Define the minimum number of days a bill segment (other than the final segment) must span using **Minimum Days for Billing**. This is useful to prevent initial bill segments that span only a few days.

Fastpath:

For more information about minimum days, refer to [Preventing Short Bill Segments](#).

Select the **Bill Segment Type** that controls both how bill segments for this SA Type will be created and how the related financial transaction affects the general ledger and the customer's debt.

Fastpath:

For more information about bill segment types, refer to [Setting Up Bill Segment Types](#).

Use **Default Description on Bill** to define the verbiage that should print on the customer's bill.

Note:

Rates overwrite this description. The Default Description on Bill is not applicable for service agreements whose charges are calculated using a rate. Why? Because the description that appears on the bill segment is defined on the rate schedule's rate version calculation group.

Billable charges overwrite this description. The Default Description on Bill is not applicable for service agreements whose charges are calculated using a billable charge. Why? Because the description that appears on the bill segment is defined on the billable charge.

Use the **Billing Processing Sequence** if you need to control the order in which service agreements linked to this SA type are processed by billing and interval data creation processes.

Fastpath:

Refer to [Processing Sequence Considerations](#) for more information.

Use **Bill Print Priority** to define the order in which the SA type's bill segments should appear on bills (relative to the other SA types that appear on a bill).

Note:

The values for this field are customizable using the Lookup table. This field name is BILL_PRT_PRIO_FLG.

Use **Max Bill Threshold** if you want the system to generate a bill error when a bill segment is produced in batch that exceeds a given value. These bill errors will appear on the standard billing queries and To Do lists. If, after reviewing the high value bill segment, an operator truly intends to send the bill out, they should regenerate the bill. Refer to [How To Correct A Bill Segment That's In Error](#) for more information.

Warning:

The value entered in this field will DEFAULT onto service agreements of this type when they are first created. An operator may change the default value on a service agreement in case a specific customer has unusually high bills that continually error out. It's important to be aware that if you change the value of High Bill Amount on an SA type and there already exist service agreements of this type, the existing service agreements will contain the original value (the new value on the SA type will not be propagated on the existing service agreements).

Use **Graph Unit Of Measure** to define the unit of measure of the graphed consumption on the bill (if any).

Turn on **Allow Estimates** if the system is allowed to generate estimated consumption if meter reading(s) cannot be found at billing time. This value is defaulted onto service agreements and can be overridden on an individual service agreement.

Fastpath:

For more information about estimated consumption, refer to [The Theory Behind Consumption Estimation](#).

Turn on **Characteristic Premise Required** if a characteristic premise must be linked to the service agreement when the service agreement is activated. The characteristic premise is used to define the taxing authorities associated with the service agreement's bill segments. It is also used to identify where the service agreement's service is located on various windows.

Fastpath:

For more information about how characteristic premise is used, refer to [An Illustration Of A Bill Factor And Its Characteristics](#).

Use the **Initial Start Date Option** to control how billing should calculate the consumption period for the very first bill for service agreements of this type. This field is not applicable for sub SA types or SA types with a special role of Billable Charge. Valid values are Include First Day, Add 1 Day Always and Add 1 Day for Back-to-back. Refer to [Initial Consumption Period Considerations](#) for more information.

Non-metered service agreements may have the end date of their bill segments defined on a user-maintained bill period schedule. This option is used when bill segments must fall on strict calendar boundaries (e.g., quarterly bills that end on the last day of the quarter). If this SA type should be billed like this, select Use Bill Period in the **Use Calendar Billing** field. When this option is used, you must define the **Bill Period** whose schedule defines the bill segment end dates.

Fastpath:

For more information about bill period schedules, refer to [Designing Bill Periods](#). For more information about other bill end date methods, refer to [Ways To Control The End Date Of A Bill Segment](#).

Instead of the Use Bill Period method, non-metered service agreements may have their bill segment end date based on the first day of service. For example, if service started on the 16th of some month, the ongoing bill segments will start on roughly the 16th of each month. This option is frequently used to bill for garbage or cable service. If this SA type should be billed like this, select Anniversary Future Billing or Anniversary Past Billing in the **Use Calendar Billing** field. When either option is used, you must define the **Anniversary Bill Frequency**. This frequency defines the amount of time between bill segments.

Fastpath:

For more information about anniversary billing, refer to [Using The Anniversary Method](#). For more information about other bill end date methods, refer to [Ways To Control The End Date Of A Bill Segment](#).

Total Bill Amount indicates whether service agreements of this type can use the total amount to bill field on the service agreement page. Valid values are Not Allowed and Required. Only SA types used to bill for deposits or loans should have this field set to Required.

If Required is selected, you must enter the **Total Amount To Bill Label**. The **Total Amount To Bill Label** defines the label that prefixes the total bill amount on the service agreement page for service agreements of this SA type.

Fastpath:

For more information about total amount to bill and deposit service agreements, refer to [Total Amount To Bill](#). For more information about total amount to bill and loan service agreements, refer to [Setting Up The System To Enable Loans](#) .

Recurring Charge indicates whether service agreements of this type can use the recurring charge field on the service agreement window. Valid values are Not Allowed, Optional and Required. If either Optional or Required are used, you must enter:

- **Recurring Chg Amt Label**. This defines the label that prefixes the recurring charge amount on the service agreement window for service agreements of this SA type.
- **Recurring Charge Frequency**. This defines the following:
 - Specifies the frequency at which the Recurring Charge Amount specified on service agreements of the SA Type is to be billed.
 - Serves as the basis for proration of the Recurring Charge Amount.
 - Specifies the frequency at which service agreements of the SA Type without a rate and/or meters will be billed.

Fastpath:

For more information about how to use the recurring charge information, refer to [Charitable Contribution Segmentation](#), [Merchandise Segmentation - Installment Billing](#), [Deposit Segmentation - Installment Billing](#), [Payment Arrangement Segmentation](#), [Budget Billing Segmentation](#), [The Terms Of A Loan Are Stored On A Service Agreement](#).

Turn on **Eligible for Budget** if service agreements of this type can participate in budget billing. If this switch is turned on, then you must define the **Adjustment Type (Synch Current)** that will be used to synchronize (make equal) the current amount with the payoff amount on a service agreement of this type when a budget is cancelled. (The Adjustment Type (Synch Current) field is on the main page.)

Fastpath:

Refer to [Budget Billing](#) for more information about budgets in general. Refer to [Budget Billing Segmentation](#) and [Designing and Defining Budget Plans](#) for more information.

Set the **Eligible for Non-Billed Budget** flag to Eligible for Non-Billed Budget if you want SAs of this type to be eligible to be covered by a Non-Billed Budget. If this flag is set to Eligible for Non-Billed Budget, you must also define the **Adjustment Type (Current = 0)** field (on [SA Type - Detail](#)).

Fastpath:

Refer to [Current Amount For SAs Covered By A Non-Billed Budget](#) and [SA Types for SAs Covered by Non-Billed Budgets](#) for more information.

Require Total Amount Switch versus Bill Segment Algorithm

The following table shows valid combinations of the SA type's required total amount switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not supported in the system. Otherwise, we list typical types of service agreements that will use a combination.

| Bill Segment Create Algorithm | SA Type Require Total Amount Switch: | SA Type Require Total Amount Switch: |
|-------------------------------|--------------------------------------|--------------------------------------|
| | Not allowed | Required |

| | | |
|-------------------------------------|--|----------------------------|
| Apply Rate | Metered services. Lamp services. Misc item services. Company usage. Misc recurring charges whose value is specified in a rate or is taxable. | N/A |
| Recurring Charge With Auto Stop | Payment arrangements. Merchandise installment plans. Zero-interest loans. | N/A |
| Recurring Charge For Amount To Bill | N/A | Deposit installment plans. |
| Recurring Charge | Charitable contributions. | N/A |
| Billable Charge | One time invoices. Pass through charges | N/A |
| Loan | N/A | Loans. |

Allow Recurring Charge Switch versus Bill Segment Algorithm

The following table shows valid combinations of the SA type's allow recurring charge switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not supported in the system. Otherwise, we list typical types of service agreements that will use a combination.

| Bill Segment Create Algorithm | SA Type Recurring Charge Switch: | SA Type Recurring Charge Switch: | SA Type Recurring Charge Switch: |
|--------------------------------------|--|--|--|
| | Not allowed | Optional | Required |
| Apply Rate | Metered services - no budget Lamp services Misc item services. Company usage. Misc recurring charges whose value is specified in a rate or is taxable. | Metered services - budget optional | Metered services - budget required |
| Recurring Charge With Auto Stop | N/A | Payment arrangements. Merchandise installment plans. Zero-interest loans. SEE NOTE! | Payment arrangements. Merchandise installment plans. Zero-interest loans. SEE NOTE! |

| | | | |
|-------------------------------------|--|---|---|
| Recurring Charge For Amount To Bill | N/A | Deposit installment plans. SEE NOTE! | Deposit installment plans. SEE NOTE! |
| Recurring Charge | Charitable contributions | N/A | N/A |
| Billable Charge | One time invoices. Pass through charges | N/A | N/A |
| Loan | N/A | N/A | Loans. |

Note:

Most recurring charge SA types require a recurring charge amount on their service agreements. However, the above matrix indicates you can have recurring charge SA types where this value is optional. Why? A special algorithm exists in billing that says if the recurring charge amount is 0 (zero) the system will bill the remaining payoff balance or total amount to bill. This algorithm exists so that you can easily bill the amount in one lump sum (i.e., don't bill it in installments).

Where Used

The billing information is used when the system creates a bill segment for service agreements of this type.

SA Type - Rate

Open **Admin > Customer > SA Type > Search** and navigate to the **Rate** page to define the rates that may be referenced on service agreements of a given type.

Description of Page

Turn on **Rate Required** if the bill segment creation algorithm for the SA type expects a rate schedule to be referenced on service agreements of this type.

Fastpath:

For more information, refer to [Rates](#).

Define the date that the system uses when selecting an effective-dated rate (from the service agreement's rate history) using the **Rate Selection Date**. Selecting Bill Start Date causes the system to use the rate effective on the first day of the bill segment's [consumption period](#). Selecting Bill End Date causes the system to use the rate effective on the last day of the bill segment's consumption period. Selecting Accounting Date causes the system to use the rate effective on the accounting date associated with the bill.

When a rate changes within a bill segment's consumption period, and CCB and MDM are integrated, the period may be divided into separate usage periods – one for each active rate schedule during that period. The usage periods and their related consumption (or billable quantities) are then prepared for billing, and the rate schedule calculations are applied to their associated periods.

This feature is possible if the MDM usage subscription type is configured with the base Dynamic Usage Group Determination algorithm, which determines the applicable usage group for each effective rate schedule. This algorithm requires that the CCB rate schedule has usage group extendable look-ups configured for the rate schedule and device configuration type combinations.

A typical use case is when there is a smart meter rollout in the middle of billing period and there are rate schedule changes that coincide with the meter exchange date. The usage group that is tied to the old meter will have rules that calculate scalar consumption, and the usage group that is tied to the new meter will have rules that calculate interval consumption. The end result is that the customer is billed with scalar consumption for the period where old meter was installed, and billed with interval consumption for the period where new meter is installed.

If the Contract Management module is not [turned off](#), which includes [umbrella agreement management](#), indicate the **Rate Source**. Check SA Only indicates that the rate schedule currently in effect for the service agreement should always be used. Check TOS First, then SA indicates that if the service agreement is linked to a terms of service record, the service agreement's rate could be [overridden by one linked to the terms of service](#) record.

The information in the **Rate Schedules** collection defines the rates that may be referenced on service agreements of this type. The following fields are required for each SA Type:

Rate Schedule Specify the rate schedule; its description is displayed adjacent.

Use As Default Turn on this switch for the rate to be defaulted on new service agreements.

Rate Required versus Bill Segment Algorithm

The following table shows appropriate combinations of the SA type's rate required switch and the bill segment creation algorithm defined on the SA type's bill segment type. If N/A appears in a cell, the combination is not applicable. Otherwise, we list typical types of service agreements that will use a combination. Be aware that no cross validation exists between the rate required switch and the bill segment creation algorithm when setting up the SA type.

| Bill Segment Create Algorithm | SA Type Rate Required Switch: | SA Type Rate Required Switch: |
|--------------------------------------|---|--|
| | Not allowed | Rate required on SA |
| Apply Rate | N/A | Metered services. Lamp services. Misc item services. Company usage. |
| Recurring Charge With Auto Stop | Payment arrangements. Merchandise installment plans. Zero-interest loans. | N/A |
| Recurring Charge For Amount To Bill | Deposit installment plans. | N/A |
| Recurring Charge | Charitable contributions. | N/A |
| Billable Charge | One time invoices. | Billable charges that require a rate to add-on extra charges (like taxes) or billable charges where the consumption is interfaced and the system is responsible for calculating the charges. |
| Loan | Loans. | N/A |

Where Used

This information is used to default and validate the rate specified on a service agreement. Refer to [Service Agreement - Rate Info](#) for more information.

SA Type - SP Type

Open **Admin > Customer > SA Type > Search** and navigate to the **SP Type** page to define the service point types that may be referenced on service agreements of a given type.

Description of Page

Turn on **Service Points Required** if at least one service point should be linked to service agreements of this type in order to properly bill the service agreements.

The information in the **SP Types** collection defines the service point (SP) types that may be referenced on this SA type's service agreements. The following fields are required for each SA Type:

SP Type Specify the SP type; its description is displayed adjacent.

Fastpath:

For more information about SP types, refer to [Designing SP Types](#).

Where Used

This information is used to validate the types of service points linked to a service agreement. Refer to [Service Agreement - SA / SP](#) for more information.

SA Type - Adjustment Profiles

Open **Admin > Customer > SA Type > Search** and navigate to the **Adj Profile** page to define the adjustment profiles that define adjustment types that may be referenced on service agreements of a given type.

Description of Page

Define the **Adjustment Type Profiles** that, in turn, define adjustment types that may be referenced on service agreements of a given type.

Fastpath:

For more information about adjustment type profiles, refer to [Setting Up Adjustment Type Profiles](#).

Where Used

This information is used to validate the adjustments linked to the service agreement. Refer to [Adjustment - Main Information](#) for more information.

SA Type - C&C

Open **Admin > Customer > SA Type > Search** and navigate to the **C&C** page to maintain attributes that affect how the system severs the service agreement when collection attempts fail.

Fastpath:

Refer to [Designing Your Severance Procedures](#) for more information.

Description of Page

Select the **Debt Class** associated with the SA Type. Any debt on a service agreement of this SA Type will be categorized under this debt class.

Select the **Write Off Debt Class Code** associated with the SA Type. Any debt on a service agreement of this SA Type will be categorized under this debt class during write-off processing.

Note:

Write Off Debt Class vs. Regular Debt Class. It's important to be aware that a SA type references both a regular debt class and a write-off debt class. The regular debt class controls the collection criteria applied against an account's service agreements. The regular debt class is also used to segregate an account's outstanding balance on several queries in the system. The write-off debt class controls the write-off criteria applied against an account's stopped service agreements. The reason the system supports two different debt

classes is because you may categorize your service agreements differently when you try to collect overdue debt versus when you write-off debt. Refer to [The Big Picture Of Write Off Processing](#) for more information.

The information in the **Severance Criteria** collection defines the SA Type's severance criteria. Severance criteria define the severance process to be executed for service agreements of a given SA type. The severance process may differ depending on some attribute of the customer or premise. For example, you may have a different severance process if the customer has life support equipment.

Fastpath:

The following information is not intuitively obvious. Refer to [Designing Your Severance Procedures](#) for more information.

The following fields are required for each instance:

Priority The priority controls the order in which the system determines if the severance process should be applied (the first severance process whose algorithm applies is used). Higher priorities are checked before lower priorities.

Note:

The values for this field are customizable using the Lookup table. This field name is CRIT_PRIO_FLG. Be aware that this field is used for multiple tables: [Collection Class Control](#), [Severance Criteria](#), [Write Off Control](#) and [Workflow Process Profiles](#) .

Severance Criteria Algorithm Select the algorithm to be used to check if the severance process should be initiated for service agreements of this type. If a condition is met, a severance process is created using the associated severance process template.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines if the severance of a service agreement should be processed using the associated **Severance Process Template**.

Important:

You must have at least one entry in this collection otherwise the system will not start a severance process when a service agreement of this type needs to be stopped due to non payment. This entry should have the lowest priority code and should reference a **Severance Criteria Algorithm** that references the SV CRIT DFLT algorithm type.

Severance Process Template Specify the severance process template to use to sever the service agreement; its description is displayed adjacent.

Where Used

The debt class has multiple uses:

- The system summarizes an account's debt by debt class on [Account - Main Information](#) and [Account - Financial Balances](#).
- Debt class is one component that controls how the system analyzes an account's overdue debt (the others are the account's collection class and currency). Refer to [Different Collection Criteria For Different Customers And Different Debt](#) for more information.
- Write off debt class is one component that control how the system writes off an account's stopped service agreements. Refer to [Different Write-Off Criteria For Different Customers And Different Debt](#) for more information.

The severance criteria are used when a collection event is activated that indicates that service should be severed.

SA Type - Billable Charge Template

Open **Admin > Customer > SA Type > Search** and navigate to the **BC Template** page to define the billable charge templates that can be used on service agreements of a given type.

**Note:**

Only billable charges have billable charge templates. Only service agreements that are defined as Billable Charges (in the Special Role on the Details window) may use the grid on this window.

Description of Page

The information in the **Billable Charge Template** collection defines the SA Type's permissible billable charge templates. A billable charge template contains the default bill lines, amounts and distribution codes used to levy a one-off charge. The following fields are required for each template:

Billable Charge Template Specify the billable charge template. Its description is displayed adjacent.

Use As Default Turn on this switch for the template to be defaulted on new billable charges linked to service agreements of this type (if any).

**Fastpath:**

For more information about billable charge templates, refer to [Setting Up Billable Charge Templates](#).

Where Used

This information is used to limit the billable charge templates that can be used for a given SA type.

SA Type - Characteristics

To define characteristics common to all service agreements of a given type, open **Admin > Customer > SA Type > Search** and navigate to the **Characteristics** page.

Description of Page

Use the characteristics collection to define a **Characteristic Type, Sequence, and Characteristic Value** common to all service agreements of this type.

**Note:**

You can only choose characteristic types defined as permissible on a SA Type record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

SA Type - Algorithms

Open **Admin > Customer > SA Type > Search** and navigate to the **Algorithm** page to define the algorithms that should be executed for service agreements of a given type.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

**Warning:**

These algorithms are typically significant processes. The absence of an algorithm may prevent the system from operating correctly.

The following table describes each **System Event** for which you can define algorithms.

| System Event | Optional / Required | Description |
|--------------|---------------------|-------------|
|--------------|---------------------|-------------|

Bill Completion

Optional

These algorithms are executed whenever a bill is completed for an account that contains a non-canceled service agreement of this type. The following situations necessitate the definition of a completion algorithm on an SA type:

- As explained under [Technical Implementation of A/R Transfer and Technical Implementation of Routing Billable Charges To Service Providers](#), when a bill is completed, the system needs to set up the data necessary to interface any "master" SA's charges to the service provider and to transfer the receivable balance from the customer to the service provider. The system will only do this if you specify an appropriate algorithm on the master SA types.
- As explained under [Billing For SAs Covered By The Non-Billed Budget](#), when a bill is completed for accounts that have a Non-Billed Budget SA, the system needs to distribute the Non-Billed Budget's credit balance to the covered SAs. The system will only do this if you specify an appropriate algorithm on the NBB SA types.
- As explained under [Overpayment Segmentation](#), when a bill is completed, the system may apply an excess credit from a prior overpayment to an account's service agreements.

Note. Algorithms of this type are called for all non- Canceled service agreements, regardless of whether or not they are billed. If your algorithms should only be processed under certain conditions (for example, only process this algorithm for Active service agreements), then it is the responsibility of the algorithm to check the conditions before continuing.

Bill Eligibility

Optional

These algorithms are executed during billing and allow logic to be introduced to check additional criteria to determine if an SA is eligible for billing.

| | | |
|-----------------------|----------|--|
| Break NBB SA | Optional | <p>These algorithms are executed when a Non-Billed Budget is manually stopped via the Non-Billed Budget maintenance page .</p> <p>Note that the Payment Arrangement algorithm and the Break Pay Arrangement algorithm are mutually exclusive.</p> |
| Break Pay Arrangement | Optional | <p>These algorithms are by executed by severance events when the event is created for payment arrangement SAs. This algorithm should be specified on SA types with a special role of Payment Arrangement to perform special actions that take place when a customer breaks a payment arrangement. Refer to Monitoring Payment Arrangements for more information about breaking payment arrangements.</p> |
| Budget Eligibility | Optional | <p>These algorithms are executed when determining in a service agreement is eligible for budget. Algorithms of this type are only applicable on SA types that are marked as eligible for budget and may be used to override that setting and indicate that the service agreement is not eligible.</p> <p>For example, maybe service agreements in a certain rate are not eligible. Or perhaps service agreements with a given characteristic value are not eligible.</p> |
| Cut Process Rule | Optional | <p>These algorithms are executed to create a cut process for service agreements of this type. Refer to The Big Picture Of Cut Processes for more information.</p> |

FT Freeze

Optional

These algorithms are executed whenever a financial transaction is frozen that is linked to a service agreement of this type. The following situations necessitate the definition of an FT freeze algorithm:

- As explained under [Technical Implementation of Routing Consumption To Service Providers](#), when a master SA's bill segment is frozen, the system must check if there are any service providers who need the bill segment's consumption. If so, it sets up the data necessary to interface the master SA's consumption (snapshot on the bill segment) to the service provider(s). The system will only do this if you specify an appropriate FT Freeze Algorithm on the master SA types.

- As explained under [Technical Implementation of Paying The Service Provider](#), when a financial transaction (FT) is frozen that is associated with a sub SA, the system must check if this FT should trigger the "payment" of a service provider. If so, it has to create an adjustment to increase how much we owe the service provider. The system will only do this if you specify an appropriate FT Freeze Algorithm on the sub SA types.

| | | |
|----------------------|----------|--|
| High Bill Amount | Optional | <p>This algorithm type checks for high bill amounts during batch billing. A bill threshold amount can be defined on a service agreement. By default the system compares this threshold amount to the bill segment amount during batch billing. If the bill segment amount exceeds the given threshold value, a bill error is generated. No proration takes place on the threshold amount if the bill segment's consumption period falls outside of the rate frequency's normal period.</p> <p>This algorithm may be used to override the default system behavior. It will prorate the SA's bill threshold amount before comparing it to the batch bill segment amount if the consumption period falls outside of the rate frequency's normal period.</p> |
| Landlord Reversion | Optional | <p>These algorithms are used to create, update or cancel a service agreement for a landlord when service is started, stopped or updated for a premise that references a landlord agreement.</p> <p>Algorithms of this type are called:</p> <ul style="list-style-type: none"> - When starting a new SA (start initiation) - When stopping an SA (stop initiation) - When canceling a pending start SA - When changing the stop / start dates of back-to-back service agreements |
| Loan Interest Charge | Optional | <p>These algorithms are executed whenever the interest charge needs to be calculated for a loan, such as when the loan amortization schedule is created and when a bill segment is created for a loan SA. This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.</p> |

| | | |
|-------------------------|----------|---|
| Loan Periods and Amount | Optional | <p>These algorithms are executed whenever a user clicks the Calculate button on Loan - Main or on the Start SA Confirmation dialog for a loan SA. It calculates either the number of periodic payments or the payment amount (depending on whether the user specifies the number of payments or the payment amount as input). This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.</p> |
| Loan Schedule | Optional | <p>These algorithms are executed whenever the system needs to create a loan amortization schedule for a loan, such as when you renegotiate the terms of a loan on Loan - Main. This algorithm should be specified on SA types with a special role of Loan. Refer to Defining Loan Options for more information.</p> |
| Override Proration Days | Optional | <p>This algorithm is invoked from rate application, right after base has determined if proration applies. It is used to override base days, normal days and “is within proration window” indicator, which were determined by base logic. Only one algorithm may be plugged-in to this system event. This is available only in the calculation rule based rating engine.</p> |
| Payment Arrangement | Optional | <p>These algorithms are by executed to handle the creation, breaking and canceling of payment arrangement SAs. This algorithm should be specified on SA types with a special role of Payment Arrangement to perform special actions that take place during the lifecycle of a payment arrangement. Refer to Monitoring Payment Arrangements for more information about payment arrangements.</p> <p>Note that the Payment Arrangement algorithm and the Break Pay Arrangement algorithm are mutually exclusive.</p> |

| | | |
|-------------------------------------|----------|---|
| Payment Freeze | Optional | <p>These algorithms are executed whenever a payment is frozen. The following situations necessitate the definition of such an algorithm:</p> <ul style="list-style-type: none"> - For a loan SA, such an algorithm is required to create a frozen adjustment that transfers any credit balance resulting from an overpayment to the loan's principal balance. Refer to Defining Loan Options for more information. |
| Pre-Bill Completion | Optional | <p>These algorithms are executed immediately prior to bill completion when a bill contains a bill segment for a service agreement whose SA type has such an algorithm. The following situations necessitate the definition of such an algorithm:</p> <ul style="list-style-type: none"> - If you want to delete a bill segment that's in error on the last night of a bill cycle when there are other bill segments that aren't in error, use such an algorithm. |
| Process NBB Scheduled Payment | Optional | <p>These algorithms are executed by the NBB Scheduled Payment Processing background process whenever a scheduled payment is due. If the Non-Billed Budget SA is unmonitored, this algorithm is not called. This algorithm should be specified on Non-Billed Budget SA types to create the necessary adjustments for the Non-Billed Budget SA.</p> |
| Proposal SA Acceptance | Optional | <p>These algorithms are executed when a proposal service agreement is accepted. Refer to Enabling The Creation Of A Real Service Agreement for more information.</p> |
| Proposal SA Bill Segment Generation | Optional | <p>These algorithms are executed to generate simulated bills segments for a proposal service agreement . Refer to Enabling The Generation Of Simulated Bill Segments for more information.</p> |

| | | |
|----------------------|----------|---|
| Proposal SA Creation | Optional | These algorithms are executed when a <i>proposal service agreement</i> is created. Refer to <i>Enabling The Automatic Generation Of Billing Scenarios</i> for more information. |
| SA Activation | Optional | <p>These algorithms are executed when a service agreement status changes from Pending Start to Active. It performs any additional activities that are necessary to activate an SA. The following situations necessitate the definition of such an algorithm:</p> <p>If you want to create a customer contact to indicate that a non-billed budget has been activated, use such an algorithm.</p> |
| SA Cancel | Optional | <p>These algorithms are executed when a service agreement status changes to Canceled. It performs any additional activities that are necessary to cancel an SA.</p> <p>An example of when you may use this algorithm is that perhaps your business rules dictate that the creation of a payment arrangement should create a credit rating history transaction. When a payment arrangement SA is canceled, the credit rating should be updated with an end date.</p> |
| SA Creation | Optional | <p>These algorithms are executed when a service agreement is created. The following situations necessitate the definition of such an algorithm on an SA type:</p> <ul style="list-style-type: none"> - If you want to create a To Do entry whenever a new service agreement of a given type is added, specify such an algorithm. - If you want to automatically activate SAs of a given type (instead of waiting for the background SA activation process to run), specify such an algorithm. - If you want to create a Workflow Process when a service agreement of a given type is added, specify such an algorithm. |

| | | |
|----------------|----------|--|
| SA Information | Optional | <p>We use the term "SA information" to describe the basic information that appears throughout the system to describe a service agreement. The data that appears in "SA information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the "SA information" algorithm on installation options or the system default "SA information" if no such algorithm is defined on installation options.</p> |
| SA Renewal | Optional | <p>These algorithms are executed by the Service Agreement Renewal background process whenever an SA is due for renewal or when the user clicks the Renew button (for <i>Non-Billed Budgets</i>). It performs any activities that are necessary to renew an SA and returns the new renewal and expiration dates for the SA.</p> |
| SA Stop | Optional | <p>These algorithms are executed whenever a service agreement's status changes from pending stop to stopped. The following situations necessitate the definition of a SA stop algorithm:</p> <ul style="list-style-type: none"> - For <i>Non-Billed Budgets</i> to distribute any remaining credit balance from the Non-Billed Budget SA to the covered SAs, you must specify such an algorithm. - For service credit memberships that have a <i>refundable membership fee</i>, an SA Stop algorithm attempts to refund the fee if this is the last SA linked to the membership that is being stopped. |

| | | |
|-----------------------|----------|---|
| SA Stop Initiation | Optional | <p>These algorithms are executed whenever a service agreement's status becomes pending stop. The following situations necessitate the definition of a stop initiation algorithm on an SA type:</p> <ul style="list-style-type: none"> - As explained under Finalizing Pending Stops, service agreements are normally transitioned from pending stop to stopped by a background process (or manually). For Non-Billed Budget SAs to transition to stopped automatically (without waiting for the background process), you must specify such an algorithm. <p>When does a SA become pending stop? Service agreements typically become pending stop when a user initiates a request to stop service on Start Stop - Main. A severance process with an Expire SA severance event causes a service agreement to become pending stop (when the event is executed). Additionally, the Stop Expired Service Agreements background process starts the process to initiate the stop of an SA when the expiration date is on or before the process date.</p> |
| Start Stop Field Work | Optional | <p>These algorithms are executed to create the field activities necessary to start and stop service. Refer to Starting Service and Field Activities and to Stopping Service and Field Activities for a description of when algorithms of this type are called. The following situations necessitate the definition of a start stop fieldwork creation algorithm:</p> <ul style="list-style-type: none"> - If a service agreement has field activities created to start and stop service at its service points, its SA type must have an appropriate start stop field work creation algorithm. |

SA Type - Billable Charge Overrides

The [BCU2 - Create Billable Charge](#) background process is responsible for creating billable charges for each billable charge upload staging record interfaced into the system. This process will override the values of the various switches

referenced on a billable charge upload staging line if the respective service agreement's SA type has an override value for the billable charge upload staging line's billable charge line type.

Note:

This information is optional. If you don't need to override the values of a [Billable Charge Line Type](#) you don't need to set up this information.

Open **Admin > Customer > SA Type > Search** and navigate to the **BC Upload Override** page to define override values for a given SA Type / Billable Charge Upload Staging Line Type.

Description of Page

Use the **Billable Charge Overrides** collection to define values to be overridden on billable charge lines uploaded from an external system (refer to the description above for the details). The following switches may be overridden for a given SA Type and **Billable Charge Line Type**.

- Use the **Show on Bill** switch to define the value to be defaulted into the Show on Bill indicator on billable charge upload lines that reference this line type.
- Use the **Appear in Summary** switch to define the value to be defaulted into the App in Summary indicator on billable charge upload lines that reference this line type.
- Use **Memo Only, No GL** switch to define the value to be defaulted into the Memo Only, No GL indicator on billable charge upload lines that reference this line type.
- Use **Distribution Code** to define the value to be defaulted into the Distribution Code on billable charge upload lines that reference this line type.

SA Type - Contract Option Type

Open **Admin > Customer > SA Type > Search** and navigate to the **Contract Option Type** page to define the contract option types, which are valid for service agreements of a given type.

Note:

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is [turned on](#), or the service agreement type specifies that bill determinants are *required for billing* within the SA Type - Billing tab.

Fastpath:

Contract Options are used by the system to define special options under which certain calculations supporting a contract's rate may be overridden or altered occasionally for specific periods of time. Refer to [Contract Option Background Topics](#) for more information.

Description of Page

If the SA Type's special role is Interval, you may define the **Contract Option Types** that are valid for contract options linked to a service agreement of this type.

Fastpath:

For more information, refer to [Setting Up Contract Option Types](#).

Where Used

This information is used to validate the contract options linked to the service agreement. Refer to [Service Agreement - Contract Options](#) for more information.

SA Type - Interval Info

Open **Admin > Customer > SA Type > Search** and navigate to the **Interval Info** page to define the interval profile relationship types and TOU map relationship types, which are valid for service agreements of a given type.

**Note:**

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is [turned off](#).

Description of Page

If the SA Type's special role is Interval , you may define the **Interval Profile Relationship Types** that may be linked to service agreements of this type.

**Fastpath:**

For more information about interval profile relationship types, see [Designing Interval Profile Relationship Types](#).

If the SA Type's special role is Interval , you may define the **TOU Map Relationship Types** that may be linked to service agreements of this type.

**Fastpath:**

For more information about TOU map relationship types, refer to [Designing TOU Map Relationship Types](#).

Where Used

The interval profile information is used to validate the interval profile relationship types linked to the service agreement. Refer to [Service Agreement - Interval Info](#) for more information.

The TOU map information is used to validate TOU map relationship types linked to a service agreement. Refer to [Service Agreement - Interval Info](#) for more information.

SA Type - NBB Recommendation Rule

Open **Admin > Customer > SA Type > Search** and navigate to the **NBB Rec'n Rule** page to define the recommendation rules that are valid for Non-Billed Budget SAs of this type.

Description of Page

If the SA Type's special role is Non-Billed Budget, you may define the **Recommendation Rules** that are valid on non-billed budget SAs of this type. Check the **Use As Default** box to indicate the default recommendation rule for service agreements of this type.

**Fastpath:**

For more information about Non-Billed Budgets, refer to [Defining Non-Billed Budget Options](#) .

Where Used

The Non-Billed Budget recommendation rules are used to recommend the payment amount and payment schedule for Non-Billed Budget service agreements. Refer to [Maintaining Non-Billed Budgets](#) for more information.

Setting Up Start Options

Start options save users time and prevent data entry errors because they default many values on a service agreement (e.g., the rate schedule, recurring charge amount, contract riders, contract terms, characteristics, terms and conditions, etc. can all be defaulted onto a service agreement from a start option).

A SA type may have zero or more start options.

- A SA type without start options is usually one that has a very limited number of options. For example, if a SA type has a single valid rate and no customer-specific contract values, you don't need to setup a start option (the SA's default rate can default based on the information defined when you setup the SA type).
- A SA type with multiple start options is one where many different permutations are possible. For example, a SA type that can have multiple rates and each rate can have multiple riders is a good candidate for start options (where each start option will default, for example, a specific rate and set of contract riders).

When the [Start/Stop](#) transaction is used to start service AND the service being started uses a SA type with start options, the user is asked to select one of the start options. The service agreement that's created is populated with fields from the start option.

When the [Order](#) transaction is used to start service, the user selects start options, but only indirectly. It works like this:

- A user selects a "package" of services to start service for a customer.
- A "package" contains one or more start options.
- When a user selects a package, the system creates a service agreement for each start option on the package (and defaults the information on each service agreement from the respective start option).

A start option's default values may change over time (i.e., the information on a start option is effective-dated). The start service logic uses the version of the start option that is effective on the day service starts.

Start options can cause a great deal of information to be populated on a service agreement. There are several ways to change this default information:

- A user may override this information using the [Service Agreement](#) transaction.
- If the service agreement is in the pending start state, you can use the [Start/Stop - Pending SAs](#) page to change the service agreement's SA type and/or start option.
- If the service agreement is in active or pending stop states, a button appears on [Service Agreement - Main](#) called **Apply New Start Option**. When pressed, the user is allowed to define a start option and the date its terms become effective on the service agreement. Refer to [Changing A Start Option](#) for the details of this functionality.

The topics in this section describe how to setup start options.

Note:

The merge transaction can save setup time. The [Start Options Merge](#) transaction can be used to construct a start option by copying pieces from other start options.

Start Option Considerations - Rate-Oriented SA Types

To understand the following discussion, you should be familiar with the following concepts:

- SA types that use rates have one or more valid rate schedules. Only these rate schedules may be defined on service agreements of a given type.
- One of a SA type's rate schedules may be designated as the "default" rate. The system assigns the "default" rate to new service agreements when a CSR doesn't choose a start option.
- Start options may be used by customer service reps when a service is started for a customer. A start option causes the customer's new service agreement to be populated with a specific rate and contract terms (e.g., contract riders, contract values). The use of start options is not allowed if the service's SA type does not require a start option. The use of start options is required if the service's SA type requires a start option.

Whether or not a SA Type has start options is dependent on the following factors:

- If a SA Type has only one valid rate and the rate doesn't use customer-specific contract terms (e.g., contract riders, contract values), the SA Type does not need any start options. Why? Because the system default's the SA type's default rate on new service agreement when no start option is used at start time.
- If a SA Type has only one valid rate, but under unusual circumstances, it uses customer-specific contract terms, you'll want an option for every situation (both the standard one and the unusual ones).
- If a SA Type has a single rate with a variety of contract terms (which, by definition, are different for each customer), then you'd want a start option for each permissible combination of contract terms. You'd also want to turn on the SA type's Start Option Required switch to make your CSR's pick one of the start options when service is started (rather than let the system use the SA type's default rate).
- If a SA type has multiple valid rates and a variety of contract terms (a combination of the previous two points), you'd need a start option for each permissible combination. You'd also want to turn on the SA type's Start Option Required switch to make your CSR's pick one of the start options when service is started (rather than let the system use the SA type's default rate).

Start Option Considerations - SA Types That Use Recurring Charges

To understand the following discussion, you should be familiar with the following concepts:

- Many SA types use the recurring charge algorithms to generate the bill segments. For example, if you let a customer pay for a \$900 heat pump in 3 installments of \$300, you'd have an SA type called CA/MERCH-I and indicate it uses the recurring charge algorithm.
- When a CSR creates an SA type that uses recurring charge algorithms, they can enter the recurring charge amounts on [Start/Stop Service - Start Confirmation](#) window OR they can specify a start option on this window and let the system populate the recurring charge amount. For example, if you let a customer pay for a \$900 heat pump in 3 installments of \$300, you can set up a start option called HP 3PAY with an installment amount of \$300.
- Depending on the type of service being started, you might also need to generate an adjustment when service is started in order to initialize the total debt. For example, when a customer buys a heat pump we'll need an adjustment issued to realize the entire \$900 of revenue.

The following table provides examples of recurring charge SA types with several typical start options:

| CIS Division/ SA Type | Start Option | Adjustment Type | Install Amount | Comments |
|--------------------------|--------------|-----------------|----------------|---|
| CA/CHARITY | DONATE \$5 | | 5 | This causes a charitable contribution to be created with an installment amount of \$5. |
| CA/CHARITY | DONATE \$10 | | 10 | This causes a charitable contribution to be created with an installment amount of \$10. |
| CA/PA-REGU | PAY \$10 PM | | 10 | This causes a payment arrangement to be created with an installment amount of \$10. |
| CA/PA-REGU | PAY \$20 PM | | 20 | This causes a payment arrangement to be created with an installment amount of \$20. |
| CA/PA-UNRE | PAY \$10 PM | | 10 | This causes a payment arrangement to be created with an installment amount of \$10. |

| | | | | |
|------------|-------------|----------|-----|--|
| CA/PA-UNRE | PAY \$20 PM | | 20 | This causes a payment arrangement to be created with an installment amount of \$20. |
| CA/MERCH-I | HP 3PAY | HEATPUMP | 300 | This causes a merchandise service agreement to be created with an installment amount of \$300. It also causes an adjustment to be issued to realize the \$900 of revenue. |
| CA/MERCH-I | BBQ 3PAY | BBQ | 250 | This causes a merchandise service agreement to be created with an installment amount of \$250. It also causes an adjustment to be issued to realize the \$750 of revenue. |
| CA/DEP-I | PAY \$40 PM | | 40 | This causes a deposit service agreement to be created with an installment amount of \$40. The CSR would be required to define the total deposit amount to be billed over the life of the service agreement on the secondary SA window on the Start Account window. |

Start Option Considerations - Initial Adjustment SA Types

To understand the following discussion, you should be familiar with the following concepts:

- Some SA types depend on an adjustment to book their initial debt. For example, the CA/MERCH-I SA type requires an initial adjustment to book the payoff amount for the entire cost of the merchandise. Another example would be a loan service agreement (refer to [Booking The Principal Amount Using An Adjustment](#) for the details).
- When a CSR starts an SA type that requires an initial adjustment, they can create the adjustment immediately after starting service OR then can specify a start option when they start service and let the system generate the adjustment. You could let the system create the adjustment to book the \$900 associated with the heat pump as shown in the previous section.

The following table provides examples of SA types that use adjustments with several typical start options:

| CIS Division/ SA Type | Start Option | Adjustment Type | Install Amount | Comments |
|--------------------------|--------------|-----------------|----------------|---|
| CA/MERCH-I | HP 3PAY | HEATPUMP | 300 | This causes a merchandise service agreement to be created with an installment amount of \$300. It also causes an adjustment to be issued to realize the \$900 of revenue. |
| CA/MERCH-I | BBQ 3PAY | BBQ | 250 | This causes a merchandise service agreement to be created with an installment amount of \$250. It also causes an adjustment to be issued to realize the \$750 of revenue. |
| CA/CONNECT | CONNECT | CONNECT | | This causes an adjustment to be issued to realize the connection charge. |

Start Option Considerations - Interval SA Types

Refer to [Designing Your SA Interval Billing Options](#) for information about setting up start options for interval service agreements.

Start Option - Main

Open **Admin > Customer > SA Type Start Option > Add** to define a SA type's start options.

Description of Page

Every start option is uniquely identified by the following fields:

CIS Division & SA Type Enter the Division and SA type to which the start option is linked.

Start Option Enter the unique identifier of the option. Pick something easy to recognize as this will be used by CSRs to pick an option when they start service.

Effective Date Enter the earliest effective date. It should be the same as the earliest effective date of the start option's rate (although it doesn't hurt for it to be earlier). The date defaults to the current date. (The status, below, should be Active.)

The remaining fields further describe a start option.

Enter a **Description** for the start option.

Indicate its **Status**. For new start options, the status should be Active. When it's no longer applicable, change it to Inactive.

Enter the primary **Rate Schedule** that should be defaulted onto service agreements created using this option. Refer to [Start Option Considerations For SA Types That Use Rates](#) for more information.

Fastpath:

For more information about a service agreement's rates, refer to [Service Agreement - Rate Info](#).

Enter the **Adjustment Type** that should be generated, if any, when service is started using this option. Refer to [Start Option Considerations For SA Types That Use Initial Adjustments](#) for more information.

Enter the **Recurring Charge Amount** that should be defaulted onto service agreements created using this option. This field is only visible when the SA type allows recurring charges. In addition, the prompt for this field is defined on the SA type table on the billing window (e.g., it could appear as Payment Amount, Budget Amount, or Installment Amount). Refer to [Start Option Considerations For SA Types That Use Recurring Charges](#) for more information.

Enter the **Currency Code** in which monetary amounts are denominated.

Note:

The currency code defaults from the [installation record](#).

Enter the **Total Amount to Bill** that should be defaulted onto service agreements created using this option. This is useful to initiate either a loan or a deposit. The prompt for this field is defined on the SA type table on the billing window (e.g., it could be Deposit Amount or Loan Amount).

Use **Number of Periods** to default the number of payment periods of service agreements created using this option. This field is only allowed for SA types with special role of Loan. Refer to [The Terms Of A Loan Are Stored On A Service Agreement](#) for more information.

If your SA Type has a special role of Interval, then you must enter the **Cutoff Time** and **Start Day Option** that should be defaulted onto service agreements created using this option. For start day option, you may choose Current Day or Previous Day. Refer to [Start and End Times for Billing](#) for more information about how these fields are used.

If your SA Type has a special role of Billing Determinants Required, you may enter the **Cutoff Time** and **Start Day Option** that should be defaulted onto service agreements that are created using this option. For start day option, you may choose **Current Day** or **Previous Day**.

If your SA Type has a special role of Billable Charge, then you can setup the start option to automatically create a billable charge when a service agreement is created using this start option. For example, you might have a start option that automatically creates a "one-time invoice" service agreement along with a "tree trimming" billable charge. To use this feature you should turn on the **Create Billable Charge** switch and specify the **Billable Charge Template** that will be used to create the billable charge. These fields are only allowed for SA types with special role of Billable Charge.

Fastpath:

Refer to [Setting Up Billable Charge Templates](#) for more information about templates. Refer to [An Easier Way To Create One Time Charges](#) for an example of how you can setup a campaign with packages that use this type of start option.

Note:

The duplicate action in the page actions toolbar enables you to copy another start option. Refer to [Duplicate Button](#) in the system wide standards document for more information.

Start Option - Rate Info

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Rate Info** page to define the start option's default values for contract riders and contract values.

Description of Page

The information in the **Contract Riders** collection defines the contract riders to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Bill Factor The bill factor defines the type of rider. You may only reference bill factors designated as being applicable for contract riders.

Number of Days The number of days the rider should be in effect. This value is used by the system to set the stop date on the service agreement's contract rider. If the rider has no expiration, set this field to 0. Default note: this field will be set to 0 if left blank.

Fastpath:

For more information about a rate's contract riders, refer to [Defining General Bill Factor Information](#) . For more information about a service agreement's contract riders, refer to [Service Agreement - Contract Riders](#).

The information in the **Contract Values** collection defines the contract values to be defaulted onto service agreements created using this start option. The following fields are required for each event:

Bill Factor The bill factor defines the type of value. You may only reference bill factors designated as allowing values in contract terms.

Number of Days The number of days the value should be in effect. This value is used by the system to set the stop date on the service agreement's contract value. If the value has no expiration, set this field to 0.

Value The amount of the contract value.

Fastpath:

For more information about a rate's contract values, refer to [Defining General Bill Factor Information](#) . For more information about a service agreement's contract values, refer to [Service Agreement - Contract Values](#).

Start Option - Characteristics & Qty

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Characteristics & Qty** page to define the start option's default values for characteristics and contract quantities.

Description of Page

The information in the **Characteristics** collection defines the characteristics to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Characteristic Type This defines the type of characteristic. Note: you may only define characteristics valid on service agreements.

Characteristic Value This defines the characteristic value that will be defaulted.

Fastpath:

For more information about a service agreement's characteristics, refer to [Service Agreement - Characteristics](#).

The information in the **Contract Quantity** collection defines the contract quantities to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Contract Quantity Type This defines the type of contract quantity.

Contract Quantity The amount of the contract quantity.

Fastpath:

For more information about a service agreement's contract quantities, refer to [Service Agreement - Contract Quantity](#).

Start Option - Contract Option

**Fastpath:**

Refer to [Designing Your SA Interval Billing Options](#) for information about setting up start options for interval service agreements.

**Note:**

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is [turned off](#).

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Contract Option** page to define the start option's contract option default values.

Description of Page

The collection of contract option types will be used to link contract options to a service agreement that will be created with this start option. If the contract option to create for the service agreement will be SA Specific, simply indicate the **Contract Option Type**. This will cause a new contract option to be created with this contract option type and the new contract option will be linked to the new SA at start time. If the contract option to create for the service agreement will be Shared, indicate the contract option type and the **Contract Option ID**. This will cause the specified contract option to be linked to the new SA at start time.

**Fastpath:**

For more information about contract option types, see [Designing Your Contract Option Types](#).

Start Option - Interval Info**Fastpath:**

Refer to [Designing Your SA Interval Billing Options](#) for information about setting up start options for interval service agreements.

**Note:**

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is [turned off](#).

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Interval Info** page to define the start option's interval profile and TOU map default values.

Description of Page

The collection of interval profile information will be used to link interval profiles to a service agreement that will be created with this start option. The **Interval Profile Relationship Type** indicates the value that will be linked to each new SA Profile record. For each interval profile relationship type, define either an **Interval Profile Type** or an **Interval Profile ID** depending on whether the Profile to be linked to the new service agreement should be SA Specific or Shared. For SA Specific, indicate an interval profile type. This will cause a new interval profile to be created with this interval profile type and the new interval profile will be linked to the new SA at start time. For Shared profiles, indicate the Interval Profile ID. This will cause the specified Profile to be linked to the new SA at start time.

If a **Derivation Algorithm** is linked to the interval profile type, then the algorithm and its **Creation Priority** are displayed.

**Fastpath:**

For more information about interval profile relationship types, see [Designing Interval Profile Relationship Types](#). For more information about Shared profiles vs. SA Specific profiles, see [Common Profiles vs. SA Owned Profiles](#).

The collection of TOU map information will be used to link TOU Maps to a service agreement that will be created with this start option. The **TOU Relationship Type** indicates the value that will be linked to each new SA TOU Map record. For each TOU relationship type, define either a **TOU Map Type** or a **TOU Map ID** depending on whether the map to be linked to the new service agreement should be SA Specific or Shared. For SA Specific, indicate a TOU map type. This will cause a new TOU map to be created with this TOU map type and the new TOU map will be

linked to the new SA at start time. For Shared map, indicate the TOU map id. This will cause the specified map to be linked to the new SA at start time.

If a TOU map creation algorithm is linked to the TOU Map type, then the **Derivation Algorithm** and its **Creation Priority** are displayed.

Fastpath:

For more information about TOU map relationship types, see [Designing Your TOU Map Relationship Types](#).

Start Option - TOU Contract Value

Fastpath:

Refer to [Designing Your SA Interval Billing Options](#) for information about setting up start options for interval service agreements.

Note:

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is [turned off](#).

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **TOU Contract Value** page to define the start option's default TOU contract values.

Description of Page

The **TOU Contract Value** scroll contains information to define when you would like TOU contract values to be defaulted onto service agreements created using this start option

Indicate the **Bill Factor** associated with the TOU contract values. You may only reference bill factors designated as "TOU" bill factor types and where the value may be in contract terms.

Indicate the **TOU Group**, which contains the appropriate collection of TOU codes for service agreements created using this start option.

Indicate the **Number of Days** the value should be in effect. This value is used by the system to set the stop date on the service agreement's contract value. If the value has no expiration, set this field to 0.

Use the Time of Use collection to indicate the **TOU Value** associated with each **Time of Use** codes for the TOU Group.

Fastpath:

For more information about TOU contract values, refer to [Customer Specific TOU Values](#).

Start Option - Terms and Conditions

Open **Admin > Customer > SA Type Start Option > Search** and navigate to the **Terms and Conditions** page to define the start option's default terms and conditions.

Description of Page

The information in the grid defines the terms and conditions to be defaulted onto service agreements created using this start option. The following fields are required for each instance:

Terms and Conditions This is the code that identifies a term and condition (T&C).

Number of Days The number of days the T&C should be in effect. This value is used by the system to set the end date on the service agreement's T&C. If the T&C has no expiration, set this field to 0. Default note: this field is set to 0 if left blank.

