit FT Is Frozen

Periodically, the system determines if an account's debt violates your collection criteria. If so, a collection process is created using the violated criteria's collection process template.

The Collection Process Monitor reviews an active collection process whenever one of its service agreements' debt is reduced. Financial events that can cause service agreement debt to be reduced are:

- The cancellation of a bill segment
- The freezing of a payment segment
- The freezing of an adjustment that credits a service agreement

At review time, the Collection Process Monitor removes any service agreement from a collection process when the service agreement has no debt older than the arrears date on the collection process. When all service agreements are removed, the collection process is cancelled.

Fastpath:

Refer to [The C&C Monitors](#) for more information about debt monitoring.

A Severance Process May Be Canceled When A Credit FT Is Frozen

If the customer does not respond to a collection process's prodding, the system creates a severance process for each delinquent service agreement associated with the collection process.

The system reviews an active severance process whenever its service agreements' debt is reduced. Financial events that can cause service agreement debt to be reduced are:

- The cancellation of a bill segment
- The freezing of a payment segment
- The freezing of an adjustment that credits a service agreement

At review time, the system determines if the service agreement has no debt older than the arrears date on the severance process. If so, the system looks at the severance process' severance process template:

- If the severance process template indicates that the process can be **Used to sever service**, the system cancels all pending severance events and deactivates the severance process. Note: the only severance processes that are not used to sever service are those that request reconnection of a cut service.
- If the canceled process has field activities,
- If the field activities are not linked to a field order and are still in the pending status, the system cancels the field activities.
- Otherwise, the system generates worklist entries to alert an operator that field activities have been dispatched. The operator must determine how to handle these activities because they could already be scheduled for dispatch (or completed!).

Note:

Real time cancellation. Unlike collection processes, the system cancels severance processes real time (i.e., there is no equivalent of the collection process monitor for severance processes). Why are severance processes canceled real time? Because a severance process may have events that create field activities to sever service. These events need to be canceled the moment the FT is frozen, we can't wait until a background process runs. This means that if a customer pays in person for a service agreement that is pending severance, the system will cancel the process and its field activities (if any) the moment the payment is entered.

Fastpath:

Refer to [The C&C Monitors](#) for more information about debt monitoring.

One Or More Algorithms May Be Executed

If the FT is linked to a service agreement whose SA type has Freeze Algorithms, these algorithms will be executed when the FT is frozen. Because you can code whatever you please in an algorithm, anything could happen. Examples of such algorithm include:

- An algorithm that routes consumption to third party service providers when a bill is frozen (refer to STG SND CONS for more information). This type of algorithm would be plugged in on SA types whose consumption can be interfaced to other service providers.
- A bill message can be added to the account when the system detects that its deposit has been paid in full (refer to DEP PIF MSG for more information). This type of algorithm would be plugged in on deposit SA types.

In addition, FT freeze algorithms can also be defined on an account's customer class. Because you can code whatever you please in an algorithm, anything could happen. An example of such an algorithm is one that cancels match events

when an FT is cancelled (refer to CNCL FT MEVT for more information). This type of algorithm would be plugged in on customer classes associated with open item customers.

The Big Picture of Balance Control

The balance control processes are used to check the financial integrity of your system. The contents of this section describe how these processes work.

The Balance Control Background Processes

The following diagram illustrates the balance control background processes:

BCGNEW - Create A New Balance Control Group

This process creates a Pending balance control group if one doesn't already exist. You may wonder why an entire process is dedicated to such a trivial task. The reason is because the next process, BCASSIGN, is a multi-threaded (i.e., parallel) process and we only need one Pending balance control group regardless of the number of threads used to assign balance control ID's to financial transactions.

BCASSIGN - Assign New Financial Transactions A Balance Control Group

This multi-threaded (i.e., parallel) process assigns the Pending balance control group to new FTs whose freeze date/time is before the create date/time of the balance control record.

BCGSNAP - Insert BC Members And Check Financial Integrity Of All FTs

This process performs the following two functions:

- It summarizes new financial transactions under the current Pending balance control group as follows:
- It creates a balance control member for every combination of **Division**, **SA Type** and **FT Type** referenced on the financial transactions belonging to the balance control group.
- It updates each balance control member with the following information:
- The number of financial transactions (FTs)
- The sum of the total amounts on the FTs in this balance control group.
- The sum of the current amounts on the FTs in this balance control group.

- The sum of the total amounts from all FTs (in this and all other balance control groups).
- The sum of the current amounts from all FTs (in this and all other balance control groups).
- It sets the status of the balance control group to Complete.
- It checks the integrity of the financial transactions in each historical Balance Control Group. It does this by summarizing EVERY financial transaction throughout time and determining if the sums are in sync with the values maintained on the balance control members. If integrity problems are detected, a detailed error message is displayed on the run control associated with the process.

If you opt to run the balance control processes on a nightly basis, you will find that the verification processing will take longer every night (because there are more financial transactions over time). In order to deal with this issue, the [BCGSNAP](#) process has a parameter that allows you to control which of the above functions is implemented (it's call VERIFY-ONLY-SW). In order to speed nightly processing, run this process with the switch set to "G" (this causes new financial transactions to be summarized under a new balance control). Then, once a week (or month), run this process with the switch set to "Y" (this checks the financial integrity of all financial transactions in the system).

If you run the balance control processes less frequently, you can set the VERIFY-ONLY-SW to "N" (this causes both of the above functions to execute).

Consider A Backup At This Point

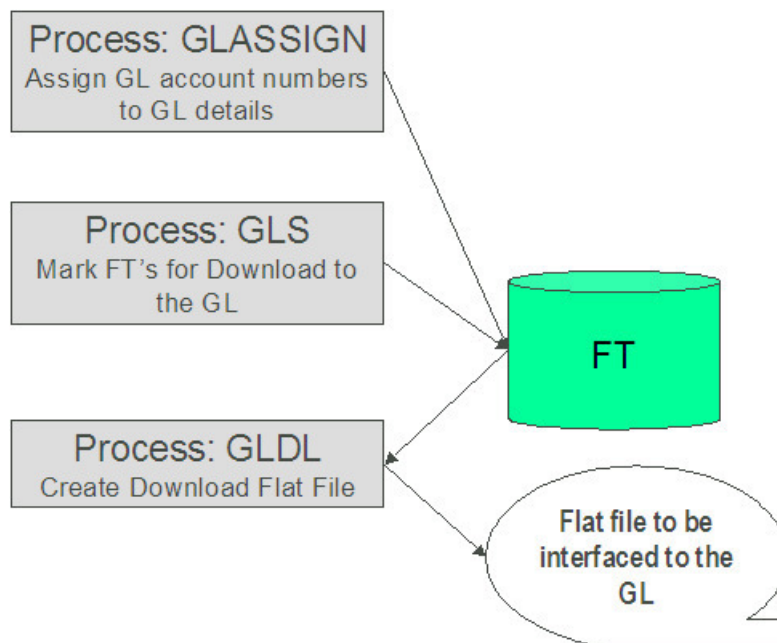

We recommend you backup your database AFTER you run the above processes. Why? So that if a financial integrity problem is spotted in the future, you can compare the current database against the backup to see what changed.

Balance Control Information Is Available Online

Your internal auditors may be interested in the total number and amount of financial transactions that have been posted since a given point in time. You can use the [Balance Control](#) page to see this information.

The GL Interface

The following diagram illustrates the GL Interface.

GLASSIGN - Assign GL Account Numbers To GL Details

The GLASSIGN process assigns GL account numbers to the GL details associated with financial transactions. GL account numbers are assigned as follows:

- Every GL detail references a distribution code.
- Every distribution code references a GL assignment algorithm. The base package algorithm simply uses the default GL account associated with the distribution code. However, you can construct your own algorithm(s) to assemble your GL account numbers in your desired fashion. Refer to [Setting Up Distribution Codes](#) for more information about the GL format algorithm.
- The GLASSIGN process simply calls each GL's details distribution code's GL assignment algorithm and updates the GL detail with the result (i.e., the GL account number). This GL account number is then used by the GLDL process when it creates the consolidated journal entry that's interfaced to the GL.

Note:

If incorrect GL account numbers get assigned to GL details... If you do not plug in the correct algorithm or your algorithm is wrong, you can correct the GL account numbers that are assigned to the GL details. How? Write a simple program that resets the GL account numbers on the erroneous GL details. Then run GLASSIGN. GLASSIGN will re-execute the distribution code GL assignment algorithm and refresh the account number accordingly.

GLS - Prepare FTs for Download

The GLS process creates FT download staging records for all FTs that are ready to be posted to the GL (the FT download staging records are stored on the FT/Process table). Each FT download staging record is marked with a batch control ID and run number.

- The batch control ID is the process responsible for creating the flat file that contains the consolidated journal entry that is interfaced to your general ledger. The batch control ID is defined on [Installation Options - Financial](#). The system comes with a single GL download program ([GLDL - Create General Ledger Download Flat File](#)). The GL account numbers are provided by the GL account algorithms that are specified on the distribution codes. Refer to [Setting Up Distribution Codes](#) for more information about the GL account algorithm.
- The run number is the batch control ID's current run number.

This process also changes the status of the FT to distributed. You may not change the FT's GL details after this time.

GLDL - Create General Ledger Download Flat File

The GLDL process creates the flat file that contains the consolidated journal entry that is interfaced to your general ledger. One header and multiple detail records are created as described below. At the conclusion of the batch process, a validation is performed to compare debits against credits. If they are not equal, the process terminates with an error.

Header Record Layout

| Field Name | Format | Source/Value/Description |
|------------|--------|---|
| REC_TYPE | A1 | 1 (1 is used for header records) |
| BATCH_CD | A8 | The code for the batch process that created the file. (This value will always be 'GLDL'.) |

| | | |
|---------------------|-------|---|
| BATCH_NBR | N10 | The batch process will be run many times. This field indicates which of those runs produced a particular output file. This may be thought of as an instance identifier for the batch process. |
| BATCH_RERUN_NBR | N10 | Any given instance of the GLDL batch process may be re-run at any time. If this instance has been re-run, this field will be populated with a number indicating how often. |
| EXTRACT_DTTM | A26 | The date and time of the run that created a particular output file. |
| DETAIL_REC_CNT | N12 | The number of details records |
| DETAIL_REC_TOTAL_DR | N13.2 | This is the sum of FINANCIAL_AMOUNTS from all detail records that were greater than zero (debits). |
| DETAIL_REC_TOTAL_CR | N13.2 | This is the sum of FINANCIAL_AMOUNTS from all detail records that were less than zero (credits). |

Detail Record Layout for GLDL

Note:

A record is created for each unique occurrence of REC_TYPE, GL_DIVISION, CURRENCY_CD, GL_ACCOUNT and ACCT_PERIOD. If a given GL account has debit and credit FINANCIAL_AMOUNTS, two records will be created - one shows the debit amount, the other shows the credit amount.

| Field Name | Format | Source/Value/Description |
|-------------|--------|---|
| REC_TYPE | A1 | 2 (2 is used for detail records) |
| GL_DIVISION | A5 | This is the GL Division from the CI_FT record. It determines a) which Accounting Calendar will be used to calculate the Accounting Period (below) and b) the default currency (i.e., if currency code is not sourced directly from the FT). |

| | | |
|------------------|-------|---|
| CURRENCY_CD | A3 | The currency in which the Amount is denominated.  Note: The Use FT's Currency Code (Y/N) batch parameter controls whether the Currency Code is retrieved directly from the FT or from the GL Division (default). |
| GL_ACCOUNT | A254 | Contains the GL account number as supplied by the distribution code's GL account algorithm . |
| ACCT_PERIOD | A6 | An accounting period in the format YYYYPP where YYYY is the fiscal year and PP is the accounting period. This is derived from the GL detail's FT's accounting date and GL division. |
| FINANCIAL_AMOUNT | N13.2 | This is the debit or credit amount. Debits are represented by positive numbers; credits are represented by negative numbers. If a given GL account has debit and credit entries, two records will be created - one shows the debit amount, the other shows the credit amount. |
| STAT_CODE | A8 | This is the GL distribution code's statistic code (if any) |
| STAT_AMOUNT | N13.6 | This is the statistical amount from the GL detail lines |

**Note:**

The GLASSIGN process updates an FT's GL details with the appropriate GL account number.

Financial Transaction

Payment segments, adjustments and bill segment have a corresponding financial transaction. The financial transaction is created by the system when any of the source transactions is created. It contains the financial effects of its corresponding adjustment / bill segment / payment segment.

**Fastpath:**

For background information, refer to [The Big Picture Of Financial Transactions](#).

The topics in this section describe the financial transaction page.

Financial Transaction - Main

Use **Menu > Financial > Financial Transaction** to update and maintain financial transaction information.

**Note:**

Navigating from source transactions. On the bill, payment, and adjustment maintenance pages, you can click the financial transaction go to button to transfer to this page.

Description of Page

Most of the attributes on this page are display-only. The following points describe the conditions under which certain fields may be modified:

- **Accounting Date** may be modified until the financial transaction (FT) is interfaced to the GL (i.e., until the **GL Distribution Status** is Distributed).
- **New Charge** may be modified until the FT is swept onto a bill (when the next bill is completed for the FT's account). If **New Charge** is modifiable and turned off, **Arrears Date** must be specified.
- **Show on Bill** and **Correction** can be modified until the FT is frozen.

The remainder of this section defines each of the fields on the page.

FT Type is the type of financial transaction. Values are: Adjustment, Adjustment Cancellation, Bill Segment, Bill Segment Cancellation, Pay Segment, and Pay Segment Cancellation. Click the go to button to view the originating transaction on the adjustment, bill, or payment page.

FT ID is the system-assigned, unique identifier of the financial transaction.

SA ID is the system-assigned, unique identifier of the service agreement to which the financial transaction is linked.

Bill ID is the system-assigned, unique identifier of the bill to which the financial transaction is linked. This field is only populated after the FT is swept onto a bill (and this happens when the next bill is completed for the FT's account).

Sibling ID is the system-assigned, unique identifier of the source transaction associated with the FT.

- If this FT is associated with a bill segment, **Sibling ID** contains the unique identifier of the bill segment.
- If this FT is associated with a payment segment, **Sibling ID** contains the unique identifier of the payment segment.
- If this FT is associated with an adjustment, **Sibling ID** contains the unique identifier of the adjustment.

Parent ID contains the following:

- If this FT is associated with a bill segment, **Parent ID** contains the unique identifier of the bill with which the bill segment is associated.
- If this FT is associated with a payment segment, **Parent ID** contains the unique identifier of the payment with which the payment segment is associated.
- If this FT is associated with an adjustment, **Parent ID** contains the adjustment type.

Create Date/Time are the date and time the FT was created.

Accounting Date is the accounting date that will be used by the general ledger to define the accounting period(s) into which the FT will be booked.

CIS Division is the CIS division associated with the FT. This comes from the CIS division linked to the FT's service agreement's SA type.

GL Division is the GL division associated with the FT. This comes from the GL division linked to the FT's service agreement's SA type.

Show on Bill indicates if the FT will be shown on the customer's bill. You should only turn this off for erroneous FTs that should not be shown to the customer. For example, if you cancel / rebill a bill segment and you want to suppress the resultant FTs on the printed bill, turn this switch off.

New Charge indicates if the FT's charge only starts aging when the FT is swept onto the next bill produced for the account. If you want to manually enter an **Arrears Date** you must turn this switch off. The system leaves this switch set when assigning an arrears date during the bill completion process. This is done so the system knows which FTs were assigned an arrears date during bill completion. If a completed bill is reopened, the arrears date is reassigned when the bill is completed.

Not In Arrears indicates if the FT's financial impact has been canceled and therefore should not be considered for arrears purposes. This switch is turned on by the system when a FT's source transaction is canceled (both the original FT and the cancellation FT are marked as **Not In Arrears**).

Match Event ID is the system-assigned, unique identifier of the match event to which the financial transaction is linked. This field is only enabled for [Open Item Accounts](#). Be aware that changing a financial transaction's match event can result in the balancing / unbalancing of the prior and newly referenced match events.

Arrears Date is the date the FT starts aging. This field is typically blank until the FT is swept onto the account's bill. If you want to start aging an FT on an historical date (for whatever reason), enter the appropriate **Arrears Date**. (Note - you must uncheck the "New Charge" box first in order to do this.) If the arrears date is assigned manually it is not updated during bill completion nor is it adjusted when a bill is reopened and completed again.

Correction causes the FT to be summarized in the correction area of the bill-at-a-glance. This is set by the system automatically when a bill segment is cancelled / rebilled after its parent bill is completed (i.e., sent to the customer).

Redundant indicates if the FT's financial impact is considered irrelevant. This only happens after an FT has reached an age that is no longer relevant for aging purposes (e.g., when the FT is older than 120 days - or whatever age has been set as the Oldest Bucket Age on the Installation Options) and when its balance is exactly equal to zero with respect to other redundant FTs of the service agreement.

Transferred Out indicates if the FT has been transferred to a service provider. This could only happen if the FT is associated with a SA that is associated with a "they bill for us" service provider. Refer to [They Bill For Us](#) for more information.

The **Frozen** switch is turned on when the FT has been frozen (i.e., posted to the service agreement's payoff and/or current balances). If this switch is on, both **Freeze Date/Time** and **Frozen By** are populated.

Current Amount contains the FT's impact on the service agreement's current amount.

Payoff Amount contains the FT's impact on the service agreement's payoff amount.

Fastpath:

For more information, refer to [Current Balance versus Payoff Balance](#).

Currency Code is the currency code associated with the FT's account.

GL Distribution Status defines the status of the FT in respect of its interface to the general ledger. When an FT is first created, its status is Pending . When an FT is frozen, this value is set to Generated. If you modify the GL details, the status becomes Modified. After it has been marked for interface to the general ledger by the GLS process, the status becomes Distributed.

GL Extract Dates display the **Scheduled** date that the GL details will be marked for interface to the general ledger. Note that this date is typically only set to a future date for FTs associated with automatic payments. **Actual** displays the date that the GL details were actually posted to the general ledger.

The grid at the bottom shows the FT's debits and credits (i.e., the detail journal lines). Debits are shown as positive amounts, credits are negative amounts. The following points describe rules governing if and how the information in the grid can be modified:

- The FT GL details may not be modified if the FT is Pending or Distributed.
- All **Amounts** must sum to zero.
- Multiple FT GL details may be set to affect the **Total Amount** (although they are normally generated with one GL checked to affect total amount).
- All FT GL's checked to affect **Total Amount** must sum to the **Payoff Amount** of the FT.

The following information is displayed:

- **Sequence number** is the system-assigned, unique identifier of the journal line.
- **Total Amount** defines if the journal line contains the total of the other journal lines. For example, on a bill segment for utility service, this would be turned on for the receivable account because its amount equals the sum of the other payable and revenue GL accounts.
- **Distribution Code** is the CIS distribution code from which the GL account constituents are derived.

- If the **GL Account** has been populated, the GL account number is displayed.

Fastpath:

Refer to [GLASSIGN - Assign GL Account Numbers To GL Details](#) for more information about how the GL account is populated.

- **Amount** defines the journal line's amount.
- **Statistic Amount** defines the statistical amount that will be posted to the GL. This value is only populated on distribution lines created for calculation rules designated as affecting GL statistical quantity.
- **Characteristic Type** and **Characteristic Value** describe the characteristic value that was used when the line's amount was calculated. This information is only displayed if the journal line was derived from bill calculation lines that were calculated using a bill factor (because only bill factor's use characteristic values). Refer to [An Illustration Of A Bill Factor And Its Characteristics](#) for more information.

Note:

Tax reporting. A journal line's characteristic value is NOT interfaced to the GL. We have included this attribute on the journal line so that tax reporting can be performed from this system (tax reporting typically necessitates showing each taxing authority - the characteristic value - that participated in a given tax payable GL account).

- If you have configured your installation options to indicate that **fund accounting** is practiced, the description of the **Fund** associated with this distribution code is displayed.

Financial Transaction - FT Process

Use **Menu > Financial > Financial Transaction** and navigate to the **FT Process** page to view those ancillary processes that may be triggered as a result of this financial transaction.

Note:

Algorithms cause financial transactions to be linked to batch processes. Financial transactions get associated with a given process / batch number when certain algorithms are executed. For example, when a bill segment is frozen, the system executes the freeze algorithms associated with the bill segment's service agreement's SA type. One of these algorithms may check if there are service providers who are interested in the bill segment's consumption, and if so, schedule the consumption to be downloaded by linking the bill segment's financial transaction to the service provider's consumption download process.

Description of Page

This page shows the **Batch Processes** associated with a given **Financial Transaction**. Information on this page may not be modified. This information appears purely for audit purposes.

Account Financial History

This portal shows how an account's current and payoff balance have changed over time. You can access the portal from **Menu > Financial Query > Account Financial History**.

Refer the portal's embedded help for more details.

Fastpath:

For information about current and payoff balance, refer to [Current Amount versus Payoff Amount](#).

Account Bill / Payment History

This portal shows an account's bills and payments. You can access the portal from **Menu > Financial Query > Account Bill / Payment History**.

For [balance-forward accounts](#), bill rows contain the balance presented on the respective bill, and payment rows contain the amount of the respective payment. However, for [open-item accounts](#), this query behaves differently. Refer to the portal's embedded help for more details.

Note:

Credit Notes or Correction Notes. The Bill Correction option on the Installation record controls whether Credit Notes or Correction Notes are allowed. The default transaction type filter displayed is for Credit Note. If your implementation uses Correction Notes, you'll need to change the transaction type filter to reflect this. This is done by overriding the label for lookup value CRNT on the customizable lookup field TXN_FLTR_TYPE_FLG .

SA Financial History

This portal shows how a service agreement's current and payoff balance have changed over time. You can access the portal from **Menu > Financial Query > SA Financial History** .

Refer to the portal's embedded help for more details.

Fastpath:

For information about current and payoff balance, refer to [Current Amount versus Payoff Amount](#).

SA Non-Accrual Accounting Balance

Note:

Only relevant if you practice non-accrual accounting. This transaction is only relevant if you practice non-accrual accounting (e.g., you only pay the taxing authorities when the customer pays you, you defer revenue recognition till a later date, or a combination of the two). Refer to [Payables Cash Accounting](#) and [Deferred Accrual Accounting](#) for more information about non-accrual accounting.

This page displays a grid that shows a service agreement's non-accrual accounting balance for each non-accrual holding distribution code that's been booked to. Use **Menu > Financial Query > SA Non-Accrual Accounting Balance** to open this page.

Description of Page

The following columns are displayed in the grid:

Holding Distribution Code This is a general ledger distribution code used as the holding account for non-accrual accounting. Each holding account that's been used by this service agreement will appear here.

Payable Distribution Code This is the general ledger distribution code to which the payable is (or will be) transferred when the cash event occurs or when the designated revenue recognition date elapses. The system supports revenue recognition on the bill due date.

Fastpath:

For more information on how the distribution codes are set up, refer to [Setting Up Distribution Codes](#).

Payoff Balance This column shows the service agreement's balance for each non-accrual holding account. If this amount is non-zero, it indicates that for this service agreement we are still holding some payables back until payment is received by the customer, at which time some or all of this amount will be transferred to the payable distribution code.

Accounting Method This column shows which accounting method is used for the distribution.

Accounting Priority This column shows the priority level associated with the distribution code. If more than one distribution code is to receive a payable then the priority level, along with debt age, will determine the order in which the transfers are made.

**Fastpath:**

For information about non-accrual accounting, refer to [Payables Cash Accounting](#) and [Deferred Accrual Accounting](#).

Balance Control

This page is used to summarize the financial transactions that belong to a particular balance control group.

**Fastpath:**

Refer to [The Big Picture of Balance Control](#) for more information.

**Note:**

Balance Control information is current only as of the Create Date/Time listed. The information displayed on the page is captured when the balance control background process is run. Any financial activity subsequent to the create date and time will not be shown.

Use **Menu > Financial Query > Balance Control** to open this page.

Description of Page

This page displays summarized financial information for a particular balance control group. It also details financial information for all SA Types that belong to the group.

The following fields are displayed on the page:

Group ID This is a sequential value that uniquely identifies a particular balance control run. The Group ID is assigned and incremented automatically every time the Balance Control background process is run.

Status This is the status of the balance control record: Pending, and Complete . The status of the balance control record will only be pending while the balance control background process is being executed. Balance control information is only reliable if the status is complete.

Create Date/Time This is the date and time that the balance control record was created. Financial information displayed on this page will only contain information for financial transactions frozen before this date and time.

Current Amount This is the sum of the current amounts of all FTs that belong to the balance control group.

Payoff Amount This is the sum of the payoff amounts of all FTs that belong to the balance control group.

Current Balance This is the sum of the current amounts of all FTs that belong to this balance control group plus all earlier balance control groups. Therefore this is the instantaneous current balance of the entire CIS as of the create date and time.

Payoff Balance This is the sum of the payoff amounts of all FTs that belong to this balance control group plus all earlier balance control groups. Therefore this is the instantaneous payoff balance of the entire CIS as of the create date and time.

The number of FT information details the number of bill segments, pay segments, adjustments and their cancellations that belong to the balance control group.

Adjustment The total number of adjustments that belong to this balance control group.

Adjustment Cancellation The total number of adjustment cancellations that belong to this balance control group.

Bill Segment The total number of bill segments that belong to this balance control group.

Bill Segment Cancellation The total number of bill cancellations that belong to this balance control group.

Pay Segment The total number of pay segments that belong to this balance control group.

Pay Segment Cancellation The total number of pay cancellations that belong to this balance control group.

The **SA Type** scroll summarizes the FTs that belong to a particular SA Type within the balance control group - otherwise all fields are defined as above. You can scroll through all SA Types that belong to the balance control group.

SA Type The SA Type being summarized.

Match Event

Warning:

Match Events are only used if you practice [Open Item Accounting](#).

Match events are used to match debit and credit financial transactions together. When financial transactions are linked to a balanced match event, they no longer affect the customer's arrears.

You can use the match event page to do the following:

- Add, change, delete, and cancel match events.
- Add and remove financial transactions from / to a match event.
- Designate financial transactions as being "in dispute" (disputed financial transactions do not affect aged debt until they are resolved).
- View all unmatched financial transactions linked to an account.

Fastpath:

Refer to [Match Events](#) for a full description of the lifecycle of a match event and a description of how the system automatically creates match events.

Match Event - Main

A typical match event matches a bill's financial transactions with a payment's financial transactions. The **Main** page allows you to define the bill(s) and payment(s) whose financial transactions are matched together. Use **Menu > Financial > Match Event > Search** to open this page.

Note:

Debit must equal credits. Before a match event impacts a customer's arrearage, its debits and credits must net to zero for every service agreement referenced on the match event. Until that time, the financial transactions on a match event continue to affect arrearage. The only exception is the case of [disputes](#).

You can match any debit and credit. While the above describes the matching of bills and payments, it's important to remember that a match event matches any type of debit with any type of credit. This means that a match event could match a bill with a credit or correction note, or a payment with a payment cancellation.

You can match any number of payments under a match event. While most match events deal with a single bill and a single payment, there's no limitation to the number of payments on a match event. The only restriction is that the debits and credits must net to zero for all service agreements.

It is better not to mix multiple bills on a single match event. For purposes of bill balance information, it is strongly recommended that you compose your match events with financial transactions limited to a single bill. If you mix financial transactions from multiple bills on a single match event you will not be able to determine the unpaid balance of a partially paid bill.

You can match specific financial transactions. While most match events deal with every financial transaction on a bill and payment, a match event can deal with individual financial transactions. For example, a match event could match a bill segment with a combination of a payment segment and a write-off adjustment. If you need to add or remove a specific financial transaction (i.e., a bill segment, payment segment, or adjustment), navigate to the **FT Details** tab. Perhaps a better way to differentiate between this page and the **FT Details** tab is to consider the example of a bill with 100 bill segments. When you link this

bill to a match event, you are actually linking its 100 financial transactions. If you wanted to add only a subset of this bill's financial transactions to the match event, you'd use the **FT Details** tab.

Fastpath:

Refer to [How To](#) for instructions describing how to perform common match event maintenance functions.

Description of Page

This page is used to maintain the financial transactions (FTs) that are linked to a match event. The remainder of this section defines each of the fields on the page.

Match Event Info and **Match Event ID** only appear after the match event exists on the database. The **ID** is a system assigned random number that stays with the match event for life. **Match Event Info** is a concatenation of important details about the match event and its account.

The next section contains the sum of the **Debit** and **Credit** financial transactions linked to the match event. If the debits and credits do not sum to zero, the **Difference** is also shown.

Account ID defines the account whose financial transactions are matched under this match event. This field is gray after the match event is added to the database.

Match Event Status defines the state of the match event.

- Match events are initially created in the open state. Please note that you may delete an open match event.
- The system automatically changes an open event's status to balanced when the sum of the **Debit(s)** equals the sum of the **Credit(s)** for each service agreement on the match event. It's worth stressing that a match event may contain financial transactions from many service agreements and each service agreement's financial transactions must sum to zero before the match event can become balanced.
- You may re open a balanced event (by adding / removing items so that the match event becomes unbalanced).
- You can cancel a balanced or open match event by changing the **Match Event Status** to cancelled. You must also define a **Cancel Reason** if you cancel a match event. Refer to [How Are Match Events Cancelled?](#) for more information about cancellation.

Turn on **Dispute** if this match event exists to designate certain financial transactions as **disputed**. In addition,

- Describe the reason for the dispute in **Remarks**.
- Link the disputed financial transactions to the match event by selecting the bill(s) below. If only a subset of a bill is disputed:
- Click on the respective hyperlink in the **Unmatched Debits** column grid (this will transfer you to the next tab with these financial transactions displayed).
- Select the bill segments that you want to designate as disputed.
- Press the **Link / Unlink** button to link the selected bill segments to the match event.

Note:

Disputing items on a balanced event. The **Dispute** switch will be protected when the match event is Balanced or Cancelled. If the items on a balanced event are being disputed, you must add / remove items so that the match event becomes Open before you can turn on the **Dispute** switch.

The remainder of the page is dynamic depending on the **Match Event Status**:

- If the status is Balanced or Open, a grid appears containing a summary of the bills, payments, credit or correction notes, and payment cancellations that contribute financial transactions to the match event (note, we refer to these collectively as "contributing objects" in the following discussion). The following columns appear in this grid:
- **Transaction Type** defines whether the contributing object is a Bill, Payment, Payment Cancellation, or Credit or Correction Note. In the rare situation when unbilled financial transactions are linked to the match event, a transaction type of Not Billed Yet appears. If the contributing object is a bill its bill id is also displayed. If sequential bill functionality is enabled, the bill's sequential id is displayed instead.
- **Matched Activity Information** contains summary information about the contributing object. This column is blank if the transaction type is Not Billed Yet.

- The remaining columns contain the count and amount of each contributing object's financial transactions categorized as follows (note, you can drill down on the count or amount to see the specific financial transactions (FT's) on the next tab).
- **Matched Debits** summarizes the contributing object's debit FT's that are linked to this match event. A checkbox appears if the count is greater than zero. If you select the checkbox and press the **Link / Unlink** button, these debits will be removed from the match event.
- **Matched Credits** summarizes the contributing object's credit FT's that are linked to this match event. A checkbox appears if the count is greater than zero. If you select the checkbox and press the **Link / Unlink** button, these credits will be removed from the match event.
- **Other Debits** summarizes the contributing object's debit FT's that are NOT linked to this match event.
- **Other Credits** summarizes the contributing object's credit FT's that are NOT linked to this match event.

Note:

Adding more financial transactions to a balanced match event. When a match event is Balanced, the grid showing unmatched FT's is suppressed (and therefore you can't add additional FT's to the match event). To expose this grid, simply change the status of the match event to Open.

- If the status is Open, a second grid appears containing a summary of the bills, payments, credit notes, correction notes and payment cancellations with at least one unmatched financial transaction (we refer to these collectively as "unmatched objects" in the following discussion). The following columns appear in this grid:
- **Transaction Type** defines whether the unmatched object is a Bill, Payment, Payment Cancellation, Credit, or Correction Note. A transaction type of Not Billed Yet is used for unbilled financial transactions (e.g., adjustments generated between bills). If the unmatched object is a bill its bill id is also displayed. If sequential bill functionality is enabled, the bill's sequential id is displayed instead.
- **Unmatched Activity Information** contains summary information about the unmatched object. This column is blank if the transaction type is Not Billed Yet.
- The remaining columns contain the count and amount of each unmatched object's financial transactions categorized as follows (note, you can drill down on the count or amount to see the specific financial transactions (FT's) on the next tab).
- **Unmatched Debits** summarizes the unmatched object's debit FT's that are not linked to any match event. A checkbox appears if the count is greater than zero. If you select the checkbox and press the **Link / Unlink** button, these debits will be added to the match event.
- **Unmatched Credits** summarizes the unmatched object's credit FT's that are not linked to any match event. A checkbox appears if the count is greater than zero. If you select the checkbox and press the **Link / Unlink** button, these credits will be added to the match event.
- **Matched Debits** summarizes the unmatched object's debit FT's that are linked to any match event.
- **Matched Credits** summarizes the unmatched object's credit FT's that are linked to any match event.

Note:

Credit Notes or Correction Notes. The Bill Correction option on the Installation record controls whether Credit Notes or Correction Notes are allowed. The default Transaction Type displayed is for Credit Note. If your implementation uses Correction Notes, you'll need to change the transaction type filter to reflect this. This is done by overriding the label for lookup value CRNT on the customizable lookup field TXN_FLTR_TYPE_FLG.

The last section contains the running total of the **Debit** and **Credit** financial transactions that have been selected / unselected in the above grids. If debits and credits do not sum to zero, the **Difference** is also shown. These values differ from the values on the top of the page as they are updated when a user selects / unselects an object (whereas the values at the top of the page are only updated when the database is changed).

The **Link / Unlink** button becomes enabled when you select an object in the grids. When you press this button, the financial transactions related to the object are added to / removed from the match event.

Match Event - FT Details

On the **Main** tab, you can add and remove bills, payments, credit notes, correction notes and payment cancellations to / from a match event. When you do this, you are actually adding and removing all of the financial transactions linked to these objects. For example, when you link a bill with 100 bill segments to a match event, you are actually linking its 100 financial transactions.

You need only use the **FT Details** tab when you need to add or remove specific financial transactions. For example, you would use the **FT Details** tab if you need to remove 1 of a bill's 100 financial transactions from a match event.

Use **Menu > Financial > Match Event > Search** and navigate to the **FT Details** page (note, you can also open this page using many of the hyperlinks on the Main and SA Subtotals tabs).

Description of Page

This page is used to maintain the financial transactions (FTs) that are linked to a match event. The remainder of this section defines each of the fields on the page.

Match Event Info and **Match Event ID** only appear after the match event exists on the database. The **ID** is a system assigned random number that stays with a match event for life. The **Match Event Info** is a concatenation of important details about the match event and its account.

The next section contains the sum of the **Debit** and **Credit** financial transactions linked to the match event. If the debits and credits do not sum to zero, the **Difference** is also shown.

The following **Filters** work together to restrict the financial transactions that appear in the grid. The following points describe the various options (note, don't forget to press the search button after specifying the various filter options):

- Use **Transaction Type Filter** to restrict the type of transactions that appear in the grid. The following options are available:
 - All. Use this option if you do not wish to restrict financial transactions based on their transaction type.
 - Bill. This option allows you to view a specific bill's financial transactions. When this option is selected, an input field appears in which you identify the **Bill ID**.
 - Credit Note. This option allows you to view a specific credit note's financial transactions. When this option is selected, an input field appears in which you identify the **Bill ID** (every credit note has a unique bill ID).
 - Correction Note. This option allows you to view a specific correction note's financial transactions. When this option is selected, an input field appears in which you identify the **Bill ID** (every correction note has a unique bill ID).
 - Not Billed Yet. This option allows you to view financial transactions that haven't appeared on a bill yet (e.g., adjustments and corrections).
 - Payment. This option allows you to view a specific payment's financial transactions. When this option is selected, an input field appears in which you identify the **Payment ID**.
 - Payment Cancellations. This option allows you to view a specific canceled payment's financial transactions. When this option is selected, an input field appears in which you identify the **Payment ID**.

Note:

Credit Notes or Correction Notes. The Bill Correction option on the Installation record controls whether Credit Notes or Correction Notes are allowed. The default Transaction Type displayed is for Credit Note. If your implementation uses Correction Notes, you'll need to change the transaction type filter to reflect this. This is done by overriding the label for lookup value CRNT on the customizable lookup field TXN_FLTR_TYPE_FLG.

- Use **Linkage Filter** to restrict the transactions based on the match event to which they are linked. The following options are available:
 - All. This option shows all financial transactions regardless of their match event.
 - Linked to another Match Event. This option shows financial transactions linked to a different match event.
 - Linked to any Match Event. This option shows financial transactions linked to any match event.
 - Linked to this Match Event. This option shows financial transactions linked to this match event.
 - Unmatched. This option shows financial transactions that are not linked to a match event.

This filter is protected and set to Linked to this Match Event if the **Transaction Type Filter** is All.

- Use **Debit / Credit Filter** to restrict the transactions based on whether they are debits or credits. The following options are available:
 - All. This option shows all debit and credit financial transactions.
 - Credit. This option shows all credit financial transactions.
 - Debit. This option shows all debit financial transactions.
- Use the **SA Filter** to define the types of service agreements whose financial transactions appear in the grid. The following options are available:
 - Address. Use this option to restrict financial transactions to those whose service agreements are linked to service points associated with a given **Address**, **City** and/or **Postal** code. Note, you can specify any combination of these fields.
 - All. Use this option if you do not wish to restrict financial transactions based on service agreement attributes.
 - Geographic Type. Use this option to restrict financial transactions to those whose service agreements are linked to service points associated with a given **Geo Type** and **Value**.
 - SA ID. Use this option to restrict financial transactions to those linked to a specific **Service Agreement**.
 - SA Type. Use this option to restrict financial transactions to those whose service agreements are linked to a given **CIS Division** and **SA Type**.

Warning:

Don't forget to click the search button after changing the filters.

The **Select All / Clear All** buttons are used to select financial transactions to add to / remove from the match event (note, after selecting the desired financial transactions, you must also press the **Link / Unlink** button at the bottom of the page).

Note:

50 financial transactions at a time. Clicking **Select All** selects the first 50 bill segments in the grid. If more than 50 financial transactions exist, you must select them in batches.

The grid that follows contains the financial transactions (FT) that match your search criteria. The following information appears in the grid:

- **Select box.** Select the FT if you want to Link / Unlink it. You implicitly link FT's that are NOT already linked and you implicitly unlink FT's that are already linked. This field is protected if the FT is linked to another match event.
- **FT Amount.** This column contains the amount of the financial transaction.
- **FT Type.** This column indicates the type of financial transaction: Bill Segment, Bill Segment Cancellation, Pay Segment, Pay Segment Cancellation, Adjustment, and Adjustment Cancellation .
- **Arrears Date.** This column contains the financial transaction's arrears date.
- **SA Information.** This column contains a summary of the financial transaction's service agreement.
- **Remarks.** This column highlights the financial transaction's match status: Linked to this match event, Not linked to a match event, Linked to another match event - match event status.
- **Premise Information.** This column contains a summary of the premise (if any) associated with the financial transaction's service agreement.

The last section contains the running total of the **Debit** and **Credit** financial transactions that have been selected / unselected in the grid. If debits and credits do not sum to zero, the **Difference** is calculated. These values differ from the values on the top of the page as they are updated when a user selects / unselects an object (whereas the values at the top of the page are only updated with the database is changed).

The **Link / Unlink** button becomes enabled when you select a row in the grid. When you press this button, the financial transactions related to the object are added to / removed from the match event.

Match Event - Subtotals

Before a match event impacts a customer's arrearage, its debits and credits must net to zero for every service agreement referenced on the match event. This page shows the sum of the debits and credits for every service

agreement that contributes at least one financial transaction to the match event. Use **Menu > Financial > Match Event > Search** and navigate to the **Subtotals** page

Description of Page

This page shows the sum of the debits and credits for every service agreement that contributes at least one financial transaction to the match event.

Match Event Info and **Match Event ID** only appear after the match event exists on the database. The **ID** is a system assigned random number that stays with a match event for life. The **Match Event Info** is a concatenation of important details about the match event and its account.

The next section contains the sum of the **Debit** and **Credit** financial transactions linked to the match event. If the debits and credits do not sum to zero, the **Difference** is also shown.

The following **Filters** work together to restrict the service agreements that appear in the grid. The following points describe the various options (note, don't forget to press the search button after specifying the various filter options):

- Use the **SA Filter** to define the types of service agreements whose financial transactions appear in the grid. The following options are available:
 - Address. Use this option to restrict service agreements to those linked to service points associated with a given **Address, City** and/or **Postal** code. Note, you can specify any combination of these fields.
 - All. Use this option if you do not wish to restrict service agreements.
 - Geographic Type. Use this option to restrict service agreements to those linked to service points associated with a given **Geo Type** and **Value**.
 - SA ID. Use this option to see a specific **Service Agreement**.
 - SA Type. Use this option to restrict service agreements to those with a given **CIS Division** and **SA Type**.
- Use **Status Filter** to restrict the service agreements based on whether the sum of the debits and credits they contribute to the match event. The following options are available:
 - All. Use this option if you do not wish to restrict service agreements based on this status.
 - Balanced. This option shows only service agreements where the sum of debit and credits nets to zero on this match event.
 - Unbalanced. This option shows only service agreements where the sum of debit and credits do not net to zero on this match event.

Warning:

Don't forget to click the search button after changing the filters.

The grid that follows contains the service agreements that match your search criteria. The following information appears in the grid:

- **SA Information.** This column contains a summary of important information about the service agreement.
- **Difference.** This column contains the difference between the **Matched Debits** and **Match Credits**. If this is non-zero, the value appears in red.
- **Matched Debits.** This column contains the sum of debit financial transactions that this service agreement contributes to this match event.
- **Matched Credits.** This column contains the sum of credit financial transactions that this service agreement contributes to this match event.
- **Premise Information.** This column contains a summary of the premise (if any) associated with the financial transaction's service agreement.

How To Perform Common Match Event Functions

How To Find The Match Event Associated With A Financial Transaction

If you need to find the match event on which a financial transaction (FT) was matched, display the FT in question on [Financial Transaction - Main](#) and then use the "go to" button adjacent to the **Match Event** to drill to the match event.

**Note:**

The easiest way to display a financial transaction is to find its corresponding [bill](#), [payment](#) or [adjustment](#) and then drill down on the desired transaction.

How To Dispute An Item

Refer to [Disputing Items](#) for background information about disputes.

If a customer wants to dispute an item:

- Turn the match event's dispute switch on.
- Link the disputed financial transaction to the match event.
- Describe in the match event's comments the reason for the dispute.

How To Match A Small Mismatch

Assume the following scenario arises:

- A bill is produced for \$2000
- The customer pays \$1993
- An unbalanced match event will result because the customer didn't pay exactly what is owed

If you want to match this payment to the bill (and leave \$7 for the next bill), do the following:

- Create a transfer adjustment of \$7 where the transfer from / to service agreement is the same. This results in a debit financial transaction (FT) of \$7 and a credit FT of \$7.
- Create a match event (or update the unbalanced match event) where the matched FTs are:
 - The \$1993 payment
 - The credit side of the transfer adjustment (\$7)
 - And the \$2000 bill
- Then, if the customer pays their next bill in full, the \$7 debit (associated with the transfer adjustment) will be swept onto it.

**Note:**

Automating small mismatches. The algorithm responsible for matching a payment to a specific bill can have a tolerance amount defined on it. If the payment is within the tolerance limit, this algorithm will do the above for you. In other words, you don't have to manually do the above if you populate the tolerance limit appropriately on this algorithm. Refer to DSOV BILL-ID for more information about this algorithm.

Deposits

In this section, we describe how to manage your deposits.

The Big Picture Of Deposits

The topics in this section provide background information about a variety of deposit issues.

**Fastpath:**

We strongly recommend familiarizing yourself with the topics described in [The Financial Big Picture](#) to fully appreciate how deposits fit into the system's financial architecture.

Cash Deposits

Before you can bill a customer for a deposit, there must be a deposit service agreement (SA). Deposit SAs will be created by a CSR using [Start/Stop Service](#) (the same page used to create all other types of service agreements).

Deposit SAs behave just like any other service agreement in that:

- A deposit SA must reference an SA type. Refer to [Service Agreement Type Controls Everything](#) for information about how SA type controls a service agreement's behavior.
- Bill segments will be produced to bill the customer for a deposit. Note, bill segments associated with deposit SAs will appear on the same bill as other bill segments related to its account (i.e., a bill could contain a combination of utility, deposit, and non-utility bill segments).
- When a customer makes a payment, it will be distributed amongst its account's SAs based on each SA's payment distribution priority. This means a single payment could relieve receivable accounts (associated with utility service agreements) and increase a payable account (associated with the deposit service agreement). Refer to [Distributing A Payment Amongst An Account's Service Agreements](#) for more information.
- You can use a transfer adjustment to relieve debt on some other type of service agreement (by transferring all or part of the deposit's credit balance to another service agreement).
- You can use an A/P adjustment to cause a check to be created if you need to manually refund a deposit.
- When you no longer require the deposit, a CSR will stop the deposit SA using [Start/Stop Service](#) (the same page used to stop all other types of service agreements). Refer to [Refunding Deposits](#) for information about how the refund actually takes place.

Fastpath:

Refer to [Deposit Class Controls Everything for information](#) about deposit interest, the recommended deposit amount algorithm, and how deposits are refunded.

Note:

An account can have many deposits. You can view all deposits (both cash and non-cash) linked to an account on [Account - Deposits](#).

Refunding Deposits

To refund a deposit, you simply need to change the deposit SA's state to pending stop. The system does everything else (i.e., calculates interest and refunds the deposit to the customer).

There are three ways in which a deposit SA's state can become pending stop:

- The Deposit Refund background process (DEPRFND) make a deposit service agreement pending stop when it detects that the customer meets the automatic refund criteria. Refer to [Defines The Conditions That Cause The System To Automatically Refund A Deposit](#) for a description of how to define the conditions that control automatic refund.
- An operator, at their discretion, may refund a deposit by stopping the deposit SA using [Start/Stop Service](#) (the same page used to stop all other types of service agreements). This page simply changes the deposit SA's state to pending stop.
- The system changes the state of a deposit service agreement to pending stop when it recognizes that all other SAs of its deposit class have also been stopped. This may be necessary, for example, when a customer's utility service agreements have been severed for non-payment. Refer to [Deposit Seizures When Other SAs Are Stopped](#) for more information.

The system changes the state of a pending stop SA to stopped when the process responsible for [Finalizing Pending Stops](#) next runs.

When a deposit SA becomes stopped, the system calculates interest through the stop date. Refer to [Controls Interest Calculation](#) for a description of how interest is calculated.

**Note:**

If you can't wait for this process to run, simply display the deposit SA on [Service Agreement - Main Information](#) and press the stop button.

When the stopped deposit SA is final billed, the system produces a final bill segment that shows the deposit amount being returned to the customer. When the bill segment's bill is completed, the deposit is refunded to the customer as per the deposit refund algorithm on the deposit's deposit class. Refer to [Controls How Deposits Are Refunded To A Customer](#) for a description of how a deposit is refunded.

**Warning:**

None of the base package deposit refund algorithms create an A/P adjustment when the deposit service agreement is final billed. Rather, they depend on the [write-off preprocessing](#) to actually refund the deposit to the customer.

Partial Refunds

You can perform a partial refund by creating an adjustment for the deposit SA. If you want to refund the adjustment with a check, this adjustment should be an A/P adjustment (i.e., one that is interfaced to A/P). If you want to refund the adjustment by offsetting some other service agreement's debt, create a transfer adjustment (transferring from the deposit SA to the SA to be relieved).

After creating the adjustment, you'll find that the deposit SA has a positive current amount due (because you debited the deposit SA to refund the credit amount). You should create another adjustment to return the current amount of the deposit to zero. It's important to use an adjustment type that only affects current amount when you do this.

After getting the deposit's current amount back to an expected amount, you will have to change the deposit SA's Total Amount To Bill to reflect the amount of deposit you want to hold for the customer. So, for example, if you were holding a \$500 deposit and you want to refund \$100, you should change the deposit SA's Total Amount To Bill to be \$400.

Total Amount To Bill

Most deposit service agreements contain a "Total Amount To Bill" field. The label for this field is defined on the SA type (on the Billing tab). For deposit SAs, it should be labeled something like **Cash Deposit Amount**. This field should reflect the deposit amount you WANT to hold on this service agreement. Please be aware of the following in respect of this field:

- If the payoff balance (i.e., the current deposit held) is less than the Total Amount To Bill, the system will generate a bill segment to charge the customer for the deposit.
- If the deposit service agreement uses a recurring charge (i.e., you bill the total amount in installments), the amount billed to the customer will not exceed the recurring charge amount (unless the bill segment is prorated).
- If the deposit service agreement does not use a recurring charge, the amount billed will equal the difference between Total Amount To Bill and the service agreement's payoff balance.
- If you need to bill an incremental deposit on an existing deposit service agreement, simply change the deposit service agreement's Total Amount To Bill.
- If the payoff balance (i.e., the current deposit held) is greater than the Total Amount To Bill, the system will NOT refund the excess deposit.

**Note:**

SA Type and Total Amount to Bill. A deposit service agreement's SA type controls if the deposit service agreement uses Total Amount to Bill. Typically, the only SA types that indicate this field can be used are loan and deposit service agreements.

Current Balance versus Payoff Balance

**Warning:**

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

The current balance on a deposit SA contains the amount of the deposit that has been billed, but not paid. The payoff balance on a deposit SA contains the amount of deposit being held. The payoff balance is a negative number because your company owes this money to the customer.

The financial ramifications of a deposit SA are predictable (if you're an accountant). The following table outlines the different financial events and their impact on the general ledger, arrearage history, and the amounts due (both current and payoff).

**Note:**

It's important to be aware that everything that is shown in this table is controlled by how you set up the deposit SA type's bill segment type, payment segment type, and adjustment types. Refer to [Service Agreement Type Controls Everything](#) for how to do this.

| Event | GL Accounting | Arrearage Rule | Effect On Payoff Amt | Effect On Current Amt | Payoff Balance | Current Balance |
|---------------------|---|----------------------------|----------------------|-----------------------|----------------|-----------------|
| Deposit billed | N/A - the GL is not affected when a deposit is billed | \$100 starts aging | 0 | +100 | 0 | 100 |
| Payment received | Cash 100 Deposit Payable <100> | \$100 relieved accordingly | -100 | -100 | -100 | 0 |
| Interest calculated | Interest Exp 5 Deposit Payable <5> | N/A | -5 | 0 | -105 | 0 |

The following points describe the events in the above table:

- **Deposit billed.** In this example, the customer is billed for \$100 deposit.
- The customer really thinks they owe the billed amount, \$100. Therefore, current amount is affected. However, if the customer was to cash out, they wouldn't owe your organization anything, therefore payoff amount is not affected.
- Notice that the GL is not affected when the deposit is billed. This is because most organizations do not show a receivable for billed deposits (as it's not a true receivable).
- Because current amount changed by \$100, arrearage history is affected accordingly.
- **Payment received.** With any luck, the client will pay the \$100 that was billed.
- The payment has a normal affect on the GL (debit cash, credit deposit payable). The deposit payable GL account is defined as the deposit SA type's Distribution Code.
- The amount the customer thinks they owe decreases by \$100, therefore current amount is affected by the payment amount. And, if the customer was to cash out, your organization would owe the customer \$100, therefore payoff amount is affected by the payment amount.
- Because current amount changed by \$100, arrearage history is affected accordingly.
- **Interest calculated.** In this example, the system calculates interest of \$5.
- The interest is posted to the GL (the interest expense distribution code is defined on the respective adjustment type).

- The interest amount didn't affect how much the customer thinks is due them. Therefore current amount is unaffected. However, if the customer was to cash out, your organization would owe them \$100 + \$5 (the interest) therefore payoff amount is affected by \$5.
- Because current amount is not changed, arrearage history is not affected.

Multiple Deposits Linked To A Single Account

The system has been designed to allow your customers to have multiple deposits. This is necessary when a deposit is restricted to a specific type of debt. For example, if separate deposits are held for regulated and unregulated debt (and a customer could hold a combination of regulated and unregulated debt), you'd need one deposit for regulated debt and another for unregulated debt.

Note:

Deposit class. A deposit's deposit class controls the service agreements that are covered by a given deposit. A deposit's deposit class is defined on its SA type. Refer to [Designing Your Deposit Classes](#) for more information.

It's important to be aware that if your company has multiple classes of deposits, the system will recommend and refund deposits for each individual deposit class. For example, if you have both regulated and unregulated deposit classes, the system will recommend separate deposits for each class. And at refund time, a deposit will be distributed to only those service agreements associated with its deposit class (i.e., a regulated deposit will not be used to satisfy unregulated debt).

Deposits and Credit & Collections

The [account debt monitor](#) monitors deposit service agreements just as it monitors every other service agreement for overdue debt. If the amount of debt on the deposit SA violates your collection criteria, a collection process will start.

Fastpath:

Refer to [The Lifecycle Of A Collection Process And Its Events](#) for more information.

It's important to be aware that deposit debt can be treated differently from other types of debt linked to an account by creating a specific debt class for the deposit SA type.

Fastpath:

Refer to [Designing Your Collection Procedures](#) for more information about how to have different collection criteria for different debt classes.

The type of severance process associated with a deposit SA is probably rather simple - you probably will want a To Do entry generated to advise an operator that a customer hasn't paid their deposit.

Fastpath:

Refer to [The Lifecycle Of A Severance Process And Its Events](#) for more information.

Please see [Deposit Seizures When Other SAs Are Stopped](#) for a description of how the system seizes an active deposit service agreement when normal (i.e., non-cash deposit) service agreements are stopped.

After a deposit SA is stopped, it will be "final billed" the next time the account is billed. Refer to [Refunding Deposits](#) for more information about how deposit refunds are "final billed". If a credit balance remains on the deposit SA after it is final billed, the [Write-Off Monitor](#) will process the deposit SA just like it processes all unpaid and final billed service agreements. If you set up the deposit SA's [write-off controls](#) properly (i.e., you plug in the appropriate refund and write-down algorithms), the write-off monitor will refund / write-down the credit balance (thus causing the deposit SA to close).

Deposit Seizures When Other SAs Are Stopped

Consider the situation when a severance process cuts a service due to non-payment. At some point, if the customer doesn't pay, you'll want to seize the deposit and apply it to the overdue debt. To implement this, the system simply stops the deposit SA when it stops the last SA in its deposit class (refer to [Finalizing Pending Stops](#) for more information about stopping service agreements). Then, when the account is next billed, the standard deposit refund process will offset outstanding debt before it is refunded to a customer.

Refer to [Refunding Deposits](#) for a complete description of how the system refunds a stopped deposit SA's balance to other service agreements in its deposit class.

Note:

Deposit class refund method is the key. It's important to stress that the only way the system will use a deposit to offset overdue debt is if the deposit's deposit class has a refund method that does this. If you've set up a deposit class' refund method to cut a check for the entire deposit amount, the system will not offset outstanding debt. Refer to [Deposit Class - Refund Method](#) for more information.

Non-Cash Deposits

When an account is required to post a deposit, they can remit cash or some other type of surety (e.g., letters of credit, surety bonds, 3rd party deposits). When cash is remitted, a deposit service agreement is used. When some other type of surety is used, a *non-cash deposit* must be created.

Non-cash deposits are held in respect of an account and an account may have an unlimited number of non-cash deposits (note: cash deposits are held in respect of a deposit service agreement that is linked to remitting account). Refer to [Account - Deposits](#) for more information.

Each non-cash deposit must reference a non-cash deposit type. Besides defining the type of surety, the non-cash deposit type also controls:

- Whether such types of non-cash deposits can be highlighted when they are due to expire via the creation of a To Do entry (refer to TD-NCDEX for more information about this To Do entry).
- Whether a reference to a cash-deposit (i.e., service agreement) must be specified. Refer to [3rd Party Deposits](#) for more information about how a cash deposit can be referenced by another party.

Fastpath:

Refer to [Setting Up Non-Cash Deposit Types](#) for more information.

In addition to non-cash deposit type, each non-cash deposit must reference a deposit class. Why? Because the system amalgamates cash and non-cash deposits when it determines if an account is holding an adequate deposit.

Fastpath:

Refer to [What Do Deposit Classes Do?](#) for more information.

If you need to use a non-cash deposit to satisfy an account's debt, you must "cash in" the non-cash deposit. When the cash arrives, create a payment and apply it to the customer's outstanding service agreements.

Third Party Deposits

A third party deposit arises when a third party remits cash to cover the deposit needs of one or more accounts. Both cash and non-cash deposits must be created to record a third party deposit. The following example will explain how to do this.

Assume the Salvation Army remits \$5,000 on behalf of 50 customers (where each customer's account is allocated \$100). In this situation, you'd create the following information in the system:

- The Salvation Army must have an account with a deposit service agreement.
- When the Salvation Army remits the funds:

Warning:

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

- Create an adjustment to "bill" the deposit service agreement (causing the deposit SA's current balance to be \$5,000 and the payoff balance to be 0).
- Add a payment for the \$5,000 against the Salvation Army's account. This payment will cause the deposit SA's current balance to be 0 and the payoff balance to be -\$5,000. Note, if you don't mind the Salvation Army's current balance to be -\$5,000 after the payment is made, you wouldn't have to create the adjustment to "bill" the deposit.
- Create a non-cash deposit for each of the 50 accounts being covered by the cash deposit. On each non-cash deposit, define the appropriate non-cash deposit type (e.g., 3rd party deposit) and amount \$100 each.
- Interest will be applied to the Salvation Army's deposit service agreement as per the interest algorithm on the deposit SA's deposit class.
- If you need to use the Salvation Army's payment to payoff overdue debt, you will use a transfer adjustment(s) to transfer from the deposit service agreement to the respective overdue service agreement(s).