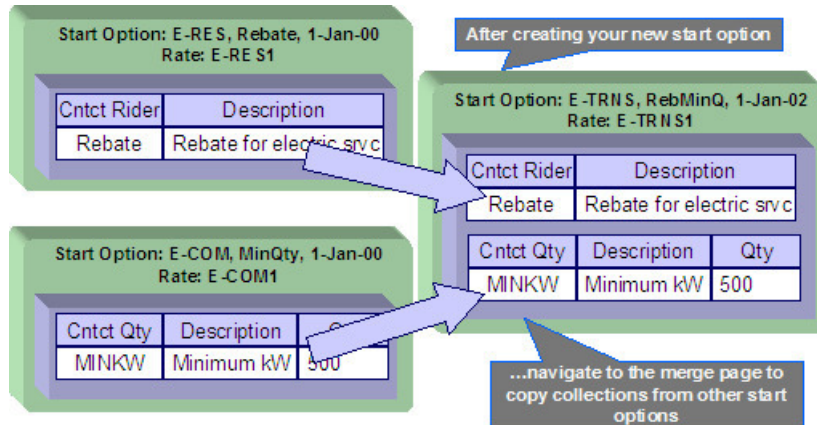

Start Option Merge

Use this page to modify an existing start option by copying information from other start options. This page may be used to copy records from the contract rider, contract value, contract quantity, characteristic, interval profile, TOU map, contract option and TOU contract value collections from one or more existing start options to another.

Note:

The target start option must exist prior to using this page. If you are creating a new start option, you must first go to the [Start Option](#) page to add the new start option and then navigate to the merge page to copy collection information.

Note:

Duplicate versus Merge. The [Start Option](#) page has [Duplication](#) capability. You would duplicate a start option if you want to a) create a new start option AND b) populate it with all the information from an existing start option. You would use the start option merge page if you want to build a start option using pieces of one or more start options.

Start Option Merge - Main

Open **Admin > Customer > SA Type Start Option Merge**.

Description of Page

Select the **Original Start Option**, which is the target for merging the start option collection information.

Select the **Merge From Start Option**, which is your template start option to copy the collections from.

Note:

You may only copy information from one Merge From start option at a time. If you wish to copy information from more than one start option, select the first Merge From start option, copy the desired records, Save, then select the next Merge From start option.

The left portion of the page will display any existing records in the collections for the original start option. The right portion of the page will display the existing records in the collections for the Merge From start option.

You may use the **Copy All** button to copy all the records in all the collections from the Merge From start option to the Original start option. If you do not choose to copy all, you may copy records individually as described below.

The left portion of the **Contract Riders** collection initially displays existing contract riders linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor** and **Number of Days** for each contract rider is displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **Contract Values** collection initially displays existing contract values linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor**, **Number of Days** and **Value** for each contract value is displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The topics, which follow, describe how to perform common maintenance tasks:

Removing A Row From A Grid

If you wish to remove a record linked to the Original start option, click the "-" button to the left of the record.

Adding A New Row To A Start Option

You may move any of the records from the Merge From start option to the original start option by selecting the left arrow adjacent to the desired row. Once a record is moved it will disappear from the Merge From information and appear in the Original information with the word Merge in the Merge Type column.

Removing An Uncommitted Row From A Start Option

If you have copied a row across by mistake, you may remove it by clicking on the right arrow adjacent to the appropriate record.

Start Option Merge - Characteristics and Quantities

Open **Admin > Customer > SA Type Start Option Merge** and navigate to the **Characteristics and Quantities** page to copy rows in the characteristic and contract quantity collections.

Description of Page

The left portion of the **Characteristics** collection initially displays existing characteristics linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Characteristic Type** and **Characteristic Value** for each characteristic are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **Contract Quantity** collection initially displays existing contract quantities linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Contract Quantity Type** and **Contract Quantity** for each contract quantity are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

Fastpath:

Refer to [Start Option Merge - Main](#) for more information about how to perform common maintenance tasks for the grids displayed on this page.

Start Option Merge - Contract Option

Open **Admin > Customer > SA Type Start Option Merge** and navigate to the **Contract Option** page to copy rows in the contract options collection.

Note:

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is [turned off](#).

Description of Page

The left portion of the **Contract Option** collection initially displays existing contract option information linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Contract Option Type**, **Contract Option ID** and **Description** of the contract option for each contract option row are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

Fastpath:

Refer to [Start Option Merge - Main](#) for more information about how to perform common maintenance tasks for the grids displayed on this page.

Start Option Merge - Interval Info

Open **Admin > Customer > SA Type Start Option Merge** and navigate to the **Interval Info** page to copy rows in the interval profile, and TOU map and TOU contract quantity collections.

Note:

This tab may not appear. This tab is suppressed if the interval billing Complex Billing module is [turned off](#).

Description of Page

The left portion of the **Interval Profiles** collection initially displays existing interval profile information linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Interval Profile Relationship Type**, **Interval Profile Type** and **Interval Profile ID** for each interval profile row are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **TOU Maps** collection initially displays existing TOU map information linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **TOU Map Relationship Type**, **TOU Map Type** and **TOU Map ID** for each TOU map row are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

The left portion of the **TOU Contract Values** collection initially displays existing TOU contract values linked to the original start option. In the **Merge Type**, you will see the word Original, for any of these records. The **Bill Factor** and **TOU Group** for each TOU contract value are displayed. In the right portion of the collection, the existing records in the merge from start option are displayed initially.

Fastpath:

Refer to [Start Option Merge - Main](#) for more information about how to perform common maintenance tasks for the grids displayed on this tab page.

Start Option Merge - Terms and Conditions

Open **Admin > Customer > SA Type Start Option Merge** and navigate to the **Terms and Conditions** page to copy terms and conditions (T&Cs).

Description of Page

The left side of the **Terms and Conditions** grid initially displays the T&Cs linked to the original start option. On the right side, the T&Cs linked to the merge from start option are displayed initially.

Fastpath:

Refer to [Start Option Merge - Main](#) for a description of how to perform common maintenance tasks for the grids displayed on this page.

Defining SA Relationship Options

We use the term "SA Relationship" to describe functionality that supports the following situations:

- When companies other than your own provide a service to your customers AND you have some type of interaction with these companies. For example, in a deregulated market, customers deal with both distribution and energy supply companies. These companies typically exchange a great deal of information about their joint customers.
- When multiple rates are associated with a service (where each rate corresponds with a sub-category of service). For example, most water companies charge for both water and wastewater service using separate rates for each. While it is possible to set up water and wastewater as separate service agreements, the SA relationship functionality allows you to set up a single "master" service agreement (for the water service) and associate with it a "sub" service agreement (for the wastewater service).

- When a party representing a group of customers negotiates a contract that is applied over and above those of the individual service agreements. For example, the head office of a national chain may negotiate for additional discounts that should be calculated together or individually. The SA relationship functionality may be used to track the covered service agreements and to calculate and transfer discounts to the head office's service agreement. Refer to the special discounts section.

Warning:

Setting up the SA relationship control tables is as challenging as your organization's business rules. If you don't have requirements similar to those described above, you don't have to set up anything. If you have these types of requirements, your setup process will be taxing as you must design and set up control tables that manage the financial and consumption interactions that take place between you, your customers, and the various service providers.

The topics in this section describe tables that control your SA relationship functionality. Refer to [Defining Workflow and Notification Options](#) for a description of the tables that control how your organization communicates with the service providers who provide service to your customers.

The Big Picture of SA Relationships and Service Providers

You must set up service providers if companies other than your own provide a service to your customers AND you have some type of interaction with these companies. You will have one service provider for each such company. For example, if you are a distribution company in a deregulated market, you will have a service provider for each company that provides any of the following services:

- Energy (commonly referred to as Energy Supply Companies, Energy Service Providers, Retailers, and Suppliers)
- Meter service (commonly referred to as Meter Service Providers and Meter Agents)
- Meter reading (commonly referred to as Meter Data Management Agencies and Meter Reading Service Providers)
- Billing (commonly referred to as Billing Agents)

The topics in this section provide background information about service providers.

Persons and Service Providers

A great deal of information about your service providers is defined using a person. For example, a service provider's name, address, phone numbers, electronic ID's, etc. are all defined on the person object.

In addition, every service provider must have a service provider object created for it. The service provider object contains information about a provider's relationships with the customer and your organization, for example:

- Do you calculate bills for the service provider? If so, do you have their rates or do they interface their charges to you? Refer to [Billing Relationships](#) for more information.
- Do you send the customers' consumption to the service provider? Do they send it to you? Refer to [Consumption Relationships](#) for more information.
- How are financial settlements between your organization and the service provider implemented (do you pay them when you get paid?, do you purchase the receivable for them?, etc.). Refer to [Service Providers Have Service Agreements Too](#) for more information.
- Etc.

Fastpath:

Refer to [Designing Your SA Relationship Types and Service Providers](#) for more information.

Note:

In some situations, you will need to set up a service provider for your own company. Refer to [When Your Company Is A Service Provider](#) for the details.

Service Providers Are Linked To Service Agreements

The following diagram illustrates a customer's bill for electric service in a deregulated market. Notice that there are separate sections for energy, distribution and meter service.

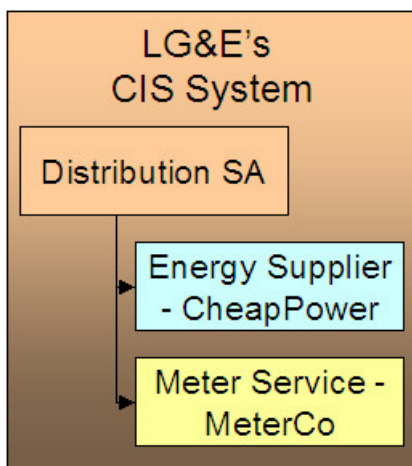

Note:

Consolidated billing. The following is an example of a bill that consolidates charges from many service providers. Rather than receive a consolidated bill, it is possible for the customer to receive 3 separate bills, one from each service provider (we refer to this as Dual billing).

| Customer's Electric Bill | |
|-----------------------------|------|
| Energy Supply - Cheap Power | \$12 |
| Distribution - LG&E | \$9 |
| Meter Service - MeterCo | \$2 |

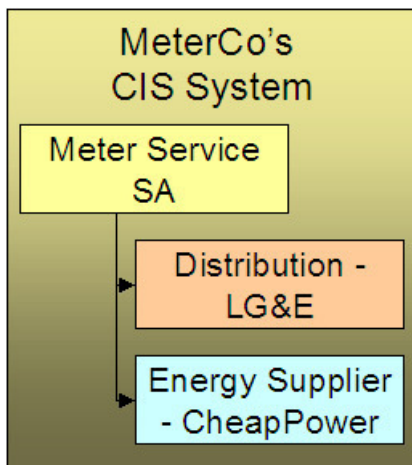

If we were to look at this customer's service agreement in the distribution company's CIS system, we'd find a service agreement for distribution charges, and linked to it would be information about the meter service and energy service providers:

If we look at this customer's service agreement in the energy supply company's CIS system, we'd find a service agreement for energy charges, and linked to it would be information about the distribution and meter service providers:

And finally, if we look at this customer's service agreement in the meter service company's CIS system, we'd find a service agreement for meter service charges, and linked to it would be information about the distribution and energy providers:

Note:

Bottom line. A customer's service providers keep track of the customer and each other in their respective CIS systems. A customer will have a service agreement (or the equivalent) in each service provider's CIS system. A customer's service agreement defines the service providers who supply each type of service.

Fastpath:

Because information about customers and their services needs to be kept up-to-date in many different CIS systems, there is a need for automated communications between service providers. Refer to [Service Providers Have To Communicate About Customers](#) for more information.

Service Providers May Change Over Time

A customer typically has a choice of service providers. Over time, their choice may change. The system keeps track of a customer's service providers throughout time so that it can accurately cancel / rebill historical bills. This means that the service provider relationship is *effective-dated*.

The following diagram illustrates how a distribution company's system keeps track of a customer's service providers (notice the customer changed energy suppliers):

How To Set Up SA Relationships On A Customer's Service Agreement

There are three ways to set up a customer's service providers:

- **Manually.** An operator can manually change a service agreement's SA relationships. The manual method is NOT recommended as changing service providers typically involves many events (e.g., you have to notify the current service provider that they will be dropped). We strongly recommend having an operator kick off a workflow process and let the workflow process notify the service providers and make the desired changes. Refer to [Defining Workflow and Notification Options](#) for more information.
- **Use Default Service Providers.** The system will default a service provider on a required SA relationship when a service agreement is activated. Refer to [Defaulting Relationship Types And Defaulting Service Providers](#) for more information.
- **Workflow Processing.** A workflow process may contain workflow events that change a service agreement's SA relationships. Refer to [Defining Workflow and Notification Options](#) for more information.

When Your Company Is A Service Provider

Besides setting up service providers for other companies that provide services to your customer, you may have to set up a service provider for your own company. You have to do this when:

- **Your organization can supply one of the services.** Refer to the illustration in [Service Providers Are Linked To Service Agreements](#). If you are LG&E and you supply energy in addition to distribution, you would need to set up a service provider for your own organization. Why? Because whenever you have a subcategory of service (e.g., energy supply), you must indicate the service provider who provides this service; even when it's you.
- **You decide to break up a service into subcategories** (and have a separate service agreement for each category). For example, a water company may choose to break up service charges into water, wastewater and storm water (they may do this because there are different rates for each category of service). The following is an example of the segregated charges associated with this water company's service charges.

| Customer's Water Bill | |
|-------------------------|------|
| Water Service - WaterCo | \$15 |
| Wastewater - WaterCo | \$6 |
| Storm Water - WaterCo | \$5 |

This water company system may benefit by creating a single service (for water) and indicating there are subcategories of service (for wastewater and storm water). Whenever you have a subcategory of service, you must indicate the service provider who provides this service. And, in this example, the water company would be the sole service provider for each subcategory of service.

| Customer's Water Bill | |
|-------------------------|------|
| Water Service - WaterCo | \$15 |
| Wastewater - WaterCo | \$6 |
| Storm Water - WaterCo | \$5 |

Note:

Refer to [We Bill For Them - Rate Ready Bill Segments Are Special](#) for restrictions in respect of using subcategories of service.

Service Providers Have To Communicate About Customers

The providers of service typically have to communicate with each other in respect of the customer's service. The following diagram illustrates the major interfaces of information between your system and your service providers.

Depending on where your organization fits in the service provider hierarchy, you may:

- Bill for other service providers (or they may bill for you). Refer to [Billing Relationships](#) for more information about billing communications.
- Send the customer's consumption to service providers (or they may send it to you). Refer to [Consumption Relationships](#) for more information about consumption communications.
- Apprise service providers of the changes to the customers' service (or they may apprise you). Refer to [How Do You Communicate With Service Providers?](#) for more information about communications between service providers.

Relationships Between Service Providers

Service providers may arrange contractual relationships with other service providers to provide additional services, e.g., an energy service provider may work with a specific meter data management agency to gather and report interval meter read data.

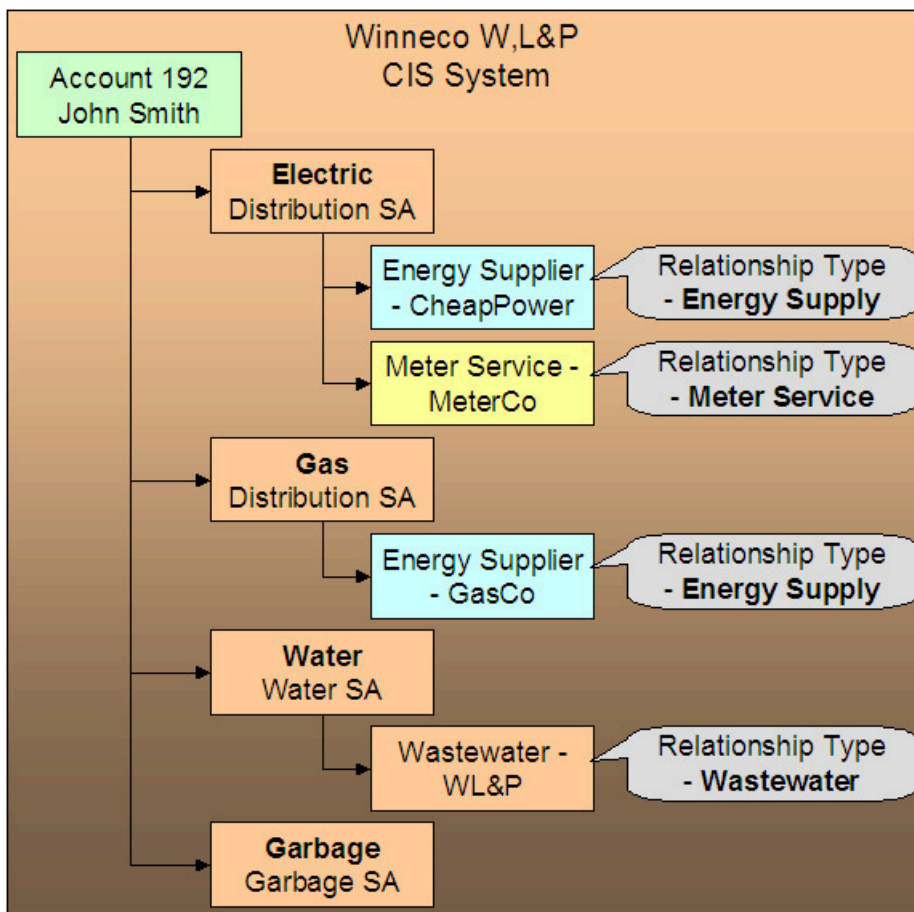

The system does nothing special to enforce or record these inter-relationships. Why? Because most service provider switches are received by notification records. Notification records indicate all the associated service providers. There is no need for the system to maintain the inter-service provider associations.

A Service Agreement Can Have Many Types Of Relationships

As described in the previous sections, a given service can be subdivided into subcategories. Each type of service can have zero, one or more subcategories. We call each subcategory a **SA Relationship Type**. The topics in this section provide information about SA relationship types.

An Example

We'll use the following example of a customer in a municipal utility's CIS system to explain SA Relationship types:

Note the following:

- Electric service has 2 SA relationship types: energy supply and meter service.
- Gas service has 1 SA relationship type: energy supply.
- Water service has 1 SA relationship type: waste water.
- Garbage service has no SA relationship types.

Note:

Bottom line. Service providers are related to the customer via "your" service agreement. Each service provider linked to a service agreement is defined in respect of a SA Relationship Type. This relationship is effective-dated because we care about how it changes over time.

Your relationship type is implied. The SA relationship type of "your" service agreement is implied, e.g., if you are a distribution company, "your" service agreement's implied SA relationship type is "distribution".

Valid Relationship Types and Service Providers Are Defined On SA Types

You control which services have SA relationships (and which don't) when you set up your SA types. Each SA type can have zero, one or more SA relationship types. Each relationship type, in turn, can have one or more valid service providers.

Fastpath:

Refer to [Setting Up SA Relationships For SA Types](#) for the page used to define the service providers and SA relationship types for each SA type.

Defaulting Relationship Types And Defaulting Service Providers

Please be aware of the following:

- A SA relationship type for a given SA type can be marked as being **Required**.
- A service provider for a given SA relationship type / SA type can be marked as being the **Default**.

If, at activation time, the customer's master SA is missing a **Required** SA relationship that has a **Default** service provider, the activation process automatically creates the SA relationship type and links to it the **Default** service provider. If a master service agreement doesn't have all **Required** SA relationships, the service agreement cannot be activated. This is handy when your organization is the default service provider for a relationship type.

Fastpath:

Refer to [Automatic Creation of Sub SAs](#) for information about how the system will automatically create sub service agreements for the defaulted SA relationship / service provider if your organization provides billing services for the service provider. Refer to [Setting Up SA Relationships For SA Types](#) for the page used to define the service providers and SA relationship types for each SA type.

Required Relationship Types and Billing

When the system attempts to create a bill segment for a service agreement whose SA type has **Required** relationship types, it checks if all such relationships are defined for the service agreement. If not, a bill segment error will be generated.

The reason this restriction exists is to handle the situation when your required relationship types change over time. For example, assume on your first day of production you only need energy suppliers defined on electric service agreements. After several months, gas deregulates. When this happens, you will need to change your control tables to indicate that your gas SA types require an energy supplier. If you don't write a default program to update your existing gas service agreements, billing will complain.

Relationship Types Do Not Impact Start/Stop

Customer service representatives (CSR's) are typically not involved with the customer's choice of service providers. Most organizations hear about a customer's service providers from the service providers or from a central body. This means that the start/stop dialog is not impacted by SA relationships. This also means that CSR's are not impacted by SA relationships (unless something goes wrong). If something goes wrong, the CSR's may need to manually correct SA relationships. Refer to [How To Set Up Service Providers On A Customer's Service Agreement](#) for more information.

Billing Relationships

When you set up a service provider, you must define your organization's billing relationship with the service provider. The following points provide examples of the billing relationships supported in the system,

- If you are an energy supply company, you may provide billing services for the distribution company. This means that your bill contains both your charges and the distribution company's charges. We refer to this as the **We Bill For Them** billing relationship.
- Alternatively, the distribution company may provide billing services for you. This means that the distribution company's bill contains your charges and their charges. We refer to this as the **They Bill For Us** billing relationship.
- Alternatively, you may both send bills to the customer. We refer to this as the **Dual Billing** relationship.
- Alternatively, if you subcategorize your services OR if your company provides one of the services that is provided by your service providers, then the system will create a separate bill segment for the subcategory of service. We refer to this as the **It's Us** billing relationship.

If you provide billing services for another service provider (i.e., you bill for them), there are two ways to determine the service provider's charges:

- You can load the service provider's rates in your system and calculate the charges for the service provider. We call this the **Rate Ready** calculation method.
- You can let the service provider calculate their own charges and interface them to you. We call this the **Bill Ready** calculation method.

If a service provider provides billing services for you (i.e., they bill for you):

- If the service provider has a suitable CIS system, they can load your rates in their system and calculate your charges for you. We call this the **Rate Ready** calculation method.
- You can calculate your charges and interface them to them. We call this the **Bill Ready** calculation method.

If you don't have a billing relationship with a service provider, you still need a service provider record to define such. Why? Because the system needs to know that it doesn't have to worry about a particular service provider in respect of billing. In addition, you may have other interactions with a service provider that have nothing to do with billing, e.g., you may send or receive consumption.

The topics in this section provide a wealth of information about the various billing relationships and the ramifications of each.

Sub Service Agreements

If you provide billing services for another service provider OR if you subcategorize your own charges, there will be a separate service agreement (SA) linked to the customer's account that holds these unique charges. We refer to this new service agreement as a **Sub SA**. We use the term "sub" because this service agreement is subservient to the "master" service agreement. By subservient we mean:

- A sub SA's start and stop dates are the same as the master SA. This statement may seem odd, but it's true – all sub SAs linked to a master service agreement have the same start and stop dates as the master.
- A sub SA's status (i.e., *pending start*, *active*, *pending stop*, *stopped*, etc.) is controlled by its master service agreement. As a rule, the master SA transitions its status first and the sub SA(s) follow.

Note: There are situations where the master service agreement transitions its status and the sub service agreement(s) does not. One example of this is when both the master and sub SAs are closed and a payment cancellation occurs that only affects the master SA. In this scenario, the master SA becomes reactivated and the sub SA remains closed. Another example is when a straggling billable charge posts to a sub SA; the master SA is not affected.

- Refer to [The Rate Ready Calculation Method](#) for additional examples of subservience.

Note:

You may find it helpful to keep in mind that sub SAs are only used for service providers with a billing relationship of It's Us and We Bill For Them. This is because these are the only relationships that have implicit billing responsibilities.

The topics in this section provide additional information about sub SAs.

Only Some Service Providers Have Sub SAs

If you do not provide billing services for a service provider, there will be no sub SAs associated with the service provider's SA relationships. Let's use an example to make the point; assume:

- Service is divided into distribution, energy and meter service charges.
- You are the distribution company and you provide billing services for the energy supply company.
- The meter service company bills the customer independently.

In this situation, the customer will receive two bills: one from you (LG&E), the other from MeterCo. Notice that your bill (LG&E) contains your distribution charges AND CheapPower's energy charges:

If we were to look at the customer information in the three service providers' respective CIS systems, we'd find the following service agreements and SA relationships for the customer:

Notice the following:

- The customer has a service agreement in each supplier's CIS system.
- Because LG&E (the distribution company) bills for CheapPower, all customers who have their energy supplied by CheapPower will have a sub SA in LG&E's system. This sub SA maintains the charges (and receivable balance) associated with CheapPower's energy charges.
- Notice that neither CheapPower's nor MeterCo's CIS systems use sub SAs. This is because neither company bills for other service providers.

Note:

Sub SAs are needed if you subcategorize your charges. The above example shows sub SAs being used when a company provides billing service for another company. Sub SAs are also used when you subcategorize your charges - each sub SA contains the rate associated with each subcategory.

Automatic Creation of Sub SAs

The system creates sub SAs for customers choosing service providers where the billing option is It's Us or We Bill For Them. The system creates sub SAs via the following mechanisms:

- The [analyze SA relationships](#) background process (ANLYZSAR) monitors newly activated SA relationships. If the respective service provider is It's Us or We Bill For Them, this process creates the sub SA(s) using the information defined on SA Type SA Relationship Type. Refer to [Setting Up SA Relationships For SA Types](#) on page 997 for more details.

Note:

The [analyze SA relationships](#) background process also activates and stops sub SAs. Refer to [Sub SA State Transition](#) for the details.

- A button exists on the [SA Relationships](#) page. This button, when pressed, creates sub SAs real-time. This button would only be used if the operator couldn't wait for the background process to run.

The SA type associated with the new sub SAs is defined when you set up each SA Type / SA Relationship Type. Refer to [Setting Up SA Relationships For SA Types](#) for more information.

If the SA type uses start options, the start option contains additional values (e.g., rates, contract riders) that are used to populate the newly created sub SAs. Note: start options are typically not used for We Bill For Them - Bill Ready service provider because we don't need to default rates, contract riders and/or contract values on billable charge sub SAs. Refer to [Setting Up SA Relationships For SA Types](#) for more information.

Note:

Manually created sub SAs. In very unusual situations, an operator may create a sub SA manually. An operator would do this using the [SA Relationship](#) transaction.

Sub SA State Transition

Sub SAs follow normal SA state transition rules, but have a few additional rules about when the transitions can take place.

The following points highlight the additional state transition rules:

- A sub SA can only become Active if its master SA is Active. Most sub SAs are activated by the [analyze SA relationships](#) background process. However, a user can manually activate a sub SA using the activate button on the [SA maintenance](#) page.
- Sub SAs become Pending Stop when their master becomes Stopped . This typically occurs when the [SA activation background process](#) stops the master SA. However, this can happen real time if a user manually stops a master SA using the stop button on the [SA maintenance](#) page.
- A sub SA can only become Stopped if its master SA is Stopped . Most sub SAs are stopped by the [analyze SA relationships](#) background process. However, a user can manually activate a sub SA using the stop button on the [SA maintenance](#) page.
- A sub SA becomes Closed if its master has been final billed and it has a balance of zero. Most sub SAs are closed when their balance becomes zero after the master SA is final billed. However, a user can manually close a sub SA using the close button on the [SA maintenance](#) page. Note, if additional billable charges are interfaced after the master has been closed, the sub SA will be Reactivated.

We Bill For Them

If you provide billing services for another service provider, then you have a We Bill For Them billing relationship with the service provider. The topics in this section provide information about this type of billing relationship.

Sub SAs Are Used When We Bill For Them

As described under [Sub Service Agreements](#), sub SAs are used for We Bill For Them service providers. The sub SAs hold the service providers charges. It's important to note that the system allows more than one sub SA to be created for a given service provider.

The Rate Ready Calculation Method

If you provide billing services for a service provider (i.e., the service provider has a billing relationship of We Bill For Them), you can load the service provider's rates in your system and calculate the charges for the service provider. We call this the **Rate Ready** calculation method.

Note:

It's **Us can be Rate Ready**. The prior paragraph indicated that the Rate Ready billing option was used for We Bill For Them service providers. If you subcategorize your services and use rates to calculate each subcategory's charges, the service provider(s) set up for your own organization will also be subject to the Rate Ready rules described below.

If a customer uses a We Bill For Them - Rate Ready service provider, the system will create a separate bill segment for the service provider's charges. Keep in mind the following in respect of these types of bill segments:

- The consumption is copied from the "master" service agreement (note: we copy item details and read details after pre-processing calculation groups, if any exist, have been applied). This means that the bill period on the sub SA's bill segment is identical to that on the normal SA. This also means that if the "master" SA is in error, bill segments for the sub SA will not be created.
- The rate defined on the sub SA is applied against this consumption. All pre-processing calculation groups defined on the service provider's rate will be used to manipulate this consumption. If you have pre-processing calculation group on your master SA's rate to apply a line loss or convert a cubic foot to a therm, you don't have to have these pre-processing calculation group on the sub SA's rate (because we copy the consumption from the master to the sub after pre-processing calculation group, if any exist, have been applied).

The following illustration should help:

Be aware of the following:

- This example is from a distribution company's perspective.
- From 1 Jan 99 through 15 Mar 99, the distribution company distributes power AND supplies energy (i.e., the distribution company is the service provider of energy).
- On 15 Mar 99, CheapPower becomes the energy supplier. However, the next bill period ends on 30 Mar 99. This means that CheapPower will only start supplying energy on 1 Apr 99. See the following note for why the effective date of the supplier switch is not the true effective date from billing's perspective.

Note:

Service Provider Changes Take Effect On The Next Bill. If the service provider is changed within a customer's billing period, the system assumes that the service provider in effect at the START of the period is effective the entire billing period. This means that a change of service providers will only take effect on the bill whose start date follows the change date.

Please be aware of the following characteristics of Rate Ready bill segments:

- You cannot cancel a Rate Ready bill segment independently from the master bill segment. If you need to cancel / rebill the sub SA's bill segment, you must cancel / rebill the master SA's bill segment.
- You cannot delete a Rate Ready bill segment independently from the master bill segment. If you need to delete the sub SA's bill segment, you must delete the master SA's bill segment.
- Similarly, if you cancel / rebill the normal SA's bill segment, all Rate Ready bill segments will be cancelled / rebilled.

Note:

Bottom line. Creating, freezing, deleting, and canceling a "master" bill segment does the same with all Rate Ready bill segments. You cannot create, freeze, delete or cancel a Rate Ready bill segment independent of its master bill segment.

The Bill Ready Calculation Method

If a customer uses a We Bill For Them - Bill Ready service provider, the service provider calculates their own charges and interfaces them to the system. We then present their charges on our bill; we don't actually calculate anything (sometimes this is referred to as "pass through" billing).

The sub SA linked to a We Bill For Them - Bill Ready must be a billable charge SA. Why? Because billable charge SAs exist to hold bill lines until such time as a bill is created for the customer's account. Refer to [Setting Up Billable Charge Templates](#) for more information.

Please be aware of the following characteristics of Bill Ready bill segments:

- Unlike Rate Ready bill segments, Bill Ready bill segments can span different time periods than the master SA. This is because you cannot predict when a service provider will interface their billable charges to you. In fact, a given bill could contain billable charges that span different periods and these charges could have been interfaced from historic and existing service providers.
- Unlike Rate Ready bill segments, Bill Ready bill segments can be created and deleted independently from the master bill segment.
- Unlike Rate Ready bill segments, Bill Ready bill segments can be cancelled independently from the master bill segment.

[Sending Consumption And Waiting For The Charges](#)

[Uploading Consumption \(Rather Than Uploading Calculated Charges\)](#)

[Calculating Taxes On Uploaded Charges](#)

Sending Consumption And Waiting For The Charges

If your organization supports We Bill For Them - Bill Ready service providers AND you are the source of consumption used by these service provider to calculate their charges, you need to be aware of the following:

- We do NOT recommend sending raw meter reads to service providers. Rather, we recommend sending these service providers the same consumption that you use on your bill segments. Remember, the system maintains a snapshot of billed consumption on bill segments associated with service agreements that are linked to service points.
- But to implement our recommendation (of only interfacing billed consumption to service providers), we need to create a bill segment for the master SA and then wait until the service provider returns the billable charge before sending out the bill. The following points describe how this works:
 - Early in the bill cycle, the system creates a bill segment for the master SA (remember, the system maintains a snapshot of billed consumption on bill segments linked to service points). When the master bill segment is frozen, the system interfaces the snapshot consumption to all service providers associated with the master service agreement who need consumption (this is defined on the service provider). Refer to [We Can Send Billed Consumption To Any Service Provider](#) for more information about interfacing consumption to service providers.
 - The bill associated with the bill segment will not be completed. Why? Because the bill segments associated with the We Bill For Them - Bill Ready service providers will be in Error. This only happens if you use the Billable Charge bill segment creation algorithm (this algorithm is plugged in on the sub SA's SA type). On the algorithm, make sure to specify a value of Y for the parameter **Wait For The Last Day Of The Bill Cycle**. By doing this, a bill segment in the Error state will exist for the sub SA until the last night of the bill cycle's window.
 - On the last night of the bill cycle window, when the system attempts to create a bill segment for the billable charge SA associated with the We Bill For Them - Bill Ready, it will either find recently interfaced billable charges or it won't. If it finds unbilled, billable charges, a bill segment will be created for the sub SA and the billable charges will be swept onto it. If it doesn't find unbilled billable charges, the bill will be completed (i.e., sent out) without the service provider's charges.

Note:

Bottom line. If a customer's account uses We Bill For Them - Bill Ready service providers, the bill will not be completed (i.e., sent out) until the last night of the bill cycle (if you use the appropriate algorithm). Why? Because we wait until the last night of the bill cycle before trying to sweep on recently interfaced billable charges. If no billable charges have been interfaced from the service provider by the last night of the bill cycle, the bill will be sent out without the service provider's charges.

Batch versus Online Bill Creation. If you create a bill online, the system will NOT create an Error bill segment for the We Bill For Them - Bill Ready service provider. Why? Because if you want to create an online bill, either the service provider has interfaced their charges or they haven't. If they have, they should be swept on the bill (via the creation of a bill segment). If they haven't, it shouldn't prevent you from completing the bill.

[Top of the Page](#)

Uploading Consumption (Rather Than Uploading Calculated Charges)

We understand this is confusing, but it is quite possible to set up the system so that the We Bill For Them - Bill Ready service provider passes in CONSUMPTION rather than the calculated bill lines. They would only do this if they are not able to calculate the charges in their system and have therefore provided you with their rates. To do this, you would set up everything as described above. In addition, when you upload the billable charges, you must specify the consumption to be rated in the billable charge's service quantity (SQ) collection.

[Top of the Page](#)

Calculating Taxes On Uploaded Charges

It is possible to set up the system to calculate taxes for billable charges. You would do this if the service providers are passing through the charges and want you to calculate the taxes.

If you want taxes calculated on top of billable charges:

- Create a service quantity (SQ) on the billable charge that contains the total monetary amount that taxes will be calculated on. Note, you would not have to do this if you have a pre-processing calculation group in your rate that calculates the total monetary amount to which taxes should be applied.

- Specify a rate on the billable charge service agreement. This rate will contain calculation rules that calculate taxes. Note, the calculation rules will be simple SQ calculation rules that apply a percentage to the value of the SQ that represents the monetary amount on which taxes should be calculated.

When the system creates the bill segment for the billable charge, it will call the rate and the rate will calculate the taxes and add additional lines (actually, bill calculation headers) to the bill segment.

Pay At Bill Time vs. Pay At Pay Time

If you provide billing services for another service provider (i.e., the service provider has a billing relationship of We Bill For Them), you will owe them money because you will be receiving money from their customers for their service. You have two options in respect of when the system increases the amount you owe the service provider:

- You can tell the system to increase how much you owe the service provider when you freeze the customer's bill segment. Some people refer to this method as "purchasing the receivable from the service provider". We call this the **Pay At Bill Time** method.
- You can tell the system to increase how much you owe the service provider only when you are paid for by the customer. We call this the **Pay At Pay Time** method.

The method used for a service provider is defined on the service provider's record.

Fastpath:

Refer to [When We Bill For Them, We Owe Them Money](#) for more information.

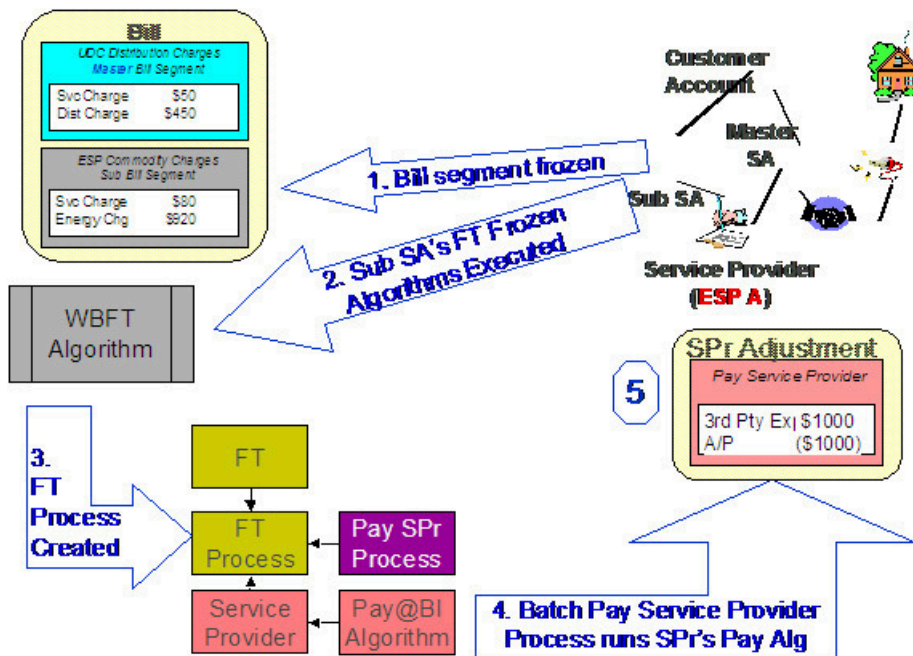

Paying The Service Provider - Technical Implementation

Warning:

This section describes, technically, how we increase the amount we owe a We Bill For Them service provider. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with increasing how much we owe a We Bill For Them service provider.

The following points explain the steps:

- When a financial transaction (FT) is frozen, the system executes the FT Freeze algorithms defined on the SA(s) SA type.
- If you've set up the system properly (i.e., you've put the appropriate FT Freeze algorithm on the sub SA's SA type), one of these algorithms will determine if there is a WBFT service provider associated with the sub SA. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that looks at new FT's and determines if a related "payable" adjustment should be created for the We Bill For Them service provider. This batch process uses the service provider's Payment Relationship and Pay Service Provider algorithm to determine when and how to create these "payable" adjustments.

Service Providers Have Service Agreements Too

Most service providers need service agreements as explained in the following topics.

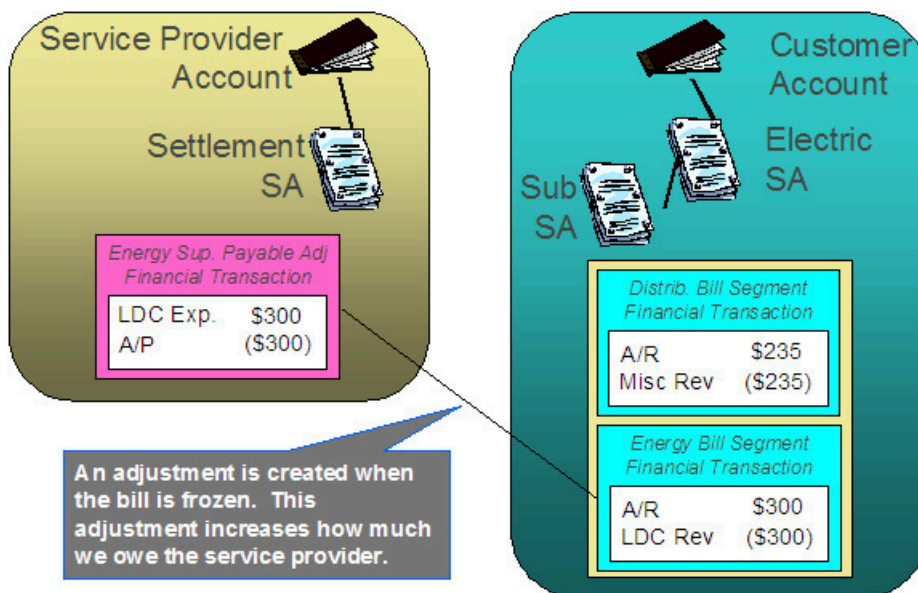

When We Bill For Them, We Owe Them Money

When you bill on behalf of a service provider (i.e., the service provider has a billing relationship of We Bill For Them), you will eventually owe them money (because the customer pays you for the service provider's service). You have two options in respect of when the system increases the amount you owe the service provider:

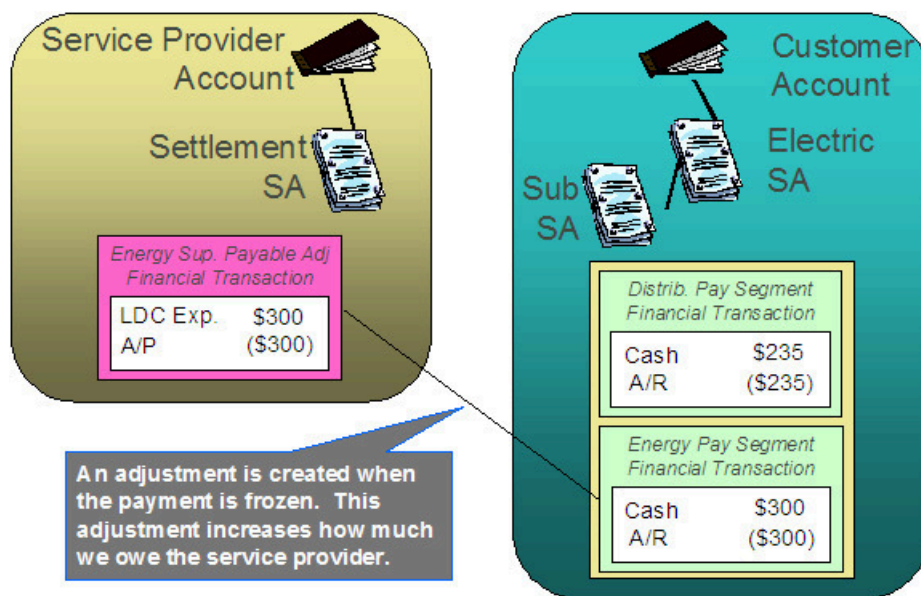

- You can tell the system to increase how much you owe the service provider when you create the customer's bill. Some people refer to this method as "purchasing the receivable from the service provider".
- You can tell the system to increase how much you owe the service provider only when you are paid for by the customer.

The system keeps track of how much you owe a service provider on a service agreement linked to the service provider's account. The system creates adjustments against this service agreement to increase how much you owe them.

If you "purchase the receivable" (i.e., you owe them when you bill the customer), an adjustment is created when the customer is billed. If you owe them only when you are paid by the customer, an adjustment is created when the customer pays. The following example illustrates an adjustment being created when the bill is frozen (illustrating the "purchase the receivable" scenario):

If you only pay the service provider when you are paid, the example would look as follows:

Adjustments and We Bill For Them Service Providers

Fastpath:

It's important that you are comfortable with the information described under [When We Bill For Them, We Owe Them Money](#) before reading this section.

Adjustments associated with We Bill For Them sub service agreements are tricky. The following points describe how the system "pays" the related service provider when adjustments are issued against the customer's sub service agreement:

- For Pay At Bill Time service providers, most adjustments are treated just like bill segments, i.e., when the adjustment's FT is frozen, a payable adjustment is created for the respective service provider. The reason "most" is underlined in the previous sentence is because A/P adjustments (i.e., adjustments used to interface check requests to your A/P system) are excluded. Why? Because A/P adjustments are used to refund overpayments to the customer. Overpayments are purely between the customer and your company (you never transferred the overpayment to the service provider because it's associated with a Pay At Bill Time service provider).
- For Pay At Pay Time service providers, A/P adjustments are treated just like payment segments, i.e., when the adjustment's FT is frozen, a payable adjustment is created for the respective service provider. All other types of adjustments are ignored. Why? Because A/P adjustments are used to refund overpayments to the customer. Think of it like this - when the customer originally overpaid, you transferred this overpayment to the Pay At Pay Time service provider; therefore, when you refund the overpayment, you get to take the money back from the service provider.

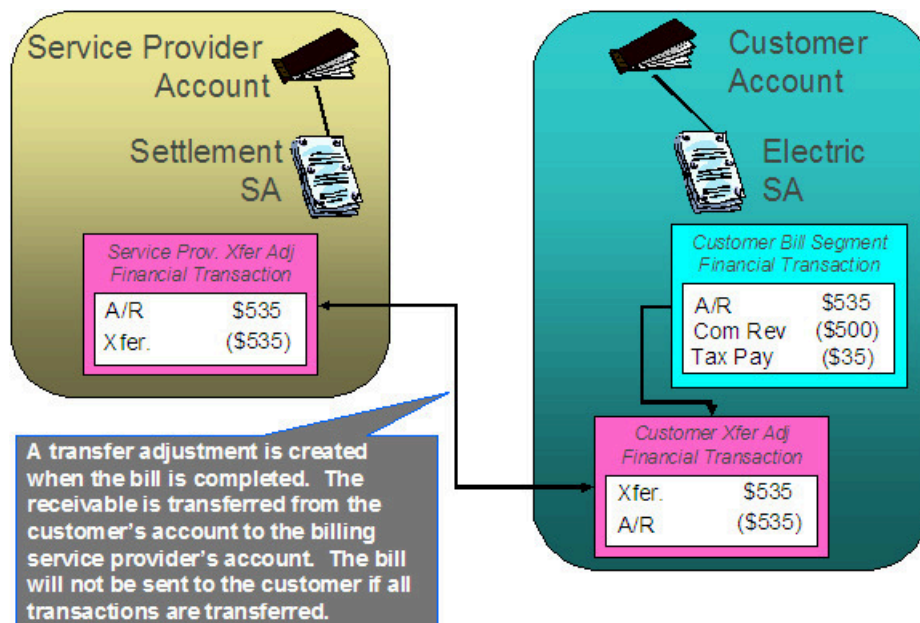

When They Bill For Us, They Owe Us Money

When a service provider bills on behalf of your organization, they will eventually owe you money (because the customer pays them for your service).

The system keeps track of how much a service provider owes you on a service agreement linked to the service provider's account. The question is, How does the system determine how much you are owed when you don't produce a bill? Well, you do produce a bill, it just doesn't get sent to the customer. We understand this is a little confusing, but think about it like this:

- The service provider is presenting your charges on their bill.
- You still have to calculate how much the customer owes your organization otherwise you'll never know how much you are owed by the service provider.

As illustrated below, when a bill is completed, the system determines if there are bill segments and/or adjustments associated with service agreements with a service provider who "bills for us". If it finds these, it transfers the receivable from the customer's service agreement to the service provider's service agreement. If all financial transactions have been transferred to the service provider, no bill is produced for the customer.

Note:

Bottom line. We always generate a bill for "us", even though we don't send it to the customer.

They Bill For Us

If a service provider provides billing services for you, then you have a They Bill For Us billing relationship with the service provider. The topics in this section provide information about this type of billing relationship.

The Customer Still Needs A Service Agreement

If a service provider bills for you, you still need a service agreement for the customer. Why? Because:

- As explained under [Service Providers Are Linked To Service Agreements](#), service providers are defined in respect of a customer's service agreement (therefore the customer must have a service agreement).
- As explained under [When They Bill For Us, They Owe Us Money](#), you still have to calculate bills for the customer.

Note:

A customer's bill history still exists. Be aware that even when a service provider bills for us, you will still be able to see the customer's billing history. It's just that the customer won't owe you anything because the receivable balance will be transferred to the service provider's account.

They Bill For Us - Bill Ready

At bill completion time, the system determines if there are bill segments and/or adjustments associated with service agreements with a service provider who "bills for us". If it finds these,

- It transfers the receivable from the customer's service agreement to the service provider's service agreement. If all financial transactions have been transferred to the service provider, no bill is produced for the customer.

- Note that payments and A/P adjustments are not transferred. Why? Because payments and A/P adjustments are purely between the customer and your company.
- Each bill segment and adjustment is marked to be interfaced to the service provider (via a separate background process).

They Bill For Us - Rate Ready

The They Bill For Us - Rate Ready option is not a recommended option. Why? Because you really have to compute how much the customer owes as explained above. If you go to the trouble of figuring out how much the customer owes, then it makes sense to interface this to the billing service provider.

The only difference between this option and They Bill For Us - Bill Ready is that the system will not interface the bill segments and adjustments to the billing service provider.

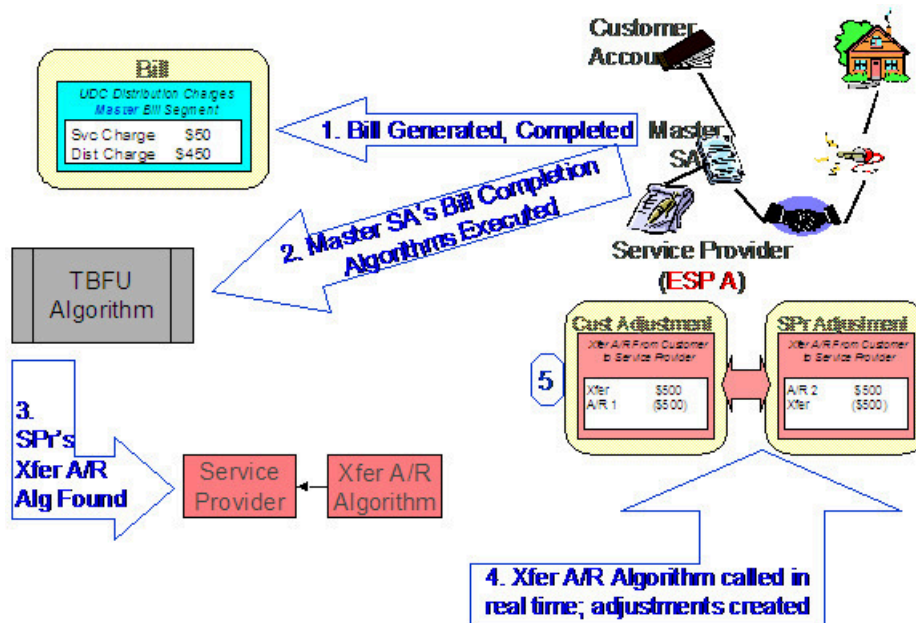

A/R Transfer - Technical Implementation

Warning:

This section describes, technically, how a customer's A/R balance is transferred to a They Bill For Us service provider. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with the transference of a customer's A/R balance to a They Bill For Us service provider.

The following points explain the steps:

- When a bill is completed, the system executes the bill completion algorithms defined on the bill's master SA(s) SA types.
- If you've set up the system properly (i.e., you've put the appropriate Bill Completion algorithm on the master SA's SA type), one of these algorithms will determine if there is a They Bill For Us service provider associated with each master SA on the bill. If so, it will execute the Transfer A/R algorithm defined on the service provider's record. This algorithm causes a transfer adjustment to be created (transferring the financial transaction's affect on the customer's balance from the customer to the service provider).

Note:

If there are multiple master SAs on a bill, the financial details associated with each respective master SA could be transferred to different service providers (e.g., one service provider could receive the financial details

for gas and another for electricity). Refer to [Different Service Providers Can Bill Different Services](#) for more information.

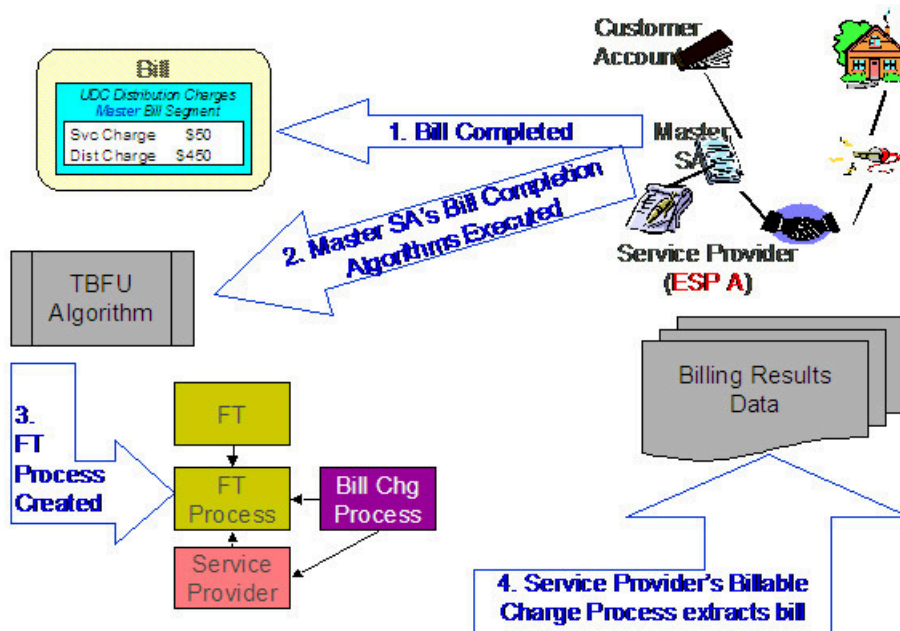

Routing Billable Charges To Service Providers - Technical Implementation

Warning:

This section describes, technically, how we send billable charges to service providers. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with sending billable charges to service providers.

The following points explain the steps:

- When a bill is completed, the system executes the bill completion algorithms defined on the bill's master SA(s) SA types.
- If you've set up the system properly (i.e., you've put the appropriate Bill Completion algorithm on the master SA's SA type), one of these algorithms will determine if there is a They Bill For Us service provider associated with each master SA on the bill. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that downloads billable charges to the service provider. The ID of the batch process that is referenced on the trigger comes from the Service Provider's Billable Charge Download Process.

Note:

If there are multiple master SAs on a bill, the financial details associated with each respective master SA could be routed to different service providers (e.g., one service provider could receive the financial details for gas and another for electricity). Refer to [Different Service Providers Can Bill Different Services](#) for more information.

Bill Routings Are Changed

If all of an account's "master" SAs have a SA relationship with a service provider who bills for us (i.e., the service provider's billing relationship is They Bill For Us), then we have nothing to send to the customer. The system still creates bill routings, but with a couple of differences:

- The Batch Process Id and Run Number are reset.

- The Customer's Name is prefixed with the text from a bill message code 6, 10103. This message code's text is *** Bill not sent.

This way, the operators can easily see that that the bill was not routed and why.

Fastpath:

Refer to [Different Service Providers Can Bill Different Services](#) for information about how the various services under an account could be billed by different service providers.

Combinations Of Service Provider Billing Methods

Consider the following situation:

In the above example, we are billing for the energy service provider and the meter service provider is billing for us. This means that we will calculate the charges for ourselves, interface charges from CheapPower, and then interface our charges and CheapPower's charges to MeterCo. MeterCo will then produce a bill for the customer that contains our distribution charges, CheapPower's energy charges, and MeterCo's service charges. To help solidify this point, let's look at how this customer would look in MeterCo's CIS system.

There are some restrictions in respect of permissible combinations of service providers that may supply service to a customer as described in the following points:

- If the system encounters a customer with a We Bill For Them (WBFT) - Bill Ready service provider and another service provider that is They Bill For Us (TBFU) - Rate Ready, a billing error will be produced. Why? Because TBFU - Rate Ready means they have everything they need to calculate our bills and therefore we do not interface bill lines to them. If we don't interface our bill lines to them, then we can't interface the charges that were interfaced from the WBFT - Bill Ready service provider. You may wonder why we don't prohibit WBFT - Rate Ready and TBFU - Rate Ready, because it's conceivable for the TBFU service provider to have our rate and the WBFT service provider's rate.
- If the system encounters a WBFT - Pay At Pay Time service provider and another service provider that is TBFU, a billing error will be produced. Why? Because when the system detects a TBFU service provider, it transfers the receivable from the customer to the service provider (and therefore the customer's account will never be paid).

Different Service Providers Can Bill Different Services

Be aware that the system determines billing relationships at the service agreement level, NOT at the account level. To make the point, check out the following customer in a distribution company's system:

Be aware of the following in respect of the above illustration:

- The distribution company (LG&E) distributes both electricity and gas.
- The customer has a choice of energy service providers for both gas and electricity.
- This customer - John Smith - purchases electricity from CheapPower, and purchases gas from GasCo.
- LG&E provides billing services for CheapPower.
- GasCo provides billing service for LG&E.

In this situation, LG&E will send bills to the customer that contain both electric distribution and energy charges (but no gas distribution charges). GasCo will also send bills to the customer; these will contain both LG&E's gas distribution charges as well as their own energy charges.

If You Deal With TBFU Service Providers, You Cannot Reopen Bills

Fastpath:

Refer to [Bill Lifecycle](#) for information about reopening previously completed bills.

If your organization deals with They Bill For Us (TBFU) service providers, a great deal happens when a bill is completed (e.g., the receivable is transferred from the customer to the service provider, we may mark the bill segments and adjustments for routing to the service provider, etc.). These things cannot be undone and therefore the system will not let you reopen bills when these things have occurred.

Note:

Technical rule. The specific rule that prevents the reopening of bills is as follows: if a bill contains a service agreement whose SA type has one or more bill completion algorithms, the system will not allow the bill to be reopened. Refer to [SA Type - Algorithms](#) for more information about bill completion algorithms.

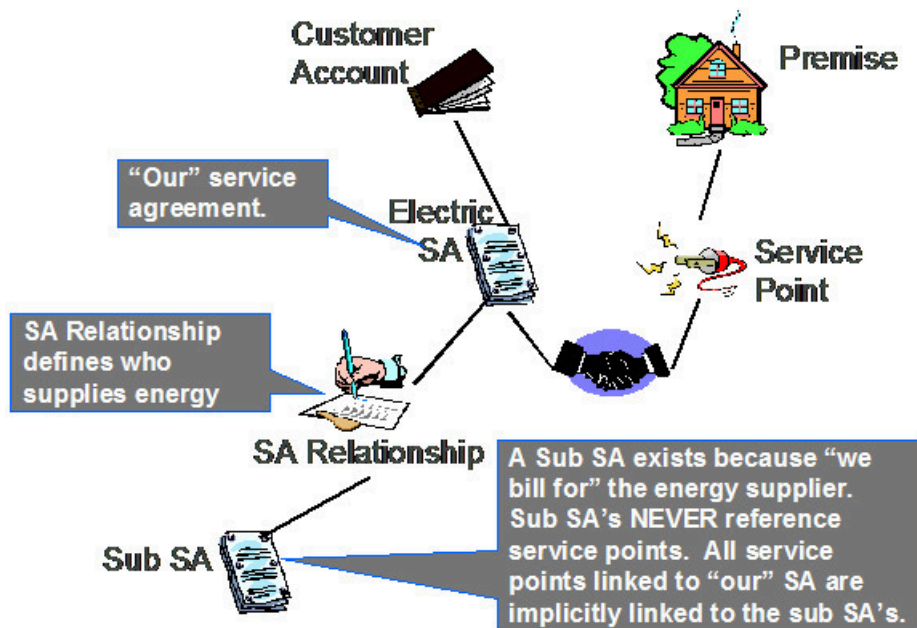

Consumption Relationships

When you set up a service provider, you must define your organization's consumption relationship with the service provider - a service provider may send the customers' consumption to you, you may send consumption to them, or you may have no consumption relationship with a given service provider.

The topics in this section provide a wealth of information about the various consumption relationships and the ramifications of each.

Only The Master SA Is Linked To Service Points

The following diagram makes the point that service points cannot be linked to sub SAs (i.e., service agreements that exist to hold charges associated with We Bill For Them service providers). This is because all service points associated with our "master" SA are implicitly linked to all sub SAs.

It's important to understand why the system does not allow sub SAs to reference service points:

- The consumption associated with all service providers should be the same, otherwise the customer will receive inconsistent bills from different service providers.

- The easiest way to ensure consumption is the same for all service providers is to make sure that they all have the same service points (which they must if sub SAs "inherit" their service points from their master).

We Can Send Billed Consumption To Any Service Provider

You can send consumption to any service provider. It doesn't matter what their billing relationship is. Information on the service provider object tells the system if AND how to send consumption to a service provider.

Rather than send raw reads to service providers, we download consumption that has been calculated and snapshot onto the "master" bill segment. We send this billed consumption because:

- It is clean and validated
- Register indexes have been subtracted
- Multiple registers have been summed

Note:

We only send consumption after a bill segment is Frozen. If your organization supports We Bill For Them - Bill Ready service providers AND you are the source of consumption used by these service providers to calculate their charges, please refer to [The Bill Ready Calculation Method](#) for an explanation of how the system waits a given amount of time for the recipient of the consumption to interface their charges back to the system before sending the bill to the customer. In other words, the bill sent to the customer should contain the bill segment that triggered the consumption download as well as bill segments containing uploaded billable charges.

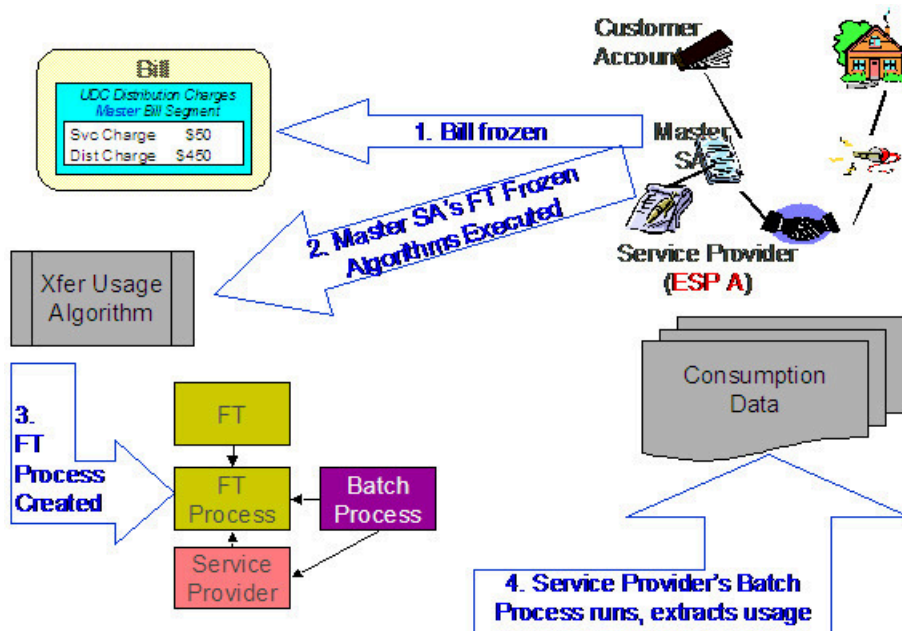

Routing Consumption To Service Providers - Technical Implementation

Warning:

This section describes, technically, how we send consumption to service providers. If you aren't technically inclined, skip this section.

The following illustration shows the logical steps involved with sending consumption to service providers.

The following points explain the steps:

- When a financial transaction (FT) is frozen, the system executes the FT Freeze algorithms defined on the SA(s) SA type.

- If you've set up the system properly (i.e., you've put the appropriate FT Freeze algorithm on the master SA's SA type), one of these algorithms will determine if there are service providers associated with the master SA who need consumption. If so, it will insert a row on the FT Process table.
- Rows on the FT process table are used as "triggers" for batch processes. In this case, the batch process that is triggered is the one that downloads billable consumption to the service provider. If multiple service providers need consumption, multiple rows will be inserted. The ID of the batch process that is referenced on the trigger comes from the Service Provider's Consumption Download Process.

We Can Receive Consumption From Service Providers

We can receive consumption from any source. We use the standard meter read upload to interface consumption from service providers. Because we use the standard meter read upload, each customer must have:

- A premise
- A service point
- A meter with registers sufficient to hold the interfaced consumption

Note:

You don't have to perfectly model the service points and meters. If you are not the distribution company, you may be worried about how to keep meter and service point information up-to-date. Be aware that you don't have to model the SP's and meters perfectly. Why? Because you just need to set up enough information so that consumption can be uploaded accurately. Let's use an example of a customer with multiple meters and service points at a premise. Rather than model this perfectly, you could set up a single SP and link to it a single meter. All that matters is that the meter has the appropriate registers to hold the interfaced consumption.

When a customer's consumption (i.e., meter reads) is uploaded from a service provider, the service provider must be defined as the "upload source" on the meter read upload staging records. The system uses this information to validate that the service provider is linked to the customer on the effective date of the read AND that they are defined as Sending Consumption To Us. Refer to [Uploading Meter Reads](#) for more information.

MDMAs And Service Cycles

Warning:

This section uses terminology and concepts described in The Cyclical Meter Read Process.

A Meter Data Management Agency (MDMA) is a service provider who reads meters. In some locales, a meter can be read by a variety of MDMAs, in other locales there is no MDMA as the meter is read by the distribution company. If your organization has MDMAs, then you need to be aware of the following:

- MDMAs must be linked to service agreements as a service provider. Like all service providers, they can change over time.
- When an MDMA is reading a service agreement's meters, the MDMA may override the customer's service cycle (and schedule) with their own cycle. If they do this, the customer's service cycle in the MDMA's system is defined on the service agreement's SA relationship information for the MDMA. Note: whether or not a service provider can override a service cycle is controlled by a switch on the service provider's record. Refer to [Setting Up Service Providers](#) on page 997 for more details.
- A service provider's service cycle schedules are maintained using the system's normal service cycle schedule. The ID of the service provider associated with each schedule is defined on the service cycle; in other words, if a service provider reads meters and they can override the customer's service cycle, the service provider's service cycles must be defined in the system. Refer to [Designing Service Cycles, Routes, And Schedules](#) for more information.
- At billing time, the system determines if a service agreement is covered by an MDMA. If so, it uses the service cycle defined on the service agreement's MDMA SA relationship record.
- If your organization ever reads the customers' meters, your regular read cycle should be maintained on your service points. You can think of the service cycle that is defined on a service agreement's MDMA SA relationship record as an override of your service points normal service cycle.

- If the meter read download process detects that a service point is linked to a service agreement with an active MDMA, it still creates a meter read download staging record; however, it marks it as Do Not Need To Read. This means that when a service point is no longer read by an MDMA, the meter read will be downloaded normally.
- Refer to [We Can Receive Consumption From Service Providers](#) for a description of how a service provider interfaces consumption into the system.

Deposits Issues

Warning:

This section uses terminology and concepts described in [The Big Picture Of Deposits](#).

Deposits should be held using normal deposit service agreements (SAs). You should NOT use the [Sub Service Agreements](#) (sub SA) functionality to hold or bill for deposits because deposit service agreements do not have the same state transition as do master SAs (e.g., you can activate or stop a deposit independent from its master).

However sub SAs can be covered by a deposit. If so, their SA type must reference a deposit class. To make the point, let's examine a few scenarios:

- Assume you have a sub SA for your own charges (this can happen when we use sub SAs to unbundle charges from the Master SA). In this case, it is likely that the sub SA and master SA will be in the same deposit class. This means that a single deposit SA would cover both the master and the sub SA.
- Assume They Bill For Us (Bill or Rate Ready). In this situation, we still have a master SA for our charges and we transfer the charges to the service provider who does the billing. In this case, it is likely that we would be holding the deposit for the service provider, not on the end-use customer. If we are in a situation where 1) we cannot hold a deposit against the service provider, and/or 2) we are not assured of the service provider paying us when the customer doesn't pay them, then we might want to put the master SA in a deposit class and hold a deposit against the customer's account using a normal deposit SA. We would not expect the service provider to bill the customer for the deposit, so we don't need a sub SA. We bill the customer directly for the deposit using our normal deposit SA.
- Assume We Bill For Them (Bill or Rate Ready). In this situation, we could hold a normal deposit SA for the customer's master SA. For sub SAs, we have two scenarios:
 - **We pay at billing time.** Since we purchase the receivable, we would want to increase our normal deposit to cover the Sub SA. To do this, the sub SA's SA type's deposit class should be the same as our master SA's deposit class.
 - **We pay at payment time.** It seems unlikely that we would want to hold a deposit on behalf of a service provider when we don't purchase the receivable. However, it is possible to do so by putting the sub SA into its own deposit class. If you did this, the system will require a separate deposit SA for the service provider's deposit. The system would calculate and refund such deposits using the algorithms defined on the new deposit SA's SA type's deposit class. It's important to be aware that the deposit is not held with respect to the specific service provider. Rather, it is just held in the system as separate deposit that could be used for any service agreement that belongs to its deposit class.

Credit and Collection Issues

Warning:

This section uses terminology and concepts described in [The Big Picture Of Credit & Collections \(C&C\)](#).

C&C is only tricky if you deal with We Bill For Them service providers. We'll run through the service provider billing relationships to explain why:

- If we have a Dual relationship with a service provider, we don't have their debt, so we only have a responsibility to tell them when we cut a customer (via a Notification). We don't have to worry about collecting their debt.
- If we have a They Bill For Us relationship with a service provider, there is no debt on the customer's SA because it gets transferred to the service provider (and the service provider's SA will fall into arrears if they don't pay us).

- If we have a We Bill For Them or It's Us relationship with a service provider, the customer's debt associated with the service provider's service is maintained on a sub SA (i.e., it is segregated from our debt). This segregation of debt is both a powerful feature and a cause of administrative difficulties. The topics in this section provide more information about this issues.

Debt Class Recommendations

A service agreement's debt class is an important element in determining how a customer's debt is collected. In general, we recommend the following:

- If the service provider has a billing relationship of It's Us, we recommend the sub SAs belong to the same debt class as the "master". Why? Because both SAs' overdue debt should probably be grouped together under a single collection process.
- If you buy the receivable from the service provider (i.e., the service provider has a payment relationship of Pay at Billing Time), we recommend the sub SAs belong to the same debt class as the "master". Why? Because both SAs' overdue debt should probably be grouped together under a single collection process.
- If you don't buy the receivable from the service provider (i.e., the service provider has a payment relationship of Pay at Pay Time), you may want to use a different debt class on the sub SA. Why? Because you may collect the service provider's debt differently.

Note:

Bottom line. If both the "master" and the sub SAs fall into arrears, you will have 1 or 2 collection processes, it all depends on the debt class assigned to each SA type.

Fastpath:

Refer to [Automating Your C&C Activities](#) for information describing how debt class plays a part in this processing.

Severing Service

Sub SAs and severance is tricky. Why?

- Because it's possible for the master SA to be in arrears when the sub SA isn't (for all the standard reasons - directed payments, cancel / rebills, etc.).
- Because it's possible for the sub SA to be on one collection process and the master to be on another (due to different debt classes or different time lines).

Both of these situations could result in severance starting for only one of the service agreements in the master / sub relationship. However, YOU CAN'T CUT SERVICE FOR ONE WITHOUT CUTTING THE OTHER because there is only one service point.

Before we describe how to deal with this conundrum, we'd like to remind you that the system starts a unique severance process for each SA (sub or normal) to be severed. It only creates a severance process for those service agreements linked to a collection process when the collection process' Start Severance event is activated. The type of severance process that is created is controlled by each service agreement's SA Type's severance criteria. Please keep in mind the following when designing these severance processes:

- **Only The "Master" Service Agreement Is Linked To Service Points.** This means only master SAs should have a "cut for non payment" severance event. Note: typically, such a severance process will expire the "master SA" several days after the cut event if funds are NOT received.
- As described under [Sub SA State Transition](#), a sub SA becomes Pending Stop (and eventually Stopped) when its "master" is stopped. This means the sub SAs will be finaled when the master is finaled.
- If you start severance on a sub SA when the master isn't being severed, you have a problem because you can't cut the sub SA independent from the master SA.

We'll use an example to illustrate how you should design your severance processes to deal with the above challenge. Assume you have a master and a sub SA where both are being managed under the same collection process. Also

assume that the Start Severance event kicks off on 18-Dec-1999. In this situation, we'd recommend the following severance processes to be kicked off.

| Master SA Severance Process | | |
|-----------------------------|-----------------|---------|
| Trigger Dt. | Event Type | Status |
| 18-Dec-99 | Set door hanger | Pending |
| Pending | Cutfor non pay | Pending |
| Pending | Expire SA | Pending |

| Sub SA Severance Process | | |
|--------------------------|--------------------|---------|
| Trigger Dt. | Event Type | Status |
| 3-Jan-00 | Create To Do Entry | Pending |

Notice that the sub SA's severance process contains a single event that generates a To Do Entry on a date in the future of the Expire SA event on the Master SA. This entry should be something like "sub being severed independent of its master". This event will only be triggered if the master SA is paid off and the sub SA isn't. Why? Because if the master SA's Expire SA event is executed, the Sub SA will be Stopped and stopping a SA cancels outstanding severance processes. If the sub gets paid, the system will cancel the sub's severance process.

Let's change the example and assume that the master starts severance and the sub doesn't. In this situation, the master SA will eventually hit the Expire SA event and the sub SA will also stop. There's no alternative.

And let's change the example again and assume the sub starts severance and the master doesn't. In this situation, the To Do Entry will only be created X days after the start of severance. If you can't stand this date being X days in the future of the creation of the severance process, create an "Severance Criteria Algorithm" that checks if the master is not being severed or collected and generates a different severance process (with a different start date). Refer to [Designing Your Severance Procedures](#) for more information about Severance Criteria Algorithms.

An Object-Oriented Perspective Of Service Providers

Warning:

Skip this section if you are not technically inclined.

The following object diagram illustrates in a concise format the various types of service providers and the plug in algorithms and processes available for each.

How Do You Communicate With Service Providers?

You communicate with service providers (and they communicate with you) using the following mechanisms:

- You can use traditional interface techniques. For example, if you send consumption to service providers every month (so they can compute their charges), you could use the Consumption Download interface.
- You can use "notifications" to communicate with service providers. Notifications are electronic transactions that service providers exchange to communicate information about a customer. For example, you could use a notification to send a message to an energy supplier when a customer stops service. Note: the term "Direct Access Service Request" (DASR) is synonymous with Notification.

The difference between notifications and traditional interfaces is subtle. Think of notifications as a generic interface that can be used to communicate many different things (e.g., you can use notifications to advise stops, meter exchanges, supplier switches). Traditional interfaces communicate only one thing (and you need one traditional interface for each "thing"). For example, one interface is devoted to downloading consumption, another is responsible for uploading pass through charges, etc.

Fastpath:

Refer to [The Big Picture Of Notification Processing](#) for more information about notification.

Off Cycle Switch

If the customer care and billing application integrates with meter data management (mdm) system, it may be set up to generate sub-bill segments for each and every service provider having **We Bill for Them - Rate Ready** or **It's Us** billing relationship, that is effective in the billing period. This requires that the meter data management system can calculate the consumption for each effective SA relationship period.

If the switch is from or to a service provider having **They Bill for Us** billing relationship, separate bills have to be generated manually for each relationship effective in the billing period. This restriction is due to requirement for CCB application to generate a bill for a **They Bill for Us** relationship, so that the customer's charges are calculated and eventually transferred to the service provider. The generated bill for **They Bill for Us** billing relationship is not sent to the customer.

Billing Master Configuration

To enable Off Cycle Switch, navigate to **Admin > General > Master Configuration** and add a new entry for Billing Master Configuration.

Specify the values for **Off Cycle Switch Option**, **Implementation Date** and **Off Cycle Switch Option for Old Bill**. Refer to the embedded help on billing master configuration portal for details.

Rate Schedule

Rate schedules assigned to the sub-SA of service provider, having **We Bill for Them - Rate Ready** or **It's Us** billing relationship, must be configured with an SQ rule (for component-based engine) or a pre-processing calculation rule (for rule-based engine) that will obtain the sub-usage's consumption and load it into the bill segment SQ collection during rate application.

For more information, refer to the base package algorithm types provided for this purpose: US (component based engine) and CI-ACRSUBUSG (rule based engine).

Sub-SA Type

When implementing this feature, sub-SA types of service provider having **We Bill for Them - Rate Ready** or **It's Us** billing relationship must be configured as non-bill determinant.

Usage Request

Usage request is sent to the Oracle Utilities Meter Data Management (MDM) system, to obtain the calculated consumption for the billing period - this is used to calculate master bill segment's charges.

In addition, sub-usage request is sent to the mdm system, for each relationship that is effective during the billing period. Calculated consumption on these sub-usage requests is used to calculate sub-bill segment charges.

Sending Consumption to Service Providers

Calculated consumption on these sub-usage requests also serves as the source for consumption download process if consumption is required to be sent to the service provider. A base package algorithm type - C1-STGCNSMP, stages the download by creating an entry in the general process table, capturing the sub-usage id, batch control for consumption download and the batch number.

Note: It is implementation responsibility to build the consumption download batch process that will extract the consumption for sub-usage request as required.

Designing Your SA Relationship Types and Service Providers

As explain in [A Service Agreement Can Have Many Types Of Relationships](#), SA relationship types and service providers are only required when you subcategorize your service agreements.

The topics in this section describe how to design your SA relationship types.

Designing SA Relationship Types

The easiest way to design SA relationship types is to start with the matrix of SA types designed in [SA Types And The Financial Design](#). For each SA type in the matrix, determine if either of the following questions is true:

- Can companies other than your own provide some subcategory of the service (and do you have some type of interaction with these companies)? For example, this would be true if you are an energy supply company because a different company is responsible for distributing the power to the customer (and you probably exchange consumption and financial transactions with this company).
- Does your organization use different rates for subcategories of the service? For example, this would be true if you use separate rates for water and wastewater service (even though both are based on the customer's water consumption).

If either of the above is true, you will need a SA relationship type for each subcategory of service.

We'll use an example to help make the point. Using the SA types we designed earlier (see [SA Types And The Financial Design](#)), we'll assume the following:

- We are designing the system for an electric, gas, water, waste water, and cable utility.
- Residential electric customers have a choice of energy supplier.
- Commercial and industrial electric customers can choose an energy supplier and a meter service provider.
- Commercial and industrial gas customers have a choice of energy supplier.

Note:

We are not showing most of the SA types that we designed earlier because they do not have subcategories of service.

| CIS BU/ SA Type | SA Relationship Type |
|--------------------|----------------------|
| G/COM | Energy supply |
| G/IND | Energy supply |
| E/RES | Energy supply |
| E/COM | Energy supply |
| | Meter service |

E/IND

Energy supply

Meter service

**Note:**

Notice that we did not design a SA relationship type for our own distribution service. This is because our relationship type is implied (e.g., if you are a distribution company, you do not have to set up a SA relationship type for distribution service because the customer's "master" service agreement is implicitly associated with distribution service).

Designing Service Providers

After you design your SA relationship types, you need to list every potential service provider for each SA relationship type.

| CIS BU/ SA Type | SA Relationship Type | Service Provider |
|--------------------|----------------------|------------------|
| G/COM | Energy supply | AmeriGas |
| | | TransGas |
| | | Green Power |
| G/IND | Energy supply | AmeriGas |
| | | TransGas |
| | | Green Power |
| E/RES | Energy supply | Green Power |
| | | Cheap Power |
| | | Us |
| E/COM | Energy supply | ElectriCorp |
| | | Cheap Power |
| | | TeniCorp |
| | Meter service | MeterCorp |
| | | Us |
| E/IND | Energy supply | ElectriCorp |
| | | Cheap Power |
| | | TeniCorp |
| | Meter service | MeterCorp |

| |
|----|
| Us |
|----|

Next, list each unique service provider identified above:

| |
|------------------|
| Service Provider |
|------------------|

| |
|----------|
| AmeriGas |
|----------|

| |
|----------|
| TransGas |
|----------|

| |
|-------------|
| Green Power |
|-------------|

| |
|-------------|
| Cheap Power |
|-------------|

| |
|----|
| Us |
|----|

| |
|-------------|
| ElectriCorp |
|-------------|

| |
|----------|
| TeniCorp |
|----------|

| |
|-----------|
| MeterCorp |
|-----------|

You will have at least one service provider for each entry in the above list. However, you may have to set up more than one service provider in the system for a given company. The topics below explain how this happens.

Billing Relationship Segmentation

As described under [Billing Relationships](#), a service provider may bill for you, you may bill for them, or you may each send a separate bill to the customer. In the table below, we have shown the assumed billing relationships for each service provider.

| Service Provider | Billing Relationship |
|-----------------------|-------------------------------|
| AmeriGas | We Bill For Them - Bill Ready |
| TransGas | We Bill For Them - Bill Ready |
| Green Power | We Bill For Them - Rate Ready |
| Cheap Power - Res | We Bill For Them - Rate Ready |
| Cheap Power - Com/Ind | Dual Billing |
| Us - Billable | It's Us |
| Us - Non billable | None |
| ElectriCorp | They Bill For Us - Bill Ready |
| TeniCorp | We Bill For Them - Bill Ready |
| MeterCorp | Dual Billing |

Notice that we had to introduce additional service providers:

- Cheap Power has two service providers - one for residential customers, the other for commercial/industrial customers. This is necessary because we provide billing service for them for residential customers (We Bill For Them - Rate Ready), but for commercial and industrial customers they bill for themselves (Dual Billing).
- Our own service provider (the service provider known as "Us") has two service providers - one for energy supply because we bill for the energy we supply (It's Us), and another for meter service because we don't create bills for meter service (None).

We Bill For Them - Payment Relationship Segmentation

As described under [Pay At Bill Time vs. Pay At Pay Time](#) when you provide billing service for a service provider you have to define if you pay the service provider when you bill the customer OR only later, when the customer pays you.

In the table below, we have shown the payment relationships for each service provider.

| Service Provider | Billing Relationship | Payment Relationship |
|-----------------------|-------------------------------|----------------------|
| AmeriGas | We Bill For Them - Bill Ready | Pay At Billing Time |
| TransGas | We Bill For Them - Bill Ready | Pay At Billing Time |
| Green Power | We Bill For Them - Rate Ready | Pay At Billing Time |
| Cheap Power - Res | We Bill For Them - Rate Ready | Pay At Billing Time |
| Cheap Power - Com/Ind | Dual Billing | N/A |
| Us - Billable | It's Us | N/A |
| Us - Non billable | None | N/A |
| ElectriCorp | They Bill For Us - Bill Ready | N/A |
| TeniCorp - Com | We Bill For Them - Bill Ready | Pay At Billing Time |
| TeniCorp - Ind | We Bill For Them - Bill Ready | Pay At Pay Time |
| MeterCorp | Dual Billing | N/A |

Notice that we had to introduce an additional service provider for TeniCorp because for commercial customer we purchase the receivable (Pay At Bill Time), but for industrial customers we only pay them when we're paid by the customer (Pay At Pay Time).

Consumption Relationship Segmentation

As described under [Consumption Relationships](#) a service provider may send the customers' consumption to you, you may send consumption to them, or you may have no consumption relationship with a given service provider.

In the table below, we have shown the consumption relationships for each service provider.

| Service Provider | Billing Relationship | Payment Relationship | Consumption Relationship |
|------------------|-------------------------------|----------------------|--------------------------|
| AmeriGas | We Bill For Them - Bill Ready | Pay At Billing Time | We Send Consumption |

| | | | |
|-----------------------|-------------------------------|---------------------|---------------------|
| TransGas | We Bill For Them - Bill Ready | Pay At Billing Time | We Send Consumption |
| Green Power | We Bill For Them - Rate Ready | Pay At Billing Time | N/A |
| Cheap Power - Res | We Bill For Them - Rate Ready | Pay At Billing Time | N/A |
| Cheap Power - Com/Ind | Dual Billing | N/A | N/A |
| Us - Billable | It's Us | N/A | N/A |
| Us - Non billable | None | N/A | N/A |
| ElectriCorp | They Bill For Us - Bill Ready | N/A | N/A |
| TeniCorp - Com | We Bill For Them - Bill Ready | Pay At Billing Time | We Send Consumption |
| TeniCorp - Ind | We Bill For Them - Bill Ready | Pay At Pay Time | We Send Consumption |
| MeterCorp | Dual Billing | N/A | N/A |

Notice that we didn't have to proliferate service providers due to consumption relationships.

Other Segmentations

The earlier parts of this discussion described the most common factors that cause the creation of service providers. However, many obscure factors could cause the introduction of more service providers. In this section we explain these more obscure factors.

Payment Method

As described under [Pay At Bill Time vs. Pay At Pay Time](#), when you provide billing service for a service provider you have to pay the service provider at some point in time. The algorithm that defines the amount to pay (and how the related adjustment is generated) is defined on the service provider record. If a service provider has different payment algorithms for different customer segments, you must split the service provider accordingly.

Transfer Receivable Method

As described under [When They Bill For Us, They Owe Us Money](#), a service provider will owe you money if they provide billing service for you. The algorithm that defines how to transfer the customer's receivable to the service provider is defined on the service provider record. If a service provider has different transfer A/R algorithms for different customer segments, you must split the service provider accordingly.

Billable Charge Download Process

As described under [They Bill For Us - Bill Ready](#), billable charges are interfaced to service providers who provide billing service for you. The background process that performs the interface of billable charges is defined on the

service provider record. If a service provider has different billable charge interfaces for different customer segments, you must split the service provider accordingly.

Consumption Download Process

As described under [We Can Send Billed Consumption To Any Service Provider](#), consumption can be sent to any service provider. The background process that performs the interface of consumption is defined on the service provider record. If a service provider has different consumption interfaces, you must split the service provider accordingly.

Notification Upload Processing

A service provider can send you notifications. Whenever a notification is uploaded, the system creates a workflow process to process each such notification. The type of workflow process that's created is controlled by the service provider's workflow process profile. If a service provider requires a different workflow process for a given type of notification (for whatever reason), you must split the service provider accordingly. For details, see [Designing Notification Upload & Workflow Procedures](#).

Notification Download Processing

The system will send notifications to service providers when something noteworthy happens and when information is needed from a service provider. The type of notification that is sent to a service provider and the background process that interfaces the notification to the service provider is defined on the service provider's notification download profile. If a service provider requires a different type of notification to be sent or they have different interface protocols for a given type of notification, you must split the service provider accordingly. For details, see [Designing Notification Downloads](#).

Financial Settlement Service Agreement

As described under [Service Providers Have Service Agreements Too](#), service providers have service agreements. These service agreements contain how much you owe the service provider (if you bill for them) and how much they owe you (if they bill for you). If you want to have separate service agreements for financial settlements associated with distinct customer segments, you must split the service provider accordingly.

Geographic Area Segmentation

The following table reflects the new service providers that were added since we started [Designing Service Providers](#).

| CIS BU/ SA Type | SA Relationship Type | Service Provider |
|--------------------|----------------------|------------------|
| G/COM | Energy supply | AmeriGas |
| | | TransGas |
| | | Green Power |
| G/IND | Energy supply | AmeriGas |
| | | TransGas |
| | | Green Power |

| | | |
|-------|---------------|-----------------------|
| E/RES | Energy supply | Green Power |
| | | Cheap Power - Res |
| | | Us - Billable |
| E/COM | Energy supply | ElectriCorp |
| | | Cheap Power - Com/Ind |
| | | TeniCorp - Com |
| | Meter service | MeterCorp |
| | | Us - Non billable |
| E/IND | Energy supply | ElectriCorp |
| | | Cheap Power - Com/Ind |
| | | TeniCorp - Ind |
| | Meter service | MeterCorp |
| | | Us - Non billable |

Next, determine the postal code ranges in which a service provider is allowed to provide service.

| CIS BU/ SA Type | SA Relationship Type | Service Provider | Postal Range |
|--------------------|----------------------|-----------------------|---------------|
| G/COM | Energy supply | AmeriGas | 94000 - 95999 |
| | | TransGas | 94000 - 95999 |
| | | Green Power | 94000 - 95999 |
| G/IND | Energy supply | AmeriGas | 94000 - 95999 |
| | | TransGas | 94000 - 95999 |
| | | Green Power | 94000 - 95999 |
| E/RES | Energy supply | Green Power | 94000 - 95999 |
| | | | 93000 - 93999 |
| | | Cheap Power - Res | 94000 - 95999 |
| | | Us - Billable | 94000 - 95999 |
| E/COM | Energy supply | ElectriCorp | 94000 - 95999 |
| | | Cheap Power - Com/Ind | 94000 - 95999 |

| | | | |
|-------|---------------|-----------------------|---------------|
| | | TeniCorp - Com | 94000 - 95999 |
| | Meter service | MeterCorp | 94000 - 95999 |
| | | Us - Non billable | 94000 - 95999 |
| E/IND | Energy supply | ElectriCorp | 94000 - 95999 |
| | | Cheap Power - Com/Ind | 94000 - 95999 |
| | | TeniCorp - Ind | 94000 - 95999 |
| | Meter service | MeterCorp | 94000 - 95999 |
| | | Us - Non billable | 94000 - 95999 |

Next, we need to strip off the SA types because the postal ranges are defined for combinations of service provider and SA relationship type. Notice the problem - we have a service provider - Green Power has different postal ranges for the same SA relationship type. You have two ways to fix this problem, you can split your service provider (have one for the gas and another for the electric), or you can split the SA relationship type (have one for the gas and another for the electric). We've chosen the former in our example.

| SA Relationship Type | Service Provider | Postal Range |
|----------------------|------------------------|---------------|
| Energy supply | AmeriGas | 94000 - 95999 |
| | TransGas | 94000 - 95999 |
| | Green Power - Gas | 94000 - 95999 |
| Energy supply | AmeriGas | 94000 - 95999 |
| | TransGas | 94000 - 95999 |
| | Green Power - Gas | 94000 - 95999 |
| Energy supply | Green Power - Electric | 94000 - 95999 |
| | | 93000 - 93999 |
| | Cheap Power - Res | 94000 - 95999 |
| | Us - Billable | 94000 - 95999 |
| Energy supply | ElectriCorp | 94000 - 95999 |
| | Cheap Power - Com/Ind | 94000 - 95999 |
| | TeniCorp - Com | 94000 - 95999 |
| Meter service | MeterCorp | 94000 - 95999 |
| | Us - Non billable | 94000 - 95999 |
| Energy supply | ElectriCorp | 94000 - 95999 |

| | | |
|---------------|-----------------------|---------------|
| | Cheap Power - Com/Ind | 94000 - 95999 |
| | TeniCorp - Ind | 94000 - 95999 |
| Meter service | MeterCorp | 94000 - 95999 |
| | Us - Non billable | 94000 - 95999 |

In the table below, we have shown the final list of service providers.

| Service Provider | Billing Relationship | Payment Relationship | Consumption Relationship |
|------------------------|-------------------------------|----------------------|--------------------------|
| AmeriGas | We Bill For Them - Bill Ready | Pay At Billing Time | We Send Consumption |
| TransGas | We Bill For Them - Bill Ready | Pay At Billing Time | We Send Consumption |
| Green Power - Electric | We Bill For Them - Rate Ready | Pay At Billing Time | N/A |
| Green Power - Gas | We Bill For Them - Rate Ready | Pay At Billing Time | N/A |
| Cheap Power - Res | We Bill For Them - Rate Ready | Pay At Billing Time | N/A |
| Cheap Power - Com/Ind | Dual Billing | N/A | N/A |
| Us - Billable | It's Us | N/A | N/A |
| Us - Non billable | None | N/A | N/A |
| ElectriCorp | They Bill For Us - Bill Ready | N/A | N/A |
| TeniCorp - Com | We Bill For Them - Bill Ready | Pay At Billing Time | We Send Consumption |
| TeniCorp - Ind | We Bill For Them - Bill Ready | Pay At Pay Time | We Send Consumption |
| MeterCorp | Dual Billing | N/A | N/A |

Designing Your SA Types And Start Options For Sub SAs

When you were [Designing Service Providers](#), you defined the service providers that were valid for every combination of SA type and SA relationship type. If you provide billing services for another service provider or if you subcategorize your own services, you another task - you have to design the SA types for your sub SAs.

As described earlier, there will be a separate [Sub Service Agreement](#) for every SA relationship for which we calculate a bill segment. Every sub SA must reference an SA type. The following table shows sample SA types (notice that they are only used for We Bill For Them and It's Us service providers).

| CIS BU/ SA Type | SA Relationship Type | Service Provider | SA Type(s) for Sub SAs |
|--------------------|----------------------|------------------------|-----------------------------------|
| G/COM | Energy supply | AmeriGas | AG1 |
| | | TransGas | TG1 |
| | | Green Power - Gas | GP-GC1 |
| G/IND | Energy supply | AmeriGas | AG1 |
| | | TransGas | TG1 |
| | | Green Power - Gas | GP-GI1 |
| E/RES | Energy supply | Green Power - Electric | GP-ER1 |
| | | Cheap Power - Res | CP-ER1 |
| | | Us - Billable | US-ER1 |
| E/COM | Energy supply | ElectriCorp | Not applicable - they bill for us |
| | | Cheap Power - Com/Ind | Not applicable - dual billing |
| | | TeniCorp - Com | TC1 |
| | Meter service | MeterCorp | Not applicable - dual billing |
| | | Us - Non billable | Not applicable - no billing |
| | | | |
| E/IND | Energy supply | ElectriCorp | Not applicable - they bill for us |
| | | Cheap Power - Com/Ind | Not applicable - dual billing |
| | | TeniCorp - Ind | TC1 |
| | Meter service | MeterCorp | Not applicable - dual billing |
| | | Us - Non billable | Not applicable - no billing |

The design steps required to set up these SA types are similar to those described under [Designing SA Types For Service Agreements With Service Points](#). The following points provide a few suggestions that will help you design your SA types for sub SAs:

- The business unit should be the same as defined for the master service agreement.
- Service type should be set up as per [Service Segmentation](#).
- Distribution code should be set up as per [Receivable Segmentation](#).
- Obviously, the sub SA switch should be turned on.

- Start options:
 - If the SA type is used for a We Bill For Them - Rate Ready service provider or for yourself, the start options should be Required because rates, contract riders and/or contract values will be populated on the sub SA from a start option. Refer to [Automatic Creation of Sub SAs](#) for more information.
 - If the SA type is used for a We Bill For Them - Bill Ready service provider, the start options should be not allowed because we don't need to default rates, contract riders and/or contract values on billable charge sub SAs.
- The payment distribution and late payment information should be set up as for any SA type. Refer to [Cash Distribution Segmentation](#) and [Late Payment Charge Segmentation](#) for more information.
- If the SA type is used for We Bill For Them - Bill Ready service provider, the special role should be Billable Charge, otherwise it should not be used. Remember, you should not use sub SAs for Cash Deposits.
- Deposit class should be used if the sub SA is covered by a deposit. Refer to [Deposits Issues](#) for more information.
- The one time charge switch should be off.
- Bill segment type:
 - If the SA type is used for a We Bill For Them - Bill Ready service provider, the bill segment type should reference a bill segment creation algorithm that creates bill segments from billable charges (and generates bill segment errors until the last night of the bill cycle). Refer to [The Bill Ready Calculation Method](#) for more information.
 - If the SA type is used for a We Bill For Them - Rate Ready service provider, the bill segment type should reference a get consumption algorithm that gets consumption from the master SA, and a bill segment creation algorithm that applies a rate.
- Specify a characteristic premise is required if the sub SA is associated with premise-oriented service.
- The calendar billing options should not be used.
- The recurring charge information should not be used.
- Sub SAs used for We Bill For Them - Rate Ready service providers should NOT be eligible for budgets and therefore the eligible for budget switch should be off. This admonition is given because budget billing causes current amount due to be out-of-sync with payoff amount due and we don't want this to happen for sub SAs. Why? Because we use the bill segments associated with these sub SAs to determine how much we owe the service provider.
- If the SA type is used for a We Bill For Them - Rate Ready service provider or for your own company, rates need to be set up; otherwise they should not be used.
- Sub SAs never reference service points. Refer to [Only The "Master" Service Agreement Is Linked To Service Points](#) for more information.
- Adjustment types profiles should be set up accordingly.
- Refer to [Credit and Collection Issues](#) for recommendations in respect of the debt class, write off debt class, and severance criteria associated with these SA types.
- Billable charge templates should not be used.
- Completion algorithms cannot be used for sub SAs.
- If the SA type is used for a We Bill For Them service provider, you should link to the SA type the FT freeze algorithm that controls how we pay the service provider. Refer to [Pay At Bill Time vs. Pay At Pay Time](#) for how this algorithm is used.
- The creation of bill segments for the sub SAs occurs after the bill segment for the related master SA is created. If you populate a [billing processing sequence](#) on an SA type for a sub SA, it is used to control the order in which the sub SAs for a given master SA are processed relative to each other.

Refer to [Setting Up SA Types](#) for how to set up these new SA types in the system.

Reference Send Consumption Algorithm On Master SA Types

As explained under [We Can Send Billed Consumption To Any Service Provider](#), when a master SA's bill segment is frozen, the system must check if there are any service providers who need the bill segment's consumption. If so, it sets up the data necessary to interface the master SA's consumption (snapshot on the bill segment) to the service

provider(s). The system will only do this if you specify an appropriate FT Freeze Algorithm on the master SA types. Refer to [SA Type - Algorithm](#) (FT Freeze Algorithm) for more information.

Reference TBFU Algorithm On Master SA Types

As explained under [They Bill For Us](#), when a bill is completed, the system needs to check if there are any service providers who bill for us associated with the bills "master" SAs. If so, it sets up the data necessary to interface the master SA's charges to the service provider and to transfer the receivable balance from the customer to the service provider. The system will only do this if you specify an appropriate FT Completion Algorithm on the master SA types. Refer to [SA Type - Algorithm](#) (Bill Completion Algorithm) for more information.

Note:

If there are multiple master SAs on a bill, the financial transactions associated with each respective master SA could be routed to different service providers (e.g., one service provider could bill for gas and another could bill for electricity). Refer to [Different Service Providers Can Bill Different Services](#) for more information.

Designing SA Types For Service Provider Financial Settlements

As explained in [Service Providers Have Service Agreements Too](#), We Bill For Them and They Bill For Us service providers require a service agreement. You must create SA types for these types of service agreements. The following points provide a few suggestions that will help you design these financial settlement SA types:

- Service type should probably be a non-service oriented service type.
- Distribution code for We Bill For Them settlement SAs should be a payable account (or treat it as a "contra" receivable. Refer to [Receivable Segmentation](#) for more information.
- The sub SA switch should be turned off.
- Start options are not allowed.
- The payment distribution and late payment information should be set up as for any SA type. Refer to [Cash Distribution Segmentation](#) and [Late Payment Charge Segmentation](#) for more information.
- Special role should not be used.
- Deposit class should be used if the settlement service agreement is covered by a deposit. This would probably only be used for They Bill For Us service providers (because they will owe us money).
- The one time charge switch should be off.
- These service agreements are not billable and therefore none of the billing information should be specified.
- The characteristic premise switch should be off.
- Rates should not be used.
- Service points should not be used.
- Adjustment types profiles should be set up accordingly.
- Debt class, write off debt class, and severance criteria should be set up accordingly.
- Billable charge templates should not be used.
- Completion algorithms should not be used.
- Freeze algorithms should not be used.

Refer to [Setting Up SA Types](#) for how to set up these new SA types in the system.

Setting Up SA Relationship Information

In the previous section, [Designing Your SA Relationship Types and Service Providers](#), we presented a case study that illustrated a mythical organization's SA relationship information. In this section we explain how to set up this information.

Setting Up SA Relationship Types

Open **Admin** > **Open Market** > **SA Relationship Type** to define your SA relationship types. Refer to [Designing SA Relationship Types](#) for more information.

Description of Page

Enter an **SA Relationship Type** code, **Description** and **Service Provider Model** for every relationship type.

Specify the **Market Service Provider Service Provider Model** if the SA relationships of the type reference a Service Provider Market Option — i.e. Market, Provider Configuration Option and Market Relationship Service Provider are specified in addition to SA Relationship Type and Service Provider.

Otherwise, specify the **Service Provider Service Provider Model**.

Setting Up Service Providers

This portal is used to maintain Service Providers.

Refer to [The Big Picture of SA Relationships and Service Providers](#) for more information.

You can access the portal from **Admin** > **Open Market** > **Service Provider**. You are brought to a query portal with options for searching for a specific service provider. Once a service provider is selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Service Provider** zone shows the details of the service provider. Refer to the zone's embedded help for more information.

Setting Up SA Types and Start Options For Sub SAs

The SA types and start options described under [Designing Your SA Types And Start Options For Sub SAs](#) must be set up. Refer to [Setting Up SA Types](#) for how to do this.