Important:

Be aware that the system will allow the sum of third party deposits to exceed the amount of the cash deposit (in our previous example, the system would allow you to create \$6,000 worth of third party non-cash deposits even though only \$5,000 of cash was remitted).

Deposit Class Controls Everything

A deposit service agreement's SA type references a deposit class. The topics in this section describe how deposit class controls the behavior of a deposit SA.

Fastpath:

Refer to [Setting Up Deposit Classes](#) for a complete description of the business rules governed by a deposit class.

Controls Interest Calculation

Interest is applied to a deposit SA when:

- A deposit SA is stopped. Refer to [Refunding Deposits](#) for a description of how a deposit SA can be stopped.
- The Apply Interest background process (DEPINTRF) determined that sufficient time has passed since interest was last calculated. The amount of time between interest calculations is defined on the deposit class.

A deposit SA's deposit class controls the following interest calculation functions:

- The frequency of interest calculation.
- The algorithm used to calculate the amount of interest (note, the interest rate is defined using a bill factor plugged in on this algorithm).
- The method used to refund the interest.

Note:

Adjustments are used to apply interest. Interest is applied to a deposit SA using an adjustment (the adjustment type is also defined on the deposit class).

Controls The Recommended Deposit Amount

The following events cause the calculation of the recommended deposit amount:

- The Deposit Review background process (DEPRVW) compares an account's existing deposit (if any) to the recommended amount.

- A user requests a deposit calculation for a new deposit service agreement by pressing the  button on the [Start Confirmation](#).

A deposit service agreement's deposit class controls the algorithm used to derive the suggested deposit amount.

Defines The Conditions That Cause The System To Recommend A New or Additional Deposit

The Deposit Review background process (DEPRVW) will recommend an additional deposit be billed if the customer doesn't satisfy the definition of a *good customer*.

It's important to be aware that if your company has multiple classes of deposits, the system will recommend deposits for each individual deposit class used by an account. For example, if an account has both regulated and unregulated deposit classes, the system will recommend separate deposits for each class.

When the Deposit Review process analyzes an account's debt, it uses the following deposit class attributes:

- The definition of a good customer (the system only recommends deposits for bad customers).
- The tolerance percent that must be exceeded before the system will recommend an additional deposit for a customer. This tolerance percent prevents the recommendation of small amounts.
- The method used to derive the recommended deposit amount.

Assuming the C1-CR-UP-DRR review method algorithm is specified on the deposit class, the system does not automatically produce bills when an additional deposit is needed. Rather, the system's recommendations appear on the [Deposit Review](#) page. To implement a recommendation, an operator should change the deposit SA's [Total Amount To Bill](#) or add a new deposit SA.

Note:

Non-cash deposits are included. It's important to be aware that the system compares the recommended deposit amount against the sum of deposits on hand for a given deposit class. When amalgamating the total deposit on hand, the system includes both cash (i.e., deposit SA's payoff balance) and non-cash deposits.

Defines Automatic Refund Conditions

The Deposit Refund background process (DEPRFND) will refund a deposit to a customer when conditions defined on the deposit SA's deposit class are met. For example, a deposit's deposit class may indicate the system should automatically refund a deposit after the deposit has been held for 6 months and the customer is a good customer (the definition of a "good customer" is also on the deposit class).

Controls How Deposits Are Refunded To A Customer

The method used to refund a deposit to a customer is defined on the deposit SA's deposit class. For example, a deposit's deposit class may indicate the system will first apply the deposit to outstanding debt first and, if funds remain, cut a check.

It's important to be aware that if your company refunds deposits by first offsetting outstanding debt, the system will only offset debt within an individual deposit class. For example, if a customer has two deposits - one for regulated debt, the other for unregulated debt - the regulated deposit will only be used to offset regulated debt.

Deposit Background Processes

The topics in this section describe the background processes that automate deposit processing.

Deposit Interest

The Deposit Interest background process (DEPINTRF) examines all cash deposit service agreements (i.e., service agreements with a SA type with a special role of Cash Deposit). If enough time has passed since interest was last calculated, interest will be calculated using the service agreement's deposit class' Interest Refund Algorithm. Note: interest will be automatically calculated every X months where X is defined in the deposit class' Months Between Interest Refund.

Deposit Refund

The Deposit Refund background process (DEPRFND) examines all cash deposit service agreements (i.e., service agreements with a SA type with a special role of Cash Deposit). If the account meets the service agreement's deposit class' Refund Criteria Algorithm, the system changes the service agreement's state to Pending Stop. Refer to [Refunding Deposits](#) for a description of what happens next.

Review Deposits

The Review Deposits background process (DEPRVW) examines all accounts with service agreements that are governed by a deposit class (i.e., service agreements with an SA type that references a deposit class). If the account fails the deposit class' Good Customer Algorithm, the system calculates the recommended deposit amount (using the deposit class' Deposit Recommendation Algorithm). If the recommended amount exceeds the amount of deposit currently requested, the system will request an additional deposit. The deposit class' **Review Method Algorithm** is used to determine what action to take if the system requests an additional deposit. The system's recommendations appear on the [Deposit Review](#) page.

You may optionally provide a Deposit Class as input to restrict the review to account whose service agreements reference that deposit class.

Note:

Preventing small recommendations. The system uses the deposit class's Review Tolerance Percentage to prevent the recommendation of small deposits by the Deposit Review background process. For example, if this field contains 10(%), the system would only recommend an additional deposit if the existing requested deposit amount is less than 90% of the recommended amount.

Multiple deposits could be recommended for an account. Because an account can have service agreements that belong to multiple deposit classes, it is possible for a multiple recommendations to be generated for an account.

Deposit Review

The Deposit Review page shows all accounts for which an additional deposit is recommended.

Note:

The [Review Deposits](#) background process inserts rows on this query.

Multiple deposits could be recommended for an account. Because an account can have service agreements that belong to multiple deposit classes, it is possible for a multiple recommendations to be generated for an account.

Open this page using **Menu > Financial Query > Deposit Review**.

Description of Page

Use **Account ID** and / or **Deposit Class** to filter the rows. Each row displays an account / deposit class that holds an inadequate deposit.

Note:

Rows are also displayed for errors. Please be aware that if the Recommend Additional Deposit background process encounters an error when it attempts to calculate an account's recommended deposit, these errors also appear as rows in this query.

Press the  button to add a new deposit SA for the customer. Pressing this button causes [Start/Stop Service](#) to open. When this page opens, you should create a new deposit service agreement for the customer (by referencing the appropriate division / SA Type).

If the customer has one or more deposit service agreements, the drill button will be enabled. Pressing it will cause the [Service Agreement - Main Information](#) page to open. When this page opens, you can change Total Amount To Bill to reflect the total amount of deposit you want to hold. When billing next runs, it will bill the customer for the marginal difference between the current deposit held and the deposit amount to bill.

Fastpath:

Refer to [Defines The Conditions That Cause The System To Recommend A New or Additional Deposit](#) for how rows are added to this query.

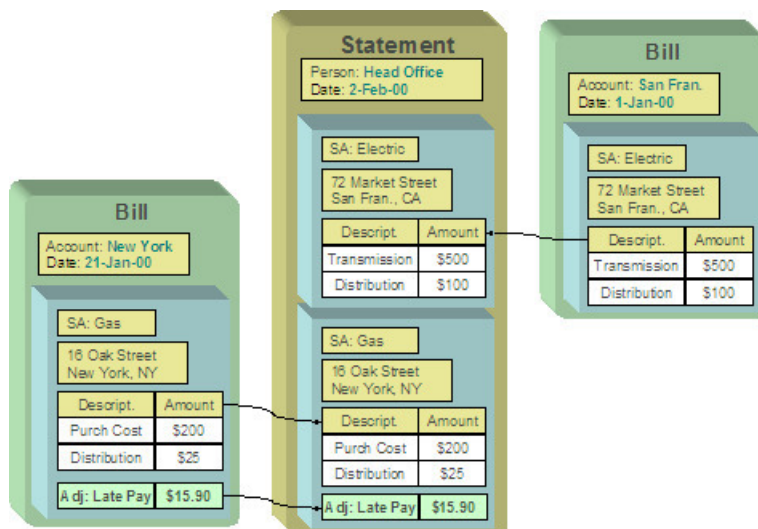

Statements

In this section, we describe how to manage your customer's statements.

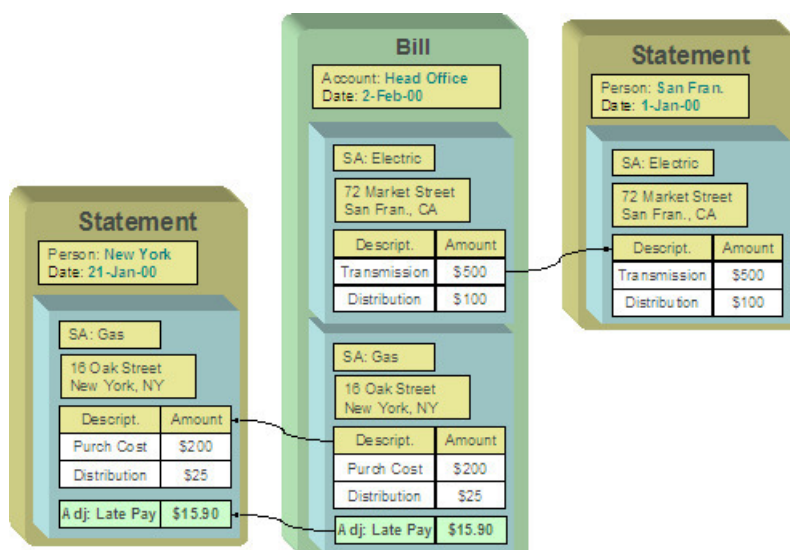

The Big Picture of Complex Statements

Statements allow you to set up a person to receive a consolidated report of the financial activity for one or more accounts and/or service agreements. This allows you to model complex account scenarios, including the following examples.

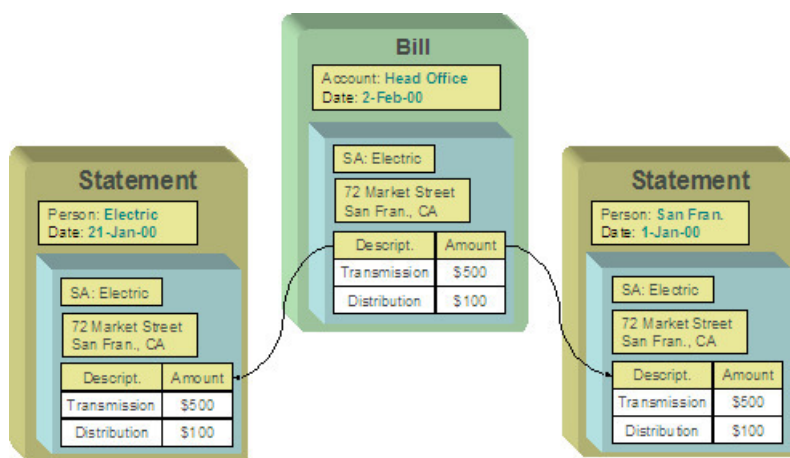

- Satellite offices for a company are each responsible for paying their own bill, but the head office would like a consolidated report of the bills for all the satellite offices once a month. In this case, each satellite office is set up as an account covering the services for their office. The head office does not want to receive individual copies of each bill, but rather a consolidated report of the financial activity for all the offices.

- The head office is responsible for paying the bill. The satellite offices should receive a copy of only their portion of the bill. In this case, a service agreement is set up for each satellite office under the head office's account. Each satellite office should receive a copy of the bill segment information for their office's service agreement.

- The head office is responsible for paying the bill. Multiple departments need to see copies of the electric portion of the bill. As illustrated by this scenario, a service agreement or account may appear on many statements.

The topics in this section provide additional information about how to set up statements.

Constructing Statements

Statements are produced for a **person**. Each statement contains the financial transactions for one or more **service agreements**. The service agreements may belong to any number of **accounts**. Over time, a person may receive many statements.

When setting up a person to receive statements, it's important to note that a person can receive different statements for different groupings of service agreements. For example, the head office may want a statement of the financial details for the western division offices separately from the eastern division offices.

For each separate statement a person wishes to receive, you will set up a statement construct. On the statement construct, you define the service agreements and/or accounts whose financial information should appear on the statement. If you specify an account on a statement construct, billing information for all the service agreements linked to the account will be included on the statement. The superset of service agreements and accounts defined on a statement construct are called the "construct details".

Fastpath:

Refer to [Statement Construct Maintenance](#) for more information.

Producing Statements

Statement Cycles

The accounts and service agreements linked to a statement construct may have different bill cycles and as a result, their bills are produced on different dates. So when should a statement containing the consolidation of all this financial information be produced? To answer this question, there is a statement cycle.

Just as with a bill cycle, the statement cycle has a schedule. A statement cycle's schedule controls when a statement should be produced. Each statement construct will point to its own statement cycle.

Fastpath:

Refer to [Statement Construct Maintenance](#) and [Statement Cycle](#) for more information.

Create Statements Background Process

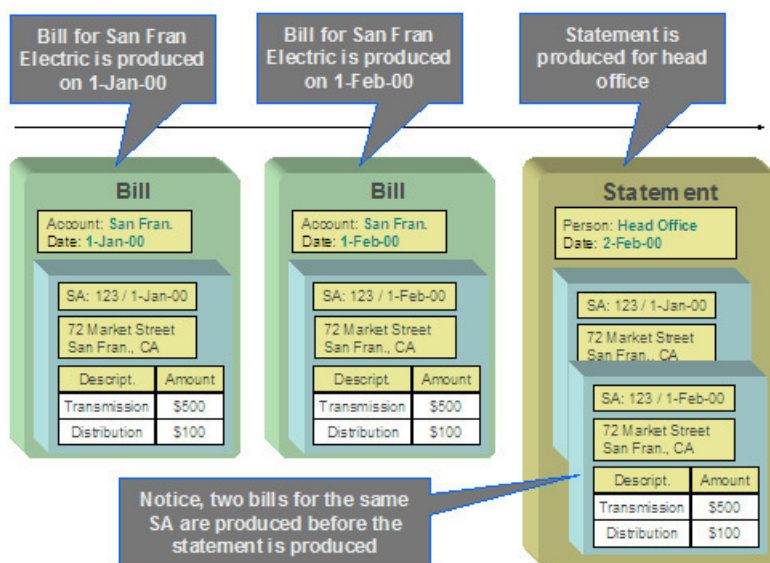

This statement construction background process (STMPRD) is responsible for periodically creating statements. It works as follows:

- All statement cycles are selected with pending schedules whose production date is on or before the business date.
- For each such cycle, all of its statement constructs are selected. For each statement construct:
 - If a statement already exists for the cycle schedule and construct, it is deleted (this allows for reproduction after a mess up). Note well, this is true even if the statement is printed as you may have only spotted the problem after viewing the printed statement.
 - A statement is created.
 - All SAs associated with the construct details effective on the business date are extracted.
 - All "SA snapshots" associated with bills whose BILL DATE is within the construct detail's start and end dates that are not already linked to one of the construct's statements are linked to the new statement. Note, an "SA snapshot" is created for every service agreement linked to an account when a bill is completed for an account.
 - If no "SA snapshots" are found, the statement is removed.

Note:

The following diagram illustrates how the above logic could result in multiple bills for a single service agreement being linked to the same statement.

**Fastpath:**

Refer to [Statement Maintenance](#) for more information about a statement and its details.

**Note:**

This process is rerunnable. If a problem occurred during the statement creation, simply run the background process again. It will clean up all existing statements for each construct in the current cycle schedule and start again.

**Fastpath:**

Refer to [Printing Statements](#) for more information for how a separate background process uses the information snapshot on a statement to construct the extract file used to print the statements.

Statement Routing

Just as with bills, statements require routing information in order for the system to understand how and where to send the statements. For example, the system needs to know the method of routing, the number of copies and the format of the statement. This information is captured on a statement construct.

Where Are Statements Sent

The system extracts a statement's address as per its statement construct's address source. Note, if the address source is Person and the person has a [seasonal address](#) effective on the business date, the seasonal address will be used.

If you need to reprint a statement because it was addressed incorrectly, correct the person's address, and then reprint the statement (by pressing the **Reprint** button on the statement). When you press this button, the statement will be marked for downloading. When your download process next runs, it simply extracts the statement construct's current address.

On-Line Statement Production

Statements may be produced on-line as well as in batch. To produce a statement on-line, simply go to the Statement page, select the correct Construct ID and choose the Generate button.

This statement will include the financial information related to bills for the accounts and service agreements linked to this construct, with the following criteria:

- The bills do not already appear on a statement
- The bill dates fall within the "effective period" for the statement construct. In other words, the bill falls within the start and end period for the statement construct details.

**Fastpath:**

Refer to [Statement Maintenance](#) for more information.

How to Regenerate a Specific Statement

There may be times when a specific statement needs to be regenerated. For example, perhaps a cancel / rebill has occurred since the statement was produced, and you wish to recreate the statement to reflect this.

If you need to regenerate a statement using up-to-date information, simply delete the statement and generate a new statement. This may be done on-line.

**Note:**

Statements may be deleted, even if they have already been printed. This enables you to delete and regenerate statements.

Fastpath:

Refer to [Statement Maintenance](#) for more information.

Printing Statements

The contents of this section describe the technical implementation of printing statements.

Statement Route Types Control The Information Merged Onto Statements

Every statement references a [statement route type](#). The route type controls the following statement print functions:

- It contains an algorithm that is responsible for extracting the information merged onto your statements. Specifically, algorithms of this type create the "flat file records" that are passed to your statement print software. Algorithms of this type are called under the following scenarios:
 - The background process that builds the flat file that's passed to your statement print software calls these algorithms to construct the "flat file records" for each statement.
 - If your statement print software has the ability to construct a real-time image of a statement (in a PDF), you can plug-in an Online Statement Image algorithm on the [Installation Record](#). This type of algorithm will call the statement's dispatch group extract algorithm to extract the information that is merged onto the statement. Refer to [Technical Implementation Of Online Statement Display](#) for the details.
- Refer to [The Statement Extract Records](#) for examples of the record layouts passed to the document composition application.
- It contains the ID of the background process that builds the flat file that's passed to your statement print software. The base package example of this process ([STMDWLD](#)) simply calls each statement's construct's route type's extract algorithm to format the information placed onto the flat file.

Technical Implementation Of Online Statement Display

Users can view an image of any statement if you setup the following:

- Plug-in an Online Statement Display algorithm on the [Installation Record](#). Refer to ONSD-ST for an example of such an algorithm. Note, if your statement print software is not capable of producing a PDF containing an image of a statement, users will not be able to view images of statements.
- Plug-in the appropriate extract algorithm on each [statement route type](#). Algorithms of this type format the records that contain the information that is passed to your printing software. Refer to STEX-TX for an example of such an algorithm.

When you plug-in these algorithms, a button appears on [Statement - Main](#). When a user presses this button, the following takes place:

- The installation record's Online Statement Display algorithm is executed.
- This algorithm calls the statement's route type's extract algorithm. This algorithm constructs the information that's merged onto the statement and returns it to the Online Statement Display algorithm. This algorithm, in turn, passes it to your statement print software.
- Your statement print software renders an image of the statement in a PDF and returns it to the Online Statement Display algorithm.
- And finally, the Online Statement Display algorithm displays the PDF in a separate Adobe session.

Technical Implementation Of Printing Statements In Batch

The background process that extracts statement information ([STMDWLD](#)) reads all statements in a given run number that are marked with its batch control ID. For each statement, it creates numerous records on a flat file. These records contain the information that is merged onto your statements.

The base package example of this process ([STMDWLD](#)) simply calls the extract algorithm on the statement route type to format the information placed onto the flat file. Refer to [Statement Route Types Control The Information On Statements](#) for more information.

Note:

If your software doesn't support online statement display. The algorithm that formats statement extract records that's plugged in on [statement route type](#) serves two purposes: 1) it formats the records used to construct online images of a statement, and 2) it formats the records downloaded to your statement print software in batch. If your statement print software does not support the rendering of statement images real time, there is no need to create an extract algorithm. Rather, you should simply develop your own download process that both formats the extract records and downloads them (and then specify this batch process on your statement route type).

Reproducing The Statement Print Flat File

You can reproduce the flat file at any time. Simply request the [STMDWLD](#) process and specify the run number associated with the historic run.

How To Reprint A Specific Statement

If you need to reprint a specific statement, navigate to [Statement - Main](#) and press the **Reprint** button.

If your implementation has [enabled the online creation of statement images](#), you can also press the **Display Statement** button on this page and then print the resultant PDF on your local printer.

The Statement Extract Records

Numerous different types of records are interfaced to the document composition application. However, they all share a common structure:

- The first 4 bytes are called the **Printer Key**. This field is a record type used by the document composition application statement template.
- The next 186 bytes are called the **Sort Key**. This field is used to ensure the various records used to construct a printed statement appear in the correct order in the interface file.
- The next 12 bytes are called the **Mailing Key**. This field is used to control the order in which the formatted statements are printed.
- The remaining bytes contain the **Statement Information** that appears on the printed statement. The type of information differs for each type of record.

The topics in this section describe each component.

Printer Keys (Record Types)

The following table defines each printer key (i.e., record type) on the statement print flat file.

| Record Type | Description | Notes |
|-------------|----------------------------|---------------------------------------|
| 0010 | Global extract information | Required. 1 per flat file. |
| 0100 | Statement record | Required. 1 per statement. |
| 0120 | Total by currency record | Required. At least one per statement. |

| | | |
|------|-----------------------------------|--|
| 0500 | Construct detail record | Required. At least one per construct detail linked to the statement construct. |
| 0900 | Service agreement record | 1 per SA |
| 1100 | Bill record | 1 per bill |
| 1300 | Financial Transaction (FT) record | 1 per FT linked to the SA. |
| 3600 | End of record type 1100 | 1 for each bill |
| 3700 | End of record type 0900 | 1 for each SA |
| 5000 | End of record type 0500 | 1 for each statement construct detail |
| 9999 | End of record type 0100 | 1 for each Statement |

Sort Key

The following table defines the structure of the sort key that appears on each statement print record. Please note that different components are filled in for each printer key.

| Field Name | Format | Record Type | Source/Value/Description |
|----------------------------------|--------|--|--|
| Statement ID | A12 | All | Prime key of the statement |
| Sequence Number | N2 | All | Set to "1" |
| Copy Number | N2 | All | Defaulted to "1" on the first copy, set to "1" when a statement is requested on-line |
| Statement record group | A2 | 0010 | Blank |
| | | 0100 | 10 |
| | | 0120 | 20 |

| | | | 1300 | Financial transaction arrears date |
| FT Type | A2 | | 0010, 0100, 0120, 0500, 0900, 1100, 3600, 3700, 5000, 9999 | Blank |
| | | | 1300 | Financial transaction type |

Mailing Key

The following table defines the structure of the mailing key that appears on each statement print record.

| Field Name | Format | Source/Value/Description |
|-------------------|---------------|---|
| Postal code | A12 | This is the postal code on address associated with the statement. |

Statement Information

The topics in this section describe the information that appears on each on each statement print record. The following links are provided so that you can move easily to specific topic within this section:

- [Global Extract Information Record \(0010\)](#)
- [Statement Record \(0100\)](#)

- [Total By Currency Record \(0120\)](#)
- [Statement Construct Detail Record \(0500\)](#)
- [Service Agreement Record \(0900\)](#)
- [Bill Record \(1100\)](#)
- [Financial Transaction \(FT\) Record \(1300\)](#)
- [End Bill Record \(3600\)](#)
- [End Service Agreement Record \(3700\)](#)
- [End Statement Construct Detail Record \(5000\)](#)
- [End Statement Record \(9999\)](#)
- [Address Sub-record](#)

Global Extract Information Record (0010)

| Field Name | Format | Source/Value/Description |
|-----------------|--------|---|
| BATCH_CD | A8 | Batch Control Code of the extract process. |
| BATCH_NBR | N10 | Batch Number of the extract process |
| BATCH_RERUN_NBR | N10 | Batch Rerun number of the extract process. |
| STATEMENT_CNT | N10 | Count of statements on this extract. Multiple copies of a statement are counted multiple as well. |
| EXTRACT_DTTM | A31 | System time of extraction. Formatted according to user profile. |
| STMT_ID_START | A12 | This is only used when a statement is produced as a result of an online request (from Statement - Main). It contains the Statement Id to extract. |
| STMT_ID_END | A12 | This is only used when a statement is produced as a result of an online request (from Statement - Main). It contains the Statement Id to extract. |
| THREAD_NBR | N10 | This field is only used if statements are extracted in batch. It contains the thread number in which the statement was extracted. |
| THREAD_CNT | N10 | This field is only used if statements are extracted in batch. It contains the total number of threads that were extracted. |
| STATEMENT_IND | A1 | Defaulted to "Y" |

Statement Record (0100)

| Field Name | Format | Source/Value/Description |
|-----------------|--------|---|
| STMT_ID | A12 | CI_STM |
| PER_ID | A10 | CI_STM_CNST |
| STMT_DT | A31 | STMT_DT from CI_STM. Formatted according to user profile. |
| COPY_NBR | N1 | "1" |
| NBR_STMT_COPIES | N1 | "1" |
| ENTITY_NAME | A64 | Main name of CI_PER (from CI_PER_NAME). |
| ADDRESS_SBR | A361 | Address where the statement should be sent (the address is defined on the statement's statement construct). |
| ENTITY_NAME1 | A64 | CI_PER |
| ENTITY_NAME2 | A64 | CI_PER |
| ENTITY_NAME3 | A64 | CI_PER |
| DESCR50 | A50 | CI_STM_CNST |

[Top of Page](#)

Total By Currency Record (0120)

One total record will be created for each currency code associated with the FT's associated with the SA snapshots linked to the statement.

| Field Name | Format | Source/Value/Description |
|-------------|--------|---|
| CURRENCY_CD | A3 | This is the currency code associated with the summary information. |
| CUR_BAL | A30 | This is the sum of CUR_AMT snapshot on the SA snapshots (CI_BILL_SA) linked to the statement. SA snapshots (CI_BILL_SAs) are referenced on CI_STM_DTL. |
| BILL_AMT | A30 | This is the sum of CUR_AMT from CI_FT's classified as "corrections" and "current charges" on bill's associated with the statement. Please note, only those FT's associated with SAs linked to the statement will be amalgamated. This is formatted according to user's display profile. |

| | | |
|-------------|-----|--|
| CUR_ADJ_AMT | A30 | This is the sum of CUR_AMT from CI_FT's classified as "adjustments" on bills associated with the statement. Please note, only those FT's associated with SAs linked to the statement will be amalgamated. This is formatted according to user's display profile. |
| CUR_PAY_AMT | A30 | This is the sum of CUR_AMT from CI_FT's classified as "payments" on bills associated with the statement. Please note, only those FT's associated with SAs linked to the statement will be amalgamated. This is formatted according to user's display profile. |

Address Sub-record

The address sub-record that in statement record (0100) is composed of the following:

| Field Name | Format | Description |
|---------------|--------|-------------|
| COUNTRY | A3 | |
| ADDRESS1 | A64 | |
| ADDRESS2 | A64 | |
| ADDRESS3 | A64 | |
| ADDRESS4 | A64 | |
| CITY | A30 | |
| NUM1 | A6 | |
| NUM2 | A4 | |
| HOUSE_TYPE | A2 | |
| COUNTY | A30 | |
| STATE | A6 | |
| POSTAL | A12 | |
| GEO_CODE | A11 | |
| IN_CITY_LIMIT | A1 | |

Statement Construct Maintenance

The statement construct enables you to indicate the collection of accounts and/or service agreements whose financial details should be consolidated for a statement to a given person. The statement construct also contains routing information needed by the system to send the statement to the person in the preferred manner.

Lifecycle of a Statement Construct

The following diagram illustrates the lifecycle of a statement construct.

Active: The statement construct will be in this status while a person is actively receiving statements for the accounts and service agreements linked to this construct. A statement construct may transition from this status to inactive.

Inactive: The statement construct will be in this status when a person no longer wishes to receive statements for the accounts and service agreements linked to this construct. A statement construct may transition from this status back to active.

Statement Construct - Main

Open this page using **Menu > Customer Information > Statement Construct > Search.**

Description of Page

Statement Construct is a concatenation of summary information about this record. It is composed of the name of the statement person, the print description and the status.

Statement Construct ID is the unique system-generated identifier for this statement construct.

Person ID is the person who receives the future statements.

Note:

A person may be linked to many statement construct records.

Status indicates whether or not this person is currently receiving statements. The values are Active and Inactive.

Fastpath:

Refer to [Lifecycle of a Statement Construct](#) for more information.

Address Source indicates where the source of the statement's address. The values are Person and Mailing Premise. If the value is person, the person's [mailing address](#) is used. If the value is mailing premise, indicate the **Mailing Premise** to use.