Setting Up SA Types For Financial Settlements

The SA types described under [Designing SA Types For Service Provider Financial Settlements](#) must be set up. Refer to [Setting Up SA Types](#) for how to do this.

Update Master SA Types With FT Freeze and Bill Completion Algorithms

Refer to [SA Type - Algorithm](#) for more information.

Setting Up SA Relationships For SA Types

This portal is used to maintain SA Type SA Relationship Types.

Refer to [Designing Your SA Relationship Types and Service Providers](#) for more information.

You can access the portal from **Admin** > **Open Market** > **SA Type SA Relationship Type**. You are brought to a query portal with options for searching for a specific SA Type SA Relationship Type. Once a record is selected, you are brought to the maintenance portal to view and maintain the selected record.

The **SA Type SA Relationship Type** zone shows the details of the SA Type SA Relationship Type. Refer to the zone's embedded help for more information.

Setting Up Market SA Relationship Options

The following sections describe how to set up Provider Configuration Options, Market Provider Configuration Options and Service Provider Market Options.

Setting Up Provider Configuration Options

This portal is used to maintain Provider Configuration Options.

You can access the portal from **Admin** > **Open Market** > **Provider Configuration Option**.

The following zones may appear as part of the portal's **Main** page:

- **Provider Configuration Option List** zone lists all Provider Configuration Option records. Broadcast a record to display the details of the selected record.
- **Provider Configuration Option** zone provides information about the selected Provider Configuration Option.
- **Market Provider Configuration Options** zone lists the existing Market Provider Configurations for the selected Provider Configuration Option. Maintenance actions are available on this zone.

Setting Up Market Provider Configuration Options

This portal is used to maintain Market Provider Configuration Options.

You can access the portal from **Admin > Open Market > Market Provider Configuration Option**. You are brought to a query portal with options for searching for a specific Market Provider Configuration Option. Once a record is selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** page:

- **Market Provider Configuration Option** zone shows the details of the Market Provider Configuration Option.
- **Service Provider Market Options** zone shows the service providers with their start dates, end dates (if applicable) and statuses. Maintenance actions are provided. A broadcast icon appears if the Service Provider Market Option has sub-SA(s) and/or entries in the Status History log. Clicking on the broadcast icon displays the following zones:
 - **Service Agreements** zone shows the Service Provider Market Option's sub-SAs.
 - **Status History** zone shows the history of changes to the Service Provider Market Option, which can include changes to Start Date, End Date and/or Status.

Negotiated Terms

The topics in this section describe the use of SA relationship functionality for applying certain types of negotiated terms. It assumes that you are familiar with SA relationship functionality in general.

Note:

Negotiated terms are optional. The functionality described in this section is only relevant if your organization offers this functionality.

Umbrella agreements. If the Contract Management module is not [turned off](#), you may also choose to use umbrella agreements to manage the functionality described here.

Imagine that the head office for a multi-site organization negotiates special terms that cover a number of its sites, each of whom have their own account and service agreement. The negotiated terms typically involve discounts. These discounts may be realized

- Under a single service agreement, separate and distinct from the service agreements that are covered, or
- Individually, for each covered service agreement. In this case, two sub-scenarios exist:
 - The discounts may be reflected on the bill segment of each service agreement, or
 - The discounts may be transferred to another service agreement (the group's service agreement). The discount does NOT appear on the individual bill segment for the service agreements that are covered by the negotiated terms.

SA relationships track and manage complex business relationships between a customer and a service provider. You can define the above relationships using service agreement relationship functionality. This is a special type of SA relationship in which the head office is the service provider.

Examples Of Special Discounts

The following topics illustrate examples of how your organization may configure the system to handle this business functionality.

Example Using Aggregated Consumption

A customer, Fresh Foods has 10 stores each with its own account and electric service agreement, i.e., each store is billed separately. Fresh Food's head office decides to negotiate a group discount that applies to one or more of the individual stores.

In the following diagram, one store's account is shown.

Example Using Aggregated Consumption

Note the following:

- An SA relationship is created for the energy SA covered by the negotiated terms.
- The service provider in the relationship is the head office.
- This relationship does not have a sub-SA because no additional billing services are provided for each individual covered service agreement.
- Discounts are calculated using the head office discount service agreement and affect only this service agreement and therefore only the head office's account.
- The master SA may have other deregulated relationships, such as the distribution relationship shown.

Note:

Aggregated consumption algorithm. In this scenario, the service provider's service agreement amalgamates the group's consumption and applies a rate to calculate the discount. This algorithm is not provided - you get to write this algorithm to meet your needs.

Example Using Site-by-site Discount

In this scenario, the discount is calculated on a site-by-site basis.

Example Using Site By Site Discount

Note the following differences between this example and the one where consumption is aggregated:

- Each service agreement participating in the discount has an SA relationship with a sub SA.
- Discounts are calculated on a site-by-site basis by the sub SA for each service agreement covered by the discount agreement.
- The discounts may be transferred to the head office service agreement using transfer adjustments. In this case, you may choose to not show the discount on the individual site's bills.

Setting Up The System To Enable Negotiated Terms

The above topics provided background information about how special negotiated terms could be supported in the system. The following discussion summarizes the various setup tasks alluded to above. These notes highlight the setup required in addition to that detailed in [Setting Up SA Relationships Information](#).

Algorithm

If you use sub SAs to calculate charges / discounts for each covered service agreement individually and you want to transfer the charges / discounts to the service provider's service agreement at bill completion, you will need to set up a bill completion algorithm to do this.

Refer to the algorithm type BCMP-TR for more information.

SA Relationship Type

You will need an SA relationship type that will be used for each type of negotiated term or discount.

Service Provider

Set up a service provider using the principal party of the negotiated discount. For example, if a head office negotiates a special agreement for its sites, you should set up a new service provider representing the head office.

- **Billing Relationship** will depend on the type of negotiated terms you choose to set up. For terms where debits / credits are calculated for each covered service agreement individually, select We Bill For Them, Rate Ready. We are effectively billing on behalf of the principal party. For terms where the discount is calculated on an

amalgamated SA there is no billing relationship because no additional billing services are provided for each covered service agreement.

- Select a **Payment Relationship** of Pay SPR Not Applicable if debits / credits to the sub-SA should not be transferred to the service provider. If you want to transfer charges at bill completion time using a bill completion algorithm, you should also select Pay SPR Not Applicable because you will not be creating adjustments to pay the principal party service at payment time or at billing time.
- Enter a **Transfer A/R Algorithm** to transfer the debit / credit from the sub-SA to the principal party's service agreement. If you do not want to transfer the debit / credit to the principal party's service agreement, you do not need to specify a transfer algorithm.

SA Type SA Relationship Type

Associate the SA relationship type setup for negotiated terms with the SA type(s) of the service agreements that are covered by the terms. The following are suggested values for the SA type SA relationship type:

- **Required.** Relationships of this type should not be required for the SA type because the negotiated terms will only cover selected service agreements with that SA type.
- **Gaps in SA Relationship** are Allowed if service agreements of this type do not have to have an SA relationship of this type with a service provider throughout the effective period of the SA.
- Add the service provider set up above to the list of valid service providers for this SA type and SA relationship type combination.

SA Type

Set up an SA type for the sub SAs that will be used to calculate discounts. This SA type should use the BCMP-TR bill completion algorithm if you want to transfer the discounts to the head office.

Note:

TBFU Deregulated Relationship with WBFT Negotiated Terms Relationship. If you have the unusual situation where a master service agreement has a relationship with a TBFU service provider as well as a negotiated term "relationship" with a WBFT service provider, and you transfer charges / discounts from the discount agreement sub SA to the WBFT service provider, you will not be able to use the algorithms provided to transfer receivables to the service providers. This is because bill completion algorithms associated with the SA type of a master service agreement are executed before any bill completion algorithms associated with the SA types of sub service agreements. Consequently the TBFU XFER algorithm associated with the master service agreement will transfer all receivables from related sub SAs to the TBFU service provider before the BCMP-TR algorithm can transfer the discount agreement receivables. You will need to modify the TBFU XFER bill completion algorithm that transfers receivables from the customer to the TBFU service provider to exclude the discount agreement receivables.

Defining Service Credit Options

Some companies allow their customers to participate in a special rewards program. The term "service credits" is used to describe a program that rewards customers for their business. The topics in this section provide details to help you set up the control tables required to support any service credit program that your company supports.

Note:

Penalty Points. The service credits functionality is described in the documentation with the assumption that it is used for accumulating points to reward your customers. However, if your company has a business need to record penalty points for a customer, the service credits functionality may be used for that purpose as well.

The Big Picture Of Service Credits

The topics in this section provide background information about service credit functionality.

Service Credit Membership

Let's look at some examples of special programs that may use service credits functionality:

- Capital credits - When customers receive their utility service from a cooperative, they are considered "members" of the cooperative and may over time receive capital credit allocations from the cooperative based on their service history and the cooperative's profits allocated during that time period.
- Frequent flier miles - Perhaps your company has made an agreement with one or more airlines to allow customers to accumulate frequent flier miles for every x amount spent on service.
- Free pay-per-view movies - Maybe your cable service offers free pay-per-view movies under certain conditions. Using service credits, you can set up your system to accumulate the free pay-per-view movies and use the free movies to offset actual movies viewed by the customer.
- Any other type of loyalty program where the customer earns credits that may later be redeemed in some way.

To participate in a program such as those described above, the customer is linked to a service credit membership. The membership record provides the following functionality:

- It defines the accounts that are linked to the membership.

Fastpath:

Refer to [Who are the Members?](#) for information about linking persons and accounts to a membership.

- It defines a [membership type](#), which controls certain behavior about the membership.
- It may define an external ID if the membership is associated with an external program, such as a frequent flier mile program.
- It may define a [service agreement](#) to use for miscellaneous financial transactions that may get created.
- It may define characteristics used to capture miscellaneous information about the membership.
- Over time, service credit events are created for a membership. The events indicate an amount that either adds or subtracts credit units (i.e., points, miles, movies, dollars, etc) for the membership.

Fastpath:

Refer to [The Big Picture of Service Credit Membership](#) for more information about functionality related to a membership.

How Are Service Credits Earned?

Service credits may be monetary rewards for service or they may be non-monetary rewards such as free movies or frequent flier miles. In any case, how the membership earns the points or rewards depends on the business rules for the program you are offering.

A typical scenario is that the service credits are earned for a membership as a result of other services linked to the membership's accounts. For example:

- Perhaps free pay-per-view movies are earned when signing up for cable service. In this case, the pay-per-view movie membership is related to the membership account's cable service agreement. Refer to [Service Credits Earned When Starting Service](#) for more information.
- Perhaps one frequent flier mile is earned for every \$10 spent on electricity. In this case, the frequent flier membership is related to the membership account's electricity service agreements (for example, electricity distribution, electricity retail and lamp service). Refer to [service credits earned through billing](#) for more information.
- For a capital credits membership, capital credit allocations are calculated based on the amount spent by the customer for standard service, for example electricity and/or gas service. In this case, the capital credit membership is related to the membership account's electricity and/or gas service agreements. For capital credits, a background process is used to calculate the allocated amounts. Refer to [Allocating Capital Credit](#) for more information.

It is also possible to earn service credits irrespective of other service for the membership's accounts. (Again, it depends on the business rules for the program you are offering.) For example, perhaps you offer 500 frequent flier miles for signing up for service with your company, regardless of the type of service chosen. In addition, assume that no additional miles are earned for ongoing service. In this example, there is no need to link the membership to any service agreements.

Fastpath:

Refer to [Service Agreements Contribute to a Membership](#) for more information.

Each earned service credit amount is linked to the membership via a [service credit event](#).

How Are Service Credits Redeemed?

Once service credits have been earned for a membership, how may a customer redeem these credits? The method by which the credits are redeemed depends on the business rules for the program you are offering. Here are some examples of how a service credit may be redeemed:

- For free pay-per-view movies, perhaps your customer's monthly cable bill is credited for any pay-per-view movies until all free movies are used. Refer to [Service Credits Redeemed Through Billing](#) for more information.
- For frequent flier miles, the information about the earned miles is exported to the appropriate airline. The miles are actually redeemed by the customer through the airline, not through your company. Refer to [Interface Membership Information to a Third Party](#) for more information.
- For a capital credit membership, the company periodically (maybe once a year) decides if credits should be redeemed (referred to as "retired") and if so, how much. The company runs a background process to calculate the "retirement" amount. When an amount is retired, the membership balance is reduced by the retirement amount and the amount is transferred to service agreements related to the membership. Refer to [Capital Credit Retirement](#) for more information.

Note:

Tracking Membership Balances. If service credits are redeemed via the system, your membership should probably be configured to keep track of a balance. Refer to [Event Amounts May Contribute to a Balance](#) for more information.

Each service credit amount redeemed through the system is linked to the membership via a [service credit event](#).

Service Agreements For a Membership

There are three types of service agreements that may be associated with a service credit membership. The following sections describe these types.

SAs Contribute to the Membership

As described in [how are service credits earned](#), many memberships are related to specific service agreements for the membership's accounts. We refer to these service agreements as the SAs that contribute to the membership because often the service credit amounts earned for the membership are based on amounts spent by the customer for these services.

During the lifetime of a membership, service agreements that contribute to a membership may be stopped and other service agreements started. For example, perhaps you have a frequent flier membership that is related to electric service. Imagine that the customer starts out with a certain rate for electric service, but later decides to opt for a different type of rate that requires expiring the old service agreement and creating a new one. How does this affect your frequent flier mile calculation? It depends on how you design the [algorithm](#) that creates the frequent flier events. Essentially, the algorithm must cater for this situation. The following diagram illustrates the scenario.

Service Credit Membership

Membership: 1231231123 – John Smith
 Type: Frequent Flier Miles for Continental
 Effective: 1/1/2000 -

Service Agreements

| SA Type | SA ID | Start Date | End Date |
|---------|------------|------------|-----------|
| E-RES | 5487936555 | 1/1/2000 | 10/1/2000 |
| E-RES | 5487944872 | 10/1/2000 | |

Bill Generated: 09/15/2000 – 10/15/2000
 Bill Segment for 1st SA: 09/15/2000-10/1/2000
 Bill Segment for 2nd SA: 10/1/2000-10/15/2000

When calculating frequent flier miles, the algorithm should include the bill amount for both SAs for the given time period.

The service agreements that contribute to a membership are not linked directly to the membership record. This would cause a maintenance burden, requiring links to be updated when service is stopped or started for applicable service agreements. Rather, this link is indirect. The list of service agreement types is defined for the membership type. The system can determine which service agreements are "linked" to the membership by looking at the SA types for the membership type.

Fastpath:

Refer to [Determine The Types of Service Agreements That Contribute to the Membership](#) for more information on designing your membership type to include appropriate SA types.

SA Used for Miscellaneous Transactions

For some memberships, you may need to define a special service agreement to use for miscellaneous transactions. For example:

If events created for a membership cause an adjustment to be created to affect the general ledger, rather than allowing the system to arbitrarily pick a service agreement to use for this adjustment, the SA to use should be indicated on the membership. Refer to [An Event May Cause Other Actions to Occur](#) for more information.

Membership Fee SAs

For some memberships, a [membership fee](#) may be applicable. A special service agreement is used to hold the fee. This service agreement is not linked directly to the membership, but is simply a service agreement linked to one of the membership's accounts.

Note:

Some fees may be refundable. The refunding of a fee must be handled by an algorithm. Refer to SAST-RF for information about the algorithm type provided with the base product.

Designing Your Service Credit Options

This section helps you to determine how to design your service credit membership types and service credit event types.

Designing Your Membership Types

This section discusses the options to consider when designing your service credit membership types.

First consider the type of unit that your membership's service credit events represent.

- Is it related to a currency? If so, ensure that your currency is correctly defined on the [currency](#) page.
- Is it a non-currency unit, such as movies, points or miles? If so, you need to define the unit on the [credit unit](#) page.

Next, consider other behavior that your membership may exhibit.

- Should your membership [calculate an overall balance](#) ?

- Will miscellaneous financial transactions be created for you membership over its lifetime? If so you may need to link a [service agreement to your membership](#).
- Should events linked to your membership reference a [fiscal year](#) ?

The table below illustrates three types of memberships: one for capital credits, one for frequent flier miles and one for free pay-per-view movies.

| Membership Type | Description | Unit Type / Currency or Credit Unit | Has Balance? | Require SA? | Fiscal Year? |
|-----------------|------------------------------------|-------------------------------------|--------------|-------------|--------------|
| STDCAPCR | Standard capital credit membership | Currency / \$ | Yes | Yes | Yes |
| FFDELTA | Delta frequent flier miles | Credit Unit / Miles | No | No | No |
| FREEPPV | Free pay-per-view movies | Credit Unit / Movies | Yes | No | No |

The following points explain the settings for each membership above:

- The capital credit membership uses a currency of US dollars for its units. Over time, capital credits are allocated and retired. The overall balance of the credits and debits should be calculated and displayed for information purposes. It is common for the allocation and retirement of capital credits to affect the GL, and as a result, a membership SA is required for posting these financial effects. Finally, in a capital credit situation, the allocation is typically related to a specific fiscal year. When calculating and displaying balances, the balance for each fiscal year must also be available. As a result, the fiscal year must be set to required.
- For the frequent flier membership type, a separate membership type must be created for each different airline. This is because a separate membership must exist for each separate airline in order to keep track of the accumulated miles correctly. The membership type does not have a balance because the accumulated miles are interfaced to the airline and the airline keeps track of the balance. In this example, no SA is required because an assumption is being made that the creation of frequent flier miles does not affect the GL. (Accumulating miles is no liability or expense for the company. The miles are simply accumulated on behalf of a third party.) Finally, the frequent flier miles do not need to indicate a fiscal year.
- For the free pay-per-view movies membership, we assume that the credits are redeemed from within the system. For example, perhaps a calculation rule calculation algorithm or pre-processing calculation rule redeems the free pay-per-view movies over time as customers are billed for the movies. As a result, the membership should have a balance. In this example, no SA is required because an assumption is being made that any affect on the GL is posted at the time the free movies are redeemed (i.e., when calculating a bill). (This is just an example. It's possible that you may want to post to the GL when free movies are accumulated to mark a payable for the company.) Finally, free pay-per-view movies do not need to indicate a fiscal year.

More options must be considered for each membership type.

Consider Whether the Membership Should Indicate Subcategories

For some types of memberships, the amount of each service credit event is further grouped by a subcategory. Refer to [Events May Indicate a Subcategory](#) for more information.

Use subcategories if multiple subtypes of credits may be accumulated and redeemed and if balances need to be tracked for each subcategory.

For our sample membership types, only the capital credits type should indicate subcategories.

| Membership Type | Description | Subcategories |
|-----------------|-------------|---------------|
|-----------------|-------------|---------------|

| | | |
|----------|------------------------------------|-----------------------------|
| STDCAPCR | Standard capital credit membership | Distribution Transportation |
| FFDELTA | Delta frequent flier miles | |
| FREEPPV | Free pay-per-view movies | |

Determine the Types of Service Agreements Linked to the Membership

Memberships typically exist to reward customers for participating in standard service with the company. Refer to [How Are Service Credits Earned?](#) for more information. If memberships of this type are related to standard service for your company, determine the SA types for these service agreements.

Note:

Standard Service SA Types. These service agreement types are probably different from the type of service agreement you may link as the membership SA. The membership SA is used for miscellaneous charges like general ledger posting. These SA types are related to electricity service, gas service, etc.

For our three examples, assume that the company provides electric service and cable. The capital credits are related only to electric service, frequent flier miles are accumulated for a combination of services, and free pay-per-view movies are related only to cable service.

| Membership Type | Description | SA Types |
|-----------------|------------------------------------|--|
| STDCAPCR | Standard capital credit membership | E-RES (Electric Residential) AL-RES (Area Lighting) |
| FFDELTA | Delta frequent flier miles | E-RES (Electric Residential) AL-RES (Area Lighting) CABLE -RES (Cable Residential) |
| FREEPPV | Free pay-per-view movies | CABLE-RES (Cable Residential) |

Consider Special Functionality Needed When Adding, Activating or Inactivating a Membership

Should a letter or bill message be generated when a membership is created or activated? Should anything happen when a membership is inactivated? If so, you may need to define one or more algorithms to be plugged in on the membership type.

For our examples, let's say that a bill message is generated when a frequent flier or free pay-per-view membership is created. Let's say that a letter is generated when a capital credits membership is activated. We also assume that when a capital credits membership becomes inactive, any outstanding balance is redeemed. For the frequent flier miles and pay-per-view memberships, we assume nothing special occurs when the membership becomes inactive.

Fastpath:

Refer to [Lifecycle of a Membership](#) for more information about the various status values for a membership.

| Membership Type | Description | Algorithm System Event | Algorithm |
|-----------------|------------------------------------|-------------------------|-----------------------|
| STDCAPCR | Standard capital credit membership | Membership Activation | Send Letter |
| | | Membership Inactivation | Redeem Balances |
| FFDELTA | Delta frequent flier miles | Membership Creation | Generate Bill Message |

FREEPPV

Free pay-per-view movies

Membership Creation

Generate Bill Message

**Note:**

Sample Algorithms. The base package does not provide sample algorithms for all the above examples. Refer to [Service Credit Membership Type - Algorithm](#) for more information about the algorithms provided with the system.

Determine Whether The Membership Requires Additional Information

Is there any information about your membership that you need to capture that is not already provided by the base system logic? If the answer is yes, you may need to define characteristics for your membership. Use the [characteristic collection](#) on the membership type to define the types of characteristics allowed for memberships of this type. You may also define default values for you membership's characteristics.

Designing Your Service Credit Event Types

Now that you have designed your membership types, you need to design the types of service credit events that may be created for your membership.

In many cases, a credit event should cause additional functionality to occur. Algorithms are executed when an event is completed and when an event is canceled and are used to perform additional functionality. The following points illustrate possible algorithms that may be needed when a credit event is completed.

- Validate the event as compared to other events. For example, perhaps a new event should never cause the overall membership balance to fall below zero. You could use an algorithm on the service credit event type to check this condition.
- Create an adjustment that posts to the general ledger. Your credit event may not affect the customer's balance when created, but perhaps it should have an effect on the general ledger. For these types of credit events, you may need to create an adjustment to post to the GL.
- Create adjustments to affect the customer's balance. When "redeeming" a credit, you may need to transfer a monetary amount to one or more of the customer's service agreements.
- Create a bill message. Perhaps when a credit is accumulated, you want to inform the customer via a message on the bill indicating the credit amount. A temporary bill message is added to one of the membership's accounts.

**Note:**

One Account Message of the Same Message Type. The temporary bill message collection on the account allows only one bill message of the same bill message type. If it's possible for multiple types of events to be generated for the same account, consider creating a different bill message type for each event type.

- Stamp a batch code and batch run number onto the event. This would be used when your event information needs to be interfaced to an external system.

The following points illustrate possible algorithms that may be needed when a credit event is canceled.

- Validate the event as compared to other events. For example, perhaps canceling an event should never cause the overall membership balance to fall below zero.
- Cancel adjustments that may have been created when the event was completed.

To illustrate examples of when to use some of the algorithms above, we'll design event types for the membership types designed above.

Designing Capital Credit Event Types

The following event types illustrate typical events for a capital credits membership.

| SC Event Type | Description | Membership Type | Algorithm System Event | Algorithm |
|---------------|---|-----------------|------------------------|---|
| ALLOCATECCR | Capital credit allocation | STDCAPCR | Event Creation | Create Simple Adjustment |
| | | | Event Creation | Generate Bill Message |
| | | | Event Cancellation | Validate Balance Not < Zero |
| | | | Event Cancellation | Cancel Related Adjustments |
| RETIRECCR | Retire capital credit (apply to customer's balance) | STDCAPCR | Event Creation | Validate Balance Not < Zero |
| | | | Event Creation | Create Adjustments to Affect Customer's Balance |
| | | | Event Cancellation | Cancel Related Adjustments |
| FORFEITCCR | Forfeit capital credit (retirement not applied to customer's balance) | STDCAPCR | Event Creation | Validate Balance Not < Zero |
| | | | Event Creation | Create Simple Adjustment (affect GL only) |
| | | | Event Cancellation | Validate Balance Not < Zero |
| | | | Event Cancellation | Cancel Related Adjustments |

These event types assume the following:

- When credit events are allocated, the customer is notified via a bill message, the general ledger is affected so a simple GL only adjustment is created. If an event of this type is canceled, any adjustments that were created should be canceled. The event amount should always be positive, so checking that the membership balance does not fall below zero is only checked for event cancellation.
- When capital credits are retired, it's possible that the full membership balance is not applied to the customer's balance. For the portion of the retirement that does affect the customer's balance, you need an algorithm that applies the credits to the customer's service agreements via adjustments. Cancellation of this event should cause any related adjustments to be canceled. It's assumed that the amount of this event is a credit so checking that the membership balance does not fall below zero is only checked for event completion.
- For the portion of the retirement that is not applied to the customer's balance, the event amount should simply affect the GL so a GL only adjustment is created. Cancellation of this event should cause any related adjustments to be canceled. It's assumed that the amount of this event is a credit so checking that the membership balance does not fall below zero is only checked for event completion.

Note:

Service credit event types are independent of subcategories. A capital credits membership typically uses subcategories. When events are created for different subcategories, the same service credit event type may be used. As a result, all subcategories use the same event completion and event cancellation algorithms.

Designing Frequent Flier Event Types

The following event types illustrate typical events for a frequent flier membership:

| SC Event Type | Description | Membership Type | Algorithm System Event | Algorithm |
|---------------|-----------------------------|-----------------|------------------------|----------------------------|
| ADDMILES | Add miles to the membership | FFDELTA | Event Creation | Generate Bill Message |
| | | | Event Creation | Populate Batch Information |
| | | | Event Cancellation | Event may not be canceled. |

This event type assume the following:

- A new event should generate a bill message.
- Information about the event amount should be interfaced to an external system so batch information should be populated when the event is completed.
- Events of this type may not be canceled because the information is interfaced to an external system. Rather, to reverse an event, simply create a new event whose amount is a credit. This credit amount is also interfaced to an external system.

Note:

Sample Algorithm. The system does not provide a sample cancellation algorithm that prevents the event from being canceled.

- There is no validation to ensure that the balance does not fall below zero. Recall that this membership was defined as not requiring a balance.

Notice that only one type of event has been defined for this membership. That is because the credits for this membership are not redeemed via this system. Rather they are accumulated on behalf of an external system.

Designing Pay-per-view Event Types

The following event types illustrate typical events for a free pay-per-view movies membership:

| SC Event Type | Description | Membership Type | Algorithm System Event | Algorithm |
|---------------|----------------------------|-----------------|------------------------|-----------------------------|
| ADDPV | Free pay-per-view movies | FREEPPV | Event Creation | Generate Bill Message |
| | | | Event Cancellation | Validate Balance Not < Zero |
| REDEEMPPV | Redeem pay-per-view movies | FREEPPV | Event Creation | Validate Balance Not < Zero |

Event Creation

Generate Bill
Message

These event types assume the following:

- Any type of new event should generate a bill message.
- For adding free movies, it is assumed that the quantity is positive so when the event is cancelled, the algorithm verifies that the balance does not become negative.
- For redeeming free movies, it is assumed that the quantity is negative so when the event is completed, the algorithm verifies that the balance does not become negative.
- These events do not affect the general ledger and they do not directly affect the customer's balance so no adjustment algorithm is needed.

How Are Service Credit Events Created?

Now that you have designed the behavior of your service credit events, an important issue is to determine how these events are created. Consider your business practice for each type of membership.

Let's use our sample memberships to work through different ways that you may create service credits.

Service Credits for Capital Credit Memberships

For a capital credit membership, capital credit allocations are calculated once a year based on billing history and the cost of service. To accomplish this, a background process calculates the amount and creates the service credits. Refer to [allocating capital credits](#) for a sample process provided with the base package.

Credits are redeemed via the retirement process. The company determines when to retire capital credits based on analysis of their financial situation. This retirement process is also handled by a background process. Refer to [capital credit retirement](#) for a process provided with the base package.

For capital credits memberships, special functionality is required when a member dies. The capital credits are considered part of the person's estate and may need to be retired and applied to a beneficiary's account. This process depends on the company's business practice. However, typically, the membership status would change to inactive so that new capital credit allocations are not created for the membership. The system provides a sample inactivation algorithm called SCMI-RB that transfers part or all of the outstanding credit balance to the member's service agreements. From there, a user can cut a check to the beneficiary.

Note:

Some Credits Are Never Retired. For many cooperatives, some types of allocated credits are never retired. Refer to [Partial Retirement](#) for more information.

Service Credits for Frequent Flier Memberships

In our example, frequent flier miles were related to both the electricity and phone service. Let's assume that frequent flier miles are accumulated every \$x spent on electricity and phone service. In this example, a bill completion algorithm creates service credits based on the bill segment amounts for these service agreements. Refer to [Service Credits Earned Through Billing](#) for more information.

As mentioned before, the frequent flier miles are not redeemed using this system, but are interfaced to a third party for redemption.

Service Credits for Free Movies Memberships

Note:

Sample Algorithms. No base package algorithm types are provided to support the logic described in this example.

In this scenario, let's suppose that a customer receives three free pay-per-view movies when signing up for new service. To handle this, perhaps an SA creation algorithm creates the membership and the service credits when the service is started. Or perhaps you want to wait until the first bill is generated and a bill completion algorithm is used to generate the first credit. It depends on your business practice.

For redeeming the free pay-per-view movies, it is assumed that the movies are credited during billing after it is determined that the customer has been billed for a movie. The number of movies used for the membership is reduced until all the free movies are used.

Fastpath:

Refer to [Service Credits Redeemed Through Billing](#) for more information.

Setting Up Service Credit Options

Setting Up Credit Units

Credit unit is used for service credit membership types whose [events](#) record non-monetary units. Open **Admin > Service Credit > Credit Unit** to set up credit units.

Description of Page

The following fields display for each credit unit:

Credit Unit The unique identifier of the credit unit.

Description The description of the unit. This also acts as a label for the unit when displaying information about a service credit event.

Symbol / Label Position Indicates whether or not the label for this credit unit appears as a Prefix or as a Suffix to the service credit event amount.

Decimal Positions Indicates the number of decimal positions used for this credit unit. This information should be used by any algorithm or background process that creates a service credit event to determine how to store the event amount. It is also use to correctly display the service credit amounts.

Setting Up SC Membership Inactive Reasons

The service credit membership inactive reason must be specified when the status of a service credit membership changes to inactive. Open **Admin > Service Credit > Service Credit Membership Inactive Reason** to set up service credit inactive reasons.

Description of Page

The following fields display for each inactive reason:

Inactive Reason The unique identifier of the service credit membership inactive reason.

Description The description of the inactive reason.

Setting Up Service Credit Membership Types

SC Membership Type - Main

Service credit memberships have a membership type. Open **Admin > Service Credit > Service Credit Membership Type > Add** to define the membership type.

Description of Page

Enter a unique **Service Credit Membership Type** and **Description** for each membership type.

Use the **SA Requirement** flag to indicate whether a [miscellaneous SA](#) must be linked to memberships of this type. The possible values are SA Required and SA Not Allowed .

Note:

The value defaults to SA Required.

Use the **Fiscal Year Requirement** flag to indicate whether events linked to memberships of this type should indicate a [fiscal year](#). The possible values are Fiscal Year Required and Fiscal Year Not Allowed.

Note:

Default Note. The value defaults to Fiscal Year Not Allowed.

Use the **SCM Event Balance** flag to indicate whether or not a [balance of service credit events](#) linked to memberships of this type should be calculated and displayed. The possible values are Has a Balance and No Balance.

Note:

Default Note. The value defaults to Has a Balance.

Use the **SC Membership Type Unit** flag to indicate whether or not the unit for the event amounts for events linked to memberships of this type is Currency or Credit Unit. When the unit is currency, indicate the **Currency Code**. When the unit is credit unit, indicate the **Credit Unit**.

If events linked to memberships of this type must indicate a subcategory, enter a valid **Subcategory Name** and **Description** for each subcategory applicable to this membership.

Fastpath:

Refer to [Events May Indicate a Subcategory](#) for more information.

Use the **SA Types** grid to indicate the types of [service agreements that contribute to memberships](#) of this type. Indicate the **CIS Division** and **SA Type** for each type of service agreement that is related to a membership of this type.

SC Membership Type - Algorithm

Open **Admin > Service Credit > Service Credit Membership Type > Search** and navigate to the **Algorithm** page to define any algorithms that are associated with a membership type.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** for which you can define algorithms.

| System Event | Optional / Required | Description |
|---------------------|---------------------|--|
| Membership Creation | Optional | Use this system event for algorithms that are executed when a membership is created. |

| | | |
|-------------------------|----------|--|
| Membership Activation | Optional | Use this system event for algorithms that are executed when a membership becomes active. |
| | |  <p>Note:</p> <p>Creating Memberships In Active Status. A membership may be created in either pending status or in active status, based on your business practice. For memberships created in active status, the system executes the membership creation algorithms and the membership activation algorithms.</p> |
| Membership Inactivation | Optional | Use a system event of Membership Inactivation for algorithms that are executed when a membership becomes inactive . |

SC Membership Type - Characteristics

To define characteristics that can be defined for service credit memberships of a given type, open **Admin > Service Credit > Service Credit Membership Type > Search** and navigate to the **Characteristics** page.

Description of Page

Use the characteristics collection to define characteristics that can be defined for service credit memberships of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on service credit memberships of a given type. Turn on the **Default** switch to default the **Characteristic Type** when service credit memberships of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Setting Up Service Credit Event Types

Service credit events created for a service credit membership have an event type. Open **Admin > Service Credit Event Type > Add** to set up service credit event types.

Description of Page

Enter a unique **Service Credit Event Type** and **Description** for each event type.

Indicate the **Service Credit Membership Type** to which this event type belongs.

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** for which you can define algorithms.

| System Event | Optional / Required | Description |
|--------------------|---------------------|--|
| Event Completion | Optional | Use a system event of Event Completion for algorithms that are executed when an event is completed. Refer to An Event May Cause Other Actions to Occur for more information. |
| Event Cancellation | Optional | Use this system event for algorithms that are executed when an event is canceled. |

Service Credit Examples

In this section, we provide examples of how to define your control tables to support functionality related to different types of service credit memberships. While your company may not define your environment exactly the same way, this section should help solidify your understanding of how to set up your company's service credit options.

Defining Control Tables for a Refundable Fee

If your membership requires payment of a [fee](#) that is refundable, you must define an SA type to use for the refundable fee.

Adjustment Type for Refundable Fee

This example assumes that the fee is set up similarly to a deposit. The adjustment used to charge the fee would affect the current balance, but not the payoff balance or the general ledger because the fee is not considered a "receivable", rather it is an amount collected and held for the customer.

Create an [adjustment type](#) for levying the fee. Indicate the fee amount and indicate the ADJT-CA adjustment FT creation algorithm, which affects the current balance, but not the payoff balance or the general ledger.

Note:

Adjustment Type Profiles. Be sure to add this adjustment type to an appropriate adjustment type profile and ensure this profile is linked to your SA type.

SA Type for Refundable Fee

Create an SA type to use for the fee. This SA type should be marked as not billable.

Indicate the appropriate adjustment type profile that includes the adjustment type to levy the fee.

Indicate an appropriate payment segment type that references the PSEG-NM payment segment FT algorithm. This algorithm affects the payoff amount and current amount by the payment amount, which should cause the current amount to become zero and the payoff amount to become a credit for the fee amount when the fee is paid.

Start Option for Refundable Fee

For this SA type, define a start option that causes an adjustment to be levied as part of the start service process.

Fastpath:

Refer to [Including The Membership Fee](#) on campaigns and packages for more information about levying the fee via the order transaction.

Algorithm for Refunding the Fee

The base product provides an algorithm type SAST-RF that refunds a fee when [service agreements that contribute to the membership](#) are stopped. You must create an algorithm for this algorithm type and enter the SA type created above as an input parameter.

This SA stop algorithm must be plugged in on all SA types that you defined for the [membership type](#).

Defining Control Tables for a Nonrefundable Fee

If your membership requires payment of a [fee](#) that is not refundable, you can set this up in two ways:

- You can create a special SA type to handle charging the fee. For this SA type, define a start option that causes an adjustment to be levied as part of the start service process. This adjustment contains your fee. You may use this option if the membership is related to multiple types of services and not all services need to be present in order to create the membership.
- You can levy an adjustment on one of the other service agreements that is being started. To do this, you would use a start option to define an adjustment to be levied as part of the start service process. You may use this option if the membership is related to a single service (for example, free pay-per-view movies).

For our example, we will set up the SA for the nonrefundable fee with a separate 'fee' SA type.

Adjustment Type for Nonrefundable Fee

Create an [adjustment type](#) for levying the fee. Indicate the fee amount and indicate the ADJT-NM adjustment FT creation algorithm, which affects the current balance and payoff balance by the adjustment amount, and affects the general ledger.

Note:

Adjustment Type Profiles. Be sure to add this adjustment type to an appropriate adjustment type profile and ensure this profile is linked to your SA type.

SA Type for Nonrefundable Fee

Create an SA type to use for the fee. This SA type should be marked as not billable.

Indicate the appropriate adjustment type profile that includes the adjustment type to levy the fee.

Indicate an appropriate payment segment type that references the PSEG-NM payment segment FT algorithm. This algorithm affects the payoff amount and current amount by the payment amount, which causes the current amount to become zero and the payoff amount to become a credit for the fee amount when the fee is paid.

Start Option for Nonrefundable Fee

For this SA type, define a start option that causes an adjustment to be levied as part of the start service process.

Fastpath:

Refer to [Including The Membership Fee](#) on campaigns and packages for more information about levying the fee via the order transaction.

Defining an SA Type for Miscellaneous Transactions

Does your membership require a [service agreement](#) to support miscellaneous transactions? If so, you need to consider the SA type to use for this service agreement. This SA type should be marked as not billable.

If you choose to use the order transaction to set up the membership, this SA type must be defined on the [algorithm that creates the membership](#).

It is possible that you may require a start option for this SA type, for example if you want to define a characteristic for service agreements of this type.

Using Campaigns/Packages to Set Up Membership

If enrollment in a membership is a common occurrence for your customers when starting service, you should consider using the [order](#) page to start service for the customer and to create the membership as well.

Note:

This section only makes sense if you are familiar with the [Sales and Marketing](#) chapter.

The recommendation is to use a question/miscellaneous field to ask the customer service representative to indicate the appropriate membership type. Algorithms validate this membership type and use it to create a membership of that type.

This section walks you through how to set up the campaign / package required to support this.

Column Reference for Membership Type

In order to ask the customer service representative to define an appropriate service credit membership type, you must define a column reference for the membership type.

Add a new column reference with the following information:

- Column Reference: SCM-TYPE
- Description: SC Membership Type
- FK Reference: SCM TYPE
- Long Description: Service Credit membership type to use when creating a service credit membership at start time.

Note:

Column Reference Algorithms. This column reference indicates a validation algorithm and a posting algorithm. However, we have not defined them yet so for now simply save this information.

Algorithms to Create Membership via Order

The base product provides two algorithm types to support the creation of a membership record via the order page: a validation algorithm type and a posting algorithm type.

Validate Membership Information

This algorithm is a column reference validation algorithm that checks that an input membership type is valid. Refer to CRVL-ME for more information. You must define an appropriate algorithm for this algorithm type, and on that algorithm you must define the column reference used to identify the membership type. For example:

- Algorithm: VAL MEM TYPE
- Description: Validate SC Membership Type
- Algorithm Type: CRVL-ME
- Parameter1: (Column Reference for Membership Type): SCM-TYPE

Post Membership Information

This algorithm is a column reference posting algorithm that creates a membership using the membership type indicated by the user. Refer to CRPS-ME for more information. You must define an appropriate algorithm for this algorithm type, and on that algorithm you must define the column reference used to identify the membership type. For example:

- Algorithm: CREATE MEMBRSHP
- Description: Validate SC Membership Type
- Algorithm Type: CRPS-ME
- Parameter1: (Column Reference for Membership Type): SCM-TYPE
- Parameter2: (Service Credit Membership Status): 10 -Pending or 20 -Active. Refer to [Lifecycle of a Membership](#) for more information.
- Parameters3-5: (Division, SA Type, Start Option): Indicate the information needed to create an SA for miscellaneous transactions.

Note:

This algorithm first looks for an existing service agreement of this division / SA type linked to the membership's accounts. If one exists, it uses that SA to link to the membership. If an SA does not exist, it creates one with the input division, SA and (optional) start option.

Update the Column Reference. Now that you have defined the validation and posting algorithms, return to your [column reference for membership type](#) and define the algorithms there.

Although your company may support multiple types of memberships, this column reference and its algorithms have been designed such that only one column reference for membership type would be needed to set up any type of membership. Although the posting algorithm for the membership type column reference indicates an SA type to use for miscellaneous transactions, a service agreement is only created and linked if your membership type indicates that an SA is required. As a result, you may use the same column reference for both memberships that require an SA and those that don't require an SA. However, if you have different membership types that require an SA and each uses a different SA type or a different start option for the membership SA, you need to define more than one posting algorithm and, as a result, more than one column reference.

Define a Campaign for Creating a Membership When Starting Service

Many factors must be considered when [designing your campaigns and packages](#). The possible creation of a membership when using the order page is simply another factor to consider.

If you plan to define a question/miscellaneous field to capture a service credit membership type, the available packages linked to the campaign should be ones that are related to memberships. For example, if your membership is related to electric service, it doesn't make sense to create a membership for a campaign designed to generate a one-time charge.

When defining a question/miscellaneous field, you must indicate its applicability. Consider whether a membership type is required, optional or only applicable for certain packages. This helps ensure that your users capture this information when appropriate.

Including the Membership Fee

You must determine the best way to setup your campaign/package to handle the levying of your membership fee, if applicable. Consider some of the following questions.

- If the membership has a fee, is it a refundable fee or a non-refundable fee?
- Is the fee always applicable for the membership? Or is it waived under certain conditions? For example, maybe the fee is applicable if a customer signs up for a single service, but the fee is waived if the customer signs up for two or more services.

The SCM type column reference and question/miscellaneous field are set up to ask the user what type of membership to create. Because the applicability of the fee may differ for each membership type, you should carefully consider the campaign / package setup to levy the fee correctly.

- If a fee is always applicable for a membership, you may consider creating a membership creation algorithm that creates a fee SA with a start option to levy the fee when the membership is created.

**Note:**

Sample Algorithm. The base product does not provide a membership creation algorithm to do this.

- If the fee is not always applicable for a membership, you must determine when the fee is applicable. The recommendation is to include the fee SA type in the SAs-to-create collection for the appropriate package. For example,
 - If the fee is applicable when the customer signs up for a single service, you should define a package for each single service that includes one SA to create for the single service and the fee SA as another SA to create.
 - If the fee is waived when the customer signs up for two or more services, you should define a package for each combination of the multiple services. These packages do not include the fee SA in the SAs to create.
- If the customer signing up for service is a former customer who has returned, perhaps the fee was paid earlier when the customer originally had service. In this case, maybe your business practice is to waive the fee at this time. To do this, you should set up a question/miscellaneous field for the user to mark that this is a returning customer. Based on the answer to this question, perhaps only packages that do not levy any fee are eligible for selection.

Defining Another Person for Your Account

It is common for a capital credit membership to define more than one person for the account being turned on and linked to a membership. A typical example is a married couple. Both spouses are indicated on the account and financially responsible persons and as a result, both are considered [members](#).

Column reference algorithms have been provided by the base product to enable linking a second person to your account via the [order](#) page.

This section walks you through how to set up the column reference and campaign to support this.

**Note:**

Linking A Second Person to the Account. This logic is not restricted to service credit functionality. Any campaign may be designed to include the ability to link a second person to the account being started.

Column References for Additional Person

In order to ask the customer service representative to link an additional person for the account, you must define several column references to use as questions/miscellaneous fields.

- We should assume that the person may already exist in the database. As a result, a question to record the person ID is needed.
- If the person does not already exist, the user should capture the person's name, an ID type and an ID number. Questions for these three fields are needed. The system uses this information to create a new person.
- Whether we are using an existing person or creating a new one, the person's link to the account must include an account relationship type. A question to record the account relationship type is needed.

Add a new column reference for person ID:

- Column Reference: PERSON-ID
- Description: Person ID
- FK Reference: PER
- Long Description: Person ID of the additional person to link to the order's account.

Add a new column reference for person name:

- Column Reference: PERSON-NAME
- Description: Person Name
- FK Reference: not applicable
- Long Description: Name of a new person to create.

Add a new column reference for identifier type:

- Column Reference: PER-ID-TYPE
- Description: Person Identifier Type
- FK Reference: ID TYPE
- Long Description: Person Identifier type for the primary ID of the additional person to link to the order's account.

Add a new column reference for identifier number:

- Column Reference: PER-ID-NUM
- Description: Person ID Number
- FK Reference: not applicable
- Long Description: Identifier number for the primary ID of the additional person to link to the order's account.

Add a new column reference for account relationship type:

- Column Reference: ACCT-REL-TYPE
- Description: Account Relationship Type
- FK Reference: ACCT REL
- Long Description: Relationship type to use for the link between the additional person and the order's account.

Note:

Column Reference Algorithms. One of the column references above must indicate a validation algorithm and a posting algorithm. However, we have not defined them yet so for now simply save this information. We recommend using the account relationship type record because that is used for all additional persons.

Algorithms to Link Additional Person via Order

The base product has provided two algorithm types to support the linking of an additional person to the account via the order page: a validation algorithm type and a posting algorithm type.

Validate Addition Person Information

This algorithm is a column reference validation algorithm which checks that either a person id or person name, a valid ID type and ID number are provided and that a valid account relationship type is provided. Refer to CRVL-PE for more information. You must define an appropriate algorithm for this algorithm type and on that algorithm you must define the column reference used for the five fields required for this validation. For example:

- Algorithm: VAL ADD PER
- Description: Validate Additional Person Info
- Algorithm Type: CRVL-PE
- Parameter1: (Column Reference for Person ID): PERSON-ID
- Parameter2: (Column Reference for Person Name): PERSON-NAME
- Parameter3: (Column Reference for Person ID Type): PER-ID-TYPE
- Parameter4: (Column Reference for Person ID Number): PER-ID-NUM
- Parameter5: (Column Reference for Account Relationship Type): ACCT-REL-TYPE

Post Addition Person

This algorithm is a column reference posting algorithm that may link an existing person to the order's account or create a new person and link that person to the order's account. Refer to CRPS-PE for more information. You must define an appropriate algorithm for this algorithm type, and on that algorithm you must define the column reference used for the five fields required for this logic. For example:

- Algorithm: LINK ADDNTL PER
- Description: Link additional person to order's account
- Algorithm Type: CRPS-PE
- Parameter1: (Column Reference for Person ID): PERSON-ID
- Parameter2: (Column Reference for Person Name): PERSON-NAME

- Parameter3: (Column Reference for Person ID Type): PER-ID-TYPE
- Parameter4: (Column Reference for Person ID Number): PER-ID-NUM
- Parameter5: (Column Reference for Account Relationship Type): ACCT-REL-TYPE

Note:

Update the Column Reference. Now that you have defined the validation and posting algorithms, return to your [column reference for account relationship type](#) and define the algorithms there.

Design a Campaign to Include Linking an Additional Person

Any campaign related to a specific account may include the questions and miscellaneous fields defined here to create/link an additional person to the account.

Simply create entries in the questions and miscellaneous fields collection to prompt the user to ask for the required information. A question should exist for each column reference created above. The following table illustrates a possible setup.

| Seq | Description | Prompt on Order | Column Reference | Dependency |
|-----|--|--|------------------|-------------------|
| 10 | Account relationship type for additional person. | If you would like to link another person to this account, please enter an account relationship type. | ACCT-REL-TYPE | Must have account |
| 20 | Person ID for additional person | If the additional person already exists in the database, enter the person id. | PERSON-ID | Must have account |
| 30 | Person name for additional person | If you would like to create a new person, please enter the person name. | PERSON-NAME | Must have account |
| 40 | ID type for additional person | Please enter the ID type of the new person. | PER-ID-TYPE | Must have account |
| 50 | ID Number for additional person | Please enter the ID number of the additional person. | PER-ID-NUM | Must have account |

Service Credits Earned When Starting Service

For some memberships, you may want to add service credits when starting the program. For example, the customer gets three free pay-per-view movies when signing on for cable service. Or a customer receives 500 frequent flier miles for signing up for a combination of gas and electric service.

There are various ways that you can accomplish this. You should work with your implementers to consider the various options to determine the method that best suits your business practice.

- You could use an SA activation algorithm to create a membership and an event for the initial points. Use this method if the points are related to a single type of service agreement and the points are earned automatically when starting service (i.e., without any human decision to be made).

- You could use a membership creation or membership activation algorithm to generate a service credit event automatically. This method assumes that the decision to create the membership has been made and that the free initial points are always earned for this type of membership (i.e., regardless of the type of service created).
- You could use questions and miscellaneous fields for a campaign/package to determine a customer's eligibility for participation in the membership and for the initial free points. A column reference posting algorithm could create the membership and/or the service credit event for the free points based on the answers to the questions.
- Perhaps the initial free points are only earned after the first bill is generated. Use a bill completion algorithm to generate the initial points.

You may think of other plug-in spots that could be used to generate free initial points based on your business needs.

Service Credits Earned Through Billing

For some memberships, you may accumulate points as a result of billed amounts for other services. For example, perhaps your customers earn one frequent flier mile for every \$10 spent on the combined electricity, gas and water bills each month.

To accomplish this, you must design an algorithm to be executed at billing time. There are various plug-in spots executed at billing time that you may use, but the recommended plug-in is a post completion algorithm on the customer class. This plug-in is executed after all bill segments are frozen and most of the completion logic has occurred.

Your algorithm should determine the [service agreements that contribute to the membership](#) and calculate the service credit amount for those service agreements bill segments.

This algorithm should also consider what to do when bill segments that contributed to the event are canceled. The algorithm provide with the base product CBCM-SC checks to see if any canceled bill segments are referenced on any previous events. If so, it includes the canceled amount on the new event. This may cause the new event to be a negative amount. The assumption is that over time, earned credits will compensate for the negative event amount. For a membership that [interfaces information to a third party](#), it is assumed that the negative event amount is also interfaced.

Service Credits Redeemed Through Billing

For some memberships, your customer may redeem their earned points by receiving a discount on their bill. For example, if your cable customer has earned one free pay-per-view movie, you can give them a credit the next time they get billed for a pay-per-view movie.

The base product has not provided any algorithms to credit a bill based on earned service credits. This section will identify considerations your implementers should follow when designing algorithms to redeem service credits through billing.

The recommendation is to credit the customer's bill by generating an adjustment using a pre-bill completion algorithm. This algorithm's responsibilities are as follows:

- Determine if the appropriate bill segment(s) contain the charges that need to be credited. For example, if the service credit is for a free pay-per-view movie, determine if the customer has been billed for a pay-per-view movie.
- Determine if the customer's current service credit balance for this program. For example, how many free pay-per-view movie credits are left?
- Create an adjustment to credit the appropriate service agreement by the eligible credit amount.
- Update the service credit membership balance by creating a new SC event with a credit for the number of points redeemed. Link the adjustment to the event as a contributed to FT.
- Consider cancel/rebill situations. If a cancel/rebill has occurred, determine if there is a change to the redeemed credits. For example, if the original bill had one pay-per-view movie that was credited and the new bill also has one pay-per-view movie, no change is needed to the service credit balance. If the original bill had more pay-per-view movies than the new bill, perhaps one or more redeemed service credit points should be reinstated. If the original bill had fewer pay-per-view movies than the new bill, perhaps more points should be redeemed.

You may wonder why we don't recommend crediting the customer's bill while generating the bill segment. For example, use pre-processing calculation rule to determine if any points should be redeemed and use a calculation rule to generate a bill calculation line with the credit amount.

The reason for this is that cancel/rebill logic is not straightforward. Algorithms executed during rate application should NOT perform any updates, such as updating the service credit membership balance. The balance should be updated using a bill segment freeze algorithm or a bill completion algorithm.

When a cancellation occurs, the service credit balance should be updated to reinstate the redeemed points. Again, this should occur when the cancellation is frozen or at bill completion time. If you perform a cancel/rebill, the calculation of the rebill segment does not have the up-to-date information about the service credit balance because the reinstatement of the points by the canceled segment has not occurred yet.

Designing Your Rate Options for Capital Credits

The capital credit allocation background process relies on certain data configuration in order to function correctly. This section identifies the required data setup.

Fastpath:

Refer to [Allocating Capital Credits](#) for more information.

Identifying SQ and Sales Information for Historical Bill Segments

To allocate capital credits, the background process retrieves billing history for each SA that contributes to the membership for the given fiscal year. The process needs to calculate the service quantity (SQ) amount billed and the sales amount billed for the SA in that year.

Note:

Sales Amount. The sales amount refers to the monetary amount billed. For a capital credit allocation, this amount would generally exclude taxes and may exclude other line item amounts from the bill.

In order to calculate the amounts correctly, the background process must determine which bill calculation lines for each bill segment contain the SQ and/or sales information. Characteristics on the bill calculation lines identify which bill lines should be used.

The rest of this section uses examples to illustrate how you may configure your rate options to support this.

Define Characteristics for SQ and Sales

Char Type for identifying bill lines that hold **SQ information**

- Char Type: CCA-SQ
- Description: Capital credit allocation usage
- Type of Char: Pre-defined
- Values: Y
- Char Entities: Calculation Rule, Bill Calculation Line

Char Type for identifying bill lines that hold **sales information**

- Char Type: CCA-SALES
- Description: Capital credit allocation sales
- Type of Char: Pre-defined
- Values: Y
- Char Entities: Calculation Rule, Bill Calculation Line

Define Calculation Rules

Identify each rate schedule that may be linked to a service agreement that contributes to a capital credit membership.

For each of these rate schedules, identify the calculation rules whose resulting bill calculation line will contain a billable service quantity that should be included in the SQ calculation for allocating capital credits. For each calculation rule that qualifies, define the CCA-SQ char type (defined above) and a char value of Y.

For each rate schedule, identify the calculation rules whose resulting bill calculation line amount should be included in the sales calculation for allocating capital credits. For each calculation rule that qualifies, define the CCA-SALES char type (defined above) and a char value of Y.

Note:

Characteristic Information. The system automatically copies characteristic info from a calculation rule to its resulting bill calculation line if the char type entities include both calculation rule and bill calc line.

Define Batch Control Parameters

The background process to allocate capital credits **CPCRALOC** receives the char type and char value to identify the bill calculation lines that contain the SQ and sales amounts. Once you have your characteristics defined, update your batch control to include these values as default parameter values.

Designing Bill Factors for Credit Allocation

The **capital credit allocation** process uses an allocation factor in its calculation. A typical capital credit membership may define multiple subcategories, meaning that allocation amounts are calculated each year for the multiple subcategories. The calculation is the same for each subcategory, but the allocation factor differs.

The process has been designed to calculate the allocation for a single subcategory. If your organization requires allocations calculated for multiple subcategories, the process must be run for each subcategory. The allocation process receives a bill factor as an input parameter. As a result, a different bill factor should be set up to define the allocation factor for each subcategory.

For each subcategory, the allocation factor may differ further for the type of customer. For example, the allocation for a commercial customer may differ from the allocation factor for a residential customer. The allocation background process expects the bill factor for each subcategory to define a characteristic type of revenue class. The process determines each service agreement's revenue class by looking at the value defined on its SA type.

Following is an example of bill factors set up for a capital credit membership with two subcategories: transportation and generation.

Characteristic Type for Allocation Bill Factor

Char Type: REV-CLASS

Description: Revenue Class

Type of Char: Pre-defined

Values: (define all the valid revenue class values)

Char Entity: Bill Factor

Bill Factor for Transportation

Bill Factor Id: CCAF-TRANS

Description: Transportation Allocation Factor

Char Type: REV-CLASS

Char Source: Characteristic Collection

Char Values: (for each year, the new transportation allocation factor for each revenue class must be defined)

Bill Factor for Generation

Bill Factor Id: CCAF-GEN

Description: Generation Allocation Factor

Char Type: REV-CLASS

Char Source: Characteristic Collection

Char Values: (for each year, the new generation allocation factor for each revenue class must be defined)

Note:

The characteristic source is characteristic collection. It is the responsibility of the background process to determine the SA's revenue class and to pass this value into the bill factor routines to retrieve the correct bill factor value.

Estimating Allocation Factors. Often the company needs to estimate the allocation factors for the new fiscal year and may adjust the values several times until the calculated allocation amounts are satisfactory. Refer to [Allocating Capital Credit](#) for more information.

Partial Retirement

In the cooperative business, it is common to never retire certain capital credit allocation amounts. The amounts that do not retire should be assigned their own subcategory.

When executing the retirement background process, the subcategory to retire may be input to the process. If you have certain subcategories that you do not retire, you would simply run the background process for the subcategories that do retire.

Cooperatives typically retire amounts and transfer the amounts to a beneficiary when a member dies. This is known as "estate retirement". Refer to [Service Credits for Capital Credit Memberships](#) for more information. If your business practice designates that certain subcategories of allocated amounts do not get retired, this probably holds true for estate retirement as well. If that is the case, your membership inactivation algorithm should be designed to only retire the appropriate amounts by subcategory.

Interface Membership Information to a Third Party

For some memberships, you may accumulate points for a third party, for example accumulating frequent flier miles for an airline. For these types of memberships, you must interface the event information to the third party.

To interface information to a third party, you may choose one of the following options:

- Design an extract program to interface the information
- Use workflow and notification to interface the information via the XAI tool

Interface Via an Extract Program

The service credit event may indicate a batch code and batch run number. Design a program to extract event information to a third party. This extract program would select service credit events marked with its batch code and the current run number.

Your service credit event must define a completion algorithm that stamps the appropriate batch code and run number. The base product provides an algorithm type to perform this logic. Refer to SCEC-BT for more information.

Use Workflow & Notification to Interface Info

Workflow and notification allows you to send information to a third party via an extract program or via XAI. The service credit event has its own logic for interfacing via an extract program, so you would use workflow and notification only if you need to interface to the third party via XAI.

Fastpath:

Refer to [Designing Notification Downloads](#) for more information.

Other Considerations For Interfacing Info to a Third Party

Because event information is extracted to a third party, you must consider how to handle adjustments to the event amount. For example, if your event is generated based on the creation of a bill segment, what should happen if that bill segment is cancelled?

You may want to prevent these types of events from getting canceled. Validation like this may be added via a user exit or using an event cancellation algorithm.

Note:

Sample Algorithms. The product does not provide any base algorithms to prevent an event from being canceled.

You should allow negative event amounts to be created so that this information may also be sent to the third party's system.

Defining Loan Options

The topics in this section describe how to set up the system to enable loan functionality.

Note:

Loans are optional. The system configuration requirements described in this section are only relevant if your organization loans money to customers.

The Terms Of A Loan Are Stored On A Service Agreement

Loans are initiated by creating a loan service agreement for a customer. The loan service agreement (and its SA Type) contains the loan's terms:

- The **loan amount** is held in the service agreement's Total Amount to Bill.
- The **customer's periodic payment amount** is held in the service agreement's Recurring Charge Amount.
- The **number of amortization periods** (e.g., 36 months, 240 months, etc.) is held in the service agreement's Number of Payment Periods.
- If the **interest rate** is the same for all customers with this type of loan service agreement, the interest rate is defined on the service agreement's SA type (using a bill factor). A specific interest rate can be defaulted from a start option contract value. If a specific interest rate applies to the customer, the SA type's interest rate can be overridden by specifying a bill factor value on the customer's service agreement (where the bill factor value contains the specific interest rate for the customer).
- The SA type controls the **periodicity of the bills** (e.g., monthly or bi-weekly).

Because a loan is defined using a service agreement, the typical functionality that is controlled by the service agreement's SA type is supported, including:

- How and when it is billed.
- How payments are booked in the GL (and the payment priority relative to other service agreements).
- How its debt is monitored by credit and collections.
- How late payment charges are calculated.

Loan service agreements are created using [Start/Stop](#) just like all other service agreements. The start/stop transaction has special loan functionality that allows an operator to specify the service agreement-specific loan terms described above. A start option can be specified to override the SA type's interest bill factor.

Note:

Automatic calculation of periodic payment amount / number of periods. The system calculates a loan's periodic payment amount or number of payments (whichever is left blank). You can have the system do this on [Start/Stop Maintenance](#) (using the **Calculate** button that appears on the [start service confirmation window](#)), and on [Loan - Main](#) (by clicking the **Calculate** button). Regardless of where you do this, the calculation is performed by an algorithm on the loan's SA type. Refer to the LPDA-SI algorithm type for more information about the base package algorithm.

Payoff Balance and Current Balance for Loans

As described under [Current Amount versus Payoff Amount](#), a loan service agreement's current balance and payoff balance differ during the lifetime of the loan. Current balance contains how much the customer owes to remain current (typically their periodic payment amount), and payoff balance contains the amount the customer would have to pay to payoff the loan (typically the principal balance plus any accrued interest charges).

Unlike other SAs, loans have two accounts receivable distribution codes: long term and short term. These two codes allow the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). The current balance for a loan is always the amount of the short-term receivables. The payoff balance for a loan is always the net of the short-term receivables and the long-term receivables.

If the SA has a [special role](#) of Loan, the financial transaction algorithms supplied with the base package transfer the current amount between the long-term receivables and the short-term receivables in the GL. For example, when a bill segment is generated for the loan SA, the amount of the periodic payment is transferred from the long-term receivables to the short-term receivables. Don't worry, the examples in the following sections show exactly what these transactions look like.

An operator can see the how the bills, payments and adjustments have affected the GL, current balance and payoff balance using [SA Financial History](#).

The following sections provide examples of how adjustments, bills and payments are recorded in the GL and the subsequent effect on the current and payoff balances. When reading the examples, remember that the payoff balance is always the net of the short-term receivable and the long-term receivable balances.

Booking The Principal Amount Using An Adjustment

When a loan service agreement is activated (i.e., when its status changes from pending start to active), an adjustment is created to book the principal amount. If the customer takes out a loan of 10,000, the adjustment's financial transaction looks as follows:

| Event | GL Accounting | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
|--|---|---------------------------|--------------------------|-----------------|----------------|
| Loan service agreement is activated (and an adjustment is created to book the principal) | Long Term Loan Receivable 10,000 Cash <10,000> | 0 | 10,000 | 0 | 10,000 |

This adjustment is issued if:

- The service agreement's SA type indicates a [special role](#) of Loan.

- The loan service agreement's Total Amount to Bill contains an amount (i.e., the loan amount).
- The loan service agreement was created using a [start option](#) on [Start/Stop Maintenance](#) AND the start option references an [adjustment type](#) and this adjustment type has been set up as follows:
 - The adjustment type's distribution code should reference the GL account to credit (e.g., Cash).
 - The adjustment type's FT algorithm reference $\text{Payoff Amt} = \text{Adj Amt} / \text{Current Amt} = 0$ (booking principal only impacts a customer's payoff balance).

Note that because this financial transaction doesn't have a current amount (the customer doesn't actually owe a current amount yet), there is no need to book anything to the short-term receivables distribution code.

Loan Amortization Schedule Calculation

The amortization schedule is a projection of the amount of principal and interest in each payment over the life of the loan. The amortization schedule may change, for example if the interest rate changes or the customer makes an overpayment (reducing the principal balance).

A loan's amortization schedule is calculated when an operator clicks the **Calculate** button on [Loan - Main](#). Please be aware that when this button is clicked, an algorithm plugged in on the loan [SA type](#) actually calculates the amortization schedule (refer to the algorithm type LSCH-SI for more information).

Billing For Loans And Interest Calculation

A bill segment is produced for a loan when its service agreement's account is next billed.

Factors on a loan's SA type controls when a bill segment is produced for a loan. Typically SA types for loan service agreements are set up to use anniversary [calendar billing](#). For this configuration:

- You must indicate the type of anniversary billing in the calendar billing option. Currently, we only support the Anniversary Future Billing (meaning that loans are billed in advance just like a classic home loan is). Refer to [Using The Anniversary Method](#) for more information about how this billing method controls the end date of the loan bill segment.
- You must reference [an anniversary billing frequency](#) consistent with the [recurring charge frequency](#) (e.g., monthly, quarterly, etc.).

To set up for a loan that is billed on a monthly basis, you would define the following fields in SA Type - Billing:

- **Use Calendar Billing:** Anniversary Future Billing
- **Anniversary Bill Frequency:** Monthly
- **Total Bill Amount:** Required
- **Recurring Charge:** Required
- **Recurring Charge Frequency:** Monthly
- **Total Amount To Bill Label:** Loan Amount
- **Recurring Chg Amt Label:** Payment Amount

If your type of loan must be billed on an exact date (for example, always on the 15th of the month) or with an exact number of days between each bill (for example, every 14 days), then your loan should be set up to use the calendar billing option of Use Bill Period. In order for your loan bills to be created on specific dates, the system makes the following assumptions:

- Your [bill cycle schedule](#) for the loan's account is defined with the dates that you want the loan to bill and is defined with the window start date equal to the window end date.
- You define a [bill period](#) schedule corresponding to your bill cycle schedule. Each bill period schedule's bill date should match your bill cycle window start date and each bill period schedule's bill segment end date should be set to the loan period end date.
- Considerations for the first bill. If the loan SA Type's Initial Start Date Option indicates that the first day of the service agreement should be billed, then the loan SA's start date should match the window start date of the next bill cycle schedule for the account. If the loan SA Type's Initial Start Date Option indicates that first day of the

service agreement should not be included, then the loan SA's start date should be one day prior to the window start date of the next bill cycle schedule for the account.

- Define your [recurring charge frequency](#) to match the frequency of your bill periods.

How the bill segment affects the customer's balance, and how it affects the general ledger are controlled by several algorithms defined on the loan service agreement's [SA type](#) and [bill segment type](#):

- The SA type's loan schedule algorithm controls how the [loan amortization schedule](#) is calculated.
- The SA type's loan interest charge algorithm controls how interest is calculated.
- The bill segment type's create algorithm controls how the bill lines are constructed.
- The bill segment type's financial algorithm controls how the general ledger is affected by the bill.

The second entry in the following table contains an example of the financial transaction produced by the base package algorithms (note, the first financial transaction in the table was described under [Booking The Principal Amount Using An Adjustment](#)).

| Event | GL Accounting | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
|-------------------------------------|--|---------------------------|--------------------------|-----------------|--|
| Loan service agreement is activated | Long Term Loan Receivable 10000 Cash <10000> | 0 | 10,000 | 0 | 10,000 long-term: 10,000 |
| First bill segment is produced | Interest: Long Term Loan Receivable 41.66 Interest Revenue <41.66> Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71> | 438.71 | 41.66 | 438.71 | 10,041.66 short-term: 438.71 long-term: 9,602.95 |

Several important points are illustrated above:

- When a bill segment is produced for a loan service agreement, the following takes place (if you use a bill segment creation algorithm of Create Bill Segment for Loans):
 - The loan SA type's bill segment creation algorithm calls the SA type's loan interest charge algorithm.
 - The base package loan interest charge algorithm calculates simple interest based on: 1) unbilled principal (i.e., the service agreement's payoff balance minus the current balance), 2) the number of billing periods covered by the bill, and 3) the [interest rate](#). Refer to the algorithm type LINT-SI for more information about the base package interest calculation algorithm.

Note:

No interest on interest and no interest on past due amounts. Just like a classic home loan, the base package algorithms do not calculate interest on interest, nor do they calculate interest on past due amounts. If you want to levy a late payment charge, use the SA type's late payment processing. If your organization calculates interest differently, you must develop your own algorithm(s).

- The SA type's bill segment creation algorithm uses the calculated interest to format the bill segment's bill lines. It creates one bill line to show the amount of interest in the payment, and another bill line to show the amount of principal. The principal amount is equal to the service agreement's periodic payment amount minus the amount of calculated interest.
- The financial transaction illustrated above is created if you use a bill segment financial algorithm of $\text{Payoff Amt} = \text{Interest} / \text{Current Amt} = \text{Bill Amount}$ on the loan's bill segment type. The following explains how this algorithm works:
 - The SA's current balance increases by the amount of the loan's periodic payment amount (i.e., its recurring charge amount). In other words, the amount the customer thinks they owe increases by 438.71.
 - The SA's payoff balance increases by the amount of interest. In other words, if the customer wanted to payoff the loan, they'd owe 10,041.66.
 - The *Interest* portion of the GL accounting is straightforward (if you're an accountant). It simply takes the amount of interest and debits it to the SA type's receivable distribution code (long-term receivables) and credits it to the distribution code defined on the interest rate's bill factor (typically interest revenue).
 - The *Transfer* portion of the GL accounting transfers moneys from long-term receivables (i.e., the unbilled principal) to short term receivables (the billed portion of the debt). The amount transferred is equal to the FT's effect on the service agreement's current balance, allowing the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). Remember that the payoff balance is the net of the short-term and long-term receivables.

Paying What Is Owed

When a payment is made for a loan:

- The service agreement's payoff amount is reduced by the payment amount.
- The service agreement's current amount is reduced by the payment amount.

The events that happen when a customer makes a payment against a loan is controlled by the FT algorithm plugged in on the loan service agreement's payment segment type. We'll use an example to help explain how this algorithm works. The 3rd entry in the following table illustrates the financial transaction produced when a payment is made (note, the first two financial transactions were described above).

| Event | GL Accounting | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
|-------------------------------------|---|---------------------------|--------------------------|-----------------|-----------------------------|
| Loan service agreement is activated | Long Term Loan Receivable 10000 Cash <10000> | 0 | 10,000 | 0 | 10,000 long-term: 10,000 |

| | | | | | |
|-----------------------------------|---|---------|---------|--------|------------------------|
| First bill segment is produced | Interest: | 438.71 | 41.66 | 438.71 | 10,041.66 |
| | Long Term Loan Receivable 41.66 | | | | short-term: 438.71 |
| | Interest Revenue <41.66> | | | | long-term: 9,602.95 |
| | Transfer Long Term To Short Term: | | | | |
| | Short Term Loan Receivable 438.71 | | | | |
| | Long Term Loan Receivable <438.71> | | | | |
| Payment is made | Affect Cash | -438.71 | -438.71 | 0 | 9,602.95 |
| | Cash 438.71 | | | | short-term: 0 |
| | Long Term Loan Receivable <438.71> | | | | long-term: 9,602.95 |
| | Transfer Long Term To Short Term: | | | | |
| | Long Term Loan Receivable 438.71 | | | | |
| | Short Term Loan Receivable <438.71> | | | | |

The financial transaction illustrated above is created if you use a payment segment FT creation algorithm of Payoff Amt = Current Amt = Pay Amt on the loan's payment segment type. The following explains how this algorithm works:

- The SA's current balance decreases by the amount of the payment amount. In other words, the customer thinks they owe 0 after the payment. Note refer to [Overpayments](#) for information about how an overpayment affects the SA's balances and the general ledger.
- The SA's payoff balance decreases by the amount of the payment. In other words, if the customer wanted to payoff their loan, they'd owe 9,602.95.
- The *Cash* portion of the GL accounting is straightforward (if you're an accountant). It simply takes the amount of the payment and debits it to the payment segment type's distribution code (typically cash) and credits it to the SA type's receivable distribution code (long-term receivable).
- The *Transfer* portion of the GL accounting effectively reduces short-term receivables by the FT's effect on the customer's current balance. This reduction is handled by an offsetting increase to long-term receivables (to make up for reduction made when the cash was applied). Again, this differentiation between short-term and long-term receivables allows the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term).

Overpayments On Loans

You can determine whether you want to accept loan overpayments. Overpayments reduce the principal amount (the amount owed on the loan), which follows the philosophy adopted by a typical home loan.

When the payment is made, any overpayments are distributed according to the overpayment distribution algorithm defined for the customer class. Any customer classes for which you want to allow loan overpayments should use an overpayment distribution algorithm that keeps the overpayment on the loan SA.

When the payment transaction is frozen, the system checks to see if there is a credit amount on the loan SA's current balance. If a credit exists, the customer has made an overpayment and an adjustment is created to zero out the current balance and transfer the amount of the credit from the SA's short-term receivable to long-term receivable. The adjustment may appear on the customer's next bill to show the additional amount paid against the principal.

The algorithm that controls this adjustment to remove the credit on current balance is plugged in on the loan service agreement's SA type and is applied on the SA Type - Payment Freeze system event.

The third and fourth entries in the following table illustrate an overpayment (note, the first two financial transactions were described above).

| Event | GL Accounting | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
|-------------------------------------|--|---------------------------|--------------------------|-----------------|--|
| Loan service agreement is activated | Long Term Loan Receivable 10000 Cash <10000> | 0 | 10,000 | 0 | 10,000 long-term: 10,000 |
| First bill segment is produced | Interest: Long Term Loan Receivable 41.66 Interest Revenue <41.66> Transfer Long Term To Short Term: Short Term Loan Receivable 438.71 Long Term Loan Receivable <438.71> | 438.71 | 41.66 | 438.71 | 10,041.66 short-term: 438.71 long-term: 9,602.95 |

| | | | | | |
|---|--|---------|---------|---------|-------------------------|
| Payment is made (with an overpayment of 200.00) | Affect Cash | -638.71 | -638.71 | -200.00 | 9,402.95 |
| | Cash 638.71 | | | | short-term: <200.00> |
| | Long Term Loan Receivable <638.71> | | | | long-term: 9,602.95 |
| | Transfer Long Term To Short Term: | | | | |
| | Long Term Loan Receivable 638.71 | | | | |
| | Short Term Loan Receivable <638.71> | | | | |
| Create adjustment to remove SA's credit. | Transfer Short Term Credit to Long Term: | 200.00 | 0 | 0 | 9,402.95 |
| | Short Term Loan Receivable 200.00 | | | | short-term: 0 |
| | Long Term Loan Receivable <200.00> | | | | long-term: 9,402.95 |
| | | | | | |

In the third financial transaction illustrated above, the billed amount of the payment works essentially the same as that illustrated under [Paying What Is Owed](#). If the Keep Overpayment on Loan SA algorithm is plugged in on the overpayment distribution event on the customer class, the overpayment amount is applied to the loan SA, creating a credit on the SA's current balance. The following explains how this algorithm works:

- If the account has an loan SA and there is an excess credit, the credit is applied to the loan SA (as long as this does not cause the loan SA to have a credit payoff balance).
- If there is not a loan SA to which the credit can be applied, the algorithm checks to see if there is an open excess credit SA for the account.
 - If so, the excess credit amount is applied to the excess credit SA.
 - If not, the algorithm creates an excess credit SA and applies the amount to this SA.

The fourth financial transaction illustrated above is created if the Create Adjustment to Remove SA's Credit algorithm is plugged in on the loan's SA type's payment freeze event. The following explains how this algorithm works:

- If the SA's current balance is less than zero, the algorithm creates a frozen adjustment that removes the credit by transferring the credit from the short-term receivable to the long-term receivable. This adjustment ID is captured on the pay segment so the adjustment can be canceled if the payment is later canceled. Note that the adjustment cancel reason used by the system in this case is specified on the Financial Transaction Options [Feature Configuration](#) using the Adjustment Cancel Reason For Payment Linked To Adjustment option type.
- The SA's current balance increases by the amount of the credit transfer. In other words, the customer thinks they owe 0 after the transfer.
- The SA's payoff balance doesn't change because the payoff balance is always the net of the short-term and long-term receivables. In other words, if the customer wanted to payoff their loan, they'd still owe 9,402.95.

Note:

Overpayments and interest. The base package interest calculation algorithm (plugged in on the loan's SA type) does not take into consideration the exact date that the overpayment is made when calculating the interest for the period. It only takes into consideration the outstanding principal amount (payoff balance - current balance) at the time of the interest calculation.

Adjusting Loan Amounts

You would issue ad hoc adjustments if you need to change a loan's payoff and/or current balance outside of the normal billing / payment functions.

An adjustment can:

- Reduce a loan's payoff balance.
- Reduce a loan's current balance (i.e., how much the customer thinks they currently owe).
- Reduce both the loan's payoff and current balance.

For adjustments that affect payoff amount only:

- These adjustments are used to change the principal owed, e.g., if an additional amount is loaned.
- The adjustment's adjustment type should reference the Payoff Amt = Adj / Current Amt = 0 FT algorithm.
- GL lines will be generated to reflect the change to principal.

For adjustments that reduce current amount only:

- These adjustments can be used to change the amount that the customer must pay as part of the next bill.
- The adjustment's adjustment type should reference the Payoff Amt = 0 / Current Amt = Adj Amount (no GL) FT algorithm.
- Typically, GL lines are not generated for FTs that only affect the customer's current balance. However, moneys must be transferred from long to short in the amount of the adjustment (as described above under [Payoff Balance and Current Balance for Loans](#)).

For adjustments that reduce both payoff and current amount:

- These adjustment types can be used to levy additional charges, such as late fees, or to correct interest calculations.
- The adjustment's adjustment type should reference the Payoff Amt = Adj / Current Amt = Adj FT algorithm.
- GL lines are generated to reflect the change to principal. In addition, GL lines must be generated to transfer money from long to short in the amount of the adjustment (as described above under [Payoff Balance and Current Balance for Loans](#)).

Note:

Adjustments that affect the principal balance (payoff balance - current balance) affect the term of the loan because interest is based on the principal balance.

Adjustments can cause credit balances to exist. If you credit the loan SA, it is possible for the current balance to become negative. You may need to create additional adjustments that affect the current amount, depending on whether the customer needs to pay this amount as part of the next payment.

Writing Off Loans

Loans are written off using the standard write-off processing.

Fastpath:

Refer to [The Big Picture Of Write Off Processing](#) for background information.

We illustrate the classic financial transactions that transpire to financially write-off a loan to help illustrate important points (these are the fourth and fifth entries in the following table):

| Event | GL Accounting | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
|---|--|---------------------------|--------------------------|-----------------|----------------------|
| Loan service agreement is activated | Long Term Loan Receivable 1000 | 0 | 10,000 | 0 | 10,000 |
| | Cash <1000> | | | | long-term: 10,000 |
| First bill segment is produced | Interest: | 438.71 | 41.66 | 438.71 | 10,041.66 |
| | Long Term Loan Receivable 41.66 | | | | short-term: 438.71 |
| | Interest Revenue <41.66> | | | | long-term: 9,602.95 |
| | Transfer Long Term To Short Term: | | | | |
| | Short Term Loan Receivable 438.71 | | | | |
| | Long Term Loan Receivable <438.71> | | | | |
| Payment is made (with an overpayment of 200.00) | Affect Cash | -638.71 | -638.71 | -200.00 | 9,402.95 |
| | Cash 638.71 | | | | short-term: <200.00> |
| | Long Term Loan Receivable <638.71> | | | | long-term: 9,602.95 |
| | Transfer Long Term To Short Term: | | | | |
| | Long Term Loan Receivable 638.71 | | | | |
| | Short Term Loan Receivable <638.71> | | | | |
| Create adjustment to remove SA's credit. | Transfer Short Term Credit to Long Term: | 200.00 | 0 | 0 | 9,402.95 |
| | Short Term Loan Receivable 200.00 | | | | short-term: 0 |
| | Long Term Loan Receivable <200.00> | | | | long-term: 9,402.95 |
| | | | | | |

| | | | | | |
|---|--|-----------|-----------|----------|---|
| Sync up current with payoff balance | Transfer Long Term To Short Term: Short Term Loan Receivable 9,402.95 Long Term Loan Receivable <9,402.95> | 9,402.95 | 0 | 9,402.95 | 9,402.95 short-term: 9,402.95 long-term: 0 |
| Transfer balance to a write-off SA | Transfer From Loan SA: Write Off Xfer Clearing 9,402.95 Long Term Loan Receivable <9,402.95> Long Term Loan Receivable 9,402.95 Short Term Loan Receivable <9,402.95> Transfer To Write Off SA: Bad Loans Expense 9,402.95 Write Off Xfer Clearing <9,402.95> Note, these will cause a balance of 9,402.55 to exist on the write-off service agreement. | -9,402.95 | -9,402.95 | 0 | 0 |

The only unusual portion of the last two financial transactions is the impact on short and long term receivables. Please see the examples above under [Billing For Loans And Interest Calculation](#) and [Paying What Is Owed](#) to understand how any impact to a loan's current balance causes this type of financial transfer to occur.

Distribution Codes for Loans

As explained above under [Payoff Balance and Current Balance for Loans](#), loans have two accounts receivable distribution codes: long term and short term. These two codes allow the general ledger to differentiate between unbilled loan receivables (long term) and billed loan receivables (short term). Both receivables distribution codes are defined on the loan SA type.

In addition, loans have a distribution code used to book interest revenue. The interest revenue distribution code is defined on the loan's bill factor value for a revenue class (defined on the loan's SA type). For example, on the bill

factor you can use one distribution code to book interest revenue from the residential revenue class and another distribution code to book interest revenue from the commercial revenue class. In this example, you create two loan SA types, one for residential revenue and the other for commercial revenue.

Loans may also have a bad loan debt (expense) distribution code that is used when writing off a loan. The bad loan debt distribution code is defined on the loan's write-off service agreement type. Refer to [Defining Credit & Collections Options](#) for more information.

Setting Up The System To Enable Loans

The above topics provided background information about how loans are supported in the system. The following discussion summarizes the various setup tasks alluded to above.

Distribution Code

You must set up the following [distribution codes](#):

- Long term receivables
- Short term receivables
- Interest revenue
- Bad loan debt

Adjustment Types

The following adjustment types are needed:

- Activate a loan. This should reference a distribution code associated with cash or the cash equivalent and an FT algorithm of $\text{Payoff Amt} = \text{Adj} / \text{Current Amt} = 0$.

Note:

Creating Checks for Loan Amounts. If you want the system to initiate a check to the customer for the loan amount, the loan activation adjustment type should indicate an **A/P Request Type Code**. Refer to [Controls The Interface To A/P & 1099 Reporting](#) for more information.

- Remove Credit (Overpayment). This adjustment should reference an FT algorithm of $\text{Payoff Amt} = 0 / \text{Current Amt} = \text{Adj Amount (no GL)}$. Even though this algorithm indicates that there is no effect on the GL, there is a special exception built in for loan SAs. The special exception creates GL details to transfer the current balance (short-term receivable) to the long-term receivable. Refer to [Overpayments](#) for more information.

Note:

Printing Overpayments on Bills. If you want the overpayment adjustment to appear on customers' bills, turn on **Print by Default** and enter a **Description on Bill** (e.g. "Additional Principal"). For more information, refer to [Controls Information Printed On The Bill](#).

- Adjustment types to perform any of the adjustments described under [Adjusting Loan Amounts](#).

Adjustment Type Profile

Create an adjustment type profile that references the adjustment types used on a loan. Besides the above adjustment types, it should also reference adjustment types to levy late payment charges (if applicable), levy non-sufficient funds charges (if applicable), refund overpayments (if applicable), sync current balance with payoff balance at write-off time, transfer balances to a write-off service agreement, and write-down small balances.

Algorithms

Add the following [algorithms](#):

- Overpayment Distribution. This algorithm is later plugged in on the customer class for the Overpayment Distribution system event. Refer to the algorithm type OVPY-LO-CSA for more information about the base package algorithm.
- Bill Segment Creation for Loans. This algorithm is later plugged in on the loan's bill segment type. Refer to the algorithm type BSBS-LO for more information about the base package algorithm.
- Bill Segment Financial Transaction Creation for Loans. This algorithm is later plugged in on the loan's bill segment type. Refer to the algorithm type BSBF-LO for more information about the base package algorithm.
- Amortization Schedule. This algorithm is later plugged in on the SA type for the Loan Schedule system event. Refer to the algorithm type LSCH-SI for more information about the base package algorithm.
- Interest Calculation. This algorithm is later plugged in on the SA type for the Loan Interest Charge system event. Refer to the LINT-SI algorithm type for more information about the base package algorithm.
- Payment Periods/Payment Amount Calculation. This algorithm is later plugged in on the SA type for the Loan Periods and Amount system event. Refer to the algorithm type LPDA-SI for more information about the base package algorithm.
- Loan SA Payment Freeze. This algorithm has a parameter that must reference the Remove Credit adjustment type defined above. This algorithm is later plugged in on the SA type for the Payment Freeze system event. Refer to the algorithm type STPZ-RMVCR for more information about the base package algorithm.

Bill Factor

You must set up a [bill factor](#) that defines the interest rate. If you have different interest rates for different types of loans, you can create a separate bill factor for each or you can use start options to override the interest rate.

On the bill factor's [bill factor value](#), make sure to reference the GL distribution code used to book interest revenue for the revenue class specified on the loan's SA type.

Customer Class

Any [customer class](#) on which you want to allow overpayments for a loan must use the overpayment distribution algorithm defined above. The overpayment distribution algorithm keeps the overpayment on the loan SA rather than transferring it to an excess credit SA, allowing a subsequent adjustment to apply the overpayment to the principal balance.

Bill Segment Type

Create a bill segment type that references the bill segment creation algorithm defined above and the FT creation algorithm defined above.

Frequency

Create [frequency](#) codes to correspond to the frequency of your loans. When setting up your SA types, you must indicate a recurring charge frequency and, if you use the Anniversary Billing Option, you must indicate an anniversary frequency.

Bill Period

If you use the Use Bill Period option, set up a bill period with an appropriate schedule of dates for billing your loan.

Bill Cycle Schedule

If you use the Use Bill Period option, the bill cycle schedule for these types of loans should be defined with an appropriate schedule of dates for billing your loan.

Collection, Severance and Write Off Processes

You should set up the appropriate credit and collections information. Refer to [Defining Credit & Collections Options](#) for more information.

SA Type

You must set up a [SA type](#) for your loan service agreements (you may need multiple SA types if you have different business rules for different types of loans). The following points describe the minimal requirements for a loan SA type.

SA Type - Main

Define the following options:

- **Distribution Code** should be a long-term receivable code.
- **Service Type** should reference something like "Miscellaneous Service".
- Specify the **Revenue Class** that, together with the interest bill factor, determines the distribution code used to book the loan interest revenue.
- **Start Option** should be turned on.
- The Payment Segment Type should reference the Normal Payment. The base package payment segment financial algorithm ($\text{Payoff Amt} = \text{Current Amt} = \text{Pay Amt}$) used for Normal Payment pay segment types creates the additional GL details to transfer the credit from long-term receivables to short-term receivables if the SA's special role is Loan.
- Turn on **Late Payment Charge** if applicable.
- Define an appropriate **Adjustment Type (Synch Current)** that will cause current balance to be synchronized with payoff balance (if the loan is [written off](#)).

SA Type - Detail

Define the following options:

- **Special Role** is Loan.
- Specify the **Interest Bill Factor** set up above. You can use start options to override.
- Use **Override Interest** to indicate whether the interest rate defined on the interest bill factor may be overridden at the SA level. If you select Allowed, the interest rate may be overridden by a contract value on a start option or the SA.
- Use the short-term receivable account defined above as the **Loan A/R Distribution Code**. If you do not want the system to differentiate between short-term receivables and long-term receivables, make the loan A/R distribution code the same as the distribution code (above).

SA Type - Billing

Fastpath:

For an overview of some of these options, be sure to refer to [Billing For Loans And Interest Calculation](#) for more information.

Define the following options:

- The [Bill Segment Type](#) should reference the value created above.

- **Characteristic Premise Required** should not be checked. (A loan SA is not a premise-based service. SA types that have this box checked are filtered out of the SA type search when the start method is Start a SA, so users will never be able to start a loan SA that requires a characteristic premise.)
- **Use Calendar Billing** must equal Anniversary Future Billing or Use Bill Period.
- **Bill Period** is required for the Use Bill Period option.
- **Anniversary Billing Frequency** is required for the Anniversary Future Billing option and must equal the periodicity of the bills (monthly, weekly, etc.).
- **Total Bill Amount** is required (it holds the principal).
- **Total Amount To Bill Label** should reference something like "Loan Amount".
- **Recurring Charge** is required (it holds the periodic payment amount).
- **Recurring Chg Amt Label** should reference something like "Payment Amount".
- **Recurring Charge Frequency** is required (it defines the periodicity associated with the recurring charge amount) and must be the same as the bill period frequency or the anniversary billing frequency (based on your **Use Calendar Billing** option).

SA Type - Rate

Turn off the **Rate Required** switch as loans do not use rates.

SA Type - SP Type

Turn off the **Service Points Required** switch as loans do not have service points.

SA Type - Adjustment Profile

Adjustment Type Profile should reference the profile set up above.

SA Type - Credit and Collections

The credit and collections information should reference a **Severance Process Template** that simply expires the loan. The **Debt Class** and **Write Off Debt Class** should reference an appropriate value consistent with your credit and collections rules. Refer to [Defining Credit & Collections Options](#) for more information.

SA Type - Algorithms

The Loan Schedule, Loan Interest Charge, Loan Periods, and Amounts and Payment Freeze [algorithms](#) defined above must be set up.

Start Options

Loans require a start option to define the adjustment type that is used to create the adjustment to book the initial principal amount when the loan is activated. Loan start options can also specify default values for loan amount, payment amount, and number of periods.

Create at least one start option for each loan SA type. The following information should be defined:

- **Adjustment Type** should reference the adjustment type defined above to book principal.
- **Recurring Charge Amount** (Payment Amount) should only be defined if you have standard loan payments.
- **Total Amount To Bill** (Loan Amount) should only be defined if you have standard loan amounts.
- **Number of Payment Periods** should be the number of payment periods in the loan (if you have a standard loan period).
- If you want to define a set of standard APRs for a loan SA Type, set up a **Contract Value** on the Rate Info page. The **Bill Factor** should match the interest bill factor specified on the [SA Type](#).

Defining Non-Billed Budget Options

A Non-Billed Budget (NBB) is a payment plan that allows your customers to pay set amounts at specified intervals (e.g. every two weeks). Non-Billed Budgets are typically used when your company bills on an infrequent basis and you want to provide your customers with a mechanism to make smaller payments more frequently. As the name suggests, bills are not created for the Non-Billed Budget's scheduled payments; customers must remember to make their payments at the scheduled intervals. The topics in this section describe how to design and set up non-billed budgets.

Note:

Non-Billed Budgets are optional. The system configuration requirements described in this section are only relevant if your organization offers Non-Billed Budgets.

What Is A Non-Billed Budget?

A Non-Billed Budget is a special type of budget or payment plan that encompasses three major elements:

- A set of scheduled payments
- The business rules used to recommend and potentially renew the payment schedule
- The business rules that govern the financial impact on the current and payoff balances of the SAs covered by the payment schedule

Non-Billed Budgets are managed via a service agreement whose SA type has a special role of Non-Billed Budget. If an SA type has a special role of Non-Billed Budget it must have one or more recommendation rules, and SAs of that type are allowed to have payment schedules.

The Financial Impact Of Non-Billed Budgets

When you set up the Non-Billed Budget SA type, you can indicate whether the Non-Billed Budget is monitored by the [account debt monitor](#) process. The following sections contain examples of financial transactions for Non-Billed Budgets that are monitored by the account debt monitor.

Note:

Unmonitored Non-Billed Budgets. SAs that are covered by unmonitored Non-Billed Budgets are subject to different financial treatment than those that are monitored. The [financial transactions relevant for unmonitored Non-Billed Budgets](#) are discussed later.

Current Amount For SAs Covered By A Non-Billed Budget

As described under [Current Amount versus Payoff Amount](#), the values of the current balance and payoff balance are the same for most financial transactions. One exception is for SAs that are covered by a Non-Billed Budget in which case the current balance is always zero and the payoff balance is always the amount the customer really owes.

When a Non-Billed Budget is activated or an SA is added to a Non-Billed Budget, the system creates adjustments for all affected SAs to set the current amount equal to zero. The adjustment type that references the Payoff Amt = 0 / Current Amt = Adj Amount (no GL) algorithm is taken from the SA's SA type.

Note:

Non-Billed Budgets and Open Item Accounts. If the Non-Billed Budget is for an open item account, no match event is created for the financial transaction that reduces the current amount to zero. This FT must be manually matched if required.

The following example shows the effect of activating a Non-Billed Budget that covers an electric SA with a current balance of 25. The transactions for the electric SA are illustrated on the right and the transactions for the non-billed budget SA are illustrated on the left.

| Event | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
|--------------------------------|---------------------------|--------------------------|-----------------|----------------|---------------------------|--------------------------|-----------------|----------------|
| | Electric SA | | | | Non-Billed Budget SA | | | |
| Starting balance | 0 | 0 | 25 | 25 | | | | |
| Non-Billed Budget is activated | -25 | 0 | 0 | 25 | | | | |

By setting the current balance for the covered SAs to zero, the SAs are insulated from the regular debt monitoring process. Depending on the Non-Billed Budget *recommendation algorithm*, the payoff balance can be ignored, divided evenly between the scheduled payments or added to the first scheduled payment.

Activating a Non-Billed Budget has no affect on its own current or payoff balances.

Scheduled And Actual Payments On The Non-Billed Budget

When a scheduled payment is due, an adjustment is created to increase the Non-Billed Budget's current balance by the expected amount. The current balance on the SA can be monitored to ensure that payments are being made on time.

When the payment is made, the Non-Billed Budget's current balance is reduced to zero and the Non-Billed Budget's payoff balance reflects the accumulated credit from the payment. This accumulated credit is transferred to the covered SAs when the next bill for the account is completed.

The following example illustrates scheduled and actual payments for the Non-Billed Budget in the previous example. The amount of the scheduled Non-Billed Budget payments is 10. Note that the first two transactions were described above.

| Event | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
|--------------------------------|---------------------------|--------------------------|-----------------|----------------|---------------------------|--------------------------|-----------------|----------------|
| | Electric SA | | | | Non-Billed Budget SA | | | |
| Starting balance | 0 | 0 | 25 | 25 | | | | |
| Non-Billed Budget is activated | -25 | 0 | 0 | 25 | | | | |
| First scheduled payment is due | | | | | 10 | 0 | 10 | 0 |
| Payment | | | | | -10 | -10 | 0 | -10 |

An algorithm (Process NBB Scheduled Payment) plugged in on the Non-Billed Budget SA type creates the appropriate financial transactions when the scheduled payment is due. The algorithm is called by the Non-Billed Budget Scheduled Payment Processing ([NBBPS](#)) background process.

The normal payment processing handles the adjustments created when the payment is made.

Note:

Non-Billed Budget Payment Cancellation. If a payment is canceled, the financial transaction is reversed.

Automatic Payments And Non-Billed Budgets. Users may set up a Non-Billed Budget to use [automatic payments](#) by setting up the account's auto pay options. Users may also exclude the Non-Billed Budget from automatic payment if the account is set up for automatic payment. The [NBB Scheduled Payment Automatic Payment Create](#) background process calls the Auto Pay Creation algorithm to create the auto payment for a Non-Billed Budget.

Overpayments for Non-Billed Budgets

Typically, payments in excess of the Non-Billed Budget's current balance are credited to an overpayment (excess credit) SA. When the next adjustment is created for a scheduled payment, the credit on the overpayment SA is used to relieve the non-billed budget current balance.

Note:

Overpayment Distribution Algorithm. The overpayment distribution is a function of the overpayment distribution algorithm plugged in on the account's customer class. We strongly recommend that the Non-Billed Budget SA type be set up so that overpayment is not allowed. Any excess payments should go to an overpayment SA. For more information about overpayment distribution, refer to [Overpayment Segmentation](#).

In the example below, the customer pays 20 for a scheduled payment instead of 10. The non-billed budget SA is illustrated on the right and the overpayment SA is illustrated on the left. The electric SA is not illustrated in the example below because scheduled payments, payments and overpayments have no effect on covered SAs. The first four transactions were illustrated above.

| Event | Non-Billed Budget SA | | | | Overpayment SA | | | |
|---------------------------------|---------------------------|--------------------------|-----------------|----------------|---------------------------|--------------------------|-----------------|----------------|
| | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
| Starting balance | | | | | | | | |
| Non-Billed Budget is activated | | | | | | | | |
| First scheduled payment is due | 10 | 0 | 10 | 0 | | | | |
| Payment | -10 | -10 | 0 | -10 | | | | |
| Second scheduled payment is due | 10 | 0 | 10 | -10 | | | | |

| | | | | | | | | |
|--------------------------------|-----|-----|----|-----|-----|-----|-----|-----|
| Over-payment | -10 | -10 | 0 | -20 | -10 | -10 | -10 | -10 |
| Third scheduled payment is due | 10 | 0 | 10 | -20 | | | | |
| Transfer Adjustment | -10 | -10 | 0 | -30 | 10 | 10 | 0 | 0 |

After the Process NBB Scheduled Payment algorithm creates the next scheduled payment, it looks for a credit amount on the overpayment SA and creates an adjustment to transfer the credit balance (or the amount of the payment if the credit is more than the scheduled payment amount) from the overpayment SA to the non-billed budget SA. The overpayment transfer adjustment type and the overpayment SA type are specified as parameters to the algorithm.

Underpayments For Non-Billed Budgets

An insufficient payment or a canceled payment leaves a current balance on the Non-Billed Budget SA.

In the example below, the customer makes a payment of 7 for the fourth scheduled payment. The example below does not show the overpayment SA (illustrated above). The first eight transactions are discussed above.

| Event | Electric SA | | | | Non-Billed Budget SA | | | |
|---------------------------------|---------------------------|--------------------------|-----------------|----------------|---------------------------|--------------------------|-----------------|----------------|
| | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
| Starting balance | 0 | 0 | 25 | 25 | | | | |
| Non-Billed Budget is activated | -25 | 0 | 0 | 25 | | | | |
| First scheduled payment is due | | | | | 10 | 0 | 10 | 0 |
| Payment | | | | | -10 | -10 | 0 | -10 |
| Second scheduled payment is due | | | | | 10 | 0 | 10 | -10 |
| Over-payment | | | | | -10 | -10 | 0 | -20 |
| Third scheduled payment is due | | | | | 10 | 0 | 10 | -20 |

| | | | | |
|--------------------------|-----|-----|----|-----|
| Transfer Adjustment | -10 | -10 | 0 | -30 |
| Fourth scheduled payment | 10 | 0 | 10 | -30 |
| Underpayment | -7 | -7 | 3 | -37 |

The Process NBB Scheduled Payment algorithm creates a trigger to ensure that the current balance is monitored by the account debt monitor. Refer to [Credit And Collections And Non-Billed Budgets](#) for more information.

Billing For SAs Covered By The Non-Billed Budget

When the next bill for the account is completed, the credit on the Non-Billed Budget is transferred to the covered SAs. The credit is prorated over the covered SAs according to the relative payoff balances on each SA.

In the example below, the electric SA's bill is 33. The first ten transactions are discussed above.

| Event | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
|---------------------------------|---------------------------|--------------------------|-----------------|----------------|---------------------------|--------------------------|-----------------|----------------|
| | Electric SA | | | | Non-Billed Budget SA | | | |
| Starting balance | 0 | 0 | 25 | 25 | | | | |
| Non-Billed Budget is activated | -25 | 0 | 0 | 25 | | | | |
| First scheduled payment is due | | | | | 10 | 0 | 10 | 0 |
| Payment | | | | | -10 | -10 | 0 | -10 |
| Second scheduled payment is due | | | | | 10 | 0 | 10 | -10 |
| Over-payment | | | | | -10 | -10 | 0 | -20 |
| Third scheduled payment is due | | | | | 10 | 0 | 10 | -20 |
| Transfer Adjustment | | | | | -10 | -10 | 0 | -30 |

| | | | | | | | |
|---------------------------------------|---|-----|---|----|----|----|-----|
| Fourth scheduled payment | | | | 10 | 0 | 10 | -30 |
| Underpayment | | | | -7 | -7 | 3 | -37 |
| Bill | 0 | 33 | 0 | 58 | | | |
| Bill completion (transfer adjustment) | 0 | -37 | 0 | 21 | 0 | 37 | 3 |

When a bill segment financial transaction is created, the current amount is set to zero for SAs that are covered by the Non-Billed Budget (if you use a bill segment FT algorithm of $\text{Payoff Amt} = \text{Bill Amt} / \text{Current Amt} = \text{Amt Due}$). Though not evident by the name, the $\text{Payoff Amt} = \text{Bill Amt} / \text{Current Amt} = \text{Amt Due}$ algorithm does set the current amount to zero for monitored Non-Billed Budgets. (For SAs with other roles, the current amount is equal to the amount due or the recurring charge.)

A bill completion algorithm transfers money from the Non-Billed Budget to the covered SAs (if you plug in the NBB Credit Transfer bill completion algorithm on the Non-Billed Budget SA type). The algorithm type supplied with the base package distributes the credit using the method described in [Distributing Non-Billed Budget Credit](#).