Statement Cycle controls when statements are produced for this statement construct. Refer to [Statement Cycle](#) for a description of how the production schedule is maintained.

Statement Route Type controls how the statement is routed to the **Person** (e.g., via email, postal service, EDI, etc.). Refer to [Statement Route Type for more information](#) on setting up statement route types.

Number of Copies indicates how many copies of the statement the person wishes to receive.

Statement Format indicates if the person receives a Detailed or a Summary statement.

Note:

The values for this field are customizable using the Lookup table. The values need to match the formats supported by your statement print software. This field name is STM_FORMAT_FLG.

Print Description is a brief description that can be printed on the statement.

The tree shows the statement construct's details. The nodes expand to show account, premise and service agreement information for the construct details.

Note:

Large statement constructs. The tree is hard to use if the statement construct has many details. In this situation, transfer to the adjacent tab page and use the filter to restrict the details that are shown.

Statement Construct - Details

This page is used to maintain the accounts and service agreements where financial transactions should appear on statements produced using this statement construct. Open this page using **Menu > Customer Information > Statement Construct > Search** and navigate to the **Details** page.

Description of Page

Statement Construct is a concatenation of summary information about this record. It is composed of the name of the statement person, the print description and the status.

Statement Construct ID is the unique system-generated identifier for this statement construct.

If a statement construct has a large number of details, you can use the **Details Filter** to limit the details that appear in the grid. The following options are available:

- All. Use this option to view all details linked to the statement construct.
- Person Name. Use this option to restrict details linked to accounts whose main customer has a primary name that matches an input **Name**.
- SAs at an Address. Use this option to only show details linked to service agreements that are linked to service points associated with a given **Address, City** and/or **Postal** code. Note, you can specify any combination of these fields.
- Statement Print Description. Use this option to restrict details to those with a given **Description**.

Don't forget to click the search button after changing the filter.

The grid contains the Accounts and/or Service Agreements whose financial information contributes to this statement construct. Each record in the grid contains the following information:

- **Construct Detail Type** defines if the construct detail is for an entire Account or a single Service Agreement. This field is protected if a statement detail was produced using this construct.
- **Service Agreement/Account** identifies the account (for Account construct details) or the service agreement (for Service Agreement) construct details. This field is protected if a statement detail was produced using this construct.
- **Statement Print Description** is available for use by the extract program to include on the printed statements to help the recipient identify the details.
- **Print Order** control where the financial transactions associated with the account / service agreement appear on the printed statement.
- **Start Date** is the date that this account / service agreement's financial transactions should begin appearing on statements.
- **End Date** is the date that this account / service agreement's financial transactions should stop appearing on statements.

Note:

Only financial transactions linked to bills whose **BILL DATE** is within the construct detail's **Start Date** and **End Dates** will appear on statements.

- **Construct Detail ID** is a system generated unique identifier of the construct detail.

Statement Maintenance

Statements allow you to set up a Person to receive a consolidated report of the financial activity for one or more accounts and/or service agreements. The topics in this section describe how to maintain statements.

Note:

The system creates most statements behind-the-scenes. Most statements are created by the system when it processes the statement cycle schedule. You should only have to access the statement pages to regenerate a statement or to add a statement real-time. For information about how the system creates statements, refer to [The Statement Creation Background Process](#).

Lifecycle of a Statement

The following diagram illustrates the lifecycle of a statement.

Pending: A statement is created in this state and will remain in this state until the statement details are extracted. When that occurs, it will transition to printed.

Printed: A statement transitions to this state after the details of a statement have been extracted.

Statement - Main

Open this page using **Menu > Financial > Statement > Search**.

Note:

Correcting erroneous statements. It's important to be aware that there are very few fields that are directly modifiable by a user. This is because a statement is a summary of financial transactions. If you need to change information on a statement, you must change the source information (e.g., change the statement's construct or complete additional bills) and then regenerate the statement. Refer to [How To Regenerate A Statement](#) for more information.

Description of Page

Statement is a concatenation of summary information about this record. It is composed of the name of the statement person, the statement construct print description, the create date of the statement and the statement status.

Statement ID is the unique system-generated identifier for this statement.

Indicate the **Construct ID** for the statement construct whose construct details should be included in this statement.

Address is a display-only field that contains the address to which the statement will be sent.

The **Statement Status** indicates the current status of the statement. The values are Pending, Printed.

**Fastpath:**

Refer to [Lifecycle of a Statement](#) for more information.

The **Create Date** indicates the date that this statement was created.

The **Batch Control** and **Batch Number** are the batch process and run in which the statement was (or will be) sent to the recipient.

**Fastpath:**

Refer to [Printing Statements](#) and to [Statement Route Type](#) for more information.

The **Statement Action** area contains buttons that you use to generate, reprint or delete a statement.

- The **Generate** button enables you to create a statement on-line. Refer to [On-line Statement Production](#) for more information.
- The **Reprint** button will stamp the latest run number for the statement's batch control. This will enable the statement to be reprinted the next time the batch control process executes. Refer to [How to Reprint A Specific Statement](#) for more information.
- The **Delete** button will remove the statement and its details from the database. Refer to [How to Regenerate a Specific Statement](#) for more information.
- The **Display** button will display an online image of the statement when pressed. Refer to [Online Statement Display](#) for more information.

**Note:**

You can only use the **Display** button if your system has been configured to display an on-line image; otherwise, a message indicating that the service is not available will appear. This option can only be configured by your technical staff. Refer to [Technical Implementation Of Online Statement Display](#) for more information.

The bottom portion of this page is dedicated to a [tree](#) that shows the statement details. The nodes expand to show every service agreement that will appear on the statement and the financial details that will be swept onto the statement for each service agreement. You may transfer to the details of any of the nodes by selecting that node. Context menus are also available for various nodes to facilitate easy navigation to other pages.

**Note:**

Large statements. The tree will be hard to use if the statement has many service agreements that contributed financial transactions to the statement. In this situation, transfer to the adjacent tab page and use the filter to restrict the service agreements that are shown.

Statement - Details

This page is used to view the service agreements that contributed financial transactions to the statement. Open this page using **Menu > Financial > Statement > Search** and navigate to the **Details** page.

Description of Page

Statement is a concatenation of summary information about the statement. It is composed of the name of the statement person, the statement construct print description, the create date of the statement and the statement status.

Statement ID is this statement's unique system-generated identifier.

If a statement has a large number of service agreements that contributed financial transactions to the statement, you can use the **SA Filter** to limit the service agreements that appear in the grid. The following options are available:

- All. Use this option to view all service agreements that contributed financial transactions to the statement.
- Person Name. Use this option to only show service agreement linked to accounts whose main customer has a primary name that matches **Person Name**.
- SAs at an Address. Use this option to only show service agreements that are linked to service points associated with a given **Address, City** and/or **Postal** code. Note, you can specify any combination of these fields.

- **Statement Print Description.** Use this option to only show service agreements associated with a construct detail with a given **Statement Print Description**.

Don't forget to click the search button after changing the filter.

The grid contains service agreements that contributed financial transactions to the statement. If a service agreement's financial transactions appeared on multiple bills, a separate line is displayed for each bill. You can press the go to button adjacent to **Bill Due Date** to be transferred to [Financial Transactions On A Bill](#) where the individual financial transactions associated with the associated service agreement and bill can be viewed. The following information is displayed in the grid:

- **Statement Print Description** is the description of the construct detail associated with the service agreement.
- **Bill's Due Date** is the date of the bill on which the service agreement's financial transactions appear. Press the adjacent go to button to be transferred to [Financial Transactions On A Bill](#) where the individual financial transactions can be viewed.
- **Premise Information** describes the characteristic premise, if any, associated with the service agreement.
- **SA Information** describes the service agreement that contributed financial transactions to the statement.
- **Account Information** describes the account associated with the service agreement whose details appear on the statement.
- **Construct Detail ID** is the unique identifier of the construct detail associated with the service agreement.
- **Statement Detail ID** is the unique identifier of the statement detail on which the service agreement's financial transactions appear.

Sales & Marketing

The sales and marketing functionality satisfies many diverse requirements. For example, you can use this functionality to:

- Enroll new customers using a single transaction (i.e., you don't have to use the person, premise, service point, and start/stop transactions to enroll a new customer who resides at a new premise).
- Sell new products to existing customers.
- Update person, account and premise information using a single transaction.
- Market your services to prospects from a marketing list (and measure the success of your efforts). If the customer responds to your sales efforts, the system will automatically setup the customer, premise and related service agreements.
- Setup marketing surveys and record your customers' responses.
- Quickly create one-time charges.
- Setup [proposals](#) for prospective services (and then send a quotation to the customer for these services).
- And more...

The topics in this section provide more information about the sales and marketing functions.

The Big Picture of Campaigns, Packages, and Orders

Three objects are at the heart of the sales and marketing functionality: **Campaigns, Packages, and Orders**.

- A **package** defines a basket of goods and services that can be offered to a customer or a prospect.
- A **campaign** is a structured effort to offer a given set of packages to existing customers or new prospects.
- An **order** is created for each customer / prospect to which a campaign is targeted.

The topics in this section provide background information about these objects.

An Overview of Campaigns, Packages and Orders

An order is used to define:

- Demographic information about a customer / prospect.
- Geographic information about the service address.
- The customer's response to eligibility-oriented questions. For example, you can pose questions like: Who is your current energy service provider? / Would you like to pay automatically? / What is your date of birth?

After the above information is defined, the [order transaction](#) presents packages that may be offered to the customer. A package controls the various types of service agreements that will be created if the customer selects the package.

Note:

The customer must be eligible for a package. When you setup a [package](#), you define its [eligibility criteria](#). For example, you can setup a package that is only applicable to commercial customers in Toronto who pay automatically and who commit to a one-year service contract.

If the customer elects to take a package, the order transaction sets up / updates [the "V"](#) (along with all of the ancillary things that happen when service is initiated, e.g., field activities are created). Please note that in addition to setting up the "V", it's also possible to populate / update other information when a package is selected. For example, you could have the system setup the customer's automatic payment options.

Note:

An order can be completed without creating service agreements. It is possible to use the order transaction to simply create / update persons and accounts. Refer to [Marketing Surveys](#) and [Setting up a New Customer Prior To Using Start/Stop](#) for more information.

All orders must reference a campaign. An order's [campaign](#) defines:

- How the campaign's orders use accounts and premises. For example, you can indicate that a given campaign is only targeted at existing premises (thus preventing the creation of a new premise when an order is completed).
- The type of information defaulted onto an order. For example, you can setup a campaign to default a given account management group on all orders linked to the campaign. This account management group will subsequently default onto the new account when the order is completed.
- The validation rules that control how its orders use accounts and premises. Specifically, on a campaign you define if an account / premise is required / optional / not allowed on its orders. In addition, if an account / premise is required or optional, you can control whether new accounts / premises can be created when an order is completed (the alternative is to force each order to use an existing account / premise). These controls prevent the unwanted proliferation of new accounts and premises for campaigns that are targeted at existing accounts and premises.
- The eligibility-oriented questions that are posed to the customer when an order is taken. For example, the questions indicated above - Who is your current energy service provider? / Would you like to pay automatically? / What is your date of birth? - are all defined on the order's campaign.
- The superset of packages that can be offered to a customer whose order references this campaign. An order's campaign defines the types of packages that may be selected.
- In addition to the above, campaigns also control high-level [eligibility rules](#) and [business process flows](#).

Note:

Bottom line. Campaigns allow you to define a group of **packages** that a customer is eligible to purchase. Every time a campaign is targeted at a customer, an **Order** is created. The information entered on the order qualifies the customer for one of the campaign's packages. If a customer elects to take a package, [the "V"](#) is setup / updated along with all of the ancillary things that happen when service is initiated, e.g., field activities are created, workflow processes are initiated, etc.

Supported Business Processes

Before providing examples of specific business processes, we'd like to highlight that you have control over some aspects of the user-interface flow (i.e., the screen navigation is not hard-coded). The following illustration highlights the potential user-interface flow:

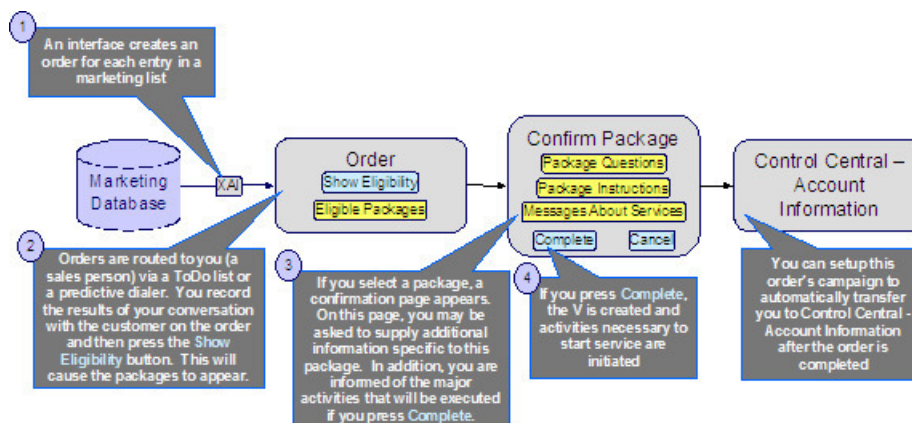

**Note:**

Bottom line. You can navigate to the order transaction from many places in the system. After you complete an order, you are transferred to an appropriate transaction. The specific transaction is controlled by you when you setup the order's [campaign](#).

The topics that follow illustrate specific business process flows that are possible in your implementation of the sales and marketing functionality.

Marketing to Prospects from a Marketing List

The following business process flow illustrates how the sales and marketing functionality would be used to market to prospects uploaded from a marketing database.

The following points describe the steps in this business process:

- An upload interface creates an [order](#) for each entry in a marketing database.

**Note:**

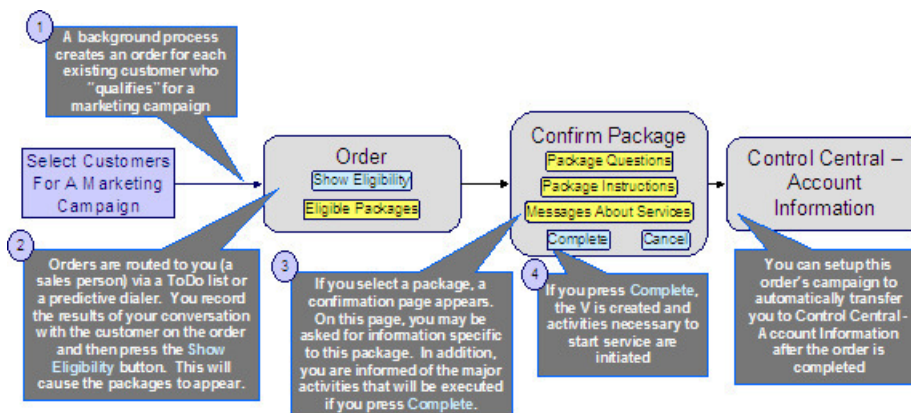

The system is not supplied with a dedicated interface to upload a marketing list.

- Each [order](#) is routed to a salesperson via a [To Do entry](#) (or via a predictive dialer if your company supports this type of technology).
- The first step in the salesperson's interaction with the prospect will be to confirm the information uploaded from the marketing list (e.g., is your Bob Smith?, is your address 15 Main St?, etc.). Any changes are made to the information saved on the order.

- The salesperson's next step involves posing eligibility-oriented questions related to the campaign. Examples of questions include:
 - **What is your date of birth?** This type of question might be asked if you have packages that are only marketed to senior citizens. Potential answers would be a valid date that's in the past.
 - **Would you be interested in our full-service option (electricity, digital cable and gas)?** Potential options are: yes and no.
 - **Who is your current electric service provider?** Potential answers are: Utility.Com, Reliant Resources, Other.
 - **Would you like to pay automatically?** Potential answers are: Yes, No.
 - **Would you like to pay using a leveled payment plan?** Potential answers are: Yes, No.
 - Etc.
- The gathered information is saved on the order and then the system displays the packages that can be offered to the customer. The available packages may be restricted based on information on the order. For example, some packages are only applicable to senior citizens, while others are only applicable to customers whose current service provider is Utility.com.
- If the customer is interested in a package, the salesperson selects it. Prior to the order being completed, the [package confirmation](#) page is shown. On this page are additional instructions about the package and a description of how the system will be updated if the package is selected (e.g., the types of service agreements will be displayed). In addition, the package may require additional information before it can be chosen. For example, the package may only be selectable if the customer agrees to pay automatically. In this situation, the package confirmation page will require the salesperson to enter the customer's bank and bank account.
- After entering all package-specific information, the order is completed. When the order is completed, the "V" is setup and all work necessary to satisfy the order is initiated (e.g., field activities are created, workflow processes are initiated, etc.).
- And finally, the user is returned to [Control Central - Account Info](#) where an overview of the customer is displayed. From this page, the user can drill down to any service agreement (or to start/stop) to perform any fine-tuning.
- Please be aware that the page to which you are transferred after order completion is controlled by a field on the order's [campaign](#). In our example, it made sense to transfer the user to Control Central as it provides a nice confirmation to the user (it shows a great deal of information about an account). However, you could setup the campaign to take the user to virtually any page in the system. You'll see good examples later in this discussion.

Marketing to Pre-Selected Customers

The following business process flow illustrates how the sales and marketing functionality would be used to market additional services to existing customers selected by a background process.

The following points describe the steps in this business process:

- A background process creates an [order](#) for each customer to be targeted under a marketing campaign.

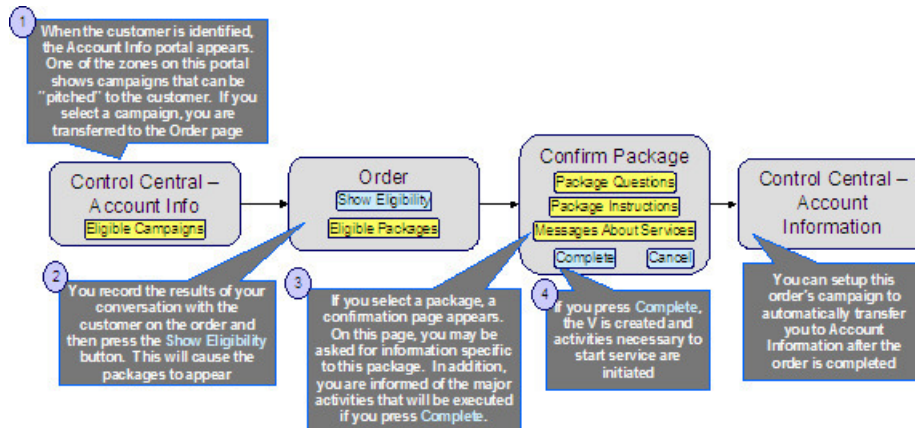

Note:

The base package does not have an example of such a background process. Please speak to your support team if you require assistance in developing this type of process.

- Sales people would then process the order as described above.

Real-Time Marketing of Additional Services to a Customer

The following business process flow illustrates how the sales and marketing functionality would be used to market additional services to existing customers when they call in.

The following points describe the steps in this business process:

- When you find the customer's record on [Control Central - Search](#), you are automatically transferred to the [Account Information](#) portal. One of the zones on this page contains the campaigns that can be offered to the customer.

Note:

The "potential campaigns" zone only appears if the CSR has modified their preferences to display this zone.

- If you select a campaign from this zone, you are transferred to the [Order](#) transaction.

Note:

An order's campaign controls whether the [Main](#) or [Questions & Misc Fields](#) tab is initially displayed when the order transaction is invoked from this zone. For example, you might want to have the **Main** tab displayed if you want the order-taker to confirm the customer's demographic information before posing questions. Alternatively, you may want to skip this step and immediately present the order-taker with the campaign's questions. Keep in mind that the user can always display the other tab regardless of what is initially displayed.

- You then process the order as described above.

Note:

An easy way to create one-time charges. The above business process illustrates how the selection of a package will create one or more new service agreements for a customer. If your organization levies one-time charges (e.g., tree trimming charges, damage assessments, etc.), you can also use the order transaction to create both a "one-time charge" service agreement and create the related billable charge when the order is completed. To do this, setup a campaign with a separate package for each possible one-time charge. If an order is created for this type of campaign and the relevant package is selected, the system will setup the new billable charge service agreement and link the billable charge to it. Refer to [An Easier Way To Create One Time Charges](#) for an example of such a campaign.

Real-Time Marketing of Services to a Prospect

The following business process flow illustrates how the sales and marketing functionality would be used to market services when a new customer calls.

Warning:

We do not recommend using this business process if your organization's service territory is predefined (i.e., if you've set up the premises and service points for your entire service territory). Why? Because it can result in the creation of new premises and / or service points and you probably don't want this to happen if you've already set everything up. While it is possible to disable the creation of new service points and premises by developing new plug-ins, we'd recommend using the business process described under [How To Add A New Customer From Control Central](#) if a new customer calls in and you have predefined premises and service points.

The following points describe the steps in this business process:

- You look for the customer using [Control Central - Search](#). Because the customer is new, you push the Add Order button on Control Central to transfer to the [Order](#) transaction.
- You then process the order as described above.

In order to take advantage of the above business process, it's important that you understand the following points:

- When the order page is opened for a new customer, the order's campaign is defaulted from the [installation record](#). The default campaign on the installation record is "generic" because we don't know anything about the customer (they are new) and therefore we cannot default a campaign targeted to their customer class or geography.
- This default campaign on the installation record must be constructed using one of the following approaches:
 - The default campaign has a package for every potential type of customer who can call up. While this is possible, it's probably not realistic as the data setup burden required to define every type of package could be onerous. However, if you have a limited number of service agreements, this approach is feasible.
 - The default campaign could just be a "dummy" campaign that has no packages. The "real" campaigns will only be shown after basic information about the customer has been recorded on the order and the "show eligibility" button is pressed. These campaigns appear in the order's [eligibility tree](#). The selection of a campaign in this tree will cause the order's campaign to be switched. Note, because the "dummy" campaign has no packages, no packages will appear in the order's eligibility tree when the dummy campaign is referenced on an order.
- The order is then processed as described above.

Setting up a New Customer Prior To Using Start/Stop

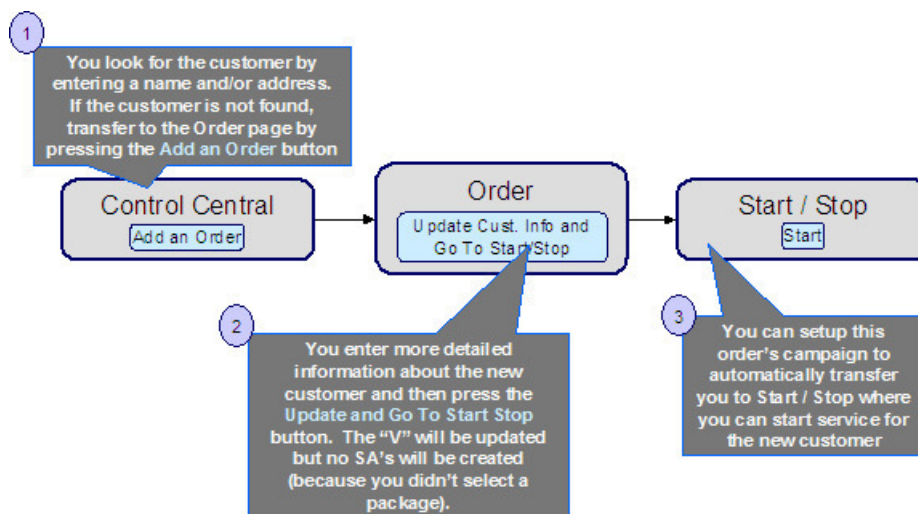

The following business process flow illustrates how the sales and marketing functionality would be used to create a new customer prior to using [Start/Stop](#) to start service at an existing premise.

Note:

The following business process is similar to that described under [How To Add A New Customer From Control Central](#). The only difference is that the [Order](#) transaction is used to create a new person and account rather than the [Person](#) transaction. The order transaction may be a better choice because it lets you define

many attributes on person, account and premise that are not accessible on the person page. For example, the order transaction lets you define the customer's automatic payment option, bill after date, override due date, etc. In addition, on an order's campaign, you can define default values of many field values (both real fields and characteristics). These default values are presented on the order transaction and may be overridden by the user at will.

The following points describe the steps in this business process:

- You look for the customer using [Control Central - Search](#). Because the customer is new, you push the "Add Order" button on Control Central to transfer to the [Order](#) transaction.
- You record additional demographic and geographic information about the new customer and confirm all values defaulted from the order's campaign. After all required information is entered, you press the Update Cust. Info and Go To Start/Stop button to create the new person and account and transfer to [Start/Stop](#) to identify the new services desired by the customer.

Note:

The button's existence and label are dynamic. In the above example, we indicated that there is a button on the order page called **Update Cust. Info and Go To Start/Stop**. This button's presence on the page and its label are controlled by fields on the [campaign](#). When pressed, the "V" is updated with information on the order and the user is transferred to the "post completion" page (which is also defined on the campaign). You would only enable this button on campaigns whose orders can be completed without selecting a package. In the above example, the campaign doesn't have any packages (because service is intended to be started using Start/Stop). In [Examples of Campaigns and Packages](#) we show other examples of how these fields would be setup for different types of campaigns.

In order to take advantage of the above business process, it's important that you understand the following points:

- When the order page is opened as a result of pressing the Add Order button on [Control Central - Search](#), the order's campaign is defaulted from the [installation record](#). The default campaign on the installation record is "generic" because nothing is known about the new customer and therefore it is impossible to default a campaign targeted to their customer class or geography.
- The campaign on the installation record should be setup to contain default information for the "average" customer. For example, if you typically deal with residential customers, the information on the default campaign should be residential-oriented.
- When a user takes an order for a new customer, they'll change the default information when appropriate. For example, if an industrial customer were being added, they'd change the customer class to "industrial" and then ask to see the campaigns such a customer is eligible to choose (these alternate campaigns are displayed in the order's [eligibility tree](#)). For example, if you've setup campaigns with [eligibility rules](#) that are targeted at industrial customers and the customer class on the order has been changed to "industrial", the user will see these campaigns in the eligibility tree. The user can then change the campaign's order by simply clicking on the desired campaign.

**Note:**

The above example illustrates how an order can be completed without causing the creation of service agreements. Refer to [Marketing Surveys](#) and [Prelude to Start Stop](#) for examples of such campaigns.

Examples of Campaigns and Packages

The topics that follow provide examples of [campaigns](#) and [packages](#) that support several different scenarios. Your organization's campaigns and packages may differ markedly from these examples. Factors that will influence your sales and marketing objects include:

- Whether the type of goods and services marketed to your customers / prospects differs depending on some trait of the customer or the region in which they are located. For example,
 - Your company may have very straightforward packages that only differ based on whether the customer is industrial, residential or commercial. If this describes your company, the setup process will be simple.
 - Alternatively, your company might offer different packages to residential customers based on whether they pay automatically, whether the customer is a senior citizen, whether they purchase multiple services from you, etc. If this describes your company, then you'll have to define the various eligibility criteria and the respective packages applicable to customers who satisfy each criterion.
- Whether premises exist prior to order taking. For example, a company that distributes a commodity has a well-defined geographic area and therefore new premises typically don't arise when orders are taken.
- Whether your company offers many different types of goods and services.
- Whether your rates have charges / discounts that are only applied to some customers. For example, you might have discounts that are applied if the customer is a senior citizen or an employee.
- Which of the [Supported Business Processes](#) you implement.

Use the information that follows to form an intuitive understanding of campaigns and packages. After attaining this understanding, you'll be ready to design your own campaigns and packages.

Campaigns Without Packages

An order that references a campaign without packages will never create service agreements. The following topics describe scenarios when such a campaign would be used.

Marketing Surveys

Some organizations conduct "marketing surveys" to determine general trends amongst their customer base. The following diagram illustrates how such a campaign might look:

Campaign – Residential Survey

Default Info For New Customers / Premises

Not applicable

Questions To Be Posed On Orders

| Question | Possible Answers |
|---|----------------------------|
| Electric or gas water heater? | Elec, Gas |
| How many low-flow toilets? | 1 through 9 |
| How many people are in your household? | 1 through >12 |
| How would you rate our service? | 1 (bad), 2 (OK), 3 (great) |
| How many outages have you experienced in the last year? | 0 through >12 |

Misc Fields To Be Captured

Not applicable

Campaign Eligibility Rules

Algorithm

Customer class is residential

Potential Packages

Not applicable

Campaign Behavior Controls

| | |
|--|-----------------|
| Enable button that allows order completion without package selection | Yes |
| Button Label | Complete Survey |
| Post completion transaction | Account Info |

Note the following about this campaign:

- If the campaign is used to establish new customers, you can define information to default onto orders created for new customers. Because marketing surveys are targeted at existing customers, you don't need new customer default information on the campaign.
- You can define questions to be posed to customers when an order is taken when you setup a campaign. For a "marketing survey" campaign, you'd define each of the survey questions and the permissible answers. When a customer is surveyed, an order is created and their answers are saved on the order.
- On a campaign, you can define additional fields to be updated on persons, accounts and premises when orders associated with the campaign are completed. For example, you could indicate that the account's override due date and automatic payment options should be confirmed when an order is taken. Because marketing surveys are typically only asking questions, you wouldn't need to define additional customer information fields to be confirmed. However, you can if you want.
- All campaigns need at least one eligibility rule. These rules control whether the campaign appears in the "eligible campaigns" [content zone](#) when a customer is selected on Control Central. These rules also control whether the campaign appears on an order's [eligibility tree](#) (campaigns that appear in this tree are alternate campaigns that may be used on the order). Our example has assumed that this is a residential customer survey and therefore it only needs a single eligibility rule. Refer to [The Big Picture Of Campaign Eligibility Rules](#) for more information.
- Because this campaign is used purely to manage a marketing survey, it doesn't need any packages. Packages are only necessary if service agreements are created when an order is completed.
- Because this campaign doesn't have packages, we have indicated that the button that allows orders to be completed without selecting a package is enabled. If you don't enable this button, a user won't be able to complete

a marketing survey (and it is only during order completion when the "V" is updated with the information on the order). Notice that we have assigned the button a label of Complete Survey.