Note:

Canceled Bill Segments. No new processing occurs when a bill segment is canceled; any credit balance remains on the covered SA.

Distributing Non-Billed Budget Credit

Both the NBB Credit Transfer bill completion algorithm type and the Non-Billed Budget SA stop algorithm type supplied with the base package use the same method of distributing a credit from a Non-Billed Budget SA to the covered SAs. The following points describe how the credit is distributed:

- Covered SAs that are already in credit (due to some other circumstance, such as a cancellation and rebill) are excluded from the distribution.
- The distribution to each covered SA will not exceed its total payoff to ensure that none of the covered SAs have a credit balance.
- The credit is prorated over the covered SAs according to the relative payoff balances on each SA.
- The calculation of the payoff balance is adjusted to exclude the current balance to ensure that the credit is prorated over the debt covered by the budget, not any ad-hoc debt for the SA.

Note:

The current balance on covered SAs should always be zero. The only exception occurs if an adjustment has been added that directly affected the SA balance. In this case, the distribution assumes that the balance is outside the non-billed budget and needs to be paid separately.

- Any excess credit remains on the Non-Billed Budget SA until the next distribution takes place or until the [Non-Billed Budget SA is stopped](#).
- The type of adjustments created is determined by the **Adjustment Type (Xfer)** specified on the Non-Billed Budget SA type.

The examples in the table below illustrate the points above.

| NBB SA Credit | SA 1 Payoff | SA 1 Current | SA 2 Payoff | SA 2 Current | SA 1 Credit Xfer | SA 2 Credit Xfer |
|---------------|-------------|--------------|-------------|--------------|------------------|------------------|
|---------------|-------------|--------------|-------------|--------------|------------------|------------------|

| | | | | | | |
|---------|---------|------|---------|-------|---------|--------|
| -100.00 | -100.00 | 0.00 | -200.00 | 0.00 | 0.00 | 0.00 |
| -100.00 | 150.00 | 0.00 | -50.00 | 0.00 | -100.00 | 0.00 |
| -300.00 | 150.00 | 0.00 | 50.00 | 0.00 | -150.00 | -50.00 |
| -100.00 | 150.00 | 0.00 | 250.00 | 0.00 | -37.50 | -62.50 |
| -100.00 | 150.00 | 0.00 | 250.00 | 50.00 | -42.86 | -57.14 |

The first example above shows that covered SAs with a credit balance are excluded from the distribution. Any excess credit remains on the Non-Billed Budget.

The second example shows that one covered SA has a credit balance, so the entire credit is distributed to the remaining SA.

The third example shows the amount distributed to a covered SA does not exceed its payoff balance. Again, any excess credit remains on the Non-Billed Budget SA.

The fourth example illustrates how the credit is prorated based on the payoff balance. The fifth example illustrates the same prorating but with a current balance on one of the SAs (SA 2). (Remember that the prorating excludes any current balance.)

The prorated amount is calculated by subtracting the current balance from the payoff balance then multiplying the result by the distribution amount and dividing by the total payoff owing of all covered SAs.

Stopping an SA Covered By a Non-Billed Budget

If a service agreement covered by a Non-Billed Budget is stopped, the system must bring the current balance and payoff balance of the covered SA back in synch. The system creates an adjustment using the Synch Current adjustment type from the SA's SA type.

In the example below, the electric SA's payoff balance is 21. The first twelve transactions are discussed above.

| Event | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance | Effect On Current Balance | Effect On Payoff Balance | Current Balance | Payoff Balance |
|--------------------------------|---------------------------|--------------------------|-----------------|----------------------|---------------------------|--------------------------|-----------------|----------------|
| | Electric SA | | | Non-Billed Budget SA | | | | |
| Starting balance | 0 | 0 | 25 | 25 | | | | |
| Non-Billed Budget is activated | -25 | 0 | 0 | 25 | | | | |
| First scheduled payment is due | | | | | 10 | 0 | 10 | 0 |
| Payment | | | | | -10 | -10 | 0 | -10 |

| | | | | | | | | |
|---------------------------------------|----|-----|----|----|-----|-----|----|-----|
| Second scheduled payment is due | | | | | 10 | 0 | 10 | -10 |
| Over-payment | | | | | -10 | -10 | 0 | -20 |
| Third scheduled payment is due | | | | | 10 | 0 | 10 | -20 |
| Transfer Adjustment | | | | | -10 | -10 | 0 | -30 |
| Fourth scheduled payment | | | | | 10 | 0 | 10 | -30 |
| Underpayment | | | | | -7 | -7 | 3 | -37 |
| Bill | 0 | 33 | 0 | 58 | | | | |
| Bill completion (transfer adjustment) | 0 | -37 | 0 | 21 | 0 | 37 | 3 | 0 |
| SA is stopped | 21 | 0 | 21 | 21 | | | | |

Note:

In addition to synching the current and payoff balance, the SA being stopped is removed from the covered SAs collection. When the last covered SA is removed from the collection, the Non-Billed Budget is also [stopped](#).

Financial Transactions For Unmonitored Non-Billed Budgets

Some companies have the concept of non-billed budgets where the payments made by the customer are optional. This functionality is implemented as an unmonitored Non-Billed Budget. Unmonitored Non-Billed Budgets allow a customer to make optional prepayments towards a bill.

As explained previously, unmonitored Non-Billed Budgets receive different financial treatment than monitored Non-Billed Budgets. The financial transaction algorithms use the **Non-Billed Budget Monitor** flag on the Non-Billed Budget's SA type to create the appropriate financial transactions. The following table describes the differences in the financial treatment of monitored and unmonitored Non-Billed Budgets.

| System Event | Monitored Non-Billed Budgets | Unmonitored Non-Billed Budgets |
|--------------|------------------------------|--------------------------------|
|--------------|------------------------------|--------------------------------|

| | | |
|---|--|--|
| When a Non-Billed Budget is activated or an SA is added to a Non-Billed Budget... | The system creates adjustments for all affected SAs to set the current balance equal to zero. | The current balances for covered SAs are not zeroed. The activate SA and Non-Billed Budget maintenance processing do not create any adjustments if the Non-Billed Budget is unmonitored. |
| When a scheduled payment is due... | An adjustment is created to increase the Non-Billed Budget's current balance by the expected amount. | There is no change to the Non-Billed Budget's current balance; it is always zero. The scheduled payment processing background process does not execute the NBB process scheduled payment algorithm . |
| When the payment is made... | The Non-Billed Budget's current balance is reduced to zero and the Non-Billed Budget's payoff balance reflects the accumulated credit from the payment. | Typically the payments are distributed to an excess credit (overpayment) SA. Refer to Distributing Payments for Unmonitored Non-Billed Budgets for more information. |
| When a bill segment financial transaction is created... | The current amount is set to zero for SAs that are covered by the Non-Billed Budget. | The covered SAs' current amounts are equal to their payoff amounts. |
| At bill completion... | Money from the Non-Billed Budget is transferred to the covered SAs. Customers may receive a bill for information purposes, but they are not required to pay it. | Money from the overpayment SA is transferred to the account's SAs. The customer is still liable to pay the outstanding balance. |
| When the Non-Billed Budget is stopped or an SA is removed from a Non-Billed Budget... | The system creates adjustments for all affected SAs to synchronize their current balances with their payoff balances, thus removing the zero current balance and replacing it with the actual current balance. | There is no change to the current balances for covered SAs as the balances already reflect the actual current balance. |

Unmonitored Non-Billed Budgets also receive different credit and collections treatment. Refer to [Credit and Collections and Unmonitored Non-billed Budgets](#) for more information.

Distributing Payments for Unmonitored Non-Billed Budgets

For Non-Billed Budgets, payments are distributed according to the payment and overpayment algorithms on the customer class. The base package payment distribution algorithm applies a payment first towards any SAs that have overdue or current balances (refer to [Distributing A Payment](#) for more information). Since the unmonitored Non-Billed Budget SA doesn't have a current balance, it is not considered by the payment distribution algorithm. If there aren't any SAs with a current balance, the overpayment distribution algorithm handles the remaining credit. You can elect to:

- Apply the overpayment to an excess credit SA. This is the method that we strongly recommend because all financial transactions are then a function of the normal payment, overpayment and billing processes.
- Apply the overpayment to the highest priority SA that is eligible for overpayment (as specified on the SA type). You can use this method to apply the overpayment to the unmonitored Non-Billed Budget SA. If you use this method, you must also set up the system to [transfer the credit from the unmonitored Non-Billed Budget](#).

**Note:**

Use An Excess Credit SA. We strongly recommend that payments for unmonitored Non-Billed Budgets are distributed to an excess credit SA. In this case, the Non-Billed Budget is just a shell to hold the covered SAs and recommend a payment schedule; all financial transactions are a function of the normal payment, overpayment and billing processes.

**Fastpath:**

Refer to [Overpayment Segmentation](#) for a detailed discussion of overpayment distribution options.

Transferring Credit from Unmonitored Non-Billed Budgets

If you distribute an overpayment to an unmonitored Non-Billed Budget SA (i.e. the unmonitored non-billed budget maintains a credit balance instead of an overpayment SA), you must plug-in a bill completion algorithm on the SA type to transfer the credit balance to the covered SAs at bill completion time. The bill completion algorithm type (BCMP-NB) supplied with the base package transfers the credit balance to the covered service agreements when the bill is completed. Additionally, the **Adjustment Type (Xfer)** on unmonitored Non-Billed Budget SA types should reference a FT algorithm of $\text{Payoff Amt} = \text{Adj} / \text{Current Amt} = \text{Adj}$ to ensure that the credit is removed from both the current and payoff balances.

**Warning:**

You must create your own SA stop algorithm type for correctly stopping an unmonitored non-billed budget that maintains a credit balance. The SA stop algorithm that is supplied with the base package does NOT transfer remaining credit from the unmonitored Non-Billed Budget SA. (The base package SA stop algorithm transfers the remaining credit using the overpayment distribution algorithm on the customer type, which you have set up to transfer to back to the unmonitored non-billed budget.)

Designing Non-Billed Budgets

The topics in this section describe functionality that you must consider when designing non-billed budgets.

Making SAs Eligible For Non-Billed Budgets

A billable SA may be covered by a Non-Billed Budget when its SA type is flagged as Eligible for Non-Billed Budget.

All SAs that are eligible for non-billed budgets should reference a bill segment type that uses the $\text{Payoff Amt} = \text{Bill Amt} / \text{Current Amt} = \text{Amt Due}$ bill segment FT algorithm. This algorithm sets the SA's current amount to zero if it is covered by a monitored Non-Billed Budget.

A list of the SAs covered by a Non-Billed Budget is maintained with the non-billed budget SA. This list is used at bill completion to determine the financial transactions that should occur.

Designing Recommendation Rules

Users (and the renewal process) ask the system to recommend the scheduled payments for a Non-Billed Budget. In general, this recommendation process must establish:

- The amount to be paid
- The dates on which the payments are due

We envision many different types of recommendation rules. For example:

- Recommend 26 scheduled payments to be made on a fortnightly basis that are due on Tuesdays.
- Recommend monthly payments that are due on the nearest workday after the 10th of the month.
- Recommend scheduled payments where the customer pays their annual charges in 10 out of 12 months where the payments are not due in November and December.

- Recommend bi-monthly payments where the payments are due on the first workday following the 5th and 20th of the month.

Additionally, the recommendation rules must determine how to handle any outstanding payoff balances for covered SAs. The true-up rule provided with the base package payment schedule algorithm type can ignore the payoff balance, divide the payoff balance evenly between the scheduled payments, or add the payoff balance to the first scheduled payment.

A recommendation rule comprises three elements:

- An algorithm to calculate an average daily amount (the NBDA-DA algorithm type provided with the base package uses premise billing history)

Note:

Calculating an Amount for Non-utility SAs. The algorithm type supplied with the base package only handles service-point oriented SAs. For example, the average daily amount algorithm calculates an average daily amount. For non-utility SAs, you must develop the appropriate algorithm types.

- Two algorithm types are provided with the base package to calculate a schedule of payments. NBPS-MON calculates a monthly schedule and NBPS-PS calculates a scheduled based on a specified number of days.
- A collection of default parameter values for the payment schedule algorithm type

A recommendation rule (based on the algorithm types provided with the base package) is illustrated below.

| Rule: Weekly | | |
|---|--------|----------|
| Avg Daily Amt Alg: Use premise history | | |
| Pay Schedule Alg Type: Number of days | | |
| Parameter | Value | Override |
| Number of days in period | 7 | Y |
| Number of payments | 52 | N |
| True-up rule | Spread | N |

Weekly Payments Recommendation Rule

Note:

Additional Parameters. Not all of the parameters associated with the weekly payment schedule algorithm type are illustrated. Refer to the NBPS-PS algorithm type for a detail description of the parameters.

The default parameter values for the payment schedule algorithm type may change over time, so the collection contains an effective date. If default values are changed, these changes do not affect Non-Billed Budgets already in effect. Existing Non-Billed Budgets keep the parameter values that were used when the Non-Billed Budget was started.

A user may override the default parameter values for the payment schedule algorithm type to customize the schedule if an override is allowed for a parameter. Additionally, a user may edit the payment schedule details at any time (provided the payment has not yet been processed).

The parameter values used for the recommendation rule are kept with the Non-Billed Budget SA, so that any customized parameter changes can be re-applied to a renewed Non-Billed Budget. For example, the parameter that determines the payment due day may default to the first of the month. To customize the schedule, this value may be changed to the fifth of the month. This amended value is kept with the Non-Billed Budget SA to ensure that the renewed budget follows the same monthly schedule.

Note:

Normally parameter values for an algorithm type are kept with the algorithm. Because the parameters may vary for each Non-Billed Budget, the parameter values are kept with the SA in the case of Non-Billed Budgets.

Refer to [Non-billed Budgets Recommendation Rule - Main](#) for information on creating recommendation rules.

Example Recommendation Rules

The following examples may be helpful in designing and implementing your recommendation rules.

Note:

Developing Your Own Payment Schedule Algorithms. The base package comes supplied with a monthly payment schedule algorithm type. You can use this algorithm as an example when creating payment schedule algorithm types for your implementation.

Fortnightly Payments Recommendation Rule Example

The following diagram illustrates a recommendation rule where the customers pay every two weeks. The current balance for any covered SAs is added to the first payment.

| Rule: Fortnightly | | |
|---|--------|----------|
| Avg Daily Amt Alg: Use premise history | | |
| Pay Schedule Alg Type: Number of days | | |
| Parameter | Value | Override |
| Number of days in period | 14 | Y |
| Number of payments | 26 | N |
| True-up rule | Spread | N |

Fortnightly Payments Recommendation Rule

Monthly Payments Recommendation Rule Example

The following diagram illustrates a recommendation rule where the customers pay twice monthly on the first of the month. The current balance for any covered SAs is spread out over the scheduled payments.

| Rule: Monthly | | |
|---|--------|----------|
| Avg Daily Amt Alg: Use premise history | | |
| Pay Schedule Alg Type: Monthly | | |
| Parameter | Value | Override |
| Day of month | 1 | Y |
| Number of payments | 12 | N |
| True-up rule | Spread | N |

Monthly Payments Recommendation Rule

Ten Out of Twelve Months Recommendation Rule Example

The following diagram illustrates a recommendation rule where the customers pay one a month except for months during a holiday season (November and December). The current balance for any covered SAs is added to the first payment.

| Rule: 10 of 12 | | |
|--|---------------------|----------|
| Avg Daily Amt Alg: Use premise history | | |
| Pay Schedule Alg Type: X out of Y months | | |
| Parameter | Value | Override |
| Total number of months | 12 | N |
| Months with no payment | 11,12 | Y |
| True-up rule | 1 st pay | N |

Ten Out of Twelve Months Recommendation Rule

Activating Non-Billed Budgets

You can plug in an algorithm (of type SACR-AT) on the SA Creation system event on the Non-Billed Budget SA type to automatically activate the Non-Billed Budget (i.e. transition it from pending start to active status). If you don't use a SA Creation algorithm to activate the Non-Billed Budget, it is activated the next time the [SA activation background process](#) runs.

When a Non-Billed Budget is activated, you can perform special processing using an algorithm plugged in on the SA Activation system event on the Non-Billed Budget SA type. The special processing can be developed to do anything that you would like, for example you could:

- Create a customer contact that with an appropriate letter template can generate a letter to inform the customer of their payment amount and payment schedule.
- Initiate the creation of a payment coupon book for a customer.

The system comes supplied with a sample algorithm type (called SAAT-CC) that simply creates a customer contact to indicate that the Non-Billed Budget is activated.

Renewing Non-Billed Budgets

A Non-Billed Budget can be renewed either manually or via a background process. When the Non-Billed Budget SA is created, the expiration date, renewal date and the recommendation rule used to create the initial budget are kept with the SA. A renewal flag on the Non-Billed Budget SA type controls if a renewal is required, optional or not allowed. If renewal is required, a user must specify a renewal date when creating the service agreement. The renewal date is defaulted on to an SA based on the valued of the **Days Before Expiration for Renewal** field on the SA type.

An algorithm on the SA type can customize the processing required to renew an SA.

The [SA renewal background process](#):

- Executes the SA renewal algorithm (specified on the SA type) when the renewal date is reached (i.e., it is on or before the process date). The base package comes with an algorithm type (SARN-NB) that determines the current recommendation rule for a non-billed budget and executes the associated payment schedule algorithm using the Non-Billed Budget SA-specific parameter values to generate a new schedule. It returns new expiration and renewal dates.
- If the renewal algorithm is successful, the renewal and expiration date fields on the SA are updated with the new values.

- If the renewal process is not successful, a To Do list entry (of type TD-SARN) is created for the account and SA.

The new payment schedule that is returned from the renewal process for a Non-Billed Budget is appended to the current schedule.

A user can manually launch the renewal process for a Non-Billed Budget SA by clicking the **Renew NBB** button on the [Non-Billed Budget maintenance page](#).

Expiring Non-Billed Budgets

Non-Billed Budget service agreements may specify an expiration date. The [SA expiration background process](#) initiates the stop process for all pending start or active SAs where the expiration date is reached (before or on the process date).

Stopping Non-Billed Budgets

When a Non-Billed Budget stop is initiated, either on request or because it has expired and is not being renewed, the Non-Billed Budget is transitioned to pending stop status. You can plug in an algorithm (of type SAIS-ST) on the SA Stop Initiation system event on the Non-Billed Budget SA type to automatically finalize and stop the SA (i.e. transition it to stopped status). If you don't use a SA Stop Initiation algorithm, the Non-Billed Budget is stopped the next time the [SA activation background process](#) runs.

To finalize a pending stop SA, the system first calls the stop SA algorithm plugged-in on the SA Stop system event on the SA type. The stop SA algorithm type (SAST-NB) supplied with the base package:

- Distributes any credit on the Non-Billed Budget to the covered SAs (using the method described in [Distributing Non-Billed Budget Credit](#))
- Distributes any excess credit remaining on the non-billed budget using the [overpayment distribution](#) algorithm for the account's customer class and the overpayment transfer adjustment type (specified as a parameter to the algorithm)
- Creates a trigger to cause the account to be reviewed by the account debt monitor
- Creates a customer contact (if the customer contact class and customer contact type parameters are populated)

Warning:

If you do not plug in an SA stop algorithm that transfers the credit balance from the non-billed budget to its covered SAs (or an excess credit SA), the stopped Non-Billed Budget may have a credit balance. You must then manually distribute this credit.

After the SA stop algorithm is finished, the SA stop processing performs the following steps if the SA type has a special role of Non-Billed Budget:

- If the Non-Billed Budget is monitored, create adjustments to synchronize the current and payoff balance of covered SAs using the **Adj. Type (Synch Current)** adjustment type from the covered SAs' SA types
- Remove the covered SAs from the Non-Billed Budget
- Remove all the scheduled payments from the non-billed budget
- Create an adjustment to synchronize current and payoff on the Non-Billed Budget SA using the **Adj. Type (Synch Current)** adjustment type from the Non-Billed Budget's SA type

Note:

Synchronizing current and payoff effectively sets the current amount to zero on the Non-Billed Budget SA, as the payoff amount should have been reduced to zero by the distribution and overpayment processing in the algorithm for SA Stop.

Fastpath:

Refer to [The Lifecycle Of A Service Agreement](#) for more information about how a pending stop SA is stopped and closed.

Automatic Payment and Non-Billed Budgets

If a customer wants to pay their non-billed budget scheduled payments automatically, the account must be set up for automatic payment. In addition, the Non-Billed Budget must indicate that automatic payment is being used.

Fastpath:

Refer to [How To Set Up Automatic Payment For A Non-Billed Budget](#) for more information.

When this is done, a background process referred to as NBBAPAY creates automatic payments on the scheduled payment date by calling the automatic payment creation algorithm plugged in on the installation record.

Note:

You must ensure that your auto pay creation algorithm supports Non-Billed Budget scheduled payments. The APAY-CREATE algorithm type supplied with the base package supports non-billed budget scheduled payments.

Credit and Collections and Non-Billed Budgets

Unless the Non-Billed Budget is **unmonitored**, the **account debt monitor** (ADM) monitors a Non-Billed Budget SA's current amount just as it does for any other SA. The scheduled payment algorithm creates a trigger to ensure that the account debt monitor reviews the account the next time it runs. The review date on the trigger record is set to the process business date.

A separate **debt class** is needed for Non-Billed Budget SA types, thus allowing you to define collection class controls, debt criteria and collection process templates specifically for Non-Billed Budgets. The debt criteria should be set up to trigger a collection process when the arrears amount exceeds \$0.01 for more than n payment periods plus the number of grace days that you want to allow.

The collection process template can perform any of the events in standard collection processes, such as sending letters to customers and creating severance processes. At a minimum, the collection process template should be set up to start a severance process for all service agreements in the debt class. (Since the debt class is specifically for Non-Billed Budgets, the Non-Billed Budget is the only SA that will be subject to a severance process.)

The Non-Billed Budget severance process template should include the following event types:

- Populate a characteristic on the SA to indicate that the SA is broken. The base package comes supplied with a severance event algorithm type (SVEV-NB) that sets an SA characteristic to indicate that it was "severed".
- [Expire Severance Agreement](#) to move the SA to the pending stop state.

When the system subsequently stops the Non-Billed Budget, the system removes the covered SAs from the Non-Billed Budget and synchronizes their current balances with their payoff balances. Since the SAs have current balances again, they are subject to the account debt monitor, which can start subsequent collection processes for any of the SAs that meet the debt criteria for their debt class.

Fastpath:

Refer to [Stopping Non-billed Budgets](#) for a complete description of the events that occur when a Non-Billed Budget is stopped.

Customers can catch up on their payments and avoid having their Non-Billed Budget broken as long as their current balance doesn't violate the debt criteria for the Non-Billed Budget's collection process.

Credit and Collections and Unmonitored Non-Billed Budgets

If the **Non-Billed Budget Monitor** flag on the Non-Billed Budget's SA type is set to Unmonitored, the **NBB Scheduled Payment Processing** background process does not create a trigger for the account debt monitor. Additionally, the Non-Billed Budget's current amount is always equal to zero, so it never violates any debt collection

criteria. We recommend using a debt class that has the **Eligible for Collection** flag turned off, such as the N/A debt class.

For unmonitored Non-Billed Budgets, the current balance is kept on the covered SAs so they are subject to the account debt monitor and any debt criteria for their SA types' debt classes. For more information, refer to [Financial Transactions for Unmonitored Non-Billed Budgets](#).

Non-Billed Budget Status

A Non-Billed Budget SA's status is just like any other SA's status. In addition, you can use a characteristic to keep an explicit status relevant to the Non-Billed Budget:

- A base package severance event algorithm type (SVEV-NB) creates a characteristic value to indicate if a Non-Billed Budget is "broken" (i.e. stopped as a result of a severance process).
- A base package break Non-Billed Budget algorithm type (NBBR-BRK) creates a characteristic value to indicate if a Non-Billed Budget is "canceled" (i.e. manually stopped by a user).

An active Non-Billed Budget implicitly has a "kept" status (i.e. all scheduled payments have been made).

Alerts For Non-Billed Budgets

The system provides [alerts](#) to highlight the existence of Non-Billed Budgets. These alerts are important to assist the customer service representatives:

- An alert is displayed if the account has a Non-Billed Budget that is not stopped (e.g., pending start, active or pending stop).
- When a user denies a Non-Billed Budget (for whatever reason), the user should create a [customer contact](#) with a given [customer contact type](#). This type of alert prevents the customer from shopping around. An existing alert algorithm type (CC BY TYPCL) can highlight these customer contacts.
- For customers who are permanently forbidden from having a Non-Billed Budget, the user should put a permanent [alert on the account](#).
- Use an algorithm to highlight cancelled or severed non-billed budgets with an entry in the alert zone. The algorithm type to do this is not provided. Use PP BY STATUS and CCAL-WF as examples of how to create this type of algorithm.

Fastpath:

For more information about introducing alert conditions on Control Central, refer to [Installation Options - Algorithms](#).

Non-Billed Budget Recommendation Rule

Recommendation rules are used to recommend scheduled payments for Non-Billed Budgets. For information about designing recommendation rules, refer to [Designing Recommendation Rules](#).

To define recommendation rules, navigate to **Admin > Financial > NBB Recommendation Rule > Add**.

Description of Page

Enter an easily recognizable **Recommendation Rule** code and **Description** for each recommendation rule.

Specify the **Average Daily Amount Algorithm** used to calculate the average daily amount for this recommendation rule.

Specify the **Payment Schedule Algorithm Type** used to create the recommended payment scheduled for Non-Billed Budgets that use this recommendation rule. The Payment Schedule Algorithm Type cannot be modified if a Non-Billed Budget SA that is not stopped or cancelled is using this recommendation rule.

Payment Schedule Parameters enables you to define collections of default parameter values for the payment schedule algorithm type that are effective dated. For each collection:

- **Effective Date** defines the date on which the collection of parameter values becomes effective.
- **NBB Rule Parameter Value** specifies the default value of each parameter supplied to the algorithm. Note that the payment schedule algorithm type controls the number and type of parameters.
- **Override** indicates whether the user can override the default value for the parameter.

Setting Up The System To Enable Non-Billed Budgets

The above topics provided background information about how Non-Billed Budgets are supported in the system. The topics in this section describe how to set up the system to enable Non-Billed Budget functionality.

Note:

Example Setup. This section describes typical non-billed budget configurations. Your set up and configuration may differ depending on your business needs. This section is provided for guidance only. Read the descriptions of Non-Billed Budget functionality above to understand the implications of the described setup.

NBB Distribution Codes

You must set up a Non-Billed Budget Clearance [distribution code](#) that is used on the Non-Billed Budget SA type to credit non-billed payments.

NBB Adjustment Types

Note:

Non-Billed Budget Financial Transaction Algorithms. The Non-Billed Budget adjustment types use the standard FT algorithm types that are provided with the base package. If you have not yet defined algorithms for these types in your system, do so before creating the Non-Billed Budget adjustment types.

The following adjustment types are needed:

- **Add SA To Non-Billed Budget.** This adjustment type should reference an FT algorithm of $\text{Payoff Amt} = 0 / \text{Current Amt} = \text{Adj Amount (no GL)}$. Because the adjustment affects the current balance only, there is no entry in the GL. This adjustment type is referenced on **Adjustment Type (Current=0)** on SA types that are eligible for Non-Billed Budgets. Note that this adjustment type is never used if the SA is added to an unmonitored Non-Billed Budget.
- **Bill Complete for Monitored Non-Billed Budget.** This adjustment type should reference a distribution code used for balance transfer clearing. It should reference a FT algorithm of $\text{Payoff Amt} = \text{Adj} / \text{Current Amt} = 0$. This adjustment type is referenced on **Adjustment Type (Xfer)** on SA types that are monitored Non-Billed Budgets.
- **Synch Balance for Non-Billed Budget.** This adjustment type should be set up for **Sync. Current Amount** and should reference a FT algorithm of $\text{Payoff Amt} = 0 / \text{Current Amt} = \text{Adj Amount (no GL)}$. This adjustment type is referenced on the **Adj. Type (Synch Current)** on Non-Billed Budget SA types. It is used when a Non-Billed Budget SA is stopped to synch the current balance with the payoff balance.
- **Scheduled Payment.** This adjustment type should reference an FT algorithm of $\text{Payoff Amt} = 0 / \text{Current Amt} = \text{Adj Amount (no GL)}$. Because the adjustment affects the current balance only, there is no entry in the GL. This adjustment type is referenced on the Non-Billed Budget process scheduled payment algorithm.
- **Overpayment Transfer.** This adjustment type should reference a transfer distribution code and a FT algorithm of $\text{Payoff Amt} = \text{Adj} / \text{Current Amt} = \text{Adj}$. This adjustment is referenced on the non-billed budget process scheduled payment algorithm and the stop non-billed budget algorithm. Note that if there is already a transfer adjustment type created in your system, you do not need to create a new one.

If you are setting up an unmonitored Non-Billed Budget that maintains a credit balance (as opposed to maintaining the credit balance on an overpayment SA), you need to create an adjustment type for Bill Complete for Unmonitored Non-Billed Budget. (Refer to [Transferring Credit from Unmonitored Non-billed Budgets](#) for more information.) The adjustment type should reference a transfer distribution code and a FT algorithm of $\text{Payoff Amt} = \text{Adj} / \text{Current Amt}$

= Adj. This adjustment type is referenced on **Adjustment Type (Xfer)** on SA types that are unmonitored Non-Billed Budgets.

NBB Adjustment Type Profiles

Create an adjustment type profile for Non-Billed Budgets that references the following adjustment types:

- Bill complete for monitored Non-Billed Budget
- Bill complete for unmonitored Non-Billed Budget (if used)
- Synch balance for Non-Billed Budget
- Scheduled payment
- Overpayment transfer

Create an adjustment type profile for eligible SAs that references the following adjustment types:

- Add SAs to monitored Non-Billed Budgets
- Bill complete for monitored Non-Billed Budget
- Bill complete for unmonitored Non-Billed Budget (if used)

Note:

Bill Complete Adjustment Types. Because the bill complete adjustment types transfer amounts between two SAs, they must be in profiles for both Non-Billed Budget and eligible SA types.

Overpayment Transfer Adjustment Type. The overpayment transfer adjustment type created above is used to transfer funds from an excess credit SA to a Non-Billed Budget when the scheduled payment is processed. It is also used to transfer excess funds from a Non-Billed Budget that is being closed to an excess credit SA. The transfer adjustment should therefore be added to an adjustment type profile that is referenced on the excess credit SA type.

NBB Characteristic Types

Create a Non-Billed Budget status characteristic type that specifies Service Agreement as its characteristic entity. The characteristic type should include the following predefined values:

- Non-Billed Budget Canceled
- Non-Billed Budget Severed

NBB Customer Contact Class And Types

Create a Non-Billed Budget customer contact class. The contact class may include the following customer contact types:

- Non-Billed Budget Activate
- Non-Billed Budget Renewal
- Non-Billed Budget Stop

Note:

Customer Contact Letters. If you want to send letters to your customers when a contact of any of these types is created, you must create an appropriate [letter template](#) and attach it to the contact type.

NBB Algorithms

You must define the following [algorithms](#):

- On [NBB recommendation rule](#), the Non-Billed Budget Daily Amount Calculation. Refer to the NBDA-DA algorithm type for more information about the base package algorithm.

- On [SA type](#):
 - Non-Billed Budget Process Scheduled Payment. This algorithm has parameters that must reference the Scheduled Payment and Overpayment Transfer adjustment types defined above. Another parameter references an overpayment SA type (that you may need to create if there is not already one in your system). Refer to the NBPA-PS algorithm type for more information about the base package algorithm.
 - Non-Billed Budget SA Renewal. Refer to the SARN-NB algorithm type for more information about the base package algorithm.
 - Break Non-Billed Budget SA. Refer to the NBBR-BRK algorithm type for more information about the base package algorithm.
 - SA Activation - automatically activate SA (if you want to automatically activate Non-Billed Budgets when they are created). Refer to the SACR-AT algorithm type for more information about the base package algorithm. Note that this same algorithm may be used on many SA types.
 - SA Activation - create customer contact (if you want the system to create a customer contact when NBB SAs are activated). Refer to the SAAT-CC algorithm type for more information about the base package algorithm.
 - SA Stop - automatically stop SA (if you want to automatically transition Non-Billed Budgets from pending stop to stop when their stop is initiated). Refer to the SAIS-ST algorithm type for more information about the base package algorithm. Note that this same algorithm may be used on many SA types.
 - SA Stop - Stop Non-Billed Budget. Refer to the SAST-NB algorithm type for more information about the base package algorithm.
 - Bill Completion - Non-Billed Budget Credit Transfer. Refer to the BCMP-NB algorithm type for more information about the base package algorithm.
- On [bill segment type](#), the Bill FT Algorithm (for all SAs that are eligible for NBB). Refer to the BSBF-BA algorithm type for more information about the base package algorithm. Note this is the standard bill FT algorithm type used for common bill transactions. It supports bill FT for non-billed budgets and other SA types. You only need to create it if it doesn't already exist in your system.
- On [severance event type](#), an algorithm for Non-billed Budget Severance. Refer to the SVEV-NB algorithm type for more information about the base package algorithm.

Note:

Payment Schedule Algorithm Types. For Non-Billed Budget payment schedule algorithm types, you need to define the algorithm types (if you add your own algorithm types). You do not need to define algorithms because the parameter values for the algorithm are defaulted on the recommendation rule and stored with the Non-Billed Budget SA. (Normally the algorithm holds the parameter values.) Refer to the NBPS-MON algorithm type for more information about the base package payment schedule algorithm.

NBB Debt Class And Collection Process

Set up a separate debt class, collection class control, collection process template and severance process template for Non-Billed Budgets according to the information in [Credit and Collections and Non-Billed Budgets](#).

SA Types for SAs Covered by NBBs

You must modify the SA type for any SAs that you want to allow to be covered by a Non-Billed Budget.

- Verify that the specified **Bill Segment Type** (on the Billing page) references a financial transaction algorithm to set the current amount to zero for monitored Non-Billed Budgets. The FT creation algorithm type BSBF-BA (i.e., $\text{Payoff Amt} = \text{Bill Amt} / \text{Current Amt} = \text{Amt Due}$) supplied with the base package sets the current amount to zero for SAs that are covered by monitored non-billed budgets, though this is not evident by the name. (For SAs that are not covered by a Non-Billed Budget, the current amount is equal to the amount due or the recurring charge.) Refer to [Billing For SAs Covered By The Non-Billed Budget](#) for more information.
- Set the **Eligible for Non Billed Budget** flag (on the Billing page) to Eligible for Non-Billed Budget .
- Populate the **Adjustment Type (Current = 0)** (on the Detail page) to indicate the adjustment to be used to zero out the current amount on the covered SAs when the Non-Billed Budget SA is activated. Use the Add SA To

Non-Billed Budget [adjustment](#) created above. This adjustment type is only called for SAs that are covered by a monitored Non-Billed Budget.

- Reference an **Adjustment Type Profile** (on the Adjustment Profile page) that includes the Add SA To Non-Billed Budget adjustment type referenced in the **Adjustment Type (Current = 0)** field above.
- If not already specified (for write off), an **Adj. Type (Synch Current)** (on the Main page) is also required. It is used to synchronize (make equal) the current amount with the payoff amount when the SA is removed from (i.e. no longer covered by) a Non-Billed Budget.

NBB Recommendation Rules

Set up any [NBB Recommendation Rules](#) that you want to be available for your Non-Billed Budget SAs. Use any Non-Billed Budget Daily Amount Calculation algorithms defined above. Also use the Non-billed Budget Monthly Payment Schedule (NBPS-MON) algorithm types and specify the default parameters.

Non-Billed Budget SA Types

You must set up a [SA types](#) for your Non-Billed Budget service agreements. You may need multiple Non-Billed Budget SA types if you have different business rules for different types of Non-Billed Budgets, for example, if you have both monitored and unmonitored Non-Billed Budgets or if you support Non-Billed Budgets with different renewal requirements. The following points provide guidelines for creating a non-billed budget SA type.

SA Type - Main (NBB)

Service Type should reference something like "Miscellaneous Service".

Distribution Code should be the one you set up to book credits for Non-Billed Budgets.

Revenue Class should be set to N/A. (Revenue classes are not applicable because Non-Billed Budgets do not apply a rate and revenue classes are only relevant for SA types that use a rate.)

The **Payment Segment Type** should reference the Normal Payment.

Do Not Overpay should be on. Any excess payments should go to the overpayment SA, not the Non-Billed Budget SA.

Late Payment Charge is not applicable and should not be turned on because Non-Billed Budgets are not billed.

Adj. Type (Synch Current) should reference the Synch Balance for Non-Billed Budget adjustment type created above.

SA Type - Detail (NBB)

- **Special Role** is Non-Billed Budget.
- **Adjustment Type (Xfer)** must be populated to indicate the adjustment to be used for transferring accumulated credit from the Non-Billed Budget SA to the covered SAs. This field is not used for unmonitored Non-Billed Budgets.
- **Renewal** may be optional, not allowed, or required depending on your business processes.
- If Renewal is required, specify the **Days Before Expiration for Renewal**.
- **Non-Billed Budget Monitoring** must indicate whether the Non-Billed Budget is monitored by the account debt monitor.

SA Type - Billing (NBB)

Non-Billed Budget SAs do not get billed, so the **Eligible for Billing** flag should be off.

Additionally, the **Characteristic Premise Required** should not be checked for Non-Billed Budgets.

SA Type - Rate (NBB)

Non-Billed Budget SAs do not use rates, so the **Rate Required** flag should be off.

SA Type - SP Type (NBB)

Non-Billed Budget SAs do not have service points, so the **Service Points Required** flag should be off.

SA Type - Adjustment Profile (NBB)

Adjustment Type Profile should reference the [adjustment type profile](#) for Non-Billed Budgets (set up above).

SA Type - Credit and Collections (NBB)

The credit and collections information should reference a **Severance Process Template** that calls the Non-Billed Budget Severance algorithm created above and expires the Non-Billed Budget SA. The **Debt Class** should reference an appropriate value consistent with your credit and collections rules. Typically, monitored Non-Billed Budgets should be in their own debt class. Unmonitored Non-Billed Budgets should have a **Debt Class** that is not Eligible for Collection.

The **Write Off Debt Class** is not applicable because the Non-Billed Budget contains no debt to be written off. Reference a debt class such as N/A. Refer to [Defining Credit & Collections Options](#) for more information.

SA Type - Algorithms (NBB)

The SA type [algorithms](#) defined above must be set up:

- The Non-Billed Budget Credit Transfer algorithm created above should be specified for the Bill Completion system event (not used on unmonitored Non-Billed Budgets).
- The Break Non-Billed Budget SA algorithm created above should be specified for the Break NBB SA system event.
- The Non-Billed Budget Process Scheduled Payment algorithm created above should be specified for the Process NBB Scheduled Payment system event (not used on unmonitored non-billed budgets).
- The Non-Billed Budget SA Renewal algorithm created above should be specified for the SA Renewal system event.
- If you created the Automatic SA Activation algorithm above, it should be specified for the SA Creation system event.
- The Non-Billed Budget SA Activation algorithm created above should be specified for the SA Activation system event.
- If you created the Automatic SA Stop algorithm above, it should be specified for the SA Stop Initiation system event.
- The Stop Non-Billed Budget algorithm created above should be specified for the SA Stop system event.

SA Type - NBB Recommendation Rule (NBB)

Add the recommendation rules defined above that are valid for SAs of this type. Also, indicate which recommendation rule should be used as the default.

NBB Background Processes

Ensure that the following background processes are scheduled:

- Non-Billed Budget Scheduled Payment Processing ([NBBPS](#))

- Non-Billed Budget Scheduled Payment Automatic Payment Create ([NBBAPAY](#))
- Service Agreement Renewal ([SARENEW](#))
- Stop Expired Service Agreements ([SAEXPIRE](#))

Defining Quotation Options

This section describes tables that must be set up before quotations can be created.

Fastpath:

For more information, refer to [The Big Picture of Quotations](#).

Setting Up SA Types For Quotes

The topics in this section describe additional setup responsibilities required on SA types that can have proposal service agreements.

Note:

Assumption. We have assumed that you've already designed your SA types for the services that you sell. If you haven't done this, refer to [Defining Service Agreement Types](#).

Enabling The Automatic Generation Of Billing Scenarios

As described under [Proposal SAs Contain Billing Scenarios And Template Consumption](#), a proposal SA requires billing scenarios before a quote detail can be generated. The system will automatically create billing scenarios when a proposal SA is created if you plug-in the appropriate Proposal SA Creation algorithm on each such [SA type](#). Refer to PSAC-CBS for an example algorithm (note, this algorithm can be used to create billing scenarios for both interval and non-interval service agreements).

Enabling The Generation Of Simulated Bill Segments

As described under [Creating Quotes And Quote Details](#), in order for the system to generate simulated bill segments for a proposal SA, you must plug-in a Proposal SA Bill Segment Generation algorithm on the proposal SA's [SA type](#). Refer to CBSP-AR for an example algorithm that creates a simulated bill segments for each billing scenario linked to the proposal SA by calling rate application.

Note:

Interval pricing service agreements. If you have proposal SAs that require the derivation of interval profiles from other interval profiles, you must also plug-in another Proposal SA Bill Segment Generation on the interval [SA type](#). Refer to CBSP-IDDRV for an example algorithm that performs derivation. When you plug-in this type of algorithm, don't forget to use a sequence number less than the one that generates the simulated bill segments (see above); otherwise, the derived interval profiles won't exist when rate application is called.

Enabling The Creation Of A Real SA When A Quote Detail Is Accepted

As described under [Accepting / Declining Quote Details](#), in order for the system to create a real SA when a proposal SA is accepted, you must plug-in a Proposal SA Acceptance algorithm on the proposal SA's [SA type](#). Refer to PSAA-PS for an example algorithm that creates a real SA by copying the proposal SA.

Note:

Interval pricing service agreements. If the service agreement has SA-specific interval profiles, time-of-use maps, or contract options, it's important that you setup your Proposal SA Acceptance algorithm to create fresh

interval profiles, time-of-use maps and contract options when the real SA is created (there's a parameter on PSAA-PS that will do this). Refer to [Proposal SAs And Interval Consumption](#) for more information.

Setting Up Quote Route Types

Quote route types control how quotes are [routed](#) to customers and prospects. To define a quote route type, open **Admin > Sales & Marketing > Quote Route Type**.

Fastpath:

Refer to [Printing Quotes](#) for more information about how quotes are routed to customers and prospects.

Description of Page

Enter a unique **Quote Route Type** and **Description** for every quote route type.

Quote Routing Method controls the type of information that may be defined when the respective **Quote Route Type** is selected on [Account - Person Information](#). The following options are available:

- Postal: Use this method if the routing is via the postal service.
- Fax: Use this method if the routing is via fax.
- Email: Use this method if the routing is via email.

Note:

The values for **Quote Routing Method** are customizable using the [Lookup](#) table. This field name is QTE_RTG_METH_FLG .

- The next two fields control how quotes that are routed using this method are [printed](#) (both in batch and online).
 - Use **Batch Control** to define the process that creates the flat file that is passed to your quote printing software. Refer to [Technical Implementation of Printing Quotes In Batch](#) for more information about these processes.
 - Use **Extract Algorithm** to define the plug-in that constructs the "flat file records" that contain the information merged onto quotes routed using this method. Refer to [Printing Quotes](#) for more information.

Setting Up Terms and Conditions

As described under [Legal Terms and Conditions May Be Specified On SAs](#) , your [SA type start options](#) can reference terms and conditions (T&C's) that should be defaulted onto new service agreements (both real and proposal). Each T&C is identified with a terms and condition code. To define a terms and conditions code, open **Admin > Sales & Marketing > Terms and Conditions > Add**.

Note:

T&C print order. The value of the T&C code controls the order in which the T&C appears on the printed quote. This means you should assign these codes in some type of structured format (e.g., 01...) if you would like them to appear in a certain order.

Description of Page

Enter a unique **Terms and Condition** code and **Description**. Use **Text** to describe the exact terms.

Setting Up Decline Reasons

A proposal SA decline reason must be supplied when a proposal SA is declined. Open **Admin > Sales & Marketing > Proposal SA Decline Reason** to define your reason codes.

Description of Page

Enter an easily recognizable **Decline Reason** and **Description** for each proposal SA decline reason.

Where Used

Decline reasons are used when a [quote detail is declined](#).

Setting Up Customer Classes For Quotes

An optional plug-in spot exists on [customer class](#) where you can introduce additional logic to be executed when a quote is completed for an account that belongs to this customer class. The base package comes supplied with a sample algorithm that creates a workflow process when a quote is completed (refer to the algorithm QTEC-WP for more information).

Defining Case Management Options

Case management functionality is a highly configurable tool your organization can use to manage many situations, including (but certainly not limited to) the following:

- a high-bill complaint,
- a bankruptcy,
- an inspection of a premise,
- a customer's request for literature,
- an application for new service,
- a contractor's request to extend a line,
- a customer's rejection of a quote,
- a customer's request to change service providers on a future date,
- the processing of a market message in a deregulated environment,
- ... (the list is only limited by your time and imagination)

Obviously the steps involved in the resolution of the above cases are very different. The topics in this section describe how to configure the system to manage your cases as per your organization's desires.

Note:

Separate module. The Case Management functionality is associated with a separate module. If the Case Management module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

Fastpath:

Refer to [Case Management](#) for a description of how end-users use cases.

The Big Picture Of Cases

The topics in this section provide background information about how to configure the system to support your case management requirements.

Case Type Controls Everything

Whenever a user creates a case, they must specify the type of case (e.g., high-bill complaint, literature request, etc.). The case type controls how the case is handled.

Case types hold the business rules that control cases. Since these business rules can sometimes be quite complicated, setting up case types requires planning and foresight. The topics in this section describe the type of business rules that can be configured on your case types.

Person / Account / Premise Applicability

Some types of cases may be person-oriented, others may be premise-oriented, and still others may be account-oriented. For example:

- Cases used to keep track of a literature request would reference the person who requested the literature.
- Cases used to keep track of the inspection of a property would reference the premise being inspected.
- Cases used to keep track of a high-bill complaint would reference the account associated with this bill(s) being disputed.

When you set up a case type, you define if its cases must reference a person, account, and/or premise. Note, any combination of these objects is permitted on a case.

Contact Information Applicability

When a case is created, you may want to keep track of how to contact its originator. For example, you may want to record the originator's email address or phone number. When you set up a case type, you define if contact information is required, optional or not allowed on its cases.

Business Object Association

A case type may reference a Business Object, which serves as a link between cases of that type and the options that are associated with the business object.

Additional Information

Some of your cases may require additional information (in the form of [characteristics](#)). For example, a high-bill complaint may require at least one bill. When you set up a case type, you can define the additional fields that are required. In addition, you can define default values for these fields.

The case functionality also allows you to require characteristics when a case enters a given state. Refer to [Required Fields Before A Case Enters A State](#) for the details.

Note:

Requiring supporting documents. Because any [type of characteristic](#) can be referenced on a case, you can require references to supporting documents by requiring a file location characteristic.

Access Rights

You can take advantage of the system's [security](#) to restrict cases of a given type to certain users. For example, you can restrict high-bill complaints to specific user groups.

The following points describe how to implement this type of security:

- Create an [application service](#) for each type of case you need to secure
- Define the access modes Add, Inquire and Change for each application service
- Define the applicable application service on each case type
- Link the appropriate [user groups](#) to each application service
 - For user groups that are allowed to add cases of a given type, define Add as a valid access mode.
 - For user groups that are allowed to view cases of a given type, define Inquire as a valid access mode
 - For user groups that are allowed to change cases of a given type, define Change as a valid access mode

If you restrict access to a case type's cases, you can further restrict which users can work on cases given the status of the case. Refer to [Which Users Can Transition A Case](#) for more information.

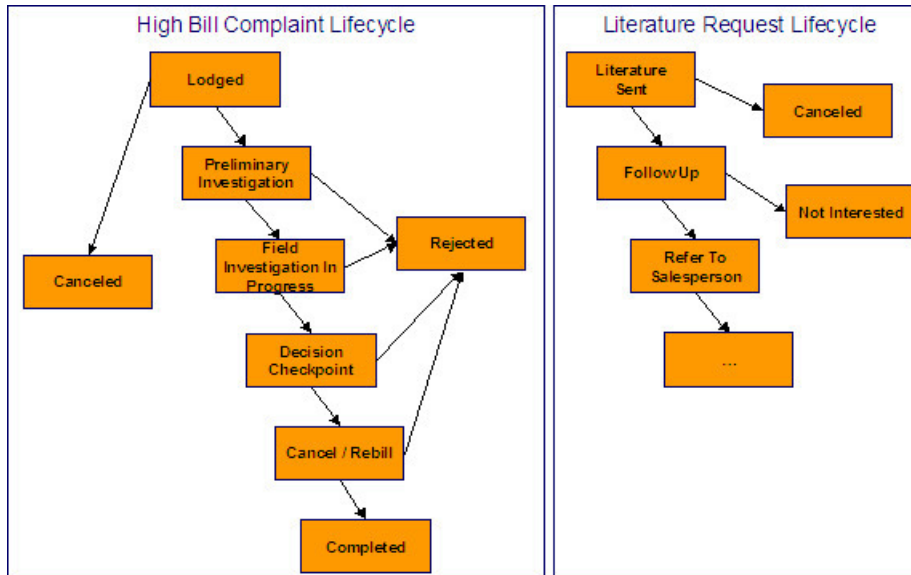

Note:

Restricting access to cases is optional. If you don't specify an application service on a case type, all users (who have access to the case transaction) may access its cases.

Lifecycle

Many objects in the system have predefined lifecycles whose rules are governed by the base-package and cannot be changed. For example, a service agreement starts out in the Pending Start state and eventually becomes Closed when it's been final billed (and paid). You can't change the system to allow a service agreement to start its life in the Closed state.

The lifecycle of cases is not governed by the base package. Rather, you define the lifecycle of your cases when you set up their case types. Examine the following diagrams; the one on the left shows the potential lifecycle of a case that manages a high-bill complaint, the one on the right shows the potential lifecycle of a case that manages a customer's literature request.

Potential Lifecycles Of Two Types Of Cases

Note:

Just examples. The above lifecycles are just examples. When you set up your case types, you must define the valid states for your case type.