- This campaign should be setup to transfer the user to [Control Central - Account Info](#) after the survey is completed.

Prelude to Start/Stop

Consider the example illustrated above under [Setting up a New Customer Prior To Start/Stop](#). In this example, the [order](#) transaction is used to create a new person and account; no service agreements are created when the order is completed. Rather, after the order is completed, the user is automatically transferred to [Start/Stop](#) where they can create service agreements. The following diagram illustrates how such a campaign might look:

Campaign – Add New Customer

| Default Info For New Customers / Premises | |
|---|---------------|
| Field | Default Value |
| Customer Class | R |
| Account Management Group | RESID |

Questions To Be Posed On Orders
Not applicable

| Misc Fields To Be Captured | | |
|----------------------------|---------------------|---------------|
| Field | Required / Optional | Default Value |
| Auto-pay source | Optional | "" |
| Auto-pay account | Optional | "" |
| Date of birth | Optional | "" |

Campaign Eligibility Rules
Algorithm
This campaign is only used to create new customers

Potential Packages
Not applicable

| Campaign Behavior Controls | |
|--|----------------------------|
| Enable button that allows order completion without package selection | Yes |
| Button Label | Update the V / Go To Start |
| Post completion transaction | Start/Stop |

Note the following about this campaign:

- Because this campaign is used to establish new customers, you should define new customer default information. The order taker can override these default values.
- If we assume you don't ask marketing / eligibility-oriented questions when you take-on a new customer then this campaign would not require any questions.
- On a campaign, you can define additional fields to be updated on the related person, account and premise when orders associated with the campaign are completed. For example, you could indicate that the account's override due date and automatic payment options should be confirmed when an order is taken. In our example, we are assuming that we want to define the customer's automatic payment options and their date of birth.

- As described under [Marketing Surveys](#), a campaign's eligibility rule(s) control whether the campaign appears in the "eligible campaigns" [content zone](#) and on an order's [eligibility tree](#). This campaign is odd in that we don't want it to ever appear as an "eligible campaign" because it's only used for NEW customers. In order to make this work you must:
 - Define an eligibility algorithm on this campaign that prevents it from appearing as an "eligible campaigns". Refer to [A Campaign That Is Never Eligible](#) for more information.
 - Update the [installation record](#) to indicate that this campaign is the one that should be used on orders created when a user presses the "Add an Order" button on [Control Central - Search](#). Refer to [Setting up a New Customer Prior To Starting Service](#) for more information about the flow of this business process.
- Because this campaign is used purely to add accounts and persons, it doesn't need any packages. Packages are only necessary if service agreements are created when an order is completed.
- Because this campaign doesn't have packages, we have indicated that the button that allows an order to be completed without selecting a package is enabled. If you don't enable this button, a user won't be able to complete the order (and it is only during order completion when the "V" is updated with the information on the order). Notice that we have assigned the button a label of Update The V and Go To Start.
- This campaign should be setup to transfer the user to [Start/Stop](#) after the order is completed.

Campaigns With Simple Packages

As explained under [Campaigns Without Packages](#), there are several situations that might necessitate a campaign without packages. In this section, we describe simple scenarios of campaigns with packages.

An Easier Way To Create One Time Charges

We use the term "one-time charge" to describe ad hoc charges, e.g., tree trimming charges, damage assessments, etc. The following points describe how one-time charges are levied if you don't use the order transaction:

- Determine if the customer to be invoiced already has an appropriate "one-time charge" service agreement. If one doesn't exist, you must create one using [Start/Stop Service](#).
- Next, a billable charge is added to the "one-time charge" service agreement (using [Billable Charge Maintenance](#)). The billable charge contains the invoice lines and amounts. The system will produce the bill for this charge when the account's bill cycle next executes.

Rather than going through the above multi-step process, you can also use the order transaction to create both a "one-time charge" service agreement AND create the billable charge. In addition, if the customer receiving the charge is new, the order transaction will also create a new person and account at the same time.

To take advantage of this facility, you must set up a campaign that has a separate package for each type of one-time charge as illustrated below. When an order is taken for such a campaign, the user simply selects the package that corresponds with the desired one-time charge. The system will then create the necessary customer and financial information when the package is confirmed.

Note:

Billing of one-time charges. The order transaction will not cause a bill to be generated for the customer. Rather, the next time the account is billed, the system will see that there's an unbilled billable charge and create a bill segment for it. This bill segment will appear on the customer's regular bill along with their other charges. If you'd prefer to create the bill for the one-time charges immediately, you could setup the campaign to automatically transfer the user to the bill transaction where they can [create an ad hoc bill](#). If you do this, you'll need to create a new plug-in algorithm on the billable charge SA type to automatically activate the service agreement when it is created (otherwise the user would have to manually activate the billable charge service agreement before the bill can be generated).

Campaign – One Time Charges

| One Off | Damaged Line | N/A | Billable Charge |

Note the following about this campaign:

- One-time charges can be levied against both new and existing customers. This means that orders associated with this campaign may cause new customers to be created. Therefore, we have specified information to default onto orders for new customers on the campaign. Note that we defined "residential-oriented" default values as the majority of one-time charges are levied against residential customers.
- If we assume you don't ask marketing / eligibility-oriented questions when you levy a one-time charge then this campaign would not require any questions.
- We have assumed that you are not capturing miscellaneous fields when you levy a one-time charge.
- As described under [Marketing Surveys](#), all campaigns need at least one eligibility rule. We have assumed that this campaign's packages can be selected by all types of customers and have therefore specified an eligibility algorithm that will be true for all customers.
- Because this campaign has packages, we have indicated that the button that allows an order to be completed without selecting a package is disabled. This means a user must choose one of the packages to complete the order.
- You might want to setup this campaign to automatically transfer the user to the bill transaction after the order is completed. See the note above the illustration for more information.
- We have assumed that this campaign can be used to levy two kinds of one-time charges - a tree trimming charge and a damaged line charge - and therefore this campaign requires two packages. Note the following about each package:
 - A package's eligibility rules control whether the package can be selected when an order is taken. With more sophisticated campaigns, you may have packages that are only applicable to certain types of customers. In our example, we've assumed that these types of one-time charges can be levied against all customers and have therefore used "universal" eligibility criteria (i.e., there are no eligibility restrictions). Refer to [A Package That Is Always Eligible](#) for more information.
 - On a package, it's possible to define additional questions to be posed if a package is selected. In our example, there are no additional questions to be posed for the one-time charge packages.
 - On a package, it's possible to define additional fields to be captured if a package is selected. In our example, there are no additional fields to be captured.

- On a package, you define the types of service agreements to be created if a package is selected. In our example, we only need a single service agreement created / updated if the package is selected and therefore there's just one entry in **SAs To Create**. Please note the following about the information used to create this service agreement:
- The **SA Type** is one that's used for a [billable charge service agreement](#).
- The SA Type's **Start Option** is one that will automatically create a billable charge when a service agreement is created (if a [start option](#) references a [billable charge template](#), a billable charge will be created when this start option is used). In our example, we have assumed a different start option has been setup for each type of one-time charge.
- Billable charge service agreements do not require service points and therefore **SP Type** is not applicable.
- We've indicated a **Start Algorithm** of Billable Charge . Refer to STRM-AS for an example of such an algorithm (type).

Campaigns With Complex Packages

The [Campaigns With Simple Packages](#) illustrated campaigns with very simple packages. In this section, we describe a campaign with more complex packages.

Packages Limited By Answers And Field Values

Assume your organization has a campaign with several packages. Each package has the following restrictions in respect of its use:

- "Package 1" can be offered to residential customers in California who are senior citizens.
- "Package 2" can be offered to residential customers in California who live in single-family homes who are not senior citizens and who heat their homes with electricity.
- "Package 3" can be offered to residential customers in California who live in single-family homes who are not senior citizens and who heat their homes with gas.
- "Package 4" can be offered to residential customers in California who live in multi-family homes who are not senior citizens.

Also assume that all customers are encouraged to pay automatically.

The following diagram illustrates how such a campaign might look:

The topics that follow describe the campaign and packages used to support this scenario. We'll start by explaining each package. Then we'll describe how the campaign will be setup. This seems backwards, but it mirrors how you should design this type of campaign:

- [Senior Citizen Package](#)
- [Single-Family Electric Package](#)
- [Single-Family Gas Package](#)
- [Multi-Family Package](#)
- [The Campaign](#)

Senior Citizen Package

The package that is offered to residential customers in California who are senior citizens has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
 - Customer class = Residential
 - Division = California
 - Birth date equates to that of a senior citizen

- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
 - The **SA Type** is one that's used for an electric residential service agreement (hence the E-RES SA type).
 - The SA Type's **Start Option** is one that will automatically setup the service agreement with the appropriate rate and contract options for a senior citizen.
 - The service agreement needs to be linked to an electric residential service point (hence the E-RES SP type).
 - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

[Top of the Page](#)

Single-Family Electric Package

The package that is offered to residential customers in California who live in single-family homes who are not senior citizens and who heat their homes with electricity has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
 - Customer class = Residential
 - Division = California
 - Birth date does not equate to that of a senior citizen
 - The premise is a single-family home
 - The premise is heated with electricity
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
 - The **SA Type** is one that's used for an electric residential service agreement (hence the E-RES SA type).
 - The SA Type's **Start Option** is one that will automatically setup the service agreement with the appropriate rate and contract options for this type of customer.
 - The service agreement needs to be linked to an electric residential service point (hence the E-RES SP type).
 - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

[Top of the Page](#)

Single-Family Gas Package

The package that is offered to residential customers in California who live in single-family homes who are not senior citizens and who heat their homes with gas has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
 - Customer class = Residential
 - Division = California
 - Birth date does not equate to that of a senior citizen
 - The premise is a single-family home
 - The premise is heated with gas
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
 - The **SA Type** is one that's used for a gas residential service agreement (hence the G-RES SA type).
 - The SA Type's **Start Option** is one that will automatically setup the service agreement with the appropriate rate and contract options for this type of customer.
 - The service agreement needs to be linked to a gas residential service point (hence the G-RES SP type).

- We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

[Top of the Page](#)

Multi-Family Package

The package that is offered to residential customers in California who live in multi-family homes who are not senior citizens has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
 - Customer class = Residential
 - Division = California
 - Birth date does not equate to that of a senior citizen
 - The premise is a multi-family home
- This package requires additional information that was not requested at the campaign-level. We're going to assume that the multi-family rate needs to know the number of units in the building. This means that this package needs an additional field (number of units).
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
 - The **SA Type** is one that's used for an electric residential service agreement (hence the E-RES SA type).
 - The SA Type's **Start Option** is one that will automatically setup the service agreement with the appropriate rate and contract options for this type of customer.
 - The service agreement needs to be linked to an electric residential service point (hence the E-RES SP type).
 - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions in this package. This is because this package doesn't have additional questions.

[Top of the Page](#)

The Campaign

Note the following about this campaign:

- Orders can be created for both new and existing customers. Because new customers are possible, we have specified information to default onto orders for new customers. Note that we defined "residential-oriented" default values (but remember, these values can be overridden on the order).
- The questions on the campaign are those whose answers play a part in each package's eligibility. You could also ask additional [marketing survey-oriented](#) questions that have nothing to do with package eligibility.
- The miscellaneous fields highlight an interesting situation. Notice that the date-of-birth and "automatic payment" fields are optional. However the field that holds the number of dwelling units is "only applicable on packages". When a field has this designation, the user will only be prompted to supply this field's value if a package is chosen where this field is applicable. In our example, only the Multi Family Package uses this field. This package will be setup to indicate that this field is required whereas the other packages will be setup to indicate that this field is not used.

Note:

Bottom line. The "miscellaneous fields" on a campaign must also include package-specific fields.

- All campaigns need at least one "highlight rule". These rules control whether the campaign appears in the "eligible campaigns" [content zone](#) when a customer is selected on Control Central. Also note that "highlight rules" also control whether the campaign appears on an order's eligibility tree (campaigns that appear in this tree are alternate campaigns that may be used on the order).
- We're going to assume that this is a residential campaign and therefore you would specify a highlight rule that returns true if the customer's customer class is residential.

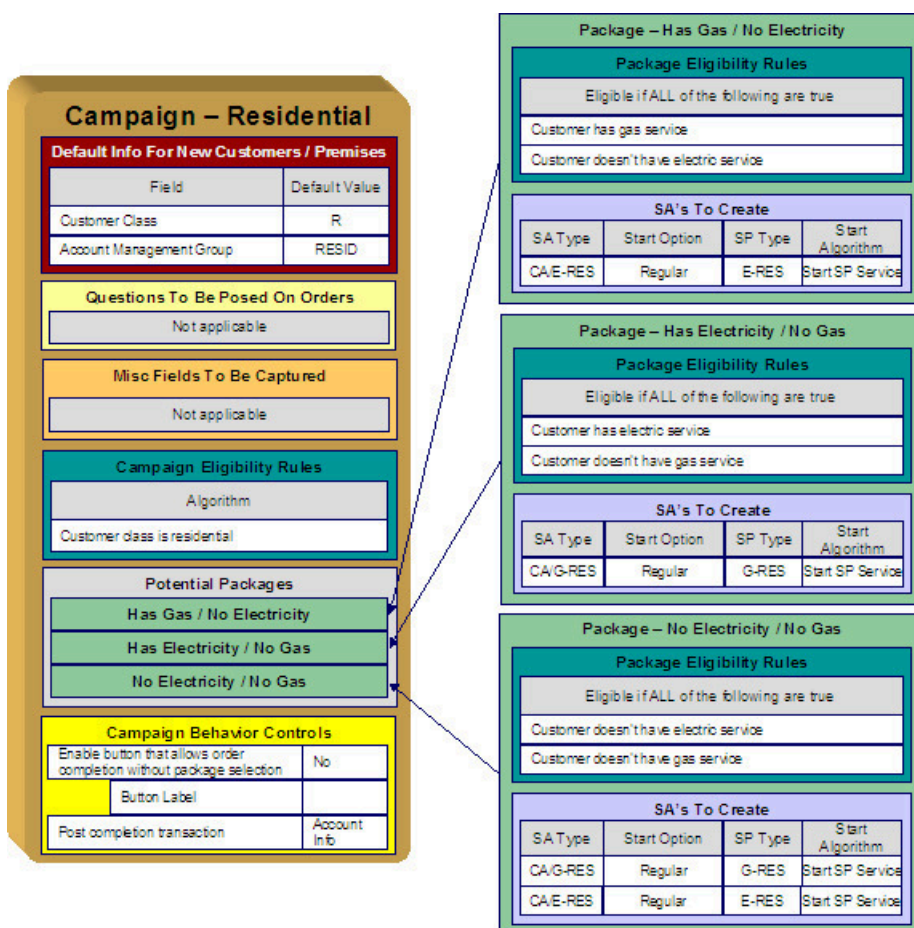

- Because this campaign has packages, we have indicated that the button that allows an order to be completed without selecting a package is disabled. This means a user must choose one of the packages to complete the order.
- This campaign is setup so that the user will be transferred to [Control Central - Account Info](#) after the order is completed. This is a subjective decision as you could transfer the user to a variety of transactions. It's just that the Account Info page provides a nice confirmation of how the customer looks after the order has updated / created new information.

Packages Limited By Current State Of Service

Assume your organization has a campaign with several packages. Each package has the following restrictions in respect of its use:

- "Package 1" can be offered to residential customers in California who have gas service, but don't have electric service.
- "Package 2" can be offered to residential customers in California who have electric service, but don't have gas service.
- "Package 3" can be offered to residential customers in California who have neither electric nor gas service.

The following diagram illustrates how such a campaign might look:

The topics that follow describe the campaign and packages used to support this scenario. We'll start by explaining each package. Then we'll describe how the campaign will be setup. This seems backwards, but it mirrors how you should design this type of campaign:

- [Has Gas / No Electricity Package](#)
- [Has Electricity / No Gas Package](#)
- [No Electricity / No Gas Package](#)

Has Gas / No Electricity Package

The package that is offered to customers that currently have gas service, but don't have electricity service has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
 - Customer has gas service
 - Customer doesn't have electricity service
- Refer to [A Package With Service Type Comparisons](#) for more information.
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
 - The **SA Type** is one that's used for an electric residential service agreement (hence the E-RES SA type).
 - The SA Type's **Start Option** is one that will setup the service agreement with the appropriate rate and contract options.
 - The service agreement needs to be linked to an electric residential service point (hence the E-RES SP type).
 - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

[Top](#)

Has Electricity / No Gas Package

The package that is offered to customers that currently have electric service, but don't have gas service has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
 - Customer has electric service
 - Customer doesn't have gas service
- We only need a single service agreement created if the package is selected and therefore there's just one entry in SAs To Create. Please note the following about the information used to create this service agreement:
 - The **SA Type** is one that's used for a gas residential service agreement (hence the G-RES SA type).
 - The SA Type's **Start Option** is one that will setup the service agreement with the appropriate rate and contract options.
 - The service agreement needs to be linked to a gas residential service point (hence the G-RES SP type).
 - We've indicated a Start Algorithm of Start SP Service. Refer to STRM-VT for an example of such an algorithm (type).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

[Top](#)

No Electricity / No Gas Package

The package that is offered to customers that don't currently have electricity or gas service has the following traits:

- It has eligibility rules that restrict its use to customers who meet the following criteria:
 - Customer doesn't have electric service
 - Customer doesn't have gas service
- We need two service agreements created (one for electricity, one for gas).
- We have not shown additional questions or miscellaneous fields in this package. This is because this package doesn't have additional questions or additional fields.

The Big Picture Of Package Eligibility Rules

The packages described under [Examples of Campaigns and Packages](#) have a variety of eligibility rules. Designing these rules can be easy or time-consuming; it all depends on the complexity of your business rules. We'll walk you through several examples to help you form an intuitive understanding of how to setup eligibility rules. Once you've acquired this intuition you'll be ready to design the eligibility rules for your own packages.

Note:

Don't confuse package eligibility rules with those associated with a campaign. Package eligibility rules control whether a customer is allowed to choose a package on the order transaction. Campaign eligibility rules control whether a campaign is highlighted on the "eligible campaigns" [content zone](#) and on an order's [eligibility tree](#).

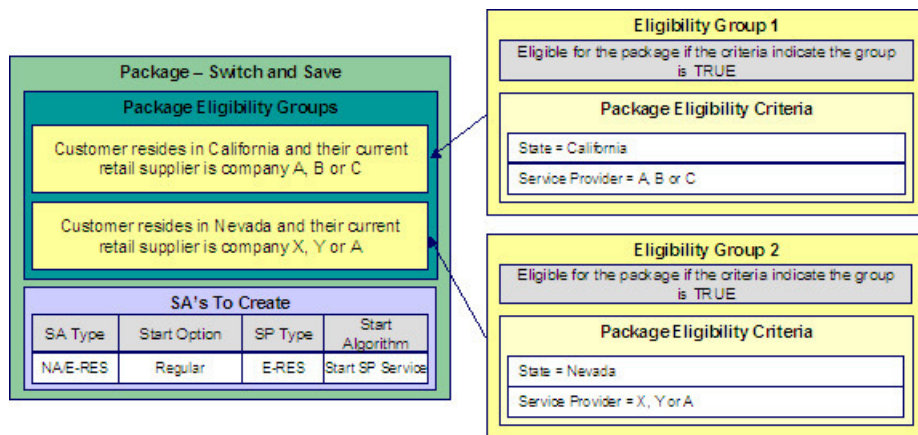

Criteria Groups versus Eligibility Criteria

Before we provide concrete examples of eligibility criteria, we need to explain two concepts: Criteria Groups and Eligibility Criteria. A package's criteria groups control whether a customer is eligible to choose a package. At a high level, it works like this:

- A criteria group has one or more eligibility criteria. A group's criteria control whether the group is considered TRUE or FALSE for a given customer.
- When you create a group, you define what should happen if the group is TRUE or FALSE. You have the following choices:
 - The customer is eligible to choose the package
 - The customer is not eligible to choose the package
 - The next group should be checked.

We'll use the following example to help illustrate these points. Assume a package exists that can only be selected if:

- The customer resides in California and their current retail supplier is company A, B or C
- OR, the customer resides in Nevada and their current retail supplier is company X, Y or A

This package requires two eligibility groups because it has two distinct conditions:

- IF (STATE = CALIFORNIA AND (SERVICE PROVIDER IN (A, B, C)))
- IF (STATE = NEVADA AND (SERVICE PROVIDER IN (X, Y, A)))

If either condition is true, then the customer is eligible for the package.

You'd need to setup the following criteria groups in order to support this requirement:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|-------------------|------------------|-------------------|
| | | | |

| | | | |
|---|---|----------|------------------|
| 1 | Customer resides in California and their current retail supplier is company A, B or C | Eligible | Check next group |
| 2 | Customer resides in Nevada and their current retail supplier is company X, Y or A | Eligible | Ineligible |

The following criteria will be required for each of the above groups:

| Group 1: Customer resides in California and their current retail supplier is company A, B or C | | | | |
|--|---------------------------------------|---------------------------------|----------------------------------|----------------------|
| Seq | Logical Criteria | If Eligibility Criteria is TRUE | If Eligibility Criteria is FALSE | If Insufficient Data |
| 10 | State = California | Check next condition | Group is false | Group is false |
| 20 | Electric retail supplier in (A, B, C) | Group is true | Group is false | Group is false |

| Group 2: Customer resides in Nevada and their current retail supplier is company X, Y or A | | | | |
|--|---------------------------------------|---------------------------------|----------------------------------|----------------------|
| Seq | Logical Criteria | If Eligibility Criteria is TRUE | If Eligibility Criteria is FALSE | If Insufficient Data |
| 10 | State = Nevada | Check next condition | Group is false | Group is false |
| 20 | Electric retail supplier in (X, Y, A) | Group is true | Group is false | Group is false |

The next section describes how you'd setup the specific logical criteria in each of the groups.

Defining Logical Criteria

When you setup an eligibility criterion, you must define two things:

- The field to be compared
- The comparison method

You have the following choices in respect of identifying the **field to be compared**:

- You can choose one of the miscellaneous fields on the order (keep in mind that miscellaneous fields also hold the answers to any questions posed on the order).
- You can execute an algorithm to retrieve a field value from someplace else in the system. This is a very powerful feature, but it's not terribly intuitive. We'll present a few examples later in this section to illustrate the power of this approach.

You have the following choices in respect of identifying the **comparison method**:

- You can choose an operator (e.g., >, <, =, BETWEEN, IN, etc.) and a comparison value.
- You can execute an algorithm whose job it will be to perform the comparison (and return TRUE, FALSE or INSUFFICIENT DATA). This is also a very powerful feature, but it's not terribly intuitive. We'll present a few examples later in this section to illustrate the power of this approach.

The [Examples Of Package Eligibility Rules](#) provide numerous examples to help you understand this design.

Examples Of Package Eligibility Rules

The topics in this section provide examples about how to setup package eligibility rules.

A Package That Is Always Eligible

If a package is always eligible, it still needs an eligibility group. Good examples of such packages are shown under [An Easier Way To Create One Time Charges](#). A package that is always eligible would require the following eligibility information:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|-------------------|------------------|-------------------|
| 1 | Always eligible | Eligible | Eligible |

The following criteria will be required for this group:

| Group 1: Always eligible | | | | | |
|--------------------------|---|---------------------------|---------------|---------------|----------------------|
| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
| 10 | Algorithm: retrieve order's account | Algorithm: Always true | Group is true | Group is true | Group is true |

This group's criterion is odd in that it's not comparing anything. In order to setup this criterion, you have to use the following "trick":

- Field to Compare. You can pick any miscellaneous field on the campaign. If the campaign has no miscellaneous fields, you'll need to setup an algorithm to retrieve a field from the order (refer to PKEL-ENRFLD for an example of this type of algorithm). In the above example, we used an algorithm to retrieve the order's account.
- Comparison Method. We chose a comparison algorithm that always returns a value of TRUE (refer to PKCC-DEFAULT for an example of this type of algorithm).
- You'll notice that if a value of TRUE is returned, the Group is true (and we've setup the group to indicate a true group means the customer is eligible for the package).

We understand this is a little complicated, but this design provides the power necessary to support very complex criteria. The following sections provide more examples to help you form a better understanding of these concepts.

A Package With A Time Span Comparison

The Senior Citizen Package has the following eligibility rules:

- Customer class = Residential
- Division = California
- Birth date equates to that of a senior citizen

These rules require only one eligibility group on the package. It would look as follows:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|----------------------------|------------------|-------------------|
| 1 | Residential, Calif, Senior | Eligible | Ineligible |

The following criteria will be required for this group:

| Group 1: Residential, Calif, Senior | | | | | |
|-------------------------------------|--|------------------------------|-------------------------|----------------|----------------------|
| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
| 10 | Algorithm: retrieve order's customer class | = R | Check next condition | Group is false | Group is false |
| 20 | Algorithm: retrieve order's division | = CA | Check next condition | Group is false | Group is false |
| 30 | Misc Field On Order: Date of Birth | Algorithm: True if senior | Group is true | Group is false | Group is false |

The first two criteria are easy; they simply retrieve a field on the order and compare it to a given value. If the comparison doesn't result in a TRUE value, the Group is false (and, the group indicates that if the group is false, the customer isn't eligible for the package). If the comparison results in a TRUE value, the next condition is checked.

The last criterion contains a time span comparison. Time span comparisons are used to compare a date to something. In our example, we have to determine the age of the customer based on their birth date. If the resultant age is > 65, they are considered to be a senior citizen. To pull this off, you can take advantage of a comparison algorithm supplied with the base package as described below.

- **Field to Compare.** The miscellaneous field in which the customer's birth date is held is selected.
- **Comparison Method.** We chose a comparison algorithm that returns a value of TRUE if the related field value (the customer's date of birth) is greater than 65 years (refer to PKCC-TIMESPN for an example of this type of algorithm).

You'll notice that if a value of TRUE is returned by the True if senior algorithm, the group is true (and we've setup the group to indicate a true group means the customer is eligible).

Note:

The time span algorithm can be used to compare days, weeks, months, etc. Refer to PKCC-TIMESPN for more information about this algorithm.

A Package With Service Type Comparison

The Has Gas / No Electricity Package has the following eligibility rules:

- Customer has gas service
- Customer doesn't have electricity service

These rules require only one eligibility group on the package. It would look as follows:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|-----------------------------------|------------------|-------------------|
| 1 | Has Gas, Doesn't Have Electricity | Eligible | Ineligible |

The following criteria will be required for this group:

| Group 1: Has Gas, Doesn't Have Electricity | | | | | |
|--|---|-------------------|----------------------|----------------|----------------------|
| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
| 10 | Algorithm: check if customer has gas service | = TRUE | Check next condition | Group is false | Group is false |
| 20 | Algorithm: check if customer has electric service | = TRUE | Group is false | Group is true | Group is false |

Both criteria are similar - they check if the customer has a given type of service and act accordingly. We used a "field to compare" algorithm to pull this off, but this algorithm is a bit counter intuitive (but understanding it will provide you with another way to implement complex eligibility criteria):

- **Field to Compare.** We chose a "field to compare" algorithm that checks if an account has service agreements that belong to a given set of service types. It returns a value of TRUE if the customer has an active service agreement that matches one of the service types in the algorithm. In our example, the "check if customer has gas service" algorithm returns a value of TRUE if the customer has at least one active service agreement whose SA type references the gas service type. The "check if customer has electric service" algorithm is almost identical, only the service type differs. Refer to PKEL-SVCTYP for an example of this type of algorithm.
- **Comparison Method.** We simply compare the value returned by the algorithm to TRUE and indicate the appropriate response.

Note:

Bottom line. The "field to compare" algorithm isn't actually returning a specific field's value. Rather, it's returning a value of TRUE or FALS (this is not a misspelling). This value is, in turn, compared by the "comparison method" and the group is set to true, false or check next accordingly.