The topics that follow describe important concepts that are illustrated in the above diagrams.

Valid States versus State Transition Rules

The orange boxes in the above diagram show the potential valid states a given case can have. The lines between the boxes indicate the state transition rules. These rules govern the states a case can move to while it's in a given state. For example, the above diagram indicates a high bill complaint that's in the Lodged state can be either Canceled or moved into the Preliminary Investigation state.

When you set up a case type, you define both its valid states and the state transition rules.

Transitory States

You can define a state in a case type as **Transitory** if you do not wish the case to exist in a particular state. For example, let's assume that an algorithm is associated with the Decision Checkpoint state (Enter Processing) that would automatically determine the next state for the case (i.e. Cancel/Rebill or Reject) and also contains logic to transition the case accordingly. In this scenario, you may not ever want the case to exist in the Decision Checkpoint state, so that a user won't ever see a high bill complaint in that state. If the other states were marked as non-transitory, and an error were to occur during the transition from Decision Checkpoint to Cancel/Rebill, the case would roll back

any changes to data made in the Cancel/Rebill (Enter Processing) state along with the changes made in the Decision Checkpoint state, and would end up in the Field Investigation In Progress state - the last non-transitory state prior to Decision Checkpoint.

One Initial State and Multiple Final States

When you set up a case type's states, you must pick one as the initial state. The initial state is the state assigned to new cases of a given type. For example, high-bill complaint cases have an initial state of Lodged, whereas literature request cases have an initial state of Literature Sent.

You must also define which statuses are considered to be "final". When a case enters a "final" state, it is complete and no further action is necessary. You might want to think of the "final" states as the potential outcomes of a case. For example, a high-bill complaint has potential outcomes of Completed, Rejected, and Canceled.

The "final" states are used by the system to differentiate between open and closed cases. For example, an alert highlights when the person / account / premise in context has open cases (this alert only exists if you've plugged-in the appropriate installation [alert](#)).

Allowing A Case To Be Reopened

You can set up your state transition rules to allow a case to be reopened (i.e., to be moved from a final state to a non-final state). Neither of the above examples allows this, but it is possible if you configure a case type accordingly.

Make Sure To Have A Canceled State

The system does not allow you to delete a case. Therefore, if you want to support logical deletion, you should have a status of Canceled early in a case type's lifecycle. Doing this allows a user to cancel (i.e., logically delete) a case.

Note:

Cancel reason. You might want to consider setting up your case types to require a cancel reason (in the form of a [predefined value characteristic](#)) when a user cancels a case. Refer to [Required Fields Before A Case Enters A State](#) for more information.

Buttons Are Used To Transition A Case From Status To Status

When a case is displayed on [Case - Main](#), a separate button is shown for each state into which the case can be transitioned. For example, a high-bill complaint case that is in the Lodged state would show two buttons: **Start Investigation** and **Cancel**. If the user presses the **Start Investigation** button, the case is transitioned to the Preliminary Investigation state. If the user presses the **Cancel** button, the case is moved to the Canceled state.

You may define the text displayed on the button differently for each state transition. This allows the action description to be varied according to the previous status. For example, the button to transition from New to Active may be labeled **Activate**, but the button to change from Closed to Active may be labeled **Reactivate**.

Refer to [Which Users Can Transition A Case](#) for instructions describing how to restrict users to specific actions.

State Transitions Are Audited

The system maintains an audit trail whenever a case transitions from one state to another. This audit is shown in the case's [log](#).

Reports and Analytics Highlight Productivity

When you set up a case type's lifecycle, keep in mind that several reports and analytics highlight how long it took cases to transition into a state. For example, you can use a report to see how long it took high-bill complaints to be completed (or initially actioned or ...). Refer to the [Reports](#) chapter for the details of case reports.

Status-Specific Business Rules

As described in [Lifecycle](#), when you set up a case type, you define the possible states its cases can pass through. The following topics describe business rules that can be configured for each state.

A Script That Helps A User Work Through A Case

You can define a [Business Process Assistant script](#) that helps a user work a case while it's in a given state. For example, when you set up the Preliminary Investigation state for the high-bill complaint case type, you can define a script. A user can then easily launch this script to help them work through a case in this state.

Please keep the following in mind when you're designing how to integrate BPA scripts with your cases:

- You can have a different script for each state. For example, you could develop a script to help a user work on a case while it's in the Preliminary Investigation state and a different script to help them work in a case while it's in the Decision Checkpoint state.
- Rather than make a user launch a script by pressing a hyperlink on the [case page](#), you can have the system automatically launch the script while the case is in a given state. Refer to [Script Launching Option](#) for more information.
- You can also have the system automatically launch a script when a user selects a To Do entry. Refer to [Launching Scripts When To Do Entries Are Selected](#) for more information.

Fastpath:

Refer to [Scripts and Cases](#) for more information about how to streamline your case processing with scripts.

Required Fields Before A Case Enters A State

You can define additional fields (i.e., characteristics) that are required before a case can enter a given state. For example,

- You can indicate a high-bill complaint must reference at least one bill before it enters the Preliminary Investigation state.
- You can indicate a case must reference a cancel reason before it enters the Canceled state.

You do this by indicating that [characteristics](#) (that were optional when the case was added) are required when a case enters a given state.

Validation Before A Case Enters A State

You can define validation that executes before a case can enter a given state. For example, you can indicate the case must have been assigned a responsible user before it can enter the Preliminary Investigation state. This validation logic is held in algorithms that are plugged in on the case type and therefore you can define any type of validation.

Additional Processing When Entering A State

You can define additional processing that should happen when a case enters a given state. For example, you can have a [letter](#) created when a high-bill complaint case is Rejected. Similarly, you can have a [To Do entry](#) created when a high bill complaint enters the Preliminary Investigation state. This additional processing is held in algorithms that are plugged in on the case type and therefore you can define any type of additional processing.

You can also incorporate state transitioning logic within routines that are executed when a case enters a state, so that you do not need to rely upon CASETRAN to transition your cases. For example, when the state entry routines of

the Preliminary Investigation status for a high-bill complaint are executed, they may be designed to transition the case into either the Rejected or Field Investigation In Progress state without waiting. Note that your Exit Validation and Exit Processing logic, if configured for the case state, will still be executed as part of the state transition. Auto-Transition logic for this state will be ignored during this transition.

Validation Before A Case Exits A State

You can define validation that executes before a case can exit a given state. For example, you might want to check the account's balance is less than a given value before a case can exit a given state. This validation logic is held in algorithms that are plugged in on the case type and therefore you can define any type of validation.

Additional Processing When Exiting A State

You can define additional processing that should happen when a case exits a given state. For example, you can have a [To Do entry](#) automatically completed when a high bill complaint leaves the Decision Checkpoint state. This additional processing is held in algorithms that are plugged in on the case type and therefore you can define any type of additional processing.

Automatic Transition Rules

You can define rules that automatically transition a case into a different state. For example, you can indicate a literature request should be transitioned to the Follow Up state 1 week after the literature is sent. Similarly, you can indicate a high-bill complaint should transition to the Decision Checkpoint state after the fieldwork is complete. These rules are held in algorithms that are plugged in on the case type and therefore you can define any type of automatic transition rules.

Cases in a state with automatic transition rules are monitored by the [CASETRAN](#) background process. Each time this program runs, the respective automatic transition plug-in is called for each such case and it transitions the case if the condition applies.

Note:

When to execute CASETRAN. Because your automatic transition rules will be dependent on your business requirements, you need to think carefully about when you run the [CASETRAN](#) background process. For example, if you have automatic transition rules that transition a case to a new state when a related field activity is completed, you would want to schedule this job to run after field activities are uploaded. If you have rules to transition a case after a customer pays a deposit, you'd want to schedule this job to run after payments are uploaded. Bottom line - your business rules will dictate the frequency of execution.

When the user adds a new case or changes the state of a case manually the system attempts to auto-transition the case to subsequent statuses as necessary. If auto-transition rules apply to the new state (and to subsequent ones) they would be executed right away. In other words, you don't need to wait for the auto-transition background process to be executed. An indication that the case was auto-transitioned online is displayed right below the action buttons section.

Note:

Auto-Transition Errors. Online auto-transition is performed recursively committing each successful state transition to the database. It is performed up to 100 times or until an error is encountered during the process. If this happens, auto-transition stops at the last **non-transitory** state into which a successful transition had occurred. Two case log entries will be generated automatically - one containing the message that a transition error has occurred, and a second containing the actual error message. A To Do entry will also be generated automatically upon rollback. The type of this To Do entry will be taken from 1) the Case Transition Exception To Do Type **option** for the **Business Object** associated with the case type, and if this is not populated, 2) the Exception To Do Type indicated on the Case Options Feature Configuration. All of the above error handling is true for both batch and online processing of cases.

Note:

Triggering Auto-Transition. If you have a customized process that affects the state of a case and you want the case to be auto-transitioned right away, i.e. not wait for the next scheduled **CASETRAN** background process to execute, you can customize that process to trigger auto-transition for the specific case, or you can put the state transition logic into the routines that execute at state entry time.

Script Launching Option

You can define whether the script associated with a given state is to be automatically launched while the case is in that state. The system supports the following options:

- Launch the script only if no script is currently active.
- Always launch the script unless this specific script is currently active.

Warning:

With this option, if a script is currently open in the page's BPA script area then it will be automatically closed and the case script will open.

- Do not automatically launch the script.

You do this by plugging-in a Script Launching algorithm for the given state. If no such plug-in is provided the script is not automatically launched.

Which Users Can Transition A Case Into A State

If you have **restricted access** to a case type, you can further restrict which user groups are allowed to transition a case into specific states. For example, you can control which user group can transition a high bill complaint into the Preliminary Investigation state. The following points describe how this is done:

- Define actions on the **application service** defined on the case type. You must define an action for each status that you need to secure.
- Define each status's corresponding action. Note, you only need to link a status to an action if it's secured. Any user with **access** to the case type can perform statuses that aren't linked to actions.
- Define the transition role for each status's valid next status. You can assign valid next statuses to be reachable via system (only), or system and user.
- Define which **user groups** have access to the actions (i.e., statuses). In addition, these user groups should have access to the Change action.

Responsible User Applicability

Some of your cases may require a "responsible user". This is the user who has overall responsibility for the case. When you set up a case type, you define if a responsible user is required, optional or not allowed on its cases.

The following points describe how to set up the system if a responsible user is not required when a case is first created, but is later in its lifecycle:

- Indicate that a responsible user is optional on the case type
- Plug-in either an **exit validation** or **entry validation** algorithm on one of the case type's states to require a responsible user at some point in a case's lifecycle

Note:

Address To Do entries to the responsible user. If you use the base-package algorithm to create a To Do entry when a case enters a given state, you can indicate that the To Do entry should be addressed to the responsible user on the case.

Scripts and Cases

There are three ways [Business Process Assistant scripts](#) can be used to manage cases:

- You can create a BPA script to help users create a case. For example, a script can help a user create a new high-bill complaint.
- Using a script to create a case can save a user a lot of time (and training efforts). This is because the script can automatically populate many fields on the case based on answers to questions.

Refer to [Initiating Scripts](#) for a description of how end-users initiate scripts.

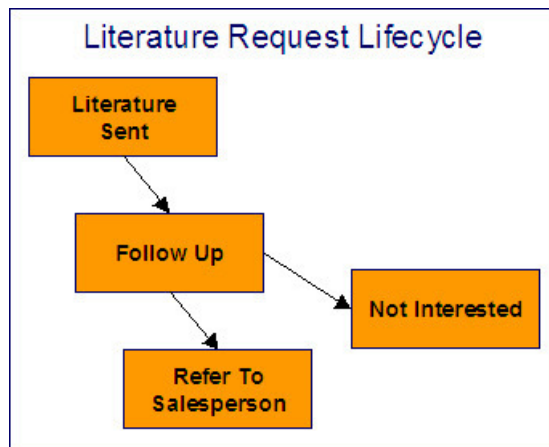

- You can create a script to help users work on a case when it's in a given state. Refer to [A Script That Helps A User Work A Case](#) for more information.
- You can [set up your case types to create To Do entries](#) to notify users when cases exist that require their attention. Users can complete many of these ToDo entries without assistance. However, you can set up the system to automatically launch a script when a user selects a ToDo entry. For example, consider a ToDo entry that highlights a high-bill complaint that requires investigation. You can set up the system to execute a specific script when a user selects this ToDo entry. This script might guide the user through the investigation process (and help them update the case). Refer to [Executing A Script When A To Do Entry Is Selected](#) for more information.

To Do's and Cases

The topics in this section provide background information about how to facilitate case management with [To Do entries](#).

Creating and Completing To Do Entries

You can configure your case types to create and complete [To Do entries](#) when a case enters or exits a state. Let's use the following [lifecycle diagram](#) to illustrate a potential use of To Do's:

Let's assume the following:

- You want a To Do entry created when a literature request case enters the Follow Up state. You want this To Do automatically completed when the case enters either the Refer To Salesperson or Not Interested states. Note, we refer to this as the "first" To Do entry below.
- You want a different To Do entry created when a case enters the Refer To Salesperson state. You do not want the system to automatically complete this entry (the sales person must manually do this). Note, we refer to this as the "second" To Do entry below.

To implement the above, you would set up a case type as follows:

- Plug-in an [entry processing](#) algorithm on the Follow Up status to create the first To Do entry.
- Plug-in an [exit processing](#) algorithm on the Follow Up status to complete the first To Do entry.
- Plug-in an [entry processing](#) algorithm on the Refer To Salesperson status to create the second To Do entry.

While the case type illustrated above had a single To Do entry "active" at any point in time, you can easily configure a case type to have multiple To Do entries active at any point in time. Let's use the following lifecycle diagram to illustrate this point:

Let's assume the following:

- You want a To Do entry created when a high bill complaint is created and you want it completed when the case reaches the Canceled, Rejected or Approved states. This To Do entry could be used by a supervisor to monitor the number of high-bill complaints logged. Note, we refer to this as the "first" To Do entry below.
- You want a different To Do entry created when the case enters the Preliminary Investigation state and you want this entry automatically completed when the case leaves this state. Note, we refer to this as the "second" To Do entry below.
- You want a different To Do entry created when the case enters the Decision Checkpoint state and you want this entry automatically completed when the case leaves this state. Note, we refer to this as the "third" To Do entry below.

To implement the above, you would set up the case type as follows:

- Plug-in an [entry processing](#) algorithm on the Lodged status to create the first To Do entry. Plug-in an [entry processing](#) algorithm on the Canceled, Rejected and Completed statuses to complete this entry.
- Plug-in an [entry processing](#) algorithm on the Preliminary Investigation status to create the second To Do entry. Plug-in an [exit processing](#) algorithm on the Preliminary Investigation status to complete this entry. We elected to use an exit processing algorithm because we only have to plug it in on one status. If we'd used an entry processing algorithm, we would need to plug it in on the 2 statuses into which a Preliminary Investigation status can transition.
- Plug-in an [entry processing](#) algorithm on the Decision Checkpoint status to create the third To Do entry. Plug-in an [exit processing](#) algorithm on the Decision Checkpoint status to complete this entry.

Launching Scripts When To Do Entries Are Selected

You can set up your case types to create To Do entries to notify users when cases exist that require their attention. Users can complete many of these To Do entries without assistance. However, you can set up the system to automatically launch a script when a user selects a To Do entry. For example, consider a To Do entry that highlights

a high-bill complaint that requires investigation. You can set up the system to execute a specific script when a user selects this type of To Do entry. This script might guide the user through the investigation process. Refer to [Executing A Script When A To Do Entry Is Selected](#) for more information.

All To Do Entries Are Visible

When a case is displayed on [Case Maintenance](#), the system summarizes the number of To Do entries associated with the case (if you've [set up your To Do types](#) appropriately).

Examples of Case Types

The topics that follow provide examples of case types related to several business processes. Use the information in this section to form an intuitive understanding of case types. After attaining this understanding, you'll be ready to design your own case types.

High Bill Complaint

Some organizations will set up a case to manage a high-bill complaint. The following diagram illustrates how such a case type might look:

Case Type – High Bill Complaint

| Person / Account / Premise Applicability | |
|--|---------------|
| Field | Applicability |
| Person | Required |
| Account | Required |
| Premise | Optional |

Secured

Yes, all actions

| Fields To Be Captured | | |
|-----------------------|---------------------|---------------|
| Field | Required / Optional | Default Value |
| Bill ID | Optional | ** |
| Cancel reason | Optional | --- |
| Reject reason | Optional | ** |

| Applicability Rules | |
|---------------------|---------------|
| Field | Applicability |
| Responsible User | Optional |
| Contact Information | Optional |

Note the following about the High Bill Complaint case type:

- Notice that we set up the case type to require a person and an account, but premise is optional. This is because a bill can span multiple premises and knowing the premise isn't so important on cases of this type.
- We need to restrict high-bill complaints to specific user groups. This means we need to [set up a specific application service](#) for this case type (that has a separate "action" for each status).
- Cases of this type have 3 additional fields over their lifetime. Notice the following:
 - The **Bill ID** characteristic is set up to be optional. This is because we've assumed that sometimes a high-bill complaint case can be lodged when you can't find the bill in question and you still want to log the case.

- Later in this section, you'll see that we've configured the Preliminary Investigation status to require a **Bill ID** before a case can enter this state.
- Both the **High Bill Complaint Cancel Reason** and **Reject Reason** are optional. Later in this section, you'll see that we've configured the Canceled and Rejected statuses to require these fields, respectively.
- Cases of this type do not need a **Responsible User** when first created. Later in this section, you'll see how we've configured the Preliminary Investigation status to require a **Responsible User** before a case can enter this state.
- Cases of this type do not need **Contact Information**. This was a subjective decision and depends on your organization's philosophy.

The topics that follow describe each of the statuses in a high-bill complaint's [lifecycle](#). We have assumed the following state transition rules:

Lodged High Bill Complaint

The following is an example of the configuration of the Lodged status for high bill complaint cases.

Lodged Status

| Basic Information | |
|-------------------|---------------|
| Field | Default Value |
| Status Condition | Initial |
| Button Label | Lodged |
| BPA Script | n/a |
| Security Action | Add |

| Valid Next Statuses | |
|---------------------------|----------------|
| Status | Use as Default |
| Preliminary Investigation | Yes |
| Canceled | No |

Required Fields When Entering This State

Not applicable

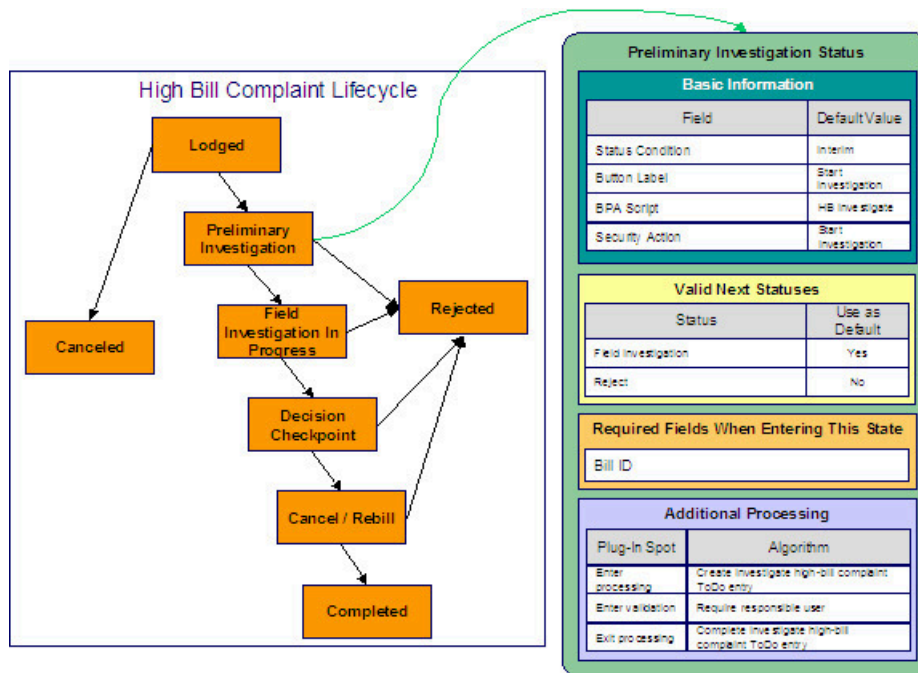

| Additional Processing | |
|-----------------------|---|
| Plug-In Spot | Algorithm |
| Enter processing | Create new high-bill complaint ToDo entry |
| Exit processing | Complete new high-bill complaint ToDo entry |

Note the following about this status:

- Lodged is the initial state. The initial state is the state populated on new cases of a given type. Remember that only one status can be defined as the initial state.
- It has a button label even though it's the initial state. The above diagram doesn't allow a user to ever transition a case into this state and therefore there will never be a button with such a label. However, it's a required field just in case you change your business rules.
- We have decided not to use a BPA script to help a user work on a high-bill complaint when it's in this state (this is probably not the best decision as BPA scripts can be quite useful).
- We have associated the Add action with this status. This means that only users with rights to the add action for the application service defined on the case type can add cases of this type.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Canceled and Preliminary Investigation states.
- Notice that the Additional Processing plug-ins create and complete a To Do entry when a case enters and exits this state, respectively.

Preliminary Investigation High Bill Complaint

The following is an example of the configuration of the Preliminary Investigation status for high bill complaint cases.

Note the following about this status:

- Preliminary Investigation is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Start Investigation**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Lodged state as this is the only state that can transition into the Preliminary Investigation state.
- We have decided not to specify a BPA script on this status. Rather, we're going to set up the To Do type used to highlight cases in this state to automatically launch an appropriate BPA script when a user selects the To Do entry.
- We have associated the Start Investigation action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Field Investigation and Rejected states.
- Notice that a **Bill ID** must be specified on the case before it can be moved into this state.
- Notice that the Additional Processing plug-ins do the following:

- Create and complete a To Do entry when a case enters and exits this state, respectively
- Require a responsible user before a case can enter this state

Field Investigation High Bill Complaint

The following is an example of the configuration of the Field Investigation In Progress status for high bill complaint cases.

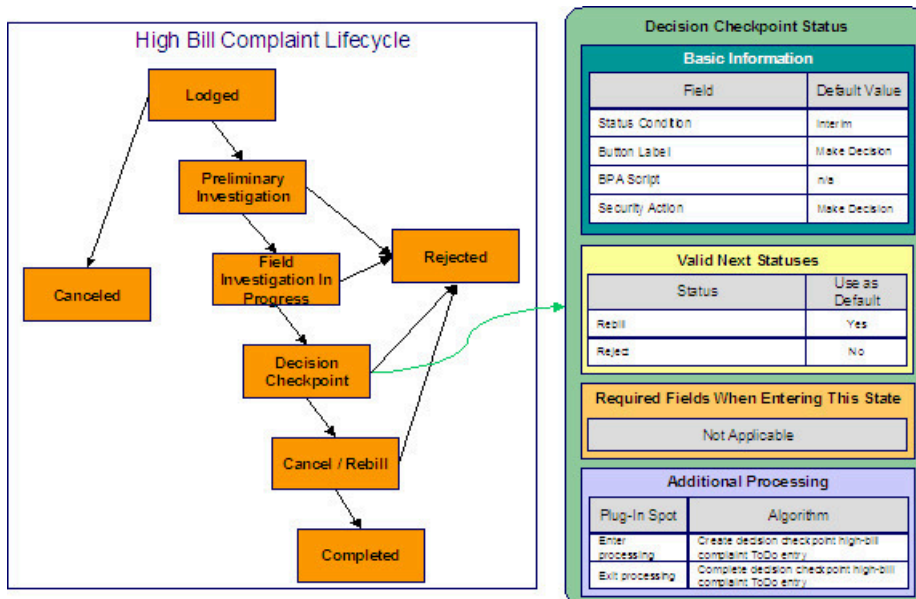

Note the following about this status:

- Field Investigation In Progress is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Send to Field**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Preliminary Investigation state as this is the only state that can transition into the Field Investigation in Progress state.
- We have decided not to specify a BPA script on this status because users don't work cases in this state (see the Additional Processing notes below for why this is the case).
- We have associated the Send to Field action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Decision Checkpoint and Rejected states.
- Notice that the Additional Processing plug-ins do the following:
 - Create a field activity when a case enters this state
 - Cause the case to automatically transition to the Decision Checkpoint state when the field activity is completed

Decision Checkpoint High Bill Complaint

The following is an example of the configuration of the Decision Checkpoint status for high bill complaint cases.

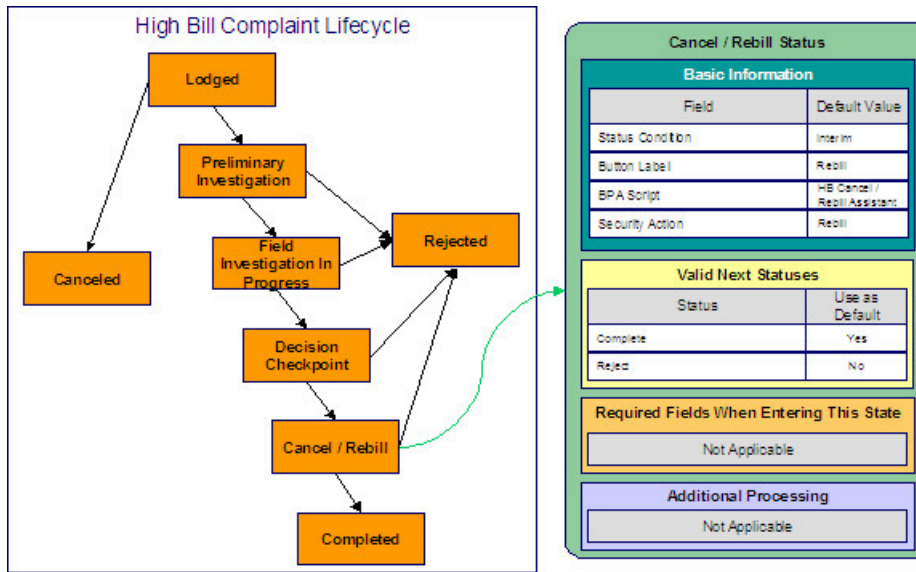

Note the following about this status:

- Decision Checkpoint is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Make Decision**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Field Investigation in Progress state as this is the only state that can transition into the Decision Checkpoint state.
- We have decided not to specify a BPA script on this status. Rather, we're going to set up the To Do type used to highlight cases in this state to automatically launch an appropriate BPA script when a user selects the To Do entry.
- We have associated the Make Decision action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state. Because the system will automatically transition cases into this state when the related field activity is complete, users will probably never press this button (and you may wish to prevent users from pressing this button by restricting security rights to the related action).
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Cancel / Rebill and Rejected states.
- Notice that the Additional Processing plug-ins create and complete a To Do entry when a case enters and exits this state, respectively.

Cancel Rebill High Bill Complaint

The following is an example of the configuration of the Cancel / Rebill status for high bill complaint cases.

Note the following about this status:

- Cancel / Rebill is an interim state (meaning that it's not an initial or final state).
- It has a button label of **Cancel / Rebill**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Decision Checkpoint state as this is the only state that can transition into the Cancel / Rebill state.
- We have referenced a BPA script that can assist a user in the cancel / rebill efforts.
- We have associated the Rebill action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that Valid Next Statuses are what restricts a case in this state to be transitioned to the Completed and Rejected states.

Completed High Bill Complaint

The following is an example of the configuration of the Completed status for high bill complaint cases.

Note the following about this status:

- Completed is a final state (meaning that no further action is necessary).

- It has a button label of **Complete**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Cancel / Rebill state as this is the only state that can transition into the Completed state.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Complete action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Completed case to be reopened, you would need to define the state into which a Completed case could be transitioned.
- Notice that the **Net Difference** must be specified on the case before it can be moved into this state. This would be the difference to the customer's balance after the cancel/rebill took place.

Rejected High Bill Complaint

The following is an example of the configuration of the Rejected status for high bill complaint cases.

Note the following about this status:

- Rejected is a final state (meaning that no further action is necessary).
- It has a button label of **Reject**. This is the label on the button that a user presses to move a case into this state. This button will appear on cases that are in the Preliminary Investigation, Field Investigation in Progress, Decision Checkpoint and Cancel / Rebill states.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Reject action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Rejected case to be reopened, you would need to define the state into which a Rejected case could be transitioned.
- Notice that a **Reject Reason** must be specified on the case before it can be moved into this state.

Canceled High Bill Complaint

The following is an example of the configuration of the Canceled status for high bill complaint cases.

Note the following about this status:

- Canceled is a final state (meaning that no further action is necessary).
- It has a button label of **Cancel**. This is the label on the button that a user presses to move a case into this state. This button will only appear on cases that are in the Lodged state as this is the only state that can transition into the Completed state.
- We have not referenced a BPA script because this is a final state (and no additional user action is necessary).
- We have associated the Cancel action with this status. This means that only users with rights to this action for the application service defined on the case type can move a case into this state.
- Notice that there are no Valid Next Statuses (because this is a final state). If you wanted to allow a Canceled case to be reopened, you would need to define the state into which a Canceled case could be transitioned.
- Notice that a **Cancel Reason** must be specified on the case before it can be moved into this state.

Setting Up Case Management Options

The topics in this section describe how to set up the system to enable case management.

Warning:

The following topics assume you thoroughly understand the concepts described under [The Big Picture Of Cases](#).

Installation Options

Case Info May Be Formatted By An Algorithm

An algorithm may be plugged in on the [installation record](#) to format the standard case information that appears throughout the system. Refer to CSIN-DFLT for an example of this algorithm.

This algorithm may be further overridden by a "Case information" plug-in on the [Case Type](#). Refer to C1-CT-INFO for an example of this algorithm.

Alert Info Is Controlled By An Installation Algorithm

An algorithm that is plugged in on the [installation record](#) is responsible for formatting the alerts that highlight if the person / account / premise in context has open cases. Refer to CCAL-CASE for an example of this algorithm.

Setting Up Application Services

As described under [Access Rights](#), you can prevent unauthorized users from accessing cases. The following points describe how to implement this type of security:

- Create an [application service](#) for each case type that needs to be secured
- Create an action on the application service for each status you need to secure
- Link the valid [user groups](#) to the application service and define which actions they can perform
- Define the application service on the [case type](#)
- Define the related action for each status on the [case type / status](#)

Setting Up Scripts

As described under [Scripts and Cases](#), BPA scripts can facilitate the creation and working of cases. Refer to the [Defining Script Options](#) for instructions describing how to set up scripts.

Setting Up To Do Types

As described under [To Do's and Cases](#), To Do entries can be used to highlight cases that require user attention.

The following points provide a high-level description of how to create (and complete) To Do entries for a case type:

- Create a To Do type for each different type of To Do entry used during a case's lifecycle
 - On the To Do type, think carefully about the roles whose users can work on the entries
 - Also consider if you would like a BPA script launched when a user selects the entry
- Specify the To Do type on the appropriate [entry processing](#) or [exit processing](#) algorithm
- If you want the system to automatically complete To Do entries, specify the To Do type on the appropriate [entry processing](#) or [exit processing](#) algorithm

Please be aware that the case maintenance transaction highlights the number of open and assigned To Do entries linked to the case being displayed on the page. However, the system can only do this if the To Do entries reference a [foreign-key characteristic](#) whose foreign key references the case table. If you use the CSEN-TD algorithm to create To Do entries when a case enters a given state, this algorithm will do this for you if:

- You have set up a [foreign-key characteristic type](#) whose [foreign key](#) references the case table
- In addition, the characteristic type must reference a characteristic entity of To Do Entry

Setting Up Characteristic Types

As described under [Additional Information](#), some of your cases may require additional information (in the form of [characteristics](#)). If this is true, you must set up the characteristic types before setting up the case types.

Refer to [Setting Up To Do Types](#) for instructions regarding a characteristic type that must be set up in order for the system to know the To Do entries that are associated with a case.

If you use the CSEN-CC algorithm to create customer contacts when a case enters a given state, you should set up a [foreign-key characteristic type](#) as follows:

- Its [foreign key](#) must reference the case table
- In addition, the characteristic type must reference a characteristic entity of Customer Contact

Setting Up Case Types

The case type maintenance transaction is used to maintain your case types. The topics in this section describe how to use this transaction.

**Fastpath:**

Refer to [The Big Picture Of Cases](#) for more information about how a case type encapsulates the business rules that govern a case.

Case Type - Main

Use this page to define basic information about a case type.

Open the case type page by selecting **Admin > Customer > Case Type > Case Type > Add**.

**Note:**

Recommendation. Before using this transaction, we strongly recommend that you review the [Examples of Case Types](#).

Main Information

Enter a unique **Case Type** code and **Description** for the case type.

Use **Long Description** to provide a more detailed explanation of the purpose of the case type.

If your implementation requires restricting case types by CIS Division, specify a **CIS Division** on the case type.

Person Usage controls the applicability of a person on cases of this type. Select Required if a person must be defined on this type of case. Select Optional if a person can optionally be defined on this type of case. Select Not Allowed if a person is not allowed on this type of case.

Account Usage controls the applicability of an account on cases of this type. Select Required if an account must be defined on this type of case. Select Optional if an account can optionally be defined on this type of case. Select Not Allowed if an account is not allowed on this type of case.

Premise Usage controls the applicability of a premise on cases of this type. Select Required if a premise must be defined on this type of case. Select Optional if a premise can optionally be defined on this type of case. Select Not Allowed if a premise is not allowed on this type of case.

Entity Relationship controls the validation of relationships on cases of this type. *All* ensures that the account belongs to the person and that the account and premise are related. *Person and Account Only* disables the account and premise validation. *Premise and Account Only* disables the person and account validation. *None* disables all validation and allows any values. This setting only impacts the validation of values entered and works in conjunction with the three usage fields described above.

If you need to restrict access to cases of this type to specific user groups, reference the appropriate **Application Service**. Refer to [Setting Up Application Services](#) for the details of how to secure access to your cases.

If you are configuring a case type to handle the processing of data defined via a **Business Object**, associating the case type with a business object serves to link the properties of the business object (e.g. BO options) with cases of that type. Refer to [Business Objects](#) for further information. In addition, refer to [Automatic Transition Rules](#) for information on the role of BO options in case auto-transition errors.

Responsible User Usage controls the applicability of a responsible user on cases of this type. Select Required if a responsible user must be defined on this type of case. Select Optional if a responsible user can optionally be defined on this type of case. Select Not Allowed if a responsible user is not allowed on this type of case. Refer to [Responsible User Applicability](#) for more information.

Contact Information Fields

There are three contact information fields: **Contact Person & Method Usage**, **Contact Instructions Usage**, and **Case Phone Usage**. These fields are used to determine whether or not each type of contact information must be entered on case records with this case type. Select Required if the contact information must be entered, select Optional if the user can choose whether or not to include the contact information on this type of case, or select Not Allowed if the contact information cannot be entered on this type of case.

Algorithms

The **Algorithms** grid contains algorithms that control functions for cases of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|------------------|---------------------|--|
| Case Information | Optional | <p>We use the term "Case information" to describe the basic information that appears throughout the system to describe a case. The data that appears in "case information" is constructed using this algorithm.</p> <p>Plug an algorithm into this spot to override the "Case information" algorithm on installation options or the system default "Case information" if no such algorithm is defined on installation options.</p> |

Case Type Tree

The tree summarizes the case type's lifecycle. You can use the hyperlinks to transfer you to the **Lifecycle** tab with the corresponding status displayed.

Case Type - Case Characteristics

To define characteristics that can be defined for cases of this type, open **Admin > Customer > Case Type > Search** and navigate to the **Case Characteristics** page.

Description of Page

Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on cases of this type. Turn on the **Default** switch to default the **Characteristic Type** when cases of this type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** box is checked. Refer to [Required Fields Before A Case Enters A State](#) for a description of how you can make option characteristics required at later stages in a case's lifecycle.

Case Type - Lifecycle

Case types that involve multiple users and multiple potential outcomes have complex lifecycles. Before you can design a case type's lifecycle, it's important that you thoroughly understand the concepts described under [Lifecycle](#) and [Status-Specific Business Rules](#). After thoroughly understanding these concepts, we recommend you perform the following design steps:

- Draw a "state transition diagram" as illustrated above under [Lifecycle](#). Keep in mind that if your state transition diagram is complex, your cases will be complex. While some cases warrant complexity, you should always ask yourself if there aren't better ways to achieve the desired results if your first effort results in complexity.
- Determine which characteristics (if any) are required during each stage of a case's lifecycle
- Determine when To Do entries (if any) should be created (and completed) during a case's lifecycle
- Determine additional validation (if any) that should be executed before a case enters and exits each state

- Determine additional processing (if any) that should transpire when a case enters or exits each state
- Determine if scripts are warranted to help users work the cases and, if so, design the scripts for each applicable state

When the above tasks are complete, you will be ready to set up a case type's lifecycle.

Open the Lifecycle page by selecting **Admin > Case Type > Case Type > Search** and navigate to the **Lifecycle** page.

Note:

You can navigate to a status by clicking on the respective node in the tree on the Main tab. You can also use the hyperlinks in the Next Statuses grid to display a specific status in the accordion.

Main Information

The **Status** accordion contains an entry for every status in the case type's [lifecycle](#).

Use **Status** to define the unique identifier of the status. This is NOT the status's description, it is simply the unique identifier used by the system.

Use **Description** to define the label that appears on the lifecycle accordion as well as the status displayed on the case.

Use **Script** to reference a BPA script that can assist a user work on a case while it's in this status. Refer to [A Script That Helps A User Work Through A Case](#) for the details.

Use **Access Mode** to define the action associated with this status. This field is disabled if an application service is not specified on the Main page. Refer to [Access Rights](#) for the details of how to use this field to restrict which users can transition a case into this state.

Use **Batch** to specify a batch control that will auto-transition the case. Any case in a status configured with a batch control will be transitioned when the batch job runs (rather than when CASETRAN is executed). For this purpose, batch process C1-CSTRS (**Case Scheduled Transition**) is supplied with base package, which will execute all Exit Status logic for the current status, and Enter Status logic for the destination status. You may choose to create a batch process with your own transition logic.

Note:

If you wish to defer transitioning a case in a particular status until the batch process on your case type status is executed, you should not populate an Auto-Transition algorithm on that status. Otherwise, CASETRAN will transition the case according to your Auto-Transition logic.

Use **Comment** to describe the status. This is for your internal documentation requirements.

Use **Sequence** to define the relative order of this status in the tree on the Main page.

Use **Status Condition** to define if this status is an Initial, Interim or Final state. Refer to [One Initial State and Multiple Final States](#) for more information about how this field is used.

Use **Transitory State** to indicate whether a case should ever exist in this state. Only Initial or Interim states can have a transitory state value of No.

The **Alert Flag** is used to indicate whether or not an alert should be displayed for customers with cases in the state. (The alert is shown via the base package Installation - Alert algorithm.)

Algorithms

The **Algorithms** grid contains algorithms that control important functions for cases of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence Number** and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

| System Event | Description |
|------------------|--|
| Auto Transition | This algorithm is executed to determine if a case that's in this state should be transitioned into another state. Refer to Automatic Transition Rules for the details. |
| Enter Processing | This algorithm holds additional processing that is executed when a case is transitioned into this state. You can also specify state transition logic within Enter Processing routines. Refer to Additional Processing When Entering A State for the details. |
| Enter Validation | This algorithm holds validation logic that executes before a case can enter a given state. Refer to Validation Before A Case Enters A State for the details. |
| Exit Processing | This algorithm holds additional processing that is executed when a case is transitioned out of this state. Refer to Additional Processing When Exiting A State for the details. |
| Exit Validation | This algorithm holds validation logic that executes before a case can be transitioned out of a given state. Refer to Validation Before A Case Exits A State for the details. |
| Script Launching | This algorithm sets the script launching option for the script associated with a given state, if any. Refer to Script Launching Option for the details. |

Next Statuses

Use the **Next Statuses** grid to define the statuses a user can transition a case into while it's in this state. Refer to [Valid States versus State Transition Rules](#) for more information. Please note the following about this grid:

- Use **Action Label** to indicate the verbiage to display on the action button used to transition to this status.
- **Sequence** controls the order of the buttons that appear on [Case - Main](#). Refer to [Buttons Are Used To Transition A Case Into A State](#) for more information.
- **Use as Default** controls which button (if any) is the default button.
- **Transition Condition** may be configured to identify a common transition path for cases of this type in the current state. This transition condition may then be referenced across multiple case types. You'll need to add values to Look Up table field **TR_COND_FLG** that fit the typical transitions for your case types (e.g. Ok, Error, etc.).

By assigning the transition condition value to a given "next status", you can design your Enter State transition or Auto-Transition logic to utilize those flag values *without specifying a status particular to a given case type*. Thus, similar logic may be used across a range of case types to transition a case into, for example, the next Ok state for the case's current status.

- **Transition Role** controls whether only the System or both System and User have the ability to transition a case into a given "next status".
- You can use the status description hyperlink to open the Status accordion to the respective status.
- When you initially set up a case type, none of the statuses will reside on the database and therefore you can't use the search to define a "next status". We recommend working as follows to facilitate the definition of this information:

- Leave the Next Statuses grid blank when you initially define a case type's statuses
- After all statuses have been saved on the database, update each status to define its Next Statuses (this way, you can use the search to select the status).

Required Characteristics

Use the **Required Characteristics** grid to define characteristics that are required when a case enters this state. Only Optional characteristics defined on the main page appear in this grid. Refer to [Required Fields Before A Case Enters A State](#) for more information.

Workflow and Notification Options

We use the term "notification" to reference the electronic transactions that you exchange with third parties when:

- They need information about a customer
- They need to change something about a customer

For example, an energy service provider sends a notification to an electric distribution company when a customer elects to use them as their energy provider.

When a notification is received, the system responds by creating a workflow process. The workflow process contains workflow events. These events perform the processing necessary to execute the notification.

Workflow processing is difficult to explain because its flexible design can be used to automate many different types of multi-event processes. For example,

- You can use workflow processing to manage the events associated with the inspection of a new premise.
- You can use workflow processing to manage the events that transpire in a deregulated market when a customer wants to switch energy service providers.

Warning:

Setting up the workflow process control tables is as challenging as your organization's business rules. If you don't have automated workflow processes, you don't have to setup anything. If you have sophisticated workflow processing requirements, your setup process will be more challenging.

The topics in this section describe tables that control your automated workflow and notification processing.

The Big Picture Of Workflow Processing

Fastpath:

Refer to [The Lifecycle Of A Workflow Process And Its Events](#) for more information about workflow processes.

The Big Picture Of Workflow Events

This section describes the various types of workflow events and their lifecycle:

How Are Workflow Events Created?

Workflow events may be created as follows:

- The process that uploads notification requests creates a workflow process to implement the notification request. The workflow process has one or more workflow event(s). The number and type of events is controlled by the workflow process template associated with the workflow process. Refer to [What Type Of Workflow Process Is Created?](#) for more information about how notification requests cause workflow processes to be created.

- Workflow events will be created when an operator creates an ad hoc workflow process. The number and type of workflow events are controlled by the workflow process template associated with the workflow process.
- An ad hoc workflow event may be created and linked to an existing workflow process by an operator at their discretion.
- The system may be customized to create a workflow process when something noteworthy happens in the system. Refer to [System Conditions May Trigger Notification and Workflow](#) for more information.

Note:

Bottom line. Most workflow events are created by the system when it creates a workflow process to implement an incoming notification. If you need to create an ad hoc workflow event, you can either create a workflow process using a template that contains the desired event OR link the desired event to an existing workflow process.

Fastpath:

For more information about creating ad hoc workflow processes and events, refer to [Workflow Process Maintenance](#).

Executing Workflow Events On Their Trigger Date

When the background process (referred to as WFET) executes a workflow event on its trigger date, it calls the activation algorithm associated with the event's event type. Because you can add and change activation algorithms at will, the variety of workflow events is infinite.

Fastpath:

Refer to [Designing Workflow Event Types](#) for more information about activation algorithms.

Workflow Event Lifecycle

The lifecycle of a workflow event is dependent on whether the event has to wait on something before it can complete or fail. For example, an event that creates a field activity has to wait until the field activity is performed before it can be considered complete.

The following diagram shows the possible lifecycle of a workflow event:

The following points explain the lifecycle of workflow events of the *normal* variety:

- *Normal* events are initially created in the pending state.
- On a pending event's trigger date, the workflow event activation process (referred to as WFET) executes the event's activation algorithm.
- An event's activation algorithm may cause a pending event to become in error. For example, if an event used to create a field activity can't find a valid service point, the algorithm could change the status of the event to be in error. A user should correct the cause of the error and then change the event's status back to pending. The pending event will be processed the next time the activation program runs.

- An event's activation algorithm may cause a pending event to fail. For example, if an event used to validate a notification detects invalid information (e.g., an incoming notification is missing the customer's account number), the event will fail.
- A pending event becomes complete when the event's activity is successful. For example, if an event used to validate a notification determines the notification is valid, the event will complete. A user may manually change the status to complete if the event type indicates that manual completion is allowed.

Fastpath:

For more information about a workflow event's trigger date, refer to [Workflow Event Dependencies & Trigger Date](#).

- A pending event will be cancelled automatically by the system if the workflow process is cancelled (a workflow process will be cancelled if an event fails or at the discretion of an operator). A user may cancel an event at will. Refer to [How Are Workflow Events Canceled](#) for more information.

The following points explain the lifecycle of workflow events of the *waiting* variety:

- *Waiting* events are initially created in the pending state.
- On a pending event's trigger date, the system executes the event. For example, if an event is used to create a "special read" field activity, on the event's trigger date, the field activity is created.
- An event's activation algorithm may cause a pending event to become in error. For example, if an event used to create a field activity can't find a valid service point, the algorithm could change the status of the event to be in error. A user should correct the cause of the error and then change the event's status back to pending. The pending event will be processed the next time the activation program runs.
- If the activation algorithm did not cause the event to become in error, the event's status is changed to waiting while the system waits for the field activity to be performed.

Fastpath:

For more information about a workflow event's trigger date, refer to [Workflow Event Dependencies & Trigger Date](#). For more information about what an event might wait on, refer to [Waiting Events And Their Waiting Process](#).

- A waiting event becomes complete when the system sees that the thing that it's waiting for is finished.
- A waiting event fails when the system sees that the thing that it's waiting for didn't complete successfully. For example, an event that sends a confirmation request to a service provider asking if it's OK for a customer to switch suppliers would fail if the service provider denies the request.
- A waiting event will be cancelled automatically by the system if the workflow process is cancelled (a workflow process will be cancelled if an event fails or at the discretion of an operator).
- A pending event will be cancelled automatically by the system if the workflow process is cancelled (a workflow process will be cancelled if an event fails or at the discretion of an operator).

Fastpath:

Refer to [Workflow Processes Can Have Multiple Branches](#) for more information about event transition in a process with multiple branches.

Workflow Event Dependencies & Trigger Date

The trigger date of most workflow events is blank when they are first created. This is because the trigger date can only be set when ALL of the preceding workflow events on which it depends are complete. An example will help explain why this design is necessary. Consider the following example that shows a simple workflow process and its events:

| Event Number | Workflow Event | Dependent On Event(s) | Trigger Date Set To X Calendar Days After Completion Of Preceding Events |
|--------------|----------------|-----------------------|--|
| | | | |

| | | | |
|----|---|-------------------|---|
| 10 | Validate new customer notification | N/A - first event | 0 |
| 20 | Set up new customer and meter | 10 | 0 |
| 30 | Send notification confirming new customer | 20 | 0 |
| 40 | Send welcome letter | 20 | 0 |

This workflow process is meant to implement the following:

- On the first day, validate the incoming notification (the one that tells us about a new customer).
- If validation is successful, set up the new customer and their meter in the system.
- After the new customer and meter are set up, send a notification to the requester that everything has been set up. Also, send a letter to the customer.

The problem is that you don't want to execute event 20 until event 10 is complete. This is achieved by indicating event 20 is dependent on event 10. The system will only populate event 20's trigger date when event 10 is complete. Similarly, you can't set the trigger dates of events 30 and 40 until the customer has been set up (event 20). So, when you set up a workflow event, you must indicate the dependent events. If you only want the next event to trigger X days after the completion of earlier events, you can indicate such.

Note:

Bottom line. The trigger date of a workflow event is set to the current date plus X days where X is the number of calendar days defined on the workflow event. If this date is not a workday for your organization, the trigger date will be set to the next workday. If the resultant date is the current date (because X is zero), the event will be activated immediately.

Fastpath:

Refer to [How Are Workflow Events Completed?](#) for information about how these events are executed.

Workflow Events May Be In Error

As explained under [Workflow Event Lifecycle](#), when the background process WFET executes an event's activation algorithm, this algorithm may cause a pending event to become in error. For example, if an event used to create a field activity can't find a valid service point, the algorithm could change the status of the event to be in error.

For every workflow event that's in error, a record is written to the [workflow event exception](#) table. To view the errors, a user should correct the cause of the error and then change the event's status back to pending. The pending event will be processed the next time the activation process runs.

Fastpath:

Refer to [Errors versus Failure](#) for information to help you differentiate between events that have failed versus those that are in error.

Some Workflow Events May Fail

Some workflow events may fail. For example:

- An event that validates an incoming notification may result in failure if the notification contains invalid information.
- An event that asks for the confirmation from a distribution company may fail if the distribution company rejects the request.

**Fastpath:**

Refer to [Errors versus Failure](#) for information to help you differentiate between events that have failed versus those that are in error.

The background process that is responsible for activating events (referred to as WFET) is the process that can cause an event to fail (failure can happen during the activation algorithm on the workflow event). When an event fails, the system:

- Updates the workflow process with message number and message parameters describing the validation problem.
- Sets the status of the event to Failed.
- Cancels the workflow process and its outstanding events.
- Calls the failure algorithm defined on the event's event type.

It's important to note that some types of events can't fail and therefore don't have a failure algorithm. For example, an event that creates a field activity can't fail, neither can an event that creates a welcome letter.

**Fastpath:**

Refer to [Workflow Processes Can Have Multiple Branches](#) for more information about event failure in a process with multiple branches.

Errors versus Failure

As explained under [Workflow Event Lifecycle](#), an event's activation algorithm may cause a pending event to become in error or to fail (amongst other things). You control the exact state when you design your workflow event type activation algorithms.