A Package With More Complex Operators

One of the eligibility groups described under [Criteria Groups versus Eligibility Criteria](#) has the following eligibility rules:

- Customer must live in California
- Service provider is A, B or C

The eligibility group in which these rules would be defined looks as follows:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|-------------------|------------------|-------------------|
|-----------|-------------------|------------------|-------------------|

| | | | |
|---|--|----------|------------|
| 1 | Lives in California, current service provider is either retailer A, B or C | Eligible | Ineligible |
|---|--|----------|------------|

The following criteria will be required for this group:

| Group 1: Lives in California, current service provider is either retailer A, B or C | | | | | |
|---|--|-------------------|----------------------|----------------|----------------------|
| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
| 10 | Algorithm: retrieve order's state | = CA | Check next condition | Group is false | Group is false |
| 20 | Misc Field On Order: Current electric supplier | IN A, B, C | Group is true | Group is false | Group is false |

This example is very simple. The only thing worth pointing out is that a number of operators can be used when you define a "comparison method". Refer to [Package - Eligibility](#) for the complete list of operators.

The Big Picture Of Campaign Eligibility Rules

In the previous section, we explained how to [Design Eligibility Rules For A Package](#). In this section, we explain how to design eligibility rules for a campaign.

A campaign's eligibility rules control two things:

- Whether the campaign appears in the Eligible Campaigns [content zone](#). This content zone suggests possible campaigns for the current customer displayed on control central. You might want to use this zone if you have different campaigns that are offered to different types of customers. Refer to [Real-time Marketing of Additional Services to a Customer](#) for an example of how this content zone can be used to "up sell" additional services.
- Whether the campaign appears on an order's [eligibility tree](#). Campaigns that appear in this tree are alternate campaigns that may be used on the order. Refer to [Real-time Marketing of Services to a Prospect](#) for an example of how an order's eligibility tree can contain alternate campaigns for an order.

Designing these criteria can be easy or time-consuming; it all depends on the complexity of your business rules. We'll walk you through several examples to help you form an intuitive understanding of how to setup campaign eligibility rules. Once you've acquired this intuition you'll be ready to design the eligibility rules for your own packages.

Note:

Don't confuse eligibility rules for a package with those associated with a campaign. Package eligibility rules control whether a customer is allowed to choose a package. Campaign eligibility rules control whether a campaign is highlighted on the Eligible Campaigns [content zone](#) and on an order's [eligibility tree](#).

Campaign Eligibility Rules Are Not Strictly Enforced

While the system prevents ineligible packages from being selected for an order (based on the [package's eligibility rules](#)), the system does not strictly enforce a campaign's eligibility rules. In other words, a user can change the campaign on an order to any active campaign. This "laxness" is intentional; otherwise it could become impossible to change an order's campaign.

It might be more helpful to think of campaign eligibility rules as "highlight conditions". These "highlight conditions" simply control whether the campaign appears in the Eligible Campaigns [content zone](#) and on an order's [eligibility tree](#).

Campaign Eligibility Rules Are Defined Using Algorithms

You define a campaign's eligibility rules using one or more algorithms on the [campaign](#). These algorithms are relatively straightforward as they simply return one of the following values:

- Eligible. Meaning the customer is eligible for the campaign.
- Ineligible. Meaning the customer is not eligible for the campaign
- Check Next Algorithm. Meaning that the next algorithm should be checked. You'd only design an algorithm to return such a value if multiple algorithms are used to determine a customer's eligibility for a campaign.

Note:

Bottom line. A customer is eligible for a campaign if at least one of its eligibility algorithms returns a value of "eligible".

The [Examples Of Campaign Eligibility Rules](#) provide numerous examples to help you understand this design.

Examples Of Campaign Eligibility Rules

The topics in this section provide examples about how to setup campaign eligibility rules.

A Campaign That Is Always Eligible

If a campaign is always eligible, it would require a simple eligibility algorithm that returns an indication that it is always eligible. A good example of such a campaign is shown under [An Easier Way To Create One Time Charges](#). Refer to CAEL-DEFAULT for an example of this type of eligibility algorithm.

A Campaign That Is Never Eligible

If a campaign is never eligible, it would require a simple eligibility algorithm that returns an indication that it is ineligible. A good example of such a campaign is shown under [Prelude To Start/Stop](#). Refer to CAEL-DEFAULT for an example of this type of eligibility algorithm.

A Campaign For Residential Customers

If a campaign should only be targeted at residential customers, it would require a simple eligibility algorithm that returns an indication of eligible if the customer's customer class is residential. A good example of such a campaign is shown under [Marketing Surveys](#). Refer to CAEL-CC for an example of this type of eligibility algorithm.

A Campaign For California, Residential Customers

If a campaign should only be targeted at residential customers in California, it would require two eligibility algorithms:

| Algorithm No | Algorithm | Example Algorithm |
|--------------|--|--|
| 1 | Indicate Check Next Algorithm if customer class is "residential" | Refer to CAEL-CC for an example of this type of eligibility algorithm. |

2

Indicate Eligible if division is "California"

Refer to CAEL-DIV for an example of this type of eligibility algorithm.

Designing Campaigns and Packages

Designing [campaigns](#) and [packages](#) can be simple or challenging. Factors that will influence the complexity of the design process include:

- Whether the type of goods and services marketed to your customers / prospects differs depending on some trait of the customer or the region in which they are located. For example,
 - Your company may have very straightforward packages that only differ based on whether the customer is industrial, residential or commercial. If this describes your company, the setup process will be simple.
 - Alternatively, your company might offer different packages to residential customers based on whether they pay automatically, whether they are a senior citizen, whether they purchase multiple services from you, etc. If this describes your company, then you'll have to define the various eligibility criteria and the respective packages applicable to customers who satisfy each criterion.
- Whether premises exist prior to order taking. For example, a company that distributes a commodity has a well-defined geographic area and therefore new premises typically don't arise when orders are taken.
- Whether your company offers many different types of goods and services.
- Whether your rates have charges / discounts that are only applied to some customers. For example, you might have discounts that are applied if the customer is a senior citizen or an employee.
- Which of the [Supported Business Processes](#) you implement.

The topics in this section provide a structured approach to design your campaigns and packages.

Determine The Place Of Start/Stop

Before you can design your campaigns and packages, you must determine if your organization will use [start / stop](#) to initiate new service agreements or whether new service can be initiated using the [order](#) transaction. Refer to [Order versus Start / Stop](#) for information to help you make this decision.

If you decide to use [start / stop](#) to initiate service, we'd recommend creating the following types of campaigns:

- Create a campaign similar to that described under [Prelude to Start / Stop](#).
- If you levy one-time charges, you may also want to create a campaign similar to that described under [An Easier Way To Create One Time Charges](#).
- If your organization performs marketing surveys, you may also want to create a campaign similar to that described under [Marketing Surveys](#).

If you decide to use the [order](#) transaction to initiate new service, follow the steps outlined in the following sections. Note that we use the example described under [Packages Limited By Answers And Field Values](#) when describing the design process.

Determine Which Types Of Service Agreements Are Created

Warning:

We have assumed that you have already designed your organization's SP types, SA types, start options and rates. If you have not yet done this, we recommend familiarizing yourself with the concepts described in [Designing SP Types, Rates](#) and [Defining Service Agreement Types](#) before designing your campaigns and packages.

Start off by determining the different types of service agreements that can be created if a package is selected. In our [example campaign](#), only one SA type is used - E-RES (electric residential service).

Determine The Different Start Options That Exist For Each Type Of Service Agreement

After you know which SA types are going to be created, determine the potential [start options](#) that can be used for each SA type. In our [example campaign](#), several start options are possible for the E-RES (electric residential service):

| SA Type | Start Option |
|---------|------------------|
| E-RES | Senior |
| E-RES | Single-Elec Heat |
| E-RES | Single-Gas Heat |
| E-RES | Multi-Family |

Determine The SP Type (if any) For Each Service Agreement

The SA types and start options control how the service agreement will look (i.e., they control the rate, contract riders, characteristics, interval profiles, time-of-use maps, etc. defaulted onto new service agreements created when a package is selected). During this step, you define the SP type of the service point that will be linked to the service agreement. If several different types of SP types can be used for a service agreement, you'll have to choose one as this is the type of service point that will be created when the service agreement is created. If you plan to allow the package to be used to start service at an existing premise (and you don't want the system to create new service points), you will have to develop new plug-ins. Please speak to your implementation group if you need more information.

In our [example campaign](#), only one SP type is created (or reused if the premise already has a service point of this type) - E-RES (electric residential service point):

| SA Type | Start Option | SP Type |
|---------|------------------|---------|
| E-RES | Senior | E-RES |
| E-RES | Single-Elec Heat | E-RES |
| E-RES | Single-Gas Heat | E-RES |
| E-RES | Multi-Family | E-RES |

Note:

Many service agreements don't need SP types. For service agreements that don't use service points (e.g., deposit service agreements, charitable contributions, one-time charges, etc.), you don't have to reference a SP type.

Determine The Method Used To Create Each Service Agreement

For each SA Type / Start Option / SP Type combination, determine the algorithm that will be used to create the service agreement and the service point. The base package is supplied with a limited number of such algorithm types (refer to STRM-AS and STRM-VT for examples).

| SA Type | Start Option | SP Type | Start Method |
|---------|--------------|---------|--------------|
|---------|--------------|---------|--------------|

| | | | |
|-------|------------------|-------|---|
| E-RES | Senior | E-RES | Algorithm: Create new service agreement and stop old service agreement if active SA with the same service type exists |
| E-RES | Single-Elec Heat | E-RES | Algorithm: Create new service agreement and stop old service agreement if active SA with the same service type exists |
| E-RES | Single-Gas Heat | E-RES | Algorithm: Create new service agreement and stop old service agreement if active SA with the same service type exists |
| E-RES | Multi-Family | E-RES | Algorithm: Create new service agreement and stop old service agreement if active SA with the same service type exists |

Extract Algorithms From The Start Method

The start methods illustrated above all require the same algorithm:

| Algorithm Type | Algorithm | Parameter Values |
|---------------------------------------|---|---------------------------|
| Create SP and create SA (see STRM-VT) | Always create new SA and stop existing SA | 2 (stop existing service) |

Determine Which Combinations Can Be Grouped Under A Package

Now you determine which combinations of service agreements can be offered to a customer as a package. In our [example campaign](#), a customer can only choose one type of service agreement (i.e., each entry in our table is mutually exclusive). This means that each entry is a separate package:

| Package | SA Type | Start Option | SP Type | Algorithm |
|---------|---------|------------------|---------|-------------------------|
| 1 | E-RES | Senior | E-RES | STRM-VT (Switch Option) |
| 2 | E-RES | Single-Elec Heat | E-RES | STRM-VT (Switch Option) |
| 3 | E-RES | Single-Gas Heat | E-RES | STRM-VT (Switch Option) |
| 4 | E-RES | Multi-Family | E-RES | STRM-VT (Switch Option) |

**Fastpath:**

Refer to [Packages Limited By Current State Of Service](#) for an example of a package that has multiple service agreements.

Determine Package Eligibility Rules

The topics in this section describe the eligibility rules for each package in our [example campaign](#).

**Note:**

Assumption. This section assumes you are comfortable with the information in [The Big Picture Of Package Eligibility](#).

Eligibility Rules For Package 1

Package 1 (the senior package) in our [example campaign](#) has the following eligibility rules:

- Customer class = Residential
- Division = California
- Birth date equates to that of a senior citizen

These rules require only one eligibility group on the package. It would look as follows:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|----------------------------|------------------|-------------------|
| 1 | Residential, Calif, Senior | Eligible | Ineligible |

The following criteria will be required for this group:

| Group 1: Residential, Calif, Senior | | | | | |
|-------------------------------------|--|------------------------------|-------------------------|----------------|----------------------|
| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
| 10 | Algorithm: retrieve order's customer class | = R | Check next condition | Group is false | Group is false |
| 20 | Algorithm: retrieve order's division | = CA | Check next condition | Group is false | Group is false |
| 30 | Misc Field On Order: Date of Birth | Algorithm: True if senior | Group is true | Group is false | Group is false |

Eligibility Rules For Package 2

Package 2 (the single-family / electric heat package) in our [example campaign](#) has the following eligibility rules:

- Customer class = Residential
- Division = California
- Birth date does not equate to that of a senior citizen

- Lives in a single-family home
- House is heated with electricity

These rules require only one eligibility group on the package. It would look as follows:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|--|------------------|-------------------|
| 1 | Residential, Calif, Non Senior, Single Family, Electric Heat | Eligible | Ineligible |

The following criteria will be required for this group:

| Group 1: Residential, Calif, Non Senior, Single Family, Electric Heat | | | | | |
|---|--|------------------------------|-------------------------|-------------------------|----------------------|
| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
| 10 | Algorithm: retrieve order's customer class | = R | Check next condition | Group is false | Group is false |
| 20 | Algorithm: retrieve order's division | = CA | Check next condition | Group is false | Group is false |
| 30 | Misc Field On Order: Date of Birth | Algorithm: True if senior | Group is false | Check next condition | Group is false |
| 40 | Misc Field On Order: Type of Residence | = S (single family home) | Check next condition | Group is false | Group is false |
| 50 | Misc Field On Order: Type of Heat | = E (electric) | Group is true | Group is false | Group is false |

Eligibility Rules For Package 3

Package 3 (the single-family / gas heat package) in our [example campaign](#) has the following eligibility rules:

- Customer class = Residential
- Division = California
- Birth date does not equate to that of a senior citizen
- Lives in a single-family home
- House is heated with gas

These rules require only one eligibility group on the package. It would look as follows:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|-------------------|------------------|-------------------|
|-----------|-------------------|------------------|-------------------|

| | | | |
|---|---|----------|------------|
| 1 | Residential, Calif, Non Senior, Single Family, Gas Heat | Eligible | Ineligible |
|---|---|----------|------------|

The following criteria will be required for this group:

| Group 1: Residential, Calif, Non Senior, Single Family, Gas Heat | | | | | |
|--|--|---------------------------|----------------------|----------------------|----------------------|
| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
| 10 | Algorithm: retrieve order's customer class | = R | Check next condition | Group is false | Group is false |
| 20 | Algorithm: retrieve order's division | = CA | Check next condition | Group is false | Group is false |
| 30 | Misc Field On Order: Date of Birth | Algorithm: True if senior | Group is false | Check next condition | Group is false |
| 40 | Misc Field On Order: Type of Residence | = S (single family home) | Check next condition | Group is false | Group is false |
| 50 | Misc Field On Order: Type of Heat | = G (gas) | Group is true | Group is false | Group is false |

Eligibility Rules For Package 4

Package 4 (the multi-family package) in our [example campaign](#) has the following eligibility rules:

- Customer class = Residential
- Division = California
- Birth date does not equate to that of a senior citizen
- Lives in a multi-family home

These rules require only one eligibility group on the package. It would look as follows:

| Group No. | Group Description | If Group is TRUE | If Group is FALSE |
|-----------|--|------------------|-------------------|
| 1 | Residential, Calif, Non Senior, Multi Family | Eligible | Ineligible |

The following criteria will be required for this group:

| | | | | | |
|--|--|--|--|--|--|
| Group 1: Residential, Calif, Non Senior, Single Family, Gas Heat | | | | | |
|--|--|--|--|--|--|

| Seq | Field to Compare | Comparison Method | If TRUE | If FALSE | If Insufficient Data |
|-----|--|------------------------------|-------------------------|-------------------------|----------------------|
| 10 | Algorithm: retrieve order's customer class | = R | Check next condition | Group is false | Group is false |
| 20 | Algorithm: retrieve order's division | = CA | Check next condition | Group is false | Group is false |
| 30 | Misc Field On Order: Date of Birth | Algorithm: True if senior | Group is false | Check next condition | Group is false |
| 40 | Misc Field On Order: Type of Residence | = M (multi family home) | Group is true | Group is false | Group is false |

Extract Algorithms From The Eligibility Rules

The eligibility rules illustrated above require the following algorithms:

| Algorithm Type | Algorithm | Parameter Values |
|--|---|--|
| Retrieve a field from the order for eligibility comparison (see PKEL-ENRFLD) | Retrieve Order's Customer Class | Field name: CUST_CL_CD |
| Retrieve a field from the order for eligibility comparison (see PKEL-ENRFLD) | Retrieve Order's Division | Field name: CIS_DIVISION |
| Time span comparison (see PKCC-TIMESPN) | Determine if birth date equates to that of a senior | Time span type: YEAR Operator: >= Comparison Value: 65 |

Extract Miscellaneous Fields From The Eligibility Rules

During this step, you extract miscellaneous fields that must be captured on the order in order drive your eligibility rules.

| Misc. Field | Where Stored | Why Is It Needed |
|-------------------|------------------------|--|
| Date of birth | Person characteristic | Numerous eligibility rules use this field to determine if a customer is a senior citizen |
| Type of Residence | Premise characteristic | Numerous eligibility rules use this field to qualify a customer for a package |

| | | |
|--------------|------------------------|---|
| Type of Heat | Premise characteristic | Numerous eligibility rules use this field to qualify a customer for a package |
|--------------|------------------------|---|

**Note:**

Fields explicitly referenced on every order. You'll notice that we didn't list those fields referenced in the eligibility rules that are explicitly referenced on every order (e.g., customer class, state, division, etc.). This is because these types of fields come "for free".

Determine Additional Information That Is Required If A Package Is Selected

During this step, you determine if there's any information that needs to be created when a package is selected that can't be defaulted from its start option. In our [example campaign](#), package 4 (the Multi-Family Home package), also needs to know the number of housing units at the premise (this information is probably needed to calculate a specific charge in the rate). None of the other packages require additional information. The extra field has been appended to our miscellaneous field table.

| Misc. Field | Where Stored | Why Is It Needed |
|--------------------------|------------------------|--|
| Date of birth | Person characteristic | Numerous eligibility rules use this field to determine if a customer is a senior citizen |
| Type of Residence | Premise characteristic | Numerous eligibility rules use this field to qualify a customer for a package |
| Type of Heat | Premise characteristic | Numerous eligibility rules use this field to qualify a customer for a package |
| Number of Units in House | Premise characteristic | The electric SA created by package 4 requires the number of units when it calculates the ongoing bill segments |

Determine If There Are Additional Questions / Fields For Your Packages

Our [example campaign](#) indicates that all customers are encouraged to pay automatically. In order to pay automatically several fields are required (Start Date, End Date, Autopay Source (i.e., bank / credit card), Account Number, Account Name, Expiration Date). These fields are not "explicitly referenced" on the order and therefore must be captured as miscellaneous fields. We have appended these fields to our list of miscellaneous fields:

| Misc. Field | Where Stored | Why Is It Needed |
|-------------------|------------------------|--|
| Date of birth | Person characteristic | Numerous eligibility rules use this field to determine if a customer is a senior citizen |
| Type of Residence | Premise characteristic | Numerous eligibility rules use this field to qualify a customer for a package |

| | | |
|----------------------------------|---|--|
| Type of Heat | Premise characteristic | Numerous eligibility rules use this field to qualify a customer for a package |
| Number of Units in House | Premise characteristic | The electric SA created by package 4 requires the number of units when it calculates the ongoing bill segments |
| Auto Pay Start Date | Account / Autopay Start Date Column | Used if a customer pays automatically |
| Auto Pay End Date | Account / Autopay End Date Column | Used if a customer pays automatically |
| Auto Pay Source | Account / Autopay Source | Used if a customer pays automatically |
| Auto Pay Account Number | Account / Autopay Account ID | Used if a customer pays automatically |
| Auto Pay Account Name | Account / Autopay Account Name | Used if a customer pays automatically |
| Auto Pay Account Expiration Date | Account / Autopay Account Expiration Date | Used if a customer pays automatically |

We're going to assume that we don't capture any additional marketing-oriented questions. If we did, we'd need additional fields to hold the response to each question.

Determine If Additional Instructions Should Be Shown

If a package is selected, you can present additional instructions to the user informing them of special tasks they should perform (or special instructions they should give to the customer). For example, you could instruct the user to inform customers who aren't senior citizens that they should call back if they become seniors as they may qualify for a better rate. These instructions can be defined on each package.

For the sake of brevity, we will assume no additional instructions are necessary when a package is selected.

Determine If There Are Campaign-Level Fields / Questions

Next, you determine if there are additional fields that need to be captured regardless of the package that's selected. For example, you may want to capture additional demographic or geographic information for marketing purposes.

While our [example campaign](#) has no such requirement, for illustration purposes we'll assume you ask the customer to rate the quality of service they have experienced (assuming they are a current customer). This additional question requires another entry in our list of miscellaneous fields.

| Misc. Field | Where Stored | Why Is It Needed |
|---------------|-----------------------|--|
| Date of birth | Person characteristic | Numerous eligibility rules use this field to determine if a customer is a senior citizen |

| | | |
|----------------------------------|---|--|
| Type of Residence | Premise characteristic | Numerous eligibility rules use this field to qualify a customer for a package |
| Type of Heat | Premise characteristic | Numerous eligibility rules use this field to qualify a customer for a package |
| Number of Units in House | Premise characteristic | The electric SA created by package 4 requires the number of units when it calculates the ongoing bill segments |
| Auto Pay Start Date | Account / Autopay Start Date Column | Used if a customer pays automatically |
| Auto Pay End Date | Account / Autopay End Date Column | Used if a customer pays automatically |
| Auto Pay Source | Account / Autopay Source | Used if a customer pays automatically |
| Auto Pay Account Number | Account / Autopay Account ID | Used if a customer pays automatically |
| Auto Pay Account Name | Account / Autopay Account Name | Used if a customer pays automatically |
| Auto Pay Account Expiration Date | Account / Autopay Account Expiration Date | Used if a customer pays automatically |
| Service Rating | Person characteristic | Campaign level marketing question |

Determine The Properties Of Every Miscellaneous Field

At this point, you have amalgamated all miscellaneous fields required for the campaign and its packages. Now you have to define the following for each field:

- Prompt On Order. This is the prompt that will prefix the field when the [order](#) is taken. The following table provides examples.
- Campaign Applicability. This controls whether the field is optional, required, or only applicable on package(s).
 - A value of required means the order taker must enter a valid value before packages are displayed for selection.
 - A value of optional means the order taker can leave the field blank prior to package selection. You can make an optional field required on individual packages. For example, you would probably make **Date of birth** required on the Senior package.
 - A value of only applicable on packages is used for fields that are only captured for specific packages. Fields of this type are suppressed prior to package selection. When you setup a package, you indicate if the field is applicable (if so, the user is only prompted for the field if the package is selected).
- Type Of Response. This controls where the field is stored when the order is completed and how it is validated. You have two options: characteristic or column.
 - If a field is a Characteristic, you must define which entity the characteristic value is to be stored on when the order is completed (Person, Account, Premise or Order). You must also define the **Characteristic Type** as this controls the characteristic value entered by the user.

- If a field's value resides in a column (as opposed to a characteristic value), you must define the [column reference](#). A field's column reference controls three things:
 - How the field's value is retrieved. A field's value is retrieved when an existing person / account / premise is referenced on an order.
 - How the field's value is validated. A field's value is validated before package eligibility is determined and before the order is completed.
 - How the field's value is posted (i.e., updated on the database). A field's value is posted when an order is completed.

Fastpath:

Refer to [Extract Column References From Miscellaneous Fields](#) for more information about column references.

- **Default Value On Order.** This controls whether the order taker is supplied with a default value when an order is created. Note well: for optional and only applicable on package fields, you can specify a different default value on each package.

| Misc. Field | Prompt On Order | Campaign Applicability | Type Of Response | Default Value On Order |
|--------------------------|---|-------------------------------|--|------------------------|
| Date of birth | What is your date of birth (used to qualify for senior discount)? | Optional | Characteristic Entity: Person Char Type: Date of birth | |
| Type of Residence | What type of residence do you live in? | Required | Characteristic Entity: Premise Char Type: Type of residence | S (single family) |
| Type of Heat | How do you heat your home? | Required | Characteristic Entity: Premise Char Type: Type of heat | E (electric) |
| Number of Units in House | How many units are in the entire house? | Only applicable on package(s) | Characteristic Entity: Premise Char Type: Number of units in house | |
| Auto Pay Start Date | What day would you like to start automatic payment processing (YYYY-MM-DD)? | Optional | Column Column Reference: Auto Pay Start Date | |
| Auto Pay End Date | What day would you like to stop automatic payment processing (leave blank if not applicable)? | Optional | Column Column Reference: Auto Pay End Date | |

| | | | | |
|----------------------------------|--|----------|----------------------------------|--------------------------------------|
| Auto Pay Source | From what type of credit card / bank will the funds be debited? | Optional | Column | |
| | | | Column Reference: | Auto Pay Source |
| Auto Pay Account Number | What is your credit card / bank account number? | Optional | Column | |
| | | | Column Reference: | Auto Pay Account Number |
| Auto Pay Account Name | What is the name on your account? | Optional | Column | |
| | | | Column Reference: | Auto Pay Account Name |
| Auto Pay Account Expiration Date | If paying with a credit card, what is the expiration date (MM-YYYY)? | Optional | Column | |
| | | | Column Reference: | Auto Pay Credit Card Expiration Date |
| Service Rating | Please rate our service | Optional | Characteristic | 1 (excellent) |
| | | | Entity: Person | |
| | | | Char Type: Service rating | |

Extract Characteristic From The Miscellaneous Fields

| Characteristic Type | Type | Valid Values | Entities On Which Characteristic Can Be Defined |
|--------------------------|--|-------------------------------------|---|
| Date of birth | Ad hoc value: use validation algorithm to confirm date is > 1-Jan-1900 and < 28-Feb-2002 | Not applicable | Person, Order |
| Type of Residence | Predefined value | S: Single-Family M: Multi-Family | Premise, Order |
| Type of Heat | Predefined value | E: Electric G: Gas | Premise, Order |
| Number of Units in House | Ad hoc value: use validation algorithm to confirm value is > 0 | Not applicable | Premise, Order |

| | | | |
|----------------|------------------|---|---------------|
| Service Rating | Predefined value | 0: Not applicable 1: Excellent 2: Very Good 3: Good 4: Poor | Person, Order |
|----------------|------------------|---|---------------|

Extract Column References From The Miscellaneous Fields

The [miscellaneous fields](#) illustrated above require the following column references (we describe the referenced algorithms at the bottom of the table):

| Column Reference | Retrieval Algorithm | Validation Algorithm | Post Algorithm | Foreign Key Reference |
|--------------------------|---|--|--|-----------------------|
| Auto Pay Start Date | Retrieve account's current automatic payment information | Validate automatic payment information | Post automatic payment information | |
| Auto Pay End Date | N/A - this field is handled by the Retrieval Algorithm on Auto Pay Start Date | N/A - this field is handled by the Validation Algorithm on Auto Pay Start Date | N/A - this field is handled by the Post Algorithm on Auto Pay Start Date | |
| Auto Pay Source | N/A - this field is handled by the Retrieval Algorithm on Auto Pay Start Date | N/A - this field is handled by the Validation Algorithm on Auto Pay Start Date | N/A - this field is handled by the Post Algorithm on Auto Pay Start Date | Auto pay source |
| Auto Pay Account Number | N/A - this field is handled by the Retrieval Algorithm on Auto Pay Start Date | N/A - this field is handled by the Validation Algorithm on Auto Pay Start Date | N/A - this field is handled by the Post Algorithm on Auto Pay Start Date | |
| Auto Pay Account Name | N/A - this field is handled by the Retrieval Algorithm on Auto Pay Start Date | N/A - this field is handled by the Validation Algorithm on Auto Pay Start Date | N/A - this field is handled by the Post Algorithm on Auto Pay Start Date | |
| Auto Pay Expiration Date | N/A - this field is handled by the Retrieval Algorithm on Auto Pay Start Date | N/A - this field is handled by the Validation Algorithm on Auto Pay Start Date | N/A - this field is handled by the Post Algorithm on Auto Pay Start Date | |

There are three types of algorithms referenced in the above table:

- Retrieval algorithm. A column's retrieval algorithm retrieves the column's current value from the database. You'll notice that only one of our columns uses a retrieval algorithm. This is because we've used a sophisticated example of a group of columns that are retrieved at the same time. When you have such a group of columns, nominate one of the columns to do the retrieval work and specify the retrieval algorithm on it.
- Validation algorithm. A column's validation algorithm validates the column's value prior to the database being updated. You'll notice that only one of our columns uses a validation algorithm. This is because we've used a sophisticated example of a group of columns that are validated as a group. When you have such a group of columns, nominate one of the columns to do the validation work and specify the validation algorithm on it.
- Post algorithm. A column's post algorithm updates the column's value on the database when the order is completed. You'll notice that only one of our columns uses a post algorithm. This is because we've used a sophisticated example of a group of columns that are posted together. When you have such a group of columns, nominate one of the columns to do the posting work and specify the posting algorithm on it.

Notice that we have indicated that one of the columns has a "foreign key reference". You declare a "foreign key reference" if the valid values for a column are defined on another table in the system (this also affects the order user interface as a dropdown appears for columns that have foreign key references). In our example, Auto Pay Source is the only column whose valid values are defined on the automatic payment source control table.

Extract Algorithms From The Column References

The column references illustrated above require the following algorithms:

| Algorithm Type | Algorithm | Parameter Values |
|--|--|--|
| Retrieve automatic payment information from an account (see CRRT-AP) | Retrieve automatic payment information from an account | Param 1 = Auto Pay Start Date Column Reference Param 2 = Auto Pay End Date Column Reference Param 3 = Auto Pay Source Column Reference Param 4 = Auto Pay External Account Id Column Reference Param 5 = Auto Pay Expiration Date Column Reference Param 6 = Auto Pay Name Column Reference |
| Validate automatic payment information (see CRVL-AP) | Validate automatic payment information | Param 1 = Auto Pay Start Date Column Reference Param 2 = Auto Pay End Date Column Reference Param 3 = Auto Pay Source Column Reference Param 4 = Auto Pay External Account Id Column Reference Param 5 = Auto Pay Expiration Date Column Reference Param 6 = Auto Pay Name Column Reference |

| | | |
|---|------------------------------------|--|
| Post automatic payment information (see CRPS-AP) | Post automatic payment information | Param 1 = Auto Pay Start Date Column Reference |
| | | Param 2 = Auto Pay End Date Column Reference |
| | | Param 3 = Auto Pay Source Column Reference |
| | | Param 4 = Auto Pay External Account Id Column Reference |
| | | Param 5 = Auto Pay Expiration Date Column Reference |
| | | Param 6 = Auto Pay Name Column Reference |

Determine Account / Premise Dependency For Each Column Reference

Later in the design process (see [Determine How The Campaign Behaves](#)), you define on the campaign whether an account (and premise) is required, optional or not allowed on its orders. Your selection impacts how you setup column references. This is a little complicated so let's use an example:

- Assume you've setup a campaign to indicate a premise can optionally be defined on its orders.
- If the order-taker doesn't define a premise on an order, any premise-oriented questions and miscellaneous fields (Q&MF) should be suppressed on the order.
- It's easy for the system to know which Q&MFs to suppress when a Q&MF's response is held in a characteristic (because you must define on the campaign if the response will reside in an account, premise, person or order characteristic). For column reference Q&MFs, the system doesn't know if the response is account-oriented, premise-oriented or neither because algorithms handle the validation / updating of the response.
- Therefore, when you use column references on a campaigns Q&MFs, you must define if the responses are account-oriented or premise-oriented (so that the system can suppress the Q&MF when the user doesn't enter an account or premise on the order).

The following table contains the column references defined above as well as their dependency

| Column Reference | Question Dependency |
|--------------------------|---------------------|
| Auto Pay Start Date | Must have account |
| Auto Pay End Date | Must have account |
| Auto Pay Source | Must have account |
| Auto Pay Account Number | Must have account |
| Auto Pay Account Name | Must have account |
| Auto Pay Expiration Date | Must have account |

You'll notice that each column reference is account-oriented (this is because automatic payment fields are stored on the respective account).

Determine If Any Properties Are Overridden On Any Package

At this point, you have defined the properties of all miscellaneous fields at the campaign level. You now need to determine if any of your packages need to override any of these properties. In general, you can only override miscellaneous fields whose campaign applicability is optional or only applicable on package(s).

Our [example campaign](#) has only two overrides:

Package 1 requires the following miscellaneous field overrides:

| Misc. Field | Override Prompt (seen if a package is selected) | Override Package Applicability | Override Default Value |
|---------------|---|--------------------------------|------------------------|
| Date of birth | Not overridden | Required | Not overridden |

Package 4 requires the following miscellaneous field overrides:

| Misc. Field | Override Prompt (seen if a package is selected) | Override Package Applicability | Override Default Value |
|--------------------------|---|--------------------------------|------------------------|
| Number of Units in House | Not overridden | Required | 2 |

Warning:

If you override field properties on a campaign's packages, you will not be able to change the properties of the field at the campaign level.

Determine The Eligibility Rules For The Campaign

Note:

Assumption. This section assumes you are comfortable with the information in [The Big Picture Of Campaign Eligibility](#).

The easiest way to determine a campaign's eligibility is to examine each package's eligibility criteria and abstract common eligibility restrictions onto the campaign. It's important to remember that campaign-level eligibility is only used to highlight if the campaign MAY contain applicable packages; campaign-level eligibility is not strictly enforced.

The packages on our [example campaign](#) are all targeted at residential customers in California. Therefore we'll take advantage of two base package algorithms to construct the campaign's eligibility criteria.

| Algorithm Type | Algorithm | Parameter Values |
|---|--|---|
| Check if account's customer class is in a predefined list (see CAEL-CC) | If customer class is "residential", check next algorithm | If customer's customer class is in list: 30 (check next) If customer's customer class is not in list: 20 (ineligible) List of customer classes: R |
| Check if account's division is in a predefined list (see CAEL-DIV) | If division is "California", customer is eligible | If customer's CIS division is in list: 10 (eligible) If customer's CIS division is not in list: 20 (ineligible) List of customer classes: CA |

Determine How The Campaign Behaves

The final step before you're ready to setup the campaign involves defining a variety of behavioral functions as described below:

- You need to define how the campaign uses accounts and premises. Specifically, on a campaign you define if an account / premise is required / optional / not allowed on its orders. In addition, if an account / premise is required or optional, you can control whether new accounts / premises can be created when an order is completed (the alternative is to force each order to use an existing account / premise). These controls prevent the unwanted proliferation of new accounts and premises for campaigns that are targeted at existing accounts and premises.
- Many fields on an order (e.g., phone type, customer class, division, account management group) can be defaulted on orders created for new customers. You will see these fields on [Order - Main](#). Think about each such field and whether a default value is appropriate. Keep in mind that the order taker can override any of these default values.
- An order taker can indicate that they want to [hold an order](#) if they need to do further research before continuing with an order. A background process (TD-ECBK) will create a [To Do entry](#) for held orders as a reminder to get back in touch with the customer on a future date. You can define the default To Do role assigned to such To Do entries when you create a campaign. Keep in mind that this value can be overridden when the order taker holds an order.
- You can indicate on a campaign the transaction to which the user should be transferred when orders are completed. Refer to [Supported Business Processes](#) for examples of how you might want to use this field.

Setup Sequence

And now you're ready to set up your campaign. The following points describe the order in which this should be done:

Warning:

We have assumed that you have already designed your organization's SP types, SA types, start options and rates. If you have not yet done this, we recommend familiarizing yourself with the concepts described in [Designing SP Types](#), [Rates](#) and [Defining Service Agreement Types](#) before designing your campaigns and packages.

- Setup any new [column references](#) required by the campaign's [miscellaneous fields](#). You will have to leave the retrieve, validate and post algorithms blank until after the next step.
- Setup any new [algorithms](#) required by:
 - The packages' [eligibility rules](#).
 - The packages' [start methods](#).
 - The campaign's [eligibility rules](#).
 - The campaign's [column references](#).
- Update the relevant [column references](#) with the appropriate retrieve, validate and post algorithms.
- Setup any new [characteristic types](#) required by the campaign's [miscellaneous fields](#).
- Create the [campaign](#) using the information you designed above. Specifically:
 - You defined the question and miscellaneous fields under [Determine The Properties Of Every Miscellaneous Field](#).
 - You defined the eligibility rules under [Determine The Eligibility Rules For The Campaign](#).
 - You defined everything else under [Determine How The Campaign Behaves](#).
 - We recommend leaving the campaign's status as Inactive until all packages are entered.
- Create the campaign's [packages](#) using the information you designed above. Specifically:
 - You defined the question and miscellaneous field overrides under [Determine If Any Properties Are Overridden On A Package](#).
 - You defined the eligibility rules under [Determine Package Eligibility Rules](#).
 - You defined the instructions under [Determine If Additional Instructions Are Required](#).
- Change the [campaign's](#) status to Active.

**Note:**

The default campaign on the installation record. If the campaign you've setup is the "default" campaign used when a user presses the Add Order button on [Control Central](#), make sure to specify it as the default campaign on the [installation record](#). Refer to [Setting up a New Customer Prior To Starting Service](#) for more information.

Other Useful Information

The topics in this section contain miscellaneous information about the sales & marketing functions.

Order versus Start/Stop

There are three different ways to start service for a customer:

- There is the process flow based start service process that supports starting premise-based service, adding new or using existing customers, and has many user configurable settings. For details please refer to [The Start Service Process and Request](#). The following explains the feature of the other two methods.
- As described under [definitions](#), you can use the [order](#) transaction to start service.
- Alternatively, you can use [start / stop](#).

The following table provides insight into the pros and cons of each method (after this table you will find our recommendations):

| Issue | Order | Start/Stop |
|--|---|--|
| New customer setup | Information about the new customer can be entered on the order page. A person / account will be setup when the order is completed. | A new person and account must be setup prior to using Start/Stop. See How To Add A New Customer From Control Central for more information. |
| New premise setup | Information about the new premise can be entered on the order page. A premise (and service points) will be setup when the order is completed. | A new premise and service point(s) must be setup prior to using Start/Stop. |
| Updates to existing customer information | Changes to a customer's existing account and/or person info may be entered on the order page. The related person and/or account will be updated when the order is completed. | Start/Stop cannot be used to update person or account information. Rather, you must transfer to the person or account page and make the necessary changes. |
| Incomplete orders | The order transaction allows you to record customer information and hold it without starting service. The customer can call back in the future and you can continue where you left off. | You cannot leave a start half-finished - you either have to complete the start or cancel it. |
| Stop current service, start new service | The order transaction does not currently provide a mechanism for stopping service (it can only be used to start service). | Start/Stop can be used to stop a customer's current service and start new service. |

| | | |
|---|--|--|
| Automatic versus manual start option selection (start options are used to default a great deal of information onto a service agreement) | If a customer selects a package, the system creates service agreements using the start options defined in the package (i.e., you do not have to select a start option for each service agreement that's created). | When you start service, you must define the specific start option for each service agreement created (actually, you only have to do this for those types of service agreements that use start options). |
| Starting premise and non-premise oriented services | If a customer selects a package, the system can create both premise and non-premise oriented service agreements. For example, when a package is selected, the system can create electric, gas, deposit, and charitable contribution SAs (based on the information defined on the package). | Multiple premise-oriented service agreements can be created in one interaction. However, a separate interaction is required for each non-premise oriented service agreement. |
| Changes after completion | An order cannot be modified after it is completed. Any changes (cancellations prior to starting service, changes of the start date, etc.) must be performed using the start/stop transaction. | The start/stop transaction allows you to cancel and make changes to pending start service agreements. |
| Field activity visibility | After an order is completed, the user is transferred to control central where field activities associated with the premise can be seen in trees and context zones. | All field activities associated with all premises associated with all pending starts / stops are shown on the start / stop transaction. |
| Address changes | Address changes entered on the order transaction are applied when an order is completed (i.e., when a package is selected). They are not held awaiting service agreement activation. | When you enter an address change on the start / stop transaction, this address change is saved until the first pending start or stop is activated. This means that the address change is effectively held until the start/stop is activated. |

Based on the above, we'd recommend the following:

- If your organization has well-defined service locations (i.e., premises) AND a premise's service point type controls the types of services offered to the customer, you should probably only use the order transaction to setup new customer information. The new service agreements should be setup using [start / stop](#). See [Prelude To Start/Stop](#) for more information.
- In all other situations, we'd recommend using the [order](#) transaction to start service. If customers typically stop and start service in tandem, we'd recommend the following steps:
 - Stop the customer's existing service using [start / stop](#).
 - Return to [Control Central - Account Info](#) and select the appropriate campaign from the appropriate portal zone. Keep in mind that the portal zones displayed on this page are based on the user's preferences and security profile. Therefore this zone may not be available to all users.
 - When you select the appropriate campaign, you'll be transferred to the [order](#) transaction where you can start the desired package for the customer.

Orders Cannot Be Changed After They Are Completed

The [Lifecycle of an Order](#) indicates that once an order is complete, it cannot become pending again. In addition to this rule, we'd like to stress that once an order is complete, you cannot make any changes to the order except to add new [log entries](#).

Premise and SP Characteristics May Be Populated From Postal Defaults

If you specify a new premise on the order transaction and you complete the order, a new premise will be created. This premise's characteristics can be populated from two different sources:

- You could have designed the campaign to have its orders capture premise characteristics. You do this by adding miscellaneous fields to the campaign that are premise characteristics.
- You could have set up [postal defaults](#) for the premise's country and postal code.

If a given characteristic is referenced on both of the above, the characteristic value on the campaign is used as the premise's characteristic value.

As described above, service points may be created when a package is selected (it depends on the [SA to Create algorithm](#) that you've used on the selected package). The base package algorithms that create a new service point when a package is selected will populate the service point's characteristics using the information on the postal defaults (if specified). Refer to STRM-VT for an example of this type of SA to create algorithm.

To Do List Processing

In the base package, there are two To Do lists that may be affected by orders:

- Highlight pending orders. This To Do list contains orders that are in the pending state. Refer to Pending To Do Entries (TD-EPND) for more information about this To Do list.
- Highlight held orders. This To Do list contains orders that are in the held state. Refer to Held To Do Entries (TD-ECBK) for more information about this To Do list. Refer to [Order - Hold Dialog](#) for more information about holding orders.

Hold and Cancel Reason Codes

In [Lifecycle of an Order](#), we illustrated how a user can hold a pending order. Before a user can hold an order, they must supply an [Order Hold Reason](#).

The same is true if a user wants to cancel a pending or held order (i.e., they must supply a [Order Cancellation Reason](#)).

These reason codes are purely for audit purposes.

Automatically Cancelling Old Orders

The system is delivered with a batch process, Cancel Pending/Held Orders (C1-CNPHO), that can be used to cancel held and/or pending orders that have been open for more than a specified number of days. Refer to the batch control description for more detail.

The delivered process is built using the [Plug-in Driven Background Processes](#) framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. For example, you can introduce a process record algorithm to create a To Do Entry instead of cancelling the order. Adjust the batch parameters to align with any custom logic you introduce.

Additional Things Can Happen When An Order Is Completed

An optional plug-in spot exists on [customer class](#) where you can introduce additional logic to be executed when an order is completed for an account that belongs to this customer class.

Another optional plug-in spot exists on [campaign](#) where you can introduce additional logic to be executed when an order is completed for the campaign.

New Premises and Accounts Are Only Created if an Order is Completed

It's important to understand that a premise and account are only created when an order is completed. This means you can explore alternatives with a prospect who resides at a new premise without introducing the premise / account. However, the system creates a person if you save an order so that an audit of the customer interaction exists in the system.

Premise Geographic Types Are Populated In An Unusual Way

A [premise's geographic ID's](#) are used by [Control Central](#) when you look for a customer / premise using geographic identifiers.

Note:

Geographic coordinates are optional. An [installation option](#) controls whether at least one geographic coordinate is required on every premise.

The following points describe how the geographic ID's are populated on premises that are created when an order is completed:

- If a [postal default](#) exists for the new premise's country / postal code, any geographic identifiers on the postal default are copied onto the new premise.
- If a postal default hasn't been setup for the new premise's country / postal code, the premise will have a single geographic identifier. It is constructed as follows:
 - The geographic type is defaulted from the [campaign](#).
 - The geographic value is set to ***.

Note:

Potential error. If neither the campaign nor the postal defaults results in a geographic type AND the [installation record](#) indicates at least one geographic type is required on a premise, an error is generated explaining that either postal defaults or the campaign should be populated with default geographic information.

Account And Premise Usage Are Controlled By The Campaign

When you set up a campaign, you define how the campaign's orders use accounts and premises. Refer to the description of Account Usage and Premise Usage under [Campaign - Main](#) for more information.

Maintaining Orders

The order transaction can be used to satisfy many diverse requirements. For example, you can use an order to:

- Enroll new customers using a single transaction (i.e., you don't have to use the person, premise, service point, and start / stop transactions to enroll a new customer who resides at a new premise).
- Sell new products to existing customers.
- Update existing person, account and premise information using a single transaction.

- Market your services to prospects uploaded from a marketing list (and measure the success of your efforts). If the customer responds to your sales efforts, the system will automatically setup the customer, premise and related service agreements.
- Setup marketing surveys and record your customers' responses.
- Quickly create one-time charges.
- Set up proposals for prospective services (and then send a quotation to the customer for these services).
- And more...

The topics in this section describe the order transaction. Refer to [The Big Picture of Campaigns, Packages and Orders](#) for general information about orders.

Lifecycle of an Order

The following diagram illustrates the lifecycle of an order.

Pending An order starts its life in the Pending state. An order remains in this state until you Cancel, Complete or Hold it.

Held You Hold an order when you want to save an order pending future information. For example, you would hold an order if you need to perform research on the perfect rate for the customer before completing the order. A Held order can be Completed or Canceled.

Complete When a customer selects a package of goods and services, the "V" is updated, service agreements are initiated, and the order becomes Complete. No changes may be made to a Complete order.

Canceled A Pending or Held order may be Canceled.

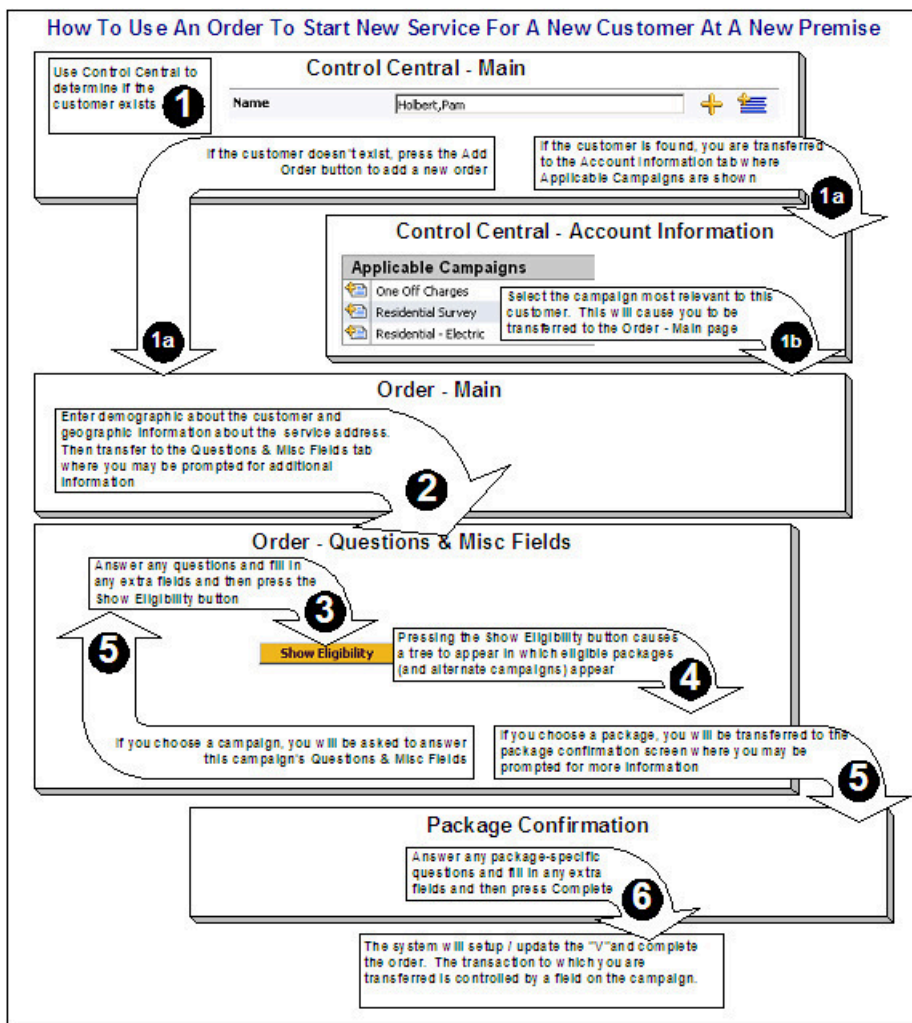

Order User Interface Flow

The diagram that appears below illustrates the anticipated navigation path used to process an order.

Warning:

An order's campaign controls many aspects of the user interface flow. The illustration that appears below is a sample of what's possible; it may not mirror how your team has setup your company's campaigns.

Order - Main

This page is used to define demographic and geographic information about the customer / prospect.

Fastpath:

Refer to [The Big Picture of Campaigns, Packages and Orders](#) for more information about orders.

Open this page using **Menu > Sales & Marketing > Order > Search**.

Fastpath:

Refer to [Order User Interface Flow](#) for information about how to use this page.

Description of Page

Order contains a concatenation of the customer's name, campaign, package (if the order is completed), status and start date. **Order ID** is the system-assigned unique identifier of the order. These values only appear after the order is added to the database.

Status contains the state of the order. Refer to [Lifecycle of an Order](#) for information about the valid values and the state transition rules. Additional information may also be displayed based on the status:

- If the order's status is Held, the following information is also displayed: the hold reason, the name of the user who held the order, and the date and time when a reminder for the order is due to be created.

- If the order's status is Canceled, the following information is also displayed: the cancel reason, the name of the user who canceled the order, and the date and time when the order was canceled.
- If the order's status is Complete, the following information is also displayed: the name of the user who completed the order and the date and time when the order was completed.

Press the **Hold** button to hold a Pending order. Refer to [Order - Hold Dialog](#) for a description of the pop-up window used to hold an order.

Press the **Cancel** button to cancel a Pending or Held order. Refer to [Order - Cancel Dialog](#) for a description of the pop-up window used to cancel an order.

If the **Campaign** has been setup to allow the completion of orders without selecting a package, a button appears to the right of **Cancel**. The label that appears in the button is defined on the **Campaign**. When pressed, the order is completed. When the order is completed,

- The "V" is setup / updated.
- All questions and miscellaneous fields (defined on the next tab) are posted to the appropriate object.
- [Optional plug-ins](#) are executed.
- You will be transferred to the order completion transaction that's defined on the **Campaign** (if any).

If the order references an existing person, account, or premise and the related person / account / premise has changed after their information was snapshot on the order, the **Out of Sync** section appears. This section highlights which objects have changed since the order was last saved. In addition, the **Sync** button appears. When pressed, the order is updated with the current field values for these objects.

An order's **Campaign** controls many aspects of the order's behavior. For example, it controls:

- The type of information defaulted onto an order.
- The eligibility-oriented questions that are displayed on the next tab.
- The superset of packages that can be offered to a customer.
- In addition to the above, campaigns also control high-level [eligibility rules](#) and [business process flows](#).

An order's **Campaign** is defaulted as follows:

- When you select a customer on [Control Central - Search](#), you are automatically transferred to the [Account Information](#) portal. One of the [zones](#) on this portal page contains the campaigns that can be offered to the customer. If you select a campaign from this zone, you are transferred to the [Order](#) transaction with the respective Campaign defaulted. Note, the Applicable Campaigns zone only appears if the CSR has modified their preferences to display this zone.
- In all other situations, the order's campaign defaults from the [Installation Record](#).

You may change an order's **Campaign** at will. Note that changing the campaign will result in the **Questions & Misc Fields** (the next tab) being refreshed with values associated with the new campaign. However, other values typically defaulted from the campaign (such as default customer class) do not get refreshed so that data you may have entered does not get overwritten.

Start Date defines the date on which service will start. This date becomes the start date on service agreements created when this order is completed. If you need to change the start date on these service agreements, transfer to [Start/Stop](#) (where all of the pending start service agreements will appear).

Note: Manual date entry is disabled on the start date and the date picker must be used when the Disable Manual Date Entry **Option Type** on the Customer Information Options [Feature Configuration](#) has been enabled.

The topics that follow describe the remaining sections on this page

Order - Main - Person Information

The **Person Information** section contains demographic information about the customer / prospect.

Warning:

This page contains a subset of person-oriented information. If you need to define other person-oriented information, transfer to [Person - Main](#) after the order is completed.

If this is a new customer, select Create New Person and enter demographic information in the fields that follow. Otherwise, select Use Existing Person and use the **Name** field or press the search button to find the customer. After you select an existing person, the following events takes place:

- The person's name appears beneath the person search (and the person context menu can now be used to drill down to person-oriented pages). Note, the person's name is formatted by a plug-in algorithm on the [installation record](#). Refer to the base package's name format algorithm (PERS-INFO) for an example. If you prefer different formatting logic, your system administrator should configure the system appropriately.
- If any of the Questions & Misc Fields (on the next tab) are used to capture person-oriented characteristics, the person's existing characteristic values are defaulted.
- If the selected person has at least one account, information about the account is displayed in the **Account Information** section (if the **Campaign** makes uses of accounts). In addition, if any of the Questions & Misc Fields (the next tab) are used to capture account-oriented characteristics, the account's existing characteristic values are populated in the respective rows on this tab.
- Information about the person is displayed in the fields that follow.

Use **Person/Business** to indicate if the customer is a Person or a Business. This value controls how the person's primary name is validated. Note, for new customers, this value defaults based on the **Campaign**.

Names are used by [Control Central](#) when you look for a customer based on their name. In addition, a person's primary name is the addressee on the person's bill unless overridden by the **Override Mailing Name** (defined on [Person - Correspondence Information](#)). To modify a name, simply move to a field and change its value. To add a new name, press + to insert a row, then fill in the information for each field. The following fields display:

- Use **Name Type** to indicate if the name is an Alias, Alternate Representation, Doing Business As, Legal, or Primary name. Note, for new persons, a value of Primary is defaulted.
- Use **Person Name** to define the person's name. Note well, the name is case sensitive.

Note:

Alternate representations of a person's name. You would use an Alternate Representation for a person's name when you have an alternate ways to define the person's primary name. Alternate representations are typically used in countries that use multiple character sets (e.g., the Primary name is entered in Chinese, the Alternate Representation is entered in English). When a person has an alternate name, both the main and alternate names can be used to search for a person. The Alternate Representation **Name Type** only appears if you have enabled alternate addresses on the installation record. Refer to the description of the Alternate Representation field under [Installation - Main](#) for more information.

Validation and formatting are performed by plug-ins. The validation that is applied to **Person Name** (e.g., a comma separating the last and first name - Smith,Patricia) is controlled by a plug-in algorithm on the [installation record](#). More than one algorithm can be plugged into this plug-in spot. Algorithms plugged into this plug-in spot can also perform formatting such as removing special characters that your implementation's business rules do not allow in person names. Other algorithms can be configured to remove or replace text.

- The **Do Not Format** switch can be used to bypass any person name formatting done by the algorithms described above. Validation such as requiring name separator is still applied, but no further formatting is applied. Setting the switch only applies while the record is being saved and is then reset. The switch is reset because the formatting is only applied when the record is subsequently changed. This switch is only shown if the Enable Person Name Format Bypass **Option Type** on the Customer Information Options [Feature Configuration](#) has been enabled

Person Contacts are used by Control Central to look for accounts and persons. For new customers, the person contact type(s) default based on the Campaign. To modify a person contact, simply move to a field and change its value. To add a new person contact, press + to insert a row, then fill in the information for each field. The following fields display:

- **Person Contact Type** indicates the type of contact such as, home phone, cell phone, or work email.

- **Contact Information** contains the specific contact information such as, the phone number or email address. Enter the contact information in the format described.

Note: Formatting is performed by a plug-in. The format that is applied to **Contact Information** is controlled by the algorithm that is plugged in on the respective person contact type (refer to Setting Up Person Contact Types for more information). If you prefer a different format, your system administrator should configure this algorithm appropriately.

- Enter the **Extension**, if any, of the contact information. (This field is only active when the contact's contact routing is phone or fax.)
- The **Primary** switch must be set for exactly one person contact for each contact routing.
- **Do Not Disturb (From)** and **Do Not Disturb (To)** indicate the times when a person contact should not be used. (**Note:** these fields are active when the Person Contact Type's Allow Do Not Disturb information is set to *Optional*.)

Phone numbers are used by **Control Central** to look for accounts and persons. For new customers, the phone type(s) default based on the **Campaign**. To modify a telephone number, simply move to a field and change its value. To add a new telephone number, press + to insert a row, then fill in the information for each field. The following fields display:

- **Phone Type** indicates the type of phone number, e.g., Home, Mobile, Business, ...
- Use **Phone Number** to define the telephone number. Enter the telephone number in the format described by the **Phone Format**.

Note:

Formatting is performed by a plug-in. The format that is applied to a **Phone Number** is controlled by the algorithm that is plugged in on the respective **Phone Type**. You can also have this plug-in convert input values into formatted values, e.g., this algorithm could transform all numbers into a formatted string. If you prefer a different format, your system administrator should configure this algorithm appropriately.

- Enter the **Extension**, if any, of the telephone number.

Note: The Person Phone grid appears when the Legacy Person Phone and Email Option Type on the Customer Information Options Feature Configuration has been enabled.

A person's **ID** has several uses:

- It is used by **Control Central** when you look for a customer / premise based on their ID.
- It is used to highlight potential duplicate persons.
- **Control Central** displays a person's primary identification in the search results area to help a user identify the customer when multiple customers match the search criteria.

The person ID usage flag on the **installation record** indicates whether or not at least one id for a person is required or optional. The ID Type defaults from the **installation record** based on the **Person Type** (Person versus Business). The following fields are used to define a customer's primary ID.

- Select the type of identification from the **ID Type** drop down.
- Enter the identification number in the **ID Number** field. Please note that if the ID number should be formatted (e.g., dashes in an American social security number), you do not have to include the delimiter (e.g. dashes). You can enter the ID number as a contiguous value and the system will format it for you. The format is shown adjacent to the **ID Number** field.

Note:

Formatting is performed by a plug-in. The format that is applied to a person ID number(e.g., dashes in an American social security number) is controlled by the algorithm that is plugged in on the respective **ID Type**. If you prefer a different format, your system administrator should configure this algorithm appropriately.

A person can have many forms of identification. The order transaction only caters for a single form of ID (as this is the most typical situation). If you want to specify additional person ID's, you must transfer to **Person - Main** after the person is created (persons are created when the order is saved).

Specify the customer's **Email ID** (if any).

Note: EmailID appears when the Legacy Person Phone and Email Option Type on the Customer Information Options Feature Configuration has been enabled.

Define the **Language** in which the person prefers their bills and correspondence printed.

Note:

Default note. The person's language defaults from [Installation Options - Person](#).

Fastpath:

Refer to [Customer Language](#) for more information on options for supporting multiple languages for your customers.

Use **Life Support / Sensitive Load** to indicate if the person has life support or sensitive load equipment. Valid values are: LS/SL (i.e., the person has life support / sensitive load equipment), None. If the customer has LS/SL equipment, make a note of the type of equipment in the **Life Support / Sensitive Load Notes**.

Note:

A premise can also have life support / sensitive load information. If the equipment is physically linked to the premise (e.g., a hospital has life support equipment), you should NOT specify the life support information on the person. Rather, after the premise is added, transfer to [Premise - Misc](#) and specify life support information on the premise.

Life support affects alerts and C&C. If life support / sensitive load information is specified, an alert will appear when the person is displayed on control central. In addition, if a person has life support or sensitive load equipment, it is possible for a different credit & collection severance process to be kicked off if the person's account associated has overdue debt. Refer to [Designing Your Severance Procedures](#) for more information.

Order - Main - Service Address

The **Service Address** section contains geographic information about the service address:

Warning:

This page contains a subset of premise-oriented information. If you need to define other premise-oriented information, transfer to [Premise - Main](#) after the order is completed.

Whether or not a premise is required or even allowed on an order is controlled by an option on the **Campaign**. If the **Campaign** disallows the use of a premise, this section will be suppressed. If the **Campaign** allows the use of a premise, an indication of whether a premise is optional or required is displayed adjacent to **Service Address**.

If a premise is allowed on the order, use the dropdown at the top of this section to tell the system about this order's premise:

- Select No Premise Information if you do not want to associate a premise with this order (e.g., for a one-time charge).
- Select Create New Premise if this is a new premise. You should enter the new premise's address in the remaining fields in this section.
- Select Use Existing Premise if an existing premise should be used on the order. Use the **Address** and **City** fields or press the search button to find the premise. Refer to [Control Central - Search Facilities](#) for suggestions in respect of how to use these fields. After you select an existing premise, the following events takes place:
 - The premise's description appears beneath the premise search fields (and the premise context menu can now be used to drill down to premise-oriented pages).
 - If any of the Questions & Misc Fields (the next tab) are used to capture premise-oriented characteristics, the premise's existing characteristic values are defaulted.
 - Information about the premise is displayed in the fields that follow.

Use **Premise Type** to describe the type of service location.

The address's constituent fields vary based on the **Country**. Please refer to the [Country](#) page for more information.

Populate **Trend Area** if the **Postal** is blank. The **Postal** and the **Trend Area** cannot both be blank as the **Trend Area** is a required field on the premise and its value is typically defaulted from [postal defaults](#).

Note:

Default note. The values of several fields on this and the next page default based on the **Country** and the **Postal**. Refer to [Setting Up Premise & Service Point Postal Defaults](#) for more information. Also note, there are several premise-oriented fields that do not appear on this transaction that will be populated on the premise based on the **Country** and **Postal** (e.g., characteristics, time zone, trend area, geo ID's).

Use **CIS Division** to define the jurisdiction in which the premise is located.

Order - Main - Account Information

The **Account Information** section contains account-oriented information.

Warning:

This page contains a subset of account-oriented information. If you need to define other account-oriented information, transfer to [Account - Main](#) after the order is completed.

Whether or not an account is required or even allowed on an order is controlled by an option on the **Campaign**. If the **Campaign** disallows the use of an account, this section will be suppressed. If the **Campaign** allows the use of an account, an indication of whether an account is optional or required is displayed adjacent to **Account Information**.

If an account is allowed on the order, use the dropdown at the top of this section to tell the system about this order's account:

- Select No Account Information if you do not want to associate an account with this order (e.g., for a person-oriented marketing survey).
- Select Create New Account if this is a new account. You should enter the new account's information in the remaining fields in this section.
- Select Use Existing Account if an existing account should be used on the order. If an existing person was selected above, one of the person's accounts (if any) will be automatically displayed in the **Account Information**. In addition, if the order references an existing person, the account search will be limited to accounts associated with this person. If an **Existing Account** is selected, the following takes place:
 - Basic information about the account appears beneath the search area (and the account context menu can now be used to drill down to account-oriented pages).
 - If any of the Questions & Misc Fields on the next tab are used to capture account-oriented characteristics, the account's existing characteristic values are defaulted.
 - Information about the account is displayed in the fields that follow.

If you have set the Installation Option CIS Division Control flag, you must define the new account's **CIS Division**. The values are restricted to the user's CIS Division(s). See Users and CIS Division for more information. The value is defaulted to user's primary CIS Division.

Customer Class plays a part in:

- If and when a customer is subject to late payment charges.
- The account's default collection class and when the account debt monitor reviews an account. Refer to [The Big Picture of Credit & Collections](#) for more information about how and when an account's debt is reviewed.
- And several other functions. Refer to [Setting Up Customer Classes](#) for more information.

Note:

Default note. For new accounts, the **Campaign** can default the **Customer Class**. If the campaign does not define a customer class, it can be defaulted from the CIS Division, if shown, or installation options.

The optional Account **Management Group** controls the roles assigned to To Do entries associated with an account. Refer to [Setting Up Account Management Groups](#) for more information.

**Note:**

Default note. For new accounts, **Management Group** defaults based on the **Campaign**.

The remaining fields are used to describe how the bill should be routed to the customer.

**Warning:**

When an order is completed, several fields that do not appear on this page that reside on [Account - Person](#) are populated. For example, **Account Relationship Type**, **Bill Format**, **Number of Copies**, **Receives Notification** are all populated with default values. If you need to override the default values, transfer to [Account - Person](#) after the account is added.

Use **Bill Route Type** to define how the bill is sent to the customer. This field's value defaults from the [Installation Record](#). This value is important as it controls many options on the remainder of this page. If the **Bill Route Type** indicates that bills are routed via Fax, the person's fax number is displayed adjacent (the system knows which of a [person's phone numbers](#) is a fax number by the **Phone Type**). If the **Bill Route Type** indicates that bills are routed via Email, the person's **Email** address is displayed adjacent. If the **Bill Route Type** indicates that bills are routed via the Postal service, you must choose an appropriate **Address Source** to define which address should be used. Refer to [Setting Up Bill Route Types](#) for more information about bill route types.

If the **Bill Route Type** indicates that bills are routed via the Postal service, you must choose the appropriate **Address Source** to define which address should be used.

- Choose Mailing Premise on Account if bills should be sent to the address associated with the Mailing Premise on the first page. This address is displayed adjacent.
- Choose Person if bills should be sent to the [person's mailing address](#) . This address is displayed adjacent.
- Choose Account Override if bills should be sent to an override address specified below. Typically, you would only choose this option if the person has multiple accounts and each account's bills should be sent to a different address.

If you select a **Address Source** of Account Override , you must enter the address to which bills will be sent in the following address constituents. The number and type of address constituents is based on the **Country** (refer to [Defining Countries](#) for more information on address constituents). These fields will be protected for other **Address Sources**. Note, the **Country** defaults from [Installation Options - System](#) and several other constituents default based on the **Country** and **Postal** if a [Postal Default](#) exists for the postal code.

**Note:**

By default, the **Address Source** field is protected on Order – Main page if the **Bill Route Type** is set to a value other than Postal. To enable the **Address Source** field for all **Bill Route Types** in most circumstances, set the Always Enable Address Source option type on the General System Configuration feature configuration to Y.

Regardless of the **Always Enable Address Source** option value, **Address Source** and **Address Information** are displayed but both are disabled when **Bill Routing Method** is *Not Postal* and **Quote Routing Method** (on Account – Persons page) is *Postal* . A message “*The Main Person receives Quotes at this address. To edit it, go to the 'Persons' tab on the Account.*” is displayed next to the **Address Source**.

Order - Questions & Misc Fields

This page has several purposes:

- The order's Campaign can define questions to be posed to customers when an order is taken. For example, you could ask the customer "marketing survey" questions (e.g., please rate our service, how do you heat your home?, etc.). This page allows you to capture the customer's response.
- The order's Campaign can also be setup to capture additional fields to be updated on the order's person / account / premise when the order is completed. For example, you could indicate that the account's override due date and automatic payment options should be captured when an order is taken. This page allows you to capture these field values.

- The order's Campaign can also be setup to pose eligibility-oriented questions that qualify the customer for packages of goods and services. For example, you might have a campaign with packages that can only be selected if the customer commits to a year's worth of service. This page allows you capture the customer's response to these types of questions.
- After entering the above information (and the information on the Main page), you can use this page to select a package of goods and services for the customer.
- You can use this page to switch the campaign on the order (which would result in new questions and miscellaneous fields appearing).

**Fastpath:**

Refer to [The Big Picture of Campaigns, Packages and Orders](#) for more information.

Open this page using **Sales & Marketing, Order** and then navigate to the **Questions & Misc Fields** tab.

**Fastpath:**

Refer to [Order User Interface Flow](#) for information about how to use this page.

Description of Page

Order contains a concatenation of the customer's name, campaign, package (if the order is completed), status and start date. **Order ID** is the system-assigned unique identifier of the order. These values only appear after the order is added to the database.

Status contains the state of the order. Refer to [Lifecycle of an Order](#) for information about the valid values and the state transition rules. Additional information may also be displayed based on the status:

- If the order's status is Held, the following information is also displayed: the hold reason, the name of the user who held the order, and the date and time when a reminder for the order is due to be created.
- If the order's status is Canceled, the following information is also displayed: the cancel reason, the name of the user who canceled the order, and the date and time when the order was canceled.
- If the order's status is Complete, the following information is also displayed: the name of the user who completed the order and the date and time when the order was completed.

Press the **Hold** button to hold a Pending order. Refer to [Order - Hold Dialog](#) for a description of the pop-up window used to hold an order.

Press the **Cancel** button to cancel a Pending or Held order. Refer to [Order - Cancel Dialog](#) for a description of the pop-up window used to cancel an order.

If the **Campaign** has been setup to allow the completion of orders without selecting a package, a button appears to the right of **Cancel**. The label that appears in the button is defined on the **Campaign**. When pressed, the order is completed. When the order is completed,

- [The "V"](#) is setup / updated.
- All questions and miscellaneous fields (defined on the next tab) are posted to the appropriate object.
- [Optional plug-ins](#) are executed.
- You will be transferred to the order completion transaction that's defined on the **Campaign** (if any).

If the order references an existing person, account, or premise and the related person / account / premise has changed after their information was snapshot on the order, the **Out of Sync** section appears. This section highlights which objects have changed since the order was last saved. In addition, the **Sync** button appears. When pressed, the order is updated with the current field values for these objects.

The number and type of **Questions & Misc Fields** is controlled by the [Campaign](#).

**Note:**

Some questions can be suppressed. The campaign contains an indication if each question is account-oriented, person-oriented, premise-oriented or order-oriented. If the question is account-oriented and no account is defined on the **Main** tab, the question will be suppressed. If the question is premise-oriented and no premise is defined on the **Main** tab, the question will be suppressed.

Each row in this grid has a **Prompt** and a **Response**. The value of each **Prompt** is defined on the **Campaign**. The **Response** holds the answer supplied by the customer. Please note the following about the **Response** field:

- On a **Campaign**, you can indicate which questions / miscellaneous fields are required. The Response for a required field is prefixed with an asterisk - * .
- The value of a Response can default from a variety of sources:
 - If an existing person was selected on the **Main** page AND the response is used to capture a [person characteristic](#), the existing characteristic value will be defaulted.
 - If an existing premise was selected on the **Main** page AND the response is used to capture a [premise characteristic](#), the existing characteristic value will be defaulted. If no value exists, the characteristic values will default based on the postal defaults associated with the service address's **Country** and **Postal**.
 - If an existing account was selected on the **Main** page AND the response is used to capture an [account characteristic](#), the existing characteristic value will be defaulted.
 - Otherwise, the characteristic value is defaulted from the **Campaign**.
- The type of field used to capture a Response is controlled by the Campaign. Depending on the type of Response you may see [Go To](#) buttons and [Search](#) buttons.

After entering the **Responses** to the **Questions & Misc Fields**, press the **Show Eligibility** button.

The following may occur when this button is pressed:

- If a new customer is specified on the Main page, a warning will advise you that a new person will be added. The system needs to add a new person so that an audit of the customer interaction exists.
- The tree expands to show the Order - Eligibility Tree containing package, ineligible package, error package, and other campaign nodes:
 - Each **Package** node contains a package that is linked to the campaign whose [Eligibility Criteria](#) allows its selection by the customer. You can expand this node to see the various service agreements that will be created if you select the package. Selecting one of these packages causes the [Order - Package Confirmation](#) page to appear in which you can confirm your selection.
 - The **Ineligible Package(s)** node contains packages whose [Eligibility Criteria](#) prevents their selection by the customer.
 - The **Error Packages** node contains packages whose [Eligibility Criteria](#) have returned errors (if any).
 - The **other campaign(s)** node contains alternative campaigns that may be substituted for the current campaign on the package. Selecting one of these campaigns will cause the campaign to be changed on this order. Changing a campaign on an order will result in new questions and miscellaneous fields appearing. Refer to [The Big Picture Of Campaign Eligibility](#) for more information.

Note:

Some nodes can be suppressed. To increase page performance with large campaigns, you can define a [feature configuration](#) to suppress the display of the Ineligible Packages, Error Packages or Other Campaign nodes. If a node is suppressed, it does not appear on the eligibility tree and the system does process the information necessary to display the node.

Order - Log

This page contains an audit trail of significant events that transpired in the history of this order.

Open this page using **Menu > Sales & Marketing > Order > Search** and navigate to the **Log** page.

Description of Page

Order contains a concatenation of the customer's name, campaign, package (if the order is completed), status and start date. **Order ID** is the system-assigned unique identifier of the order. These values only appear after the order is added to the database.

Status contains the state of the order. Refer to [Lifecycle of an Order](#) for information about the valid values and the state transition rules. Additional information may also be displayed based on the status:

- If the order's status is Held, the following information is also displayed: the hold reason, the name of the user who held the order, and the date and time when a reminder for the order is due to be created.
- If the order's status is Canceled, the following information is also displayed: the cancel reason, the name of the user who canceled the order, and the date and time when the order was canceled.
- If the order's status is Complete, the following information is also displayed: the name of the user who completed the order and the date and time when the order was completed.

Press the **Hold** button to hold a Pending order. Refer to [Order - Hold Dialog](#) for a description of the pop-up window used to hold an order.

Press the **Cancel** button to cancel a Pending or Held order. Refer to [Order - Cancel Dialog](#) for a description of the pop-up window used to cancel an order.

Campaign contains basic information about the order's campaign.

Package only appears if the order has been completed. It contains basic information about the package.

Start Date contains the date on which the service agreement's created by the order will be started.

The **Log** contains an audit trail of significant events that transpired in the history of this order. There are two types of entries in the log:

- The system automatically adds log entries when key events occur. These entries may not be removed or changed.
- Users may add log entries by pressing the + button and then specifying the Details.

Order - Package Confirmation

The Package Confirmation page allows you to check the package you selected before [the V](#) is created / updated for the customer. This page opens when you select a package from the eligibility tree on [Order - Questions & Misc Fields](#).

Warning:

If you press the **Complete** button, a variety of objects may be created (service agreements, service points, a premise, an account, field activities, etc.). If you need to change any of these objects after order completion, you must transfer to the respective page on which the object is maintained. You can also use [Start/Stop](#) to make changes to the service agreements created by this transaction.

Description of Page

Order contains a concatenation of basic information about the order. **Order ID** is the system-assigned unique identifier of the order. These values only appear after the order is added to the database.

Campaign contains basic information about the order's campaign.

Package contains basic information about the package.

Premise is the address at which service will be delivered.

Person is the name of the customer.

Account is the name of the customer and their customer class.

Start Date contains the date on which the service agreement's created by the order will be started.

The **Questions & Misc Fields** grid contains the questions and miscellaneous fields that appeared on the order. Note well, it is possible to design a campaign and a package where some fields are optional on the campaign but required for a specific package. The **Response** of all required fields for the selected package are prefixed with an asterisk. Refer to [Order - Questions & Misc Fields](#) for information about the rows in this grid.

Note:

Changing your answers could cause the package to become ineligible. As described earlier, the fields you enter on an order play are what the system uses to determine if a package can be selected for a customer. If you change the answers to the **Questions & Misc Fields**, the package may no longer be eligible and an error

will be presented to you. You will have the choice of reverting to the original answers or returning to the order page where you can select an eligible package.

Additional questions / misc fields are possible. It is possible to design a campaign where certain field values are only visible on specific packages. In this scenario, the **Questions & Misc Fields** grid may contain additional rows for a given package. Refer to [Designing Campaigns and Packages](#) for more information.

The **Instructions** grid contains package-specific suggestions. These instructions are defined on the [package](#).

The **Messages** grid contains system-generated messages that summarize what will happen if you press the **Complete** button.

Press the **Complete Order** button if you are satisfied with the information on the order. Otherwise, press **Do Not Use this Package** to change or cancel the order.

Order - Hold Dialog

The **Order - Hold** dialog opens if you press the **Hold** button on the order transaction. You use it to define why the order is being held and when you want to be reminded to check up on the order.

Description of Page

Use **Hold Reason** to define why the order is being held.

The following fields are used to control the [To Do entry](#) that will be created to remind you about this order.

- Use **Reminder Date / Time** to define the latest date on which the To Do entry should be created. The reason we indicated this should be the latest date is because the background process (TD-ECBK) that's responsible for creating these To Do entries has a parameter called "lead time". This parameter is used to define the number of days before the **Reminder Date** that the To Do entry should be created.
- If the To Do entry should be addressed to a group of users, choose a **Reminder Type** of Send to Role and enter the user group's **To Do Role**. Note, the To Do Role will default from the order's campaign.
- If the To Do entry should be addressed to a specific user, choose a **Reminder Type** of Send to User and enter the user's User ID in **To Do User**.
- **Log Notes** are used to describe why the order is being held. This information appears in the [log entry](#) that is created by the system when you hold an order.

If there are any To Do entries (with a status of Open or Assigned) that drill down to this order, a message is displayed indicating that existing To Do entries for this order will be completed. If the order is already in Hold status, existing To Do entries are completed when you click the OK button and a new To Do entry is created when the background process responsible for creating the To Do entries runs.

Order - Cancel Dialog

The Order - Cancel dialog opens if you press the **Cancel** button on the order transaction. You use it to define why the order is being canceled.

Description of Page

Use **Cancel Reason** to define why the order is being canceled.

Use **Log Notes** to describe why the order is being canceled. This information appears in the [log entry](#) that is created by the system when you cancel an order.

Maintaining Campaigns

When you add an [order](#), you must reference its [campaign](#). An order's campaign controls:

- The type of information defaulted onto an order. For example, you can setup a campaign to default a given account management group on all orders linked to this campaign. This account management group will then default onto accounts created when the campaign's orders are completed.

- The eligibility-oriented questions that are posed to the customer when an order is taken. For example, the questions indicated above - Who is your current energy service provider? / Would you like to pay automatically? / What is your date of birth? - are all defined on the order's campaign.
- The superset of packages that can be offered to a customer whose order references this campaign. An order's campaign defines the types of packages that may be selected.
- In addition to the above, campaigns also control high-level [eligibility rules](#) and [business process flows](#).

The topics in this section describe the campaign transaction.

Fastpath:

Refer to [The Big Picture of Campaigns, Packages and Orders](#) for general information about campaigns. Refer to [The Big Picture Of Campaign Eligibility Rules](#) for a discussion of how to control which campaigns can be used for different types of customers. Refer to [Designing Campaigns and Packages](#) for guidelines describing how to design your campaigns.

Lifecycle of a Campaign

The following diagram illustrates the lifecycle of a campaign.

Active An Active campaign may have orders created in respect of it.

Inactive By Inactivating the campaign, you are preventing it from being used on future orders. In addition, Inactive campaigns do not appear in the [Applicable Campaigns](#) zone.

Campaign - Main

This page is used to define basic information about a campaign.

Fastpath:

Refer to [The Big Picture of Campaigns, Packages and Orders](#) and [Designing Campaigns and Packages](#) for more information.

Open this page using **Menu > Sales & Marketing > Campaign > Search**.

Description of Page

Campaign is the user-defined code that uniquely identifies the campaign. The campaign's description appears adjacent.

Description briefly describes the campaign.

Campaign Status describes the state of the campaign. Refer to [Lifecycle of a Campaign](#) for more information.

The following fields contain values to be defaulted onto this campaign's orders. The user who takes the order may override these default values. Note well, these default values are only applicable for new persons - they will not override field values defined on existing persons.

- The system requires all persons to be defined as either a Person or a Business. Use **Default Person / Business** to define the default value for persons created by this campaign's orders.
- Every person contact defined for a person must reference a person contact type. Use **Default Person Contact Type 1**, **Default Person Contact Type 2**, and **Default Person Contact Type 3** to define the first three [person contact type](#) defaults for persons created by this campaign's orders.

Note: Person Contact Types appears when the Legacy Person Phone and Email Option Type on the Customer Information Options Feature Configuration has **not** been enabled

- Every phone number defined for a person must reference a [phone type](#). Use **Default Phone Type 1** and **Default Phone Type 2** to define the first two phone types defaults for persons created by this campaign's orders.

Note: Phone Types appears when the Legacy Person Phone and Email Option Type on the Customer Information Options Feature Configuration has been enabled.

Premise Usage controls if and how this campaign's orders use premises. You have the following options:

- Select Not Allowed if this campaign's orders do not reference a premise.
- Select Optional if this campaign's orders do not have to reference a premise. This option also means that a new OR existing premise may be specified on the order. Note, if an order references a new premise, the premise will be created when the order is completed.
- Select Optional - Existing Premise Only if this campaign's orders do not have to reference a premise. This option also means that only an existing premise may be specified on an order.
- Select Required if this campaign's orders must reference a premise. This option also means that a new OR existing premise may be specified on the order. Note, if an order references a new premise, the premise will be created when the order is completed.
- Select Required - Existing Premise Only if this campaign's orders must reference a premise. This option also means that only an existing premise may be specified on an order.

The following fields contain values to be defaulted onto this campaign's orders. The user who takes the order may override these default values. Note well, these default values are only applicable for new premises - they will not override field values defined on existing premises.

- The system requires all premises to reference a [premise type](#). Use **Default Premise Type** to define the default value for premises created by this campaign's orders.
- Every geographic ID defined for a premise must reference a [geographic type](#). Use **Default Premise Geo Type** to define the default value for premises created by this campaign's orders. Refer to [Premise Geographic Types Are Populated In An Unusual Way](#).

Account Usage controls if and how this campaign's orders use accounts. You have the following options:

- Select Not Allowed if this campaign's orders do not reference an account.
- Select Optional if this campaign's orders do not have to reference an account. This option also means that a new OR existing account may be specified on the order. Note, if an order references a new account, the account will be created when the order is completed.
- Select Optional - Existing Account Only if this campaign's orders do not have to reference an account. This option also means that only an existing account may be specified on an order.
- Select Required if this campaign's orders must reference an account. This option also means that a new OR existing account may be specified on the order. Note, if an order references a new account, the account will be created when the order is completed.
- Select Required - Existing Account Only if this campaign's orders must reference an account. This option also means that only an existing account may be specified on an order.

The following fields contain values to be defaulted onto this campaign's orders. The user who takes the order may override these default values. Note well, these default values are only applicable for new accounts - they will not override field values defined on existing accounts.

- The system requires all accounts to belong to a [customer class](#). Use **Default Customer Class** to define the default value for accounts created by this campaign's orders.
- An account may reference an [account management group](#). Use **Default Acct Management Group** to define the default value for accounts created by this campaign's orders.

If a user [holds](#) one of the campaign's orders, they can have a [To Do entry](#) generated on a future date to remind them about the order. Use **Default Hold To Do Role** to define the [group of users](#) to whom the To Do entry will be sent. Note well, the user who holds an order can indicate that the related To Do entry should be addressed to a specific user ID rather than a **Role**.

Use **Order Open Option** to define the page that is displayed when a user adds a new order for this campaign. This field is only relevant when the order transaction is invoked in "add mode" and a campaign is passed to this transaction (e.g., if a user adds an order from the [Applicable Campaigns Zone](#)).

A user can be automatically transferred to a different transaction when they complete an order. Refer to [Supported Business Processes](#) for examples of transactions that we anticipate being used. Use **Navigation Option** to define this transaction. Note,

- Leave **Navigation Option** blank if the user should remain on the order transaction after completion.
- You can setup **Navigation Options** to transfer the user to a tab other than the main tab.

If a user is allowed to complete this campaign's order's without selecting a package,

- Turn on **Allow Order Compl w/o Package** and
- Use **Order Compl w/o Package Label** to define the message to appear in the button used to complete such orders.

Fastpath:

Refer to [Campaigns Without Packages](#) for examples of campaigns where you would enable the above fields.

Use **Long Description** to provide an overview of this campaign.

The grid at the bottom of the page summarizes this campaign's questions and miscellaneous fields. To change this information, press the adjacent go to button (which will transfer you to the [Questions and Misc Fields](#) tab). To add additional information, transfer to the [Questions and Misc Fields](#) tab and press the + button.

Campaign - Questions and Misc Fields

This page is used to define the following type of information:

- An order's campaign can define questions to be posed to customers when an order is taken. For example, you could ask the customer "marketing survey" questions (e.g., please rate our service, how do you heat your home?, etc.).
- An order's campaign can also be setup to capture additional fields to be updated on the order's person / account / premise when the order is completed. For example, you could indicate that the account's override due date and automatic payment options should be captured when an order is taken.
- An order's campaign can also be setup to pose eligibility-oriented questions that qualify the customer for packages of goods and services. For example, you might have a campaign with packages that can only be selected if the customer commits to a year's worth of service.

Fastpath:

Refer to [Designing Campaigns and Packages](#) for information describing how to design this type of information for your campaigns.

Open this page using **Sales & Marketing, Campaign** and navigate to the **Question & Misc Fields** tab.

Description of Page

Warning:

This information is not intuitive; we strongly recommend that you follow the guidelines under [Designing Campaigns and Packages](#) before attempting to enter this information.

Campaign is the user-defined code that uniquely identifies the campaign. The campaign's description appears adjacent.

The **Questions & Misc Fields** scroll contains one row for each question / miscellaneous field captured on this campaign's orders. The following fields are used:

- **Prompt on Order** contains the prompt that is shown to the user when the **order** is taken. Refer to [Determine The Properties Of Every Miscellaneous Field](#) for examples.
- **Brief Description** is simply a brief description of the question / miscellaneous field.
- **Sort Sequence** controls the order in which the question appears on the order.
- **Applicability** controls whether the field is **Optional**, **Required**, or **Only Applicable on Package**.
 - A value of **Required** means the order taker must enter a valid value before packages are displayed for selection.
 - A value of **Optional** means the order taken can leave the field blank prior to package selection. You can make an **Optional** field **Required** on individual packages.
 - A value of **Only Applicable on Package** is used for fields that are only captured for specific packages. Fields of this type are suppressed prior to package selection. When you setup a **package**, you indicate if the field is applicable (if so, the user is only prompted for the field if the package is selected).
- **Type of Response** controls where the field is stored when the order is completed and how it is validated. You have two options: **Characteristic** or **Column**.
 - If a field is a **Characteristic**, you must define which entity the characteristic value is to be stored on when the order is completed (**Person**, **Account**, **Premise** or **Order**). You must also define the **Characteristic Type** as this controls the characteristic value entered by the user.
 - If a field's value resides in a **Column** (as opposed to a characteristic value), you must define the **column reference**. A field's **Column Reference** controls three things:
 - How the field's value is retrieved. A field's value is retrieved when an existing person / account / premise is referenced on an order.
 - How the field's value is validated. A field's value is validated before package eligibility is determined and before the order is completed.