The main differences between these two states is as follows:

- As described under [Some Workflow Events May Fail](#), a failed event causes the entire workflow process to fail (and it cannot be restarted).
- As described under [Workflow Events May Be In Error](#), a user can correct the cause of an error event's error and then change the event's status back to pending. The pending event will be processed the next time the activation process runs.

You should follow the following guidelines when designing your validation logic in your workflow event activation algorithms:

- If the cause of the problem is correctable by a user, you should set the state of the event to be in error.
- If the cause of the problem is not correctable by a user (e.g., you were interfaced information that cannot be corrected by your users), you should set the state of the event to fail.

Waiting Events And Their Waiting Process

Some events have to wait until something else happens before they can be Completed (or Fail). These types of events exist in the Wait state until the thing they are waiting for happens. For example, consider an event that creates a field activity - it has to wait until the field activity is complete before it can itself Complete.

Every type of event that waits for something else to happen before it completes or fails must have a corresponding background process that monitors the thing on which the event is waiting. We refer to background processes that perform this monitoring as Waiting Processes.

There will be a Waiting Process for every type of event that has to wait for something to happen. The specific background process is defined on the workflow event type. For more information, refer to [Designing Workflow Event Types](#).

The following points describe the responsibilities of a Waiting Process:

- Check on the thing on which the event is waiting. For example,
 - An event that creates a field activity has a Waiting Process that checks on the state of the field activity.

- An event that creates a request to confirm a customer's request to switch suppliers has a Waiting Process that checks if the confirmation is accepted or rejected.
- Change the state of the event to Complete or Fail based on what transpired. For example,
 - When the field activity completes, the Waiting event can Complete
 - The acceptance or rejection is received, the Waiting event can Complete or Fail
- Detect that the event has been waiting too long and do something. For example, the Waiting Process could:
 - Create a To Do entry (this might be useful if you need an operator to do something)
 - or, create an outgoing notification informing the sender of the incoming notification that something is wrong
 - or, Fail / Complete the event (you may be able to automatically assume success or failure if an event waits longer than a predefined limit)
 - or, execute the event again and reset the base time on the event (this might be useful if the event initiates an outgoing notification to ask permission from some other service provider - if it waits too long, you could simply create another outgoing notification)
 - or, whatever else you can think of developing in the process

How Are Workflow Events Canceled?

The background process that is responsible for activating events (referred to as WFET) automatically cancels workflow events when an event fails.

A pending event will be cancelled automatically by the system if the workflow process is cancelled (a workflow process will be cancelled if an event fails or at the discretion of an operator).

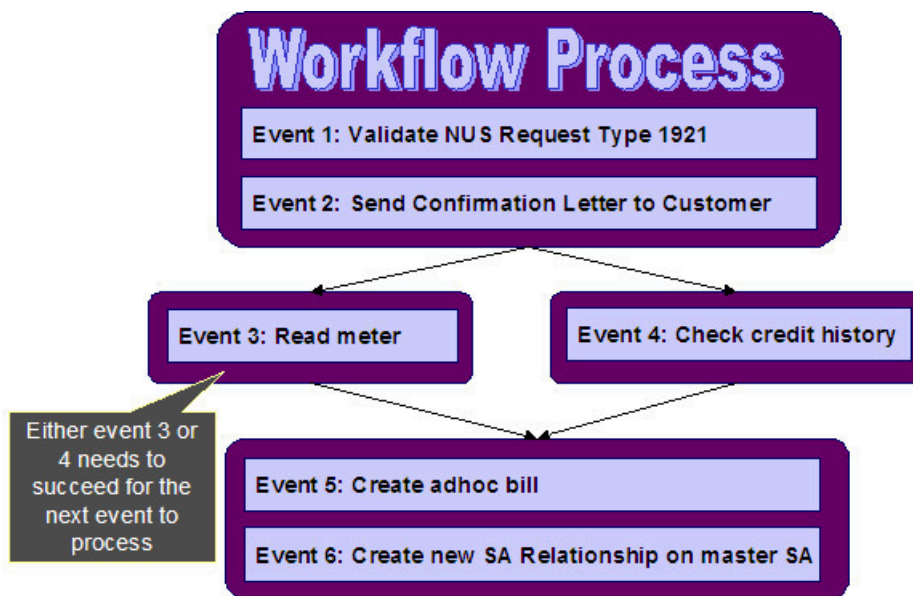

In addition, an operator may cancel a workflow event at will.

An event will be cancelled by the background process that is responsible for activating events (referred to as WFET) when it detects that ALL of its earlier, dependent events are cancelled. This is important to understand if your organization has [Workflow Processes With Multiple Branches](#).

Workflow Processes Can Have Multiple Branches

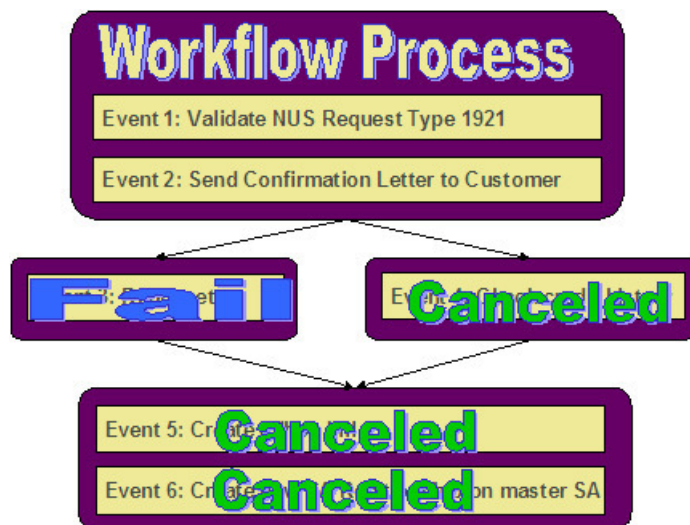

Using the workflow event dependencies, a workflow process may have multiple branches. There are several reasons why you may want to set up a process to contain multiple branches:

- There may be events that can run in parallel. This is useful if the related tasks take time to execute. For example "Read Meter" and "Send Confirmation and Wait for Response". Both can be executed in parallel and event 5 will execute based on the outcome of events 3 and 4. The following is an example of such a workflow process.

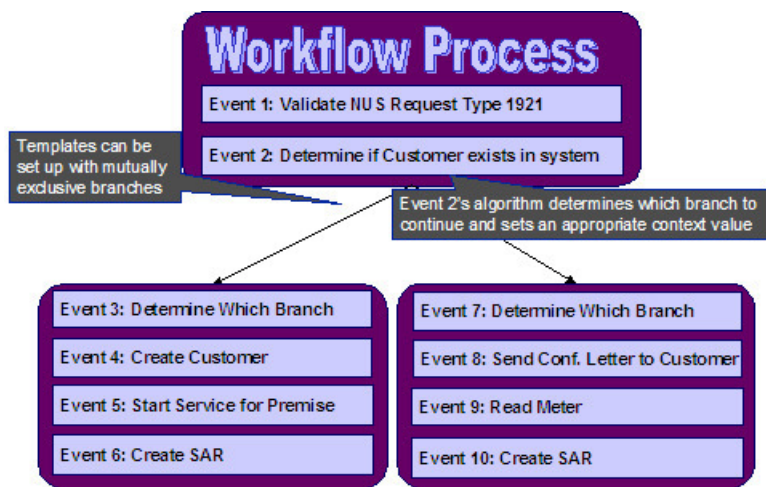

In the example above, if event 3 is canceled and event 4 completes, (or if event 4 is canceled and event 3 completes), event 5 will proceed. However, if both event 3 and event 4 are canceled, all remaining events will be canceled.

It should be noted that if either event 3 or 4 fails, ALL events in the process will be canceled, including events in a different branch.

- You may have a business process that has some common events and some events that are mutually exclusive. Rather than setting up several processes, you can set up one process that branches based on specific criteria. For example, perhaps you get to a certain point in a process that differs based on whether or not a meter is installed. If there is a meter, you follow one branch and if there is no meter, you follow a different branch.

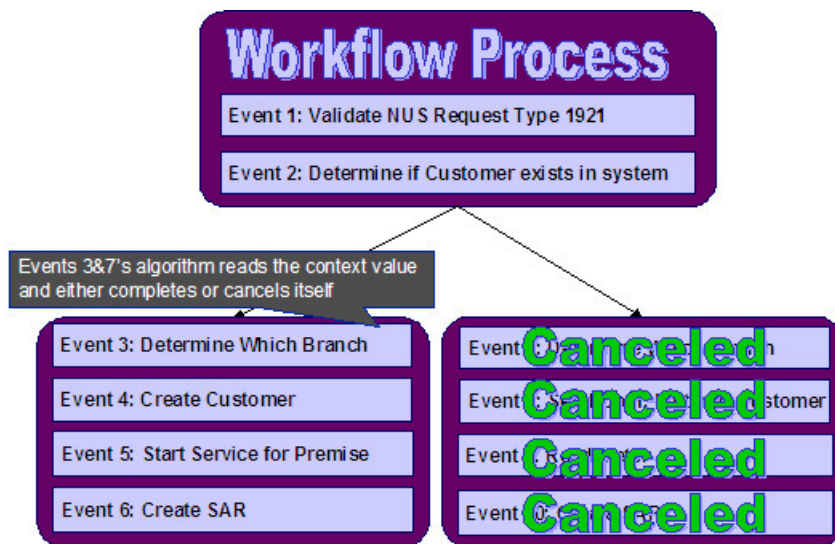

In the above example, event 2 determines if the workflow process is associated with an existing customer or a new customer.

- For a new customer; events 3, 4, 5 and 6 are executed.
- For an existing customer, events 7, 8, 9 and 10 are executed.

Event 2 does this by creating an entry in the Context collection indicating which branch should continue. (For example Context Type / Value of BRANCH / A). Events 3 and 7 should be special events whose purpose is to read the BRANCH context type and determine if its branch should continue or be canceled.

In this example, Event 3's algorithm will continue if the context value for BRANCH is A and Event 7 will only continue if the context value for BRANCH is B.

Note:

The above diagram and description indicates the use of context records to determine which branch to continue. If your implementation chooses to use characteristics instead, the same logic above may be implemented using characteristics as well.

The Big Picture of Notification Processing

We use the term "notification" to reference the electronic transactions that you exchange with third parties when:

- They need information about a customer.

- They need to change something about a customer.

For example, an electric service provider may send a notification to an electric distribution company when a customer elects to use them as their energy provider.

You may have to support a wide variety of notifications. For example:

- You may receive a notification that tells you to switch a customer's energy service provider to a different provider (if you are a distribution company).
- You may receive a notification that asks for the last 24 months of consumption history for a customer (if you maintain consumption).
- Etc.

When a notification is received, the system responds by creating a workflow process. The related workflow process contains workflow events and it is the events that actually do whatever needs to be done (e.g., change the customer's service provider, create field activities, stop service, etc.).

In addition to incoming notifications, the system creates outgoing notifications when:

- It needs to respond to an incoming notification. For example, if an incoming notification requests a customer's consumption history, the system must send the consumption history by creating an outgoing notification.
- It needs to apprise a third party that something has changed about the customer. For example, if a customer stops service, the system must tell the various service providers of such.

The topics in this section describe how notifications are interfaced into and out of the system.

Uploading Notifications Into The System

The following diagram illustrates the steps involved in the uploading of notifications into the system.

When a notification's electronic transaction is received, it must be inserted into the notification upload staging (NUS) table. Why? Because the system periodically looks for pending records in the NUS table and attempts to create a workflow process to implement the notification's request.

It's important to be aware that the events in a workflow process execute the notification request. To help solidify this concept, consider this - the first event in a workflow process typically validates the attributes on the NUS record.

Fastpath:

Refer to [Notification Upload Background Process](#) for more information about the upload process.

What Type Of Workflow Process Is Created?

Given that you can receive many different types of notifications (e.g., return consumption, switch supplier, stop service), it should make sense that each type of notification upload staging (NUS) record will probably require a different type of workflow process to implement its request. The system uses the NUS record sender's external system Id and a notification upload type to determine the type of workflow process. This works as follows:

- Every external system references a workflow process profile.
- A workflow process profile defines the type of workflow process template to use to process a given notification upload type.

Note:

Different workflow processes for the same type of notification. It's probably obvious why different notification types result in different workflow processes. You may wonder why different workflow processes would be needed by two senders who submit the same type of notification? The reason is that different senders may have different types of computer systems that handle their notification processing (or no computer system at all). For example, you may have to respond by fax to a sender who doesn't have a sophisticated computer system, whereas you may send an electronic transaction to a sender who is technically advanced. The system allows you to create different workflow process profiles for each response mechanism (e.g., sophisticated vs. fax). You then associate the appropriate workflow process with each sender.

How Are Notifications Sent Out Of The System?

In addition to processing incoming notifications from third parties, the system also sends notifications to third parties to provide them with information (and to ask them for information). It is also possible to use notifications to send information to other applications within your company.

A Notification Download Staging (NDS) record is created for every notification that is sent to the outside world. NDS records are created by workflow events (i.e., the event's activation algorithm creates a NDS record). Consider the following examples:

- Many workflow processes exist to process incoming notifications. These processes typically contain workflow events that create –NDS records to communicate with service providers. If you look at the workflow processes described under [Designing Workflow Process Templates](#), you will see many such examples.
- When something noteworthy happens, the system may need to tell a third party about it. Or perhaps you have third party software, which contains information from the system and your company needs to keep the information in sync.

Fastpath:

Refer to [System Conditions May Trigger Notification and Workflow](#) for more information about triggering notification download staging records from within the system.

System Conditions May Trigger Notification and Workflow

Note:

Outbound Messages. The mechanism for triggering communication to an external system described here does not take advantage of the configurable business object functionality that enables outbound messages to be triggered from a server-based script. Refer to [Outbound Messages](#) for more information about communicating with an external system using outbound messages.

There may be many noteworthy occurrences in the system, which should trigger the notification and workflow process.

Some of these occurrences may need to be communicated to an external system. Examples of when this may occur are as follows:

- You use an external software package, which uses information from the system and you need to send a message to this software package when certain attributes of the customer change.
- You need to inform third parties when something changes about a customer. For example, if you are a distribution company, you probably advise a customer's energy supply company when their meter is changed or when the customer stops. Or if a customer, who has been referred to a collection agency, makes a payment, you will need to inform the agency of the payment.

In many scenarios, you may want more than just a notification to be sent out, but you would also require a workflow process. For example, perhaps when a customer's mailing address changes, you want to a) send a confirmation letter to the customer's old address and their new address; b) inform a third party service provider about the change; and c) send the update to an external marketing system. In this case, the act of changing the mailing address could trigger a workflow process, which would perform the above steps.

You may have other scenarios where a noteworthy condition in the system should trigger a workflow process, which does not require a notification to be sent out of the system. For example, perhaps your company follows a sophisticated procedure for starting service, which requires certain events to transpire before other events can occur. You could create a workflow process, which gets triggered upon starting service to handle this sophistication.

In summary, when something occurs in the system, you may need to

- Create a notification download staging (NDS) record. You would do this if you only need to send a message to an external system.
- Create a notification upload staging (NUS) record. You would do this if you need to trigger a workflow process to do one or more steps. One of the workflow events in this process could create a NDS if an external system needs to be informed.

Creating a Notification Download Staging Record

To create an NDS record directly, you need the following information:

- Service Provider (who will receive the outbound message)
- NDS Type

You also need to populate relevant data using either context or characteristics. For example, if a change to a person's name should trigger an outbound message, the Person ID must be referenced.

The process that creates the NDS must determine the appropriate service provider that should receive this information based on the business rules. As for the NDS type, this is typically "hard-coded" based on what has occurred to trigger the outbound message. For example, if the customer's name changed, then the NDS Type is set to something like "Name Change".

For any NDS records automatically created by the system in sample algorithms or in system processes, the NDS type is not hard-coded. Rather, the system uses a download type condition flag value to look up the appropriate NDS type. As a result, if an implementation chooses to use these sample algorithms, but prefers to use a different NDS type, it is possible. When designing your own NDS types that are referenced by NDS records created based on system conditions, you may choose to create new download type condition flag values as well.

Refer to [Designing Notification Download Types](#) and [Setting Up Notification Download Types](#) for more information.

Creating a Notification Upload Staging Record

To create an NUS record directly, you need the following information:

- External System (to point to a service provider)
- NUS Type

You also need to populate relevant data using either context or characteristics. For example, if a change to a person's name should trigger a letter to the customer and an outbound message, the Person ID must be referenced.

The process that creates the NUS must determine the appropriate external system based on the business rules. If the steps that need to be taken as a result of this system condition are based on an internal practice, the external system

could be something like "SYSTEM". That external system would reference an appropriate workflow process profile that defines the appropriate workflow process based on the NUS type.

Determining the NUS type is similar to determining the NDS type as described in the previous section.

Refer to [Designing Notification Upload Types](#) and [Setting Up Notification Upload Types](#) for more information.

Triggering Notification & Workflow from the Application

You and your implementers must determine the noteworthy events that should trigger workflow and/or outgoing notifications based on your business practice. For example, you may communicate all meter exchanges and customer address changes to the customer's various service providers.

Next, you must assess how you are going to create the appropriate records:

- Determine if there is a plug-in spot that exists where you can create an algorithm to trigger the NUS or NDS. For example, if canceling a service agreement should trigger a notification, an SA Cancel algorithm plugged in to the SA type may be used.
- If there is no plug-in spot, determine if there is a user exit at the appropriate place for you to trigger the creation of an NUS or NDS
- You may also decide to use a database trigger to create the NUS or NDS

Once you have determined how and when to trigger the creation of notification records, have your implementers create the CM code to do the work.

The Lifecycle of Notification Download Staging

If a download staging record is routed to the outside world via XAI, a status is assigned to the download staging record.

Refer to [Lifecycle of Notification Download Staging](#) for more information.

Creating Notification and Workflow Procedures

A workflow process is created by copying the events defined on a workflow process template (a workflow process template contains the standard events).

Note:

Workflow processes can be used for any multi-event process. While this section describes how to design workflow processes to support incoming and outgoing notifications, workflow processes can be used for other multi-step processes. For example, you can use a workflow process to manage the steps involved with the installation and inspection of backflow devices at a water service point.

The topics in this section describe how to design and setup the tables that control your notification and workflow processing.

Fastpath:

For more information about notification and workflow processing, see [The Big Picture Of Workflow Events](#) and [The Big Picture Of Notification Processing](#).

Warning:

There are innumerable ways to design your notification and workflow procedures. Some designs will result in easy long-term maintenance, others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your production procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

Designing Notification Upload & Workflow Procedures

The topics in this section describe how to design the tables that control your notification upload and workflow processing.

Designing Workflow Process Profiles

The following sections describe how to design a workflow process profile. A workflow process profile controls the type of workflow process that will be created to process your incoming notifications. If you plan to use workflow processes outside of the notification upload process, you can skip to [Designing Workflow Process Templates](#).

You associate a workflow process profile with one or more external system. Whenever a notification is received from an external system, the system uses the workflow process profile to determine the type of workflow process to create to implement the notification.

The easiest way to design a workflow process profile is to choose a representative external system and design a workflow process profile for it by filling in the matrices below. After you've designed a profile, determine how many other external systems can use it. Then design the next external system's profile and determine who can reuse it. Repeat this process until all your external systems have a profile. Once the profiles are designed, you're ready to set up the workflow control tables.

Fastpath:

Refer to [The Big Picture Of Notification Processing](#) for more information about how workflow processes are used to implement incoming notifications.

The topics discussed below will gradually complete the following matrix using a simple case-study. We recommend that you use the following matrix as your guide. When the matrix is complete, you're ready to set up a workflow process profile.

WF Process Criteria

Notif. Upload Type

Designing Notification Upload Types

You will need one notification upload type for every type of notification your organization can receive from the various service providers. To "design" your notification upload types, you document the codes used by external systems to identify the transaction types on their notification upload staging records.

We have populated the Notification Upload Type column with a few classic examples that can be received by a distribution company:

WF Process Criteria

Notif. Upload Type

Retrieve a customer's consumption history

Switch a customer to a different service supplier

Switch customer to an interval meter

**Note:**

It is recommended that the unique identifier of your Notification Upload Types match the "transaction types" that are referenced on incoming notifications. If it is not possible to do this, the process that creates the upload staging records must map the external transaction types to the notification upload types that you define in the system.

In addition, as described in [System Conditions May Trigger Notification and Workflow](#), you should evaluate any condition that should cause an NUS to be created (to eventually create a workflow). A new NUS Type should be defined for each condition. For each of these, consider creating a new value for the upload condition flag so that the NUS type is not hard-coded in the system process that creates the NUS.

Navigating to Related NUS Extension

When designing the types of notifications your organization may receive, you must determine where you plan to store the detailed information related to the incoming transaction: as context linked to the NUS, as characteristics linked to the NUS or by using an extension record.

**Fastpath:**

Refer to [Process X - Populate Notification Upload Staging](#) for information about the different options available.

If you choose to capture the detailed information in a new extension record with a new user interface, then in order to be able to drill down to the related extension record, the following steps are required.

- Add a new [lookup](#) value for your new extension record for the field NT_UP_EXTSN_FLG. (This step is needed regardless of whether you want to drill down to the related record.)
- Add a [navigation option](#) pointing to the appropriate navigation key for your new transaction. This navigation option must reference a usage type of notification upload type.
- Indicate the appropriate lookup value and navigation option on the appropriate notification upload type.

Designing Workflow Process Criteria

The matrix's second dimension is dependent on workflow criteria algorithms. Workflow criteria are confusing. Think of them as optional conditions that, if met, will cause a different type of workflow process to be started when a given notification upload type is received.

You must define a Default criterion in case none of the override criteria are met. You MAY have override criteria if different situations result in different types of workflow processes. For example, let's assume some notification upload types have different workflow processes for industrial customers as compared to all other types of customer. This assumption necessitates the introduction of an override workflow process criteria; we'll call it Industrial Customer.

| WF Process Criteria | Default | Industrial Customer |
|---|---------|---------------------|
| Notif. Upload Type | | |
| Retrieve a customer's consumption history | | |
| Switch a customer to a different service supplier | | |
| Switch customer to an interval meter | | |

**Note:**

The workflow process criteria are limited by your imagination (and business requirements). We have provided the workflow process criteria you see above as an example; we don't expect you'll be able to use the exact conditions we supply. Your conditions will be based on any number of factors.

New workflow process criteria may require programming. See [How To Add A New Algorithm](#) for more information.

Designing Workflow Processes To Process Incoming Notifications

The next step involves populating each cell in the matrix with the workflow events that should be executed when the system receives a notification identified with a given notification upload type. If override criteria aren't relevant for a given notification upload type, we will mark the cell as "N/A".

| WF Process Criteria | Default | Industrial Customer |
|---|--|--|
| Notif. Upload Type | | |
| Retrieve a customer's consumption history | Validate notification - consumption history request Confirm requester is a valid service provider for the customer's service. Create notification download - send consumption history | N/A (meaning that industrial customers use the Default criteria) |
| Switch a customer to a different service supplier | Validate notification - supplier switch Confirm requester is a valid service provider for the customer's service. Check with current supplier if the switch is allowed. Switch suppliers. | N/A (meaning that industrial customers use the Default criteria) |
| Switch customer to an interval meter | Validate notification - change customer to an interval meter Create notification download - reject request (only industrial customers can have an interval meter) | Validate notification - change customer to an interval meter Confirm requester is a valid service provider for the customer's service. Create field activity to exchange current meter. Change rate on exchange date. |

Note:

Notice that the first event in each cell typically validates the notification upload staging record.

At this point, the matrix is complete. Before you're ready to design your workflow process templates you must design the processes described in the next section.

Designing Workflow Processes To Deal With Invalid Sender or Notification Upload Type

The system needs to know the type of workflow process to create when a notification is uploaded that does not contain a valid External System or Notification Upload Type (these two fields are the ones that control the type of workflow process that's created to process the uploaded notification). When these conditions are detected by the notification upload process, most utilities create an outgoing notification rejecting the uploaded notification when such conditions transpire. We've shown these in the following table.

| | |
|------------------------------------|--|
| Notification Condition | Workflow Process Events |
| Unknown Notification ID | Create notification download - reject notification, bad external system |
| Unknown Notification (Upload) Type | Create notification download - reject notification, bad notification upload type |

**Note:**

These processes are not in a workflow process profile. The above workflow process templates are not referenced in a workflow process profile. Rather, when you create these workflow process templates you label them with a **Notification Condition** of Unknown Notification ID or Unknown Notification Type. The notification upload process will then create workflow process when these events transpire.

Designing Workflow Process Templates

The following table shows the workflow process templates referenced in the previous section's matrix. Adjacent to each process is its events and an indication of when they are triggered.

| Workflow Process Template | Event Number | Workflow Event Type | Dependent On Event(s) | Trigger Date Set To X Calendar Days After Completion Of Dependent Events |
|---|--------------|--|-----------------------|--|
| Retrieve a customer's consumption | 10 | Validate notification - consumption history request | N/A - first event | 0 |
| | 20 | Confirm requester is a valid service provider for the customer's service | 10 | 0 |
| | 30 | Create notification download - send consumption history | 20 | 0 |
| Switch a customer to a different service supplier | 10 | Validate notification - supplier switch | N/A - first event | 0 |
| | 20 | Confirm requester is a valid service provider for the customer's service | 10 | 0 |
| | 30 | Check with current supplier if the switch is allowed | 20 | 0 |
| | 40 | Switch suppliers | 30 | 0 |
| Switch customer to an interval meter | 10 | Validate notification - interval meter switch | N/A - first event | 0 |

| | | | | |
|-------------------------------------|----|--|-------------------|---|
| | 20 | Confirm requester is a valid service provider for the customer's service | 10 | 0 |
| | 30 | Create field activity to exchange current meter | 20 | 0 |
| | 40 | Change rate on exchange date | 30 | 0 |
| Reject interval meter switch | 10 | Validate notification - interval meter switch | N/A - first event | 0 |
| | 20 | Create notification download - reject request | 10 | 0 |
| Reject bad notification upload type | 10 | Create notification download - reject request | N/A - first event | 0 |
| Reject bad external system | 10 | Create notification download - reject request | N/A - first event | 0 |

**Note:**

The workflow process for "Reject bad notification upload type" should reference the Notification Condition Unknown Notification Type. The workflow process for "Reject bad external system" should reference the Notification Condition Unknown Notification ID.

Designing Workflow Event Types

If we extract each unique event type from the above table, we end up with the following:

Workflow Event Type

Validate notification - consumption history request

Confirm requester is a valid service provider for the customer's service

Create notification download - send consumption history

Validate notification - supplier switch

Current supplier confirmation

Switch supplier

Validate notification - interval meter switch

Create field activity to exchange meter

Change rate

Create notification download - reject request

Next, we have to determine the algorithm that will be used when each event is activated on its trigger date. We call this algorithm the *activation algorithm*. An activation algorithm is a stand-alone routine that does whatever you need done when an event is activated. We have populated the following table with brief descriptions of the types of activation algorithms you'd need for the above workflow events.

Note:

The activation algorithms are limited by your imagination (and business requirements). We have provided the activation algorithms you see below as an example; we don't expect you'll be able to use the exact algorithms that we supply. Your algorithms will be based on any number of factors. Be aware that new activation algorithms may require programming. See [How To Add A New Algorithm](#) for more information.

| Workflow Event Type | Activation Algorithm |
|--|--|
| Validate notification - consumption history request | Validate consumption history request |
| Confirm requester is a valid service provider for the customer's service | Confirm service provider is valid requester |
| Create notification download - send consumption history | Create notification download - send consumption history |
| Validate notification - supplier switch | Validate supplier switch request |
| Current supplier confirmation | Create notification download - check if it's OK to switch customer from current supplier |
| Switch supplier | Switch supplier |
| Validate notification - interval meter switch | Validate interval meter switch request |
| Create field activity to exchange meter | Create field activity - exchange meter |
| Change rate | Change rate |
| Create notification download - reject request | Create notification download - reject request |

Next, we have to determine which types of events can fail. Refer to [Some Workflow Events May Fail](#) for background information failure. For those types of events that can fail, we will indicate their *failure algorithm* in the table. A failure algorithm is a stand-alone routine that does whatever you need none when an event fails. We have populated the following table with brief descriptions of the types of failure algorithms you'd need for the above workflow events.

Note:

The failure algorithms are limited by your imagination (and business requirements). We have provided the failure algorithms you see below as an example; we don't expect you'll be able to use the exact algorithms that we supply. Your algorithms will be based on any number of factors. Be aware that new failure algorithms may require programming. See [How To Add A New Algorithm](#) for more information.

| Workflow Event Type | Activation Algorithm | Failure Algorithm |
|---------------------|----------------------|-------------------|
|---------------------|----------------------|-------------------|

| | | |
|--|--|---|
| Validate notification - consumption history request | Validate consumption history request | Create notification download - invalid request |
| Confirm requester is a valid service provider for the customer's service | Confirm service provider is valid requester | Create notification download - invalid requester |
| Create notification download - send consumption history | Create notification download - send consumption history | N/A |
| Validate notification - supplier switch | Validate supplier switch request | Create notification download - invalid request |
| Current supplier confirmation | Create notification download - check if it's OK to switch customer from current supplier | Create notification download - reject request due to supplier rejection |
| Switch supplier | Switch supplier | N/A |
| Validate notification - interval meter switch | Validate interval meter switch request | Create notification download - invalid request |
| Create field activity to exchange meter | Create field activity - exchange meter | N/A |
| Change rate | Change rate | N/A |
| Create notification download - reject request | Create notification download - reject request | N/A |

And finally, for those events whose activation algorithm puts them into a wait state, we have to determine the waiting process that monitors the waiting events. Refer to [Waiting Events And Their Waiting Process](#) for more information about waiting.

Note:

The waiting processes are limited by your imagination (and business requirements). We have provided the waiting processes you see below as an example; you may not be able to use the exact processes that we supply as your processes will be based on any number of factors. Be aware that a new waiting process will require programming.

| Workflow Event Type | Activation Algorithm | Failure Algorithm | Waiting Process |
|--|---|--|-----------------|
| Validate notification - consumption history request | Validate consumption history request | Create notification download - invalid request | N/A |
| Confirm requester is a valid service provider for the customer's service | Confirm service provider is valid requester | Create notification download - invalid requester | N/A |
| Create notification download - send consumption history | Create notification download - send consumption history | N/A | N/A |
| Validate notification - supplier switch | Validate supplier switch request | Create notification download - invalid request | N/A |

| | | | |
|---|--|---|--|
| Current supplier confirmation | Create notification download - check if it's OK to switch customer from current supplier | Create notification download - reject request due to supplier rejection | Check if supplier has accepted process |
| Switch supplier | Switch supplier | N/A | N/A |
| Validate notification - interval meter switch | Validate interval meter switch request | Create notification download - invalid request | N/A |
| Create field activity to exchange meter | Create field activity - exchange meter | N/A | Check if field activity is complete |
| Change rate | Change rate | N/A | N/A |
| Create notification download - reject request | Create notification download - reject request | N/A | N/A |

Designing External Systems

As described under [What Type Of Workflow Process Is Created?](#), every notification upload staging (NUS) record contains an external system. An external system is the unique identifier of the sender of the notification.

To "design" your external systems, document the external id's (e.g., DUNS number) of your service providers. The following table contains a sample:

| External System | Description |
|-----------------|-----------------------|
| 102910 | Energy Supplier, Inc. |
| 392191 | Cheap Power, Inc. |

The above example would result in 2 external systems - 102910 and 392191.

Note:

It's obvious, but worth stressing, that the External System should be the exact number referenced on notifications sent by a sender.

Designing Notification Downloads

The system creates outgoing notifications when:

- It needs to respond to an incoming notification. For example, if an incoming notification requests a customer's consumption history, the system must send the consumption history by creating an outgoing notification.
- It needs to apprise a third party that something has changed about the customer or their meter. For example, if a customer stops service, the system must tell the various service providers of such.
- It needs to exchange information with another application in the company, for example a CRM system.

A Notification Download Staging (NDS) record is created for every notification that is sent to the outside world.

The topics in this section describe how to design the tables that control your notification download processing.

Designing Workflow Processes To Support Outgoing Notifications

As described under [How Are Notifications Sent Out Of The System?](#) notifications are sent out via Notification Download Staging (NDS) records. NDS records are created by workflow events (i.e., the event's activation algorithm creates notification download records). There are two types of workflow processes that contain these types of workflow events:

- Many workflow processes exist to process incoming notifications. These processes typically contain workflow events that create –NDS records to communicate with service providers. If you look at the workflow processes described under [Designing Workflow Process Templates](#), you will see many such examples.
- When something noteworthy happens, the system may need to tell a third party about it. As described in [System Conditions May Trigger Notification and Workflow](#), you may decide that the noteworthy condition should cause a workflow process to be created where one or more of the workflow events can create an NDS. The following table shows representative workflow process templates of this type.

| Workflow Process Template | Event Number | Workflow Event Type | Dependent On Event(s) | Trigger Date Set To X Days After Completion Of Dependent Events |
|---------------------------|--------------|---|-----------------------|---|
| Stop service | 10 | Create notification download - inform all parties that customer is stopping service | N/A - first event | 0 |
| Meter exchange | 10 | Create notification download - inform all parties that meter has been changed | N/A - first event | 0 |

After documenting these types of workflow process templates, follow the instructions under [Designing Workflow Event Types](#) to add any new types of events to the list.

Designing Your External System Feature Configuration

For certain types of external systems, your application may define options used to configure the interaction between your product and your external system. The feature configuration table is used to define some settings applicable to the interaction with your external system, for example:

- The Options grid allows you to define information needed to communicate with the external system. For example, if you interface with an external workforce management system for booking appointments, a feature configuration for the WFM system may use an option to define whether or not the user can manually define an appointment.
- The Messages collection allows you to map each message that you may receive from the external system to a corresponding [message](#) in this system.

Note:

Recommendation. We recommend creating a new message for every message that is being mapped. This ensures that changes to future base product messages do not affect the integration.

Define the Message Sender

If any of your messages are routed to an external system via XAI, the message must also be associated with an XAI Sender, which tells the system how to send the message.

Note:

Sender Optional. If the NDS message does not require routing, you are not required to define a message sender.

Designing Notif. Download Types

You will need one notification download type for every type of notification your organization can send to service providers. To "design" your notification download types, list:

- Every outgoing notification that you documented under [Designing Workflow Event Types](#).
- Every outgoing notification that you documented under [Designing Workflow Processes To Support Outgoing Notifications](#).
- Every outgoing notification that may be triggered from within the system as described in [System Conditions May Trigger Notification and Workflow](#). For each of these, consider creating a new value for the download type condition flag so that the download type is not hard-coded in the system process that creates the NDS.

We have populated the Notification Download Type column with a few classic examples:

| Notification Download Type | Download Type Condition Flag |
|---|------------------------------|
| Inform all parties that customer is stopping service | CUSTSTOP |
| Inform all parties that meter has been changed | METERCH |
| Send consumption history | |
| Check if it's OK to switch customer from current supplier | |
| Reject request | |

You should also consider the priority of each NDS type with respect to the other types.

Once you know the different types of download notifications, you have to determine the physical method used to route the notification to the third party. Refer to [Designing Notification Download Profiles](#) for how to do this.

If the outbound notification may be routed via XAI, you must define an XAI inbound service. This is used by the XAI MPL to retrieve information about the record related to the outbound message.

Fastpath:

Refer to [Configuring the System for XAI Messages](#) for more information on designing your XAI outgoing messages.

Designing Context Values for the NDS Type

A notification download staging record must reference some "relevant data" that allows the extract process or the XAI MPL process to retrieve the data needed to send to the external system. For example, if the person's name has changed, the NDS must reference the Person Id. When formatting the data to send to an external system, the appropriate process would take the person ID and retrieve the data needed to send to the external system.

The NDS may use either the context collection or the characteristics collection to enter this "relevant data". If you choose to use context, you may decide to define the context types for the NDS type (although it is not required).

If NDS records of this type are interfaced through XAI, then the context types and corresponding XPATH values are required for every piece of data that is required to call an application service to build the extract. The XPATH indicates the relative path in the XML document where the field value will be placed when building the XML document.

Fastpath:

Refer to [Configuring the System for XAI Messages](#) for more information on designing your XAI outbound messages.

Configuring the System for XAI Messages

The following provides links so that you can easily navigate the information related to configuring the system for XAI messages:

- [Designing Your Real Time Messages](#)
- [Designing the Real Time Message XSL](#)
- [Designing the Real Time Message NDS Types and Download Profile](#)
- [Designing the Real Time Message NDS Types and Download Profile](#)
- [Designing the Near Real Time Response](#)

Designing Your Real Time Messages

Consider the following integration scenario. A page in your product is configured to send information to an external system real time. If the connection is down, the user is warned and may authorize that the message is sent in near real time. The following sections describe how to design the control tables needed for both scenarios.

[Top of Page](#)

Designing the Real Time Message XSL

During implementation, you will determine the information required to send to the external system. The real time message engine is passed all the data available in the page model as an XML document. The request XSL must be designed to map this data into a format expected by the target.

In addition, you should create two response XSLs to transform the message received from the target system.

- One XSL is used for real time responses. The XSL transforms the message into a format understood by the page service user exit. Note that any updates to a system business object as a result of the response is the responsibility of the user exit that called the real time message engine.
- One XSL is used for non-real time responses. In this case, if the response should update a system object, the response must trigger an XUS to update the system object. Therefore, the XSL must map the response into an XML request that reference the appropriate service to update the system object.

[Top of Page](#)

Designing the Real Time Message NDS Types and Download Profile

For this scenario you must create two NDS types

- One NDS type is used for the real time message. Indicate an appropriate notification download condition. This allows the mechanism that creates the NDS to refer to this condition rather than hard-coding the NDS type.
- One NDS type is used for the near real time message. This NDS type must reference a special XAI inbound service used to indicate to the download staging sender that the XDS does not need to be created.

Note:

Download Condition. The real time message engine receives the NDS type as input. It is the user exit's responsibility to determine the appropriate NDS type based on a notification download condition.

You'll need to create an entry in the service provider's [notification download profile](#) for each NDS type.

[Top of Page](#)

Designing the Near Real Time Response

To process a response to the near real time message, you must also design the XAI inbound service to be used to process the response.

- The XSL transformation scripts that are referenced by the inbound service should populate the appropriate XML elements to allow XAI to recognize that the inbound message is a response.
- Otherwise, the inbound service should be designed to process this message as appropriate. For example, if the response should update the status of the record that initiated the outgoing request, the inbound service should reference the appropriate schema to update the appropriate record.

[Top of Page](#)

Designing Near Real Time NDS Messages

As described above, near real time NDS messages require you to define:

- A download staging receiver to process records on the NDS table.
- A download staging sender to process "responses" to the download staging receiver.

The following sections identify other control table design issues.

Consider the following integration scenario. A change to a certain type of record in your product should trigger a message to an external system to inform that system of the change. This will be a near real time message and we expect an asynchronous response.

- [Designing the XML Request and Inbound Service](#)
- [Designing the Near Real Time NDS Type](#)
- [Designing the Response](#)

Designing the XML Request and Inbound Service

You should work with the external system to determine the information they require for this message. If a system service already exists to extract all the required information, you may use that service. However, it's possible that you would need to create a new service to extract the information you need.

Your implementers must create an appropriate service and then use the schema editor to create request and response schemas based on this service.

Note:

Message ID. If you expect an asynchronous response to this message, the request and response schemas must include a private attribute to hold the MessageID.

Create an XAI inbound service for extracting the appropriate information and building the XML request.

[Top of Page](#)

Designing the Near Real Time NDS Type

Define an appropriate NDS type. The information defined here is required to successfully build the XML request.

- Indicate the XAI Inbound Service created above.
- Indicate an appropriate notification download condition. This allows the mechanism that creates the NDS to refer to this condition rather than hard-coding the NDS type.
- Use the notification download type context to identify the data required to build the request to invoke the XAI Inbound Service for this download type. In our case, context types must be defined for the business object id and the message id. Use the XPATH to indicate the relative page for this element in the request schema.

| Context Type | XPATH |
|-----------------------|--|
| Maintenance Object ID | //ExtractInfoService/ ExtractInfoHeader@MaintenanceObjectID |
| Message ID | //ExtractInfoService/ExtractInfoHeader/MessageID |

[Top of Page](#)

Designing the Response

If you expect a response to the message sent, you must also design the XAI inbound service to be used to process the response.

- The XSL transformation scripts that are referenced by the inbound service should populate the appropriate XML elements to allow XAI to recognize that the inbound message is a response.

- Otherwise, the inbound service should be designed to process this message as appropriate. For example, if the response should update the status of the record that initiated the outgoing request, the inbound service should reference the appropriate schema to update the appropriate record.

[Top of Page](#)

Designing Notif. Download Profiles

A notification download profile controls how the system routes notifications to third parties. You associate a notification download profile with one or more service providers. Whenever a notification is sent to a service provider, the system uses the notification download profile to determine the interface method and the format of notifications.

Note:

A notification download profile corresponds with a protocol used to route notifications to service providers. If you electronically route all notifications using the same protocol (for example, all service providers in a given jurisdiction may conform to the same record formatting and routing method), you will have a single notification download profile. If you have to route notifications using different protocols to different providers, you will need one notification download profile per protocol.

Using the notification download profile, you can define which outgoing messages are sent as an XML document via the XAI tool and which are sent in batch format. When a message is designated as being sent via the XAI tool, then you typically define XAI routing information. If a message is designated as being sent via batch, then you must indicate the formatting algorithm used by the extract program.

Note:

XAI Routing Information Optional. You may indicate that the message should be routed via XAI, but enter no XAI Routing information. You may do this when you are interfacing with one of your own external systems and where the system may be accessed directly. In this scenario, you are using the XAI functionality to communicate between systems using XML documents, but you don't need the routing logic within XAI. Refer to [An NDS Message That Doesn't Require Routing](#) for more information.

The easiest way to design a notification download profile is to choose a representative service provider and design a notification download profile for it by filling in the following matrix. After you've designed a profile, determine how many other service providers can use it. Then design the next service provider's profile and determine who can reuse it. Repeat this process until all your service providers have a profile. Once the profiles are designed, you're ready to set up the control tables.

| Background Process used for batch messages | Notification Download Type | Processing Method | XAI Route Type | Format Method |
|--|---|-------------------|----------------|--------------------|
| File Transfer | Inform all parties that customer is stopping service | Batch | | Format Stop |
| | Inform all parties that meter has been changed | XAI | Meter Change | |
| | Send consumption history | Batch | | Format Consumption |
| | Check if it's OK to switch customer from current supplier | XAI | Confirm Switch | |

| | | |
|----------------|-----|--------|
| Reject request | XAI | Reject |
|----------------|-----|--------|

Notice that you define the background process at the profile level, but you indicate for each download type whether it will be processed via batch or via XAI. If at least one of the processing methods is batch, then a background process must be entered, otherwise it's not applicable.

Also note that it is possible to link more than one XAI route type to each notification download type formatting method. However, this is not recommended if you expect an [asynchronous response to the NDS message](#).

After you've designed notification download profiles to cover every protocol, you are ready to set up the control tables.

Fastpath:

Refer to [Notification Download Background Processes](#).

Setting Up Notification and Workflow Procedures

In the previous sections, [Designing Notification Upload & Workflow Procedures](#) and [Designing Notification Downloads](#), we presented a case study that illustrated a mythical organization's workflow procedures. In this section, we'll explain how to set up the control tables to implement these procedures.

Setting Up Workflow Event Types

Workflow event types control what is done by a given workflow event. Open **Admin > Workflow > Workflow Event Type > Add** to define your workflow event types.

Fastpath:

Refer to [Designing Workflow Event Types](#) for more information.

Description of Page

Enter a unique **Workflow Event Type** and **Description** for the event type.

Turn on **Allow Manual Completion** if an operator is allowed to change the status of workflow events of this type to Complete.

The **Event Activation Algorithm** is used by the system when it activates a workflow event of this type. Refer to [Executing Workflow Events On Their Trigger Date](#) and [Designing Workflow Event Types](#) for more information. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that is associated with workflow event activation. The system comes supplied with several sample algorithm types that should be used as a sample if you have to write a new algorithm type.

The **Event Failure Algorithm** is used by the system when a workflow event of this type fails. This algorithm need only be defined if events of this type can fail. Refer to [Some Workflow Events May Fail](#) and [Designing Workflow Event Types](#) for more information. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that is associated with workflow event failure. The system comes supplied with several sample algorithm types that should be used as a sample if you have to write a new algorithm type.

The **Wait Process** is the background process responsible for monitoring workflow events of this type that are in the Waiting state. Refer to [Waiting Events And Their Waiting Process](#) for more information.

Setting Up Workflow Process Templates

A workflow process template defines the workflow events that will be created when a workflow process is created using a template.

Fastpath:

Refer to [Designing Workflow Process Templates](#) for more information.

Workflow Process Template - Main

Open **Admin > Workflow > Workflow Process Template > Add** to define your workflow process templates.

Description of Page

Enter a unique **Workflow Process Template** code and **Description** for the workflow process template.

The system needs to know the type of workflow process to create when a notification is uploaded that does not contain a valid External System or Notification Upload Type (these two fields are the ones that control the type of workflow process that's created to process the uploaded notification). If you create workflow process templates and label them with a **Notification Condition** of Unknown Notification ID or Unknown Notification Type, the notification upload process will create a respective workflow process when either of the above conditions are discovered. Note: most utilities create an outgoing notification rejecting the uploaded notification when such conditions transpire. The notification condition field is also available for use by your plug-in algorithms for any purpose where you need to identify a specific workflow process.

Note:

The values for this field are customizable using the Lookup table. This field name is WF_PROC_COND_FLG.

Use **Comments**, to describe the workflow process template.

When a workflow process is created, the system links one or more workflow events to it. The information in the **Workflow Responses** scroll defines these events and when they will be triggered. The following fields are required for each event:

Event Sequence. Sequence controls the order in which the workflow events are executed. The sequence number is system-assigned and cannot be changed. If you have to insert a workflow event between two existing events, you'll have to remove the latter events, insert the new event, and then re-specify the removed events.

Workflow Event Type. Specify the type of workflow event to be generated. The event type's description is displayed adjacent.

Dependent on Other Events. Turn this indicator on if the trigger date of the event can only be determined after earlier events are complete. Refer to [Workflow Event Dependencies & Trigger Date](#) for more information. If this switch is on, you must define the events on which this response depends in the **Dependent on Other Events** grid.

Days After Previous Response. Specify the number of calendar days after the completion of the dependent events on which the workflow event will be triggered. If this event is not dependent on the completion of other events, this field contains the number of calendar days after the creation of the workflow process that the related workflow event will be triggered.

When the **Dependent on Other Events** switch is on, a grid appears in which you specify the events on which this event is dependent. The following fields are required for each event:

Sequence. Sequence is system-assigned and cannot be specified or changed.

Dependent on Sequence. Specify the sequence number of the workflow event type on which the above workflow event depends.

Workflow Event Type. The system displays the ID of dependent workflow event in this column.

**Fastpath:**

For more information about workflow event templates, see [Setting Up Workflow Event Types](#). For more information about trigger dates, see [Workflow Event Dependencies & Trigger Date](#).

Where Used

A Workflow Process Profile references one or more workflow process templates. Refer to [Setting Up Workflow Process Profiles](#) for more information.

A Workflow Process references a workflow process template. Refer to [Workflow Process - Main](#) for more information.

Workflow Process Template - Template Tree

Open **Admin > Workflow > Workflow Process Template > Search** and navigate to the **Template Tree** page to view information about your workflow process template.

Description of Page

This page is dedicated to a **tree** that shows the events linked to the workflow process and information about the event dependencies. You can use this tree to both view high-level information about these objects and to transfer to the respective page in which an object is maintained.

Setting Up Notification Upload Types

Every notification upload staging record has a notification upload type. This code is one of several fields that control the type of workflow process used to process the incoming notification. Open **Admin > Integration > Notification Upload Type** to define your notification upload types.

**Fastpath:**

Refer to [Designing Notification Upload Types](#) for more information.

Description of Page

Enter a recognizable **Notification Upload Type** and **Description**.

Enter a value for the **Upload Condition Flag** when a system condition should trigger the creation of a notification record. Refer to [System Conditions May Trigger Notification and Workflow](#) for more information.

**Note:**

The values for this field are customizable using the Lookup table. This field name is NT_UP_TY_COND_FLG.

If NUS records of this type will be associated with an **Extension** record, indicate the extension here along with its **Navigation Option** to allow a user to navigate to the correct extension record when viewing the notification upload staging record. Refer to [Navigating to Related NUS Extension](#) for more information.

Where Used

A [Notification Upload Staging](#) record must reference a notification upload type.

A [Workflow Process Profile](#) references one or more notification upload types.

Setting Up External Systems

Every notification upload staging record references the system that sent the message. The external system is one of several fields that control the type of workflow process used to process the incoming notification. Refer to [External Systems](#) for more information.

Setting Up Workflow Process Profiles

The system uses a workflow process profile to determine the type of workflow process to create for incoming notifications sent by the service provider. A workflow process profile is associated with one or more service providers. Open **Admin > Workflow > Workflow Process Profile > Add** to define your workflow process profiles.

Fastpath:

Refer to [Designing Workflow Process Profiles](#) for more information.

Description of Page

Define a unique ID and **Description** for each workflow **Process Profile**.

The information in the grid defines the type of workflow process that will be created for each **Notification Upload Type**. The type of workflow process may differ depending on special criteria. For example, you may have a different workflow process if the customer is industrial (as compared to commercial and residential). You must define Default criteria in case none of the override criteria are met (the Default criteria should have the lowest priority). You MAY have override criteria if different situations result in different types of workflow processes.

The following fields are required for each criterion:

Priority The priority controls the order in which the system determines if the respective workflow process should be used to process notifications of a given type. Higher priorities are checked before lower priorities.

Note:

The values for this field are customizable using the Lookup table.

Criteria Algorithm Select the algorithm to be used to check if the workflow process should be initiated for notifications of a given type. If a condition is met, a workflow process is created using the associated workflow process template.

If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that determines if an incoming notification should be processed using the associated **Workflow Process Template**. The system comes supplied with a sample algorithm type called that should be used as a sample if you have to write a new algorithm type.

Important:

You must have at least one entry in this collection otherwise the system will not start a workflow process when an incoming notification of this type is received. This entry should have the lowest priority code and should reference a **Criteria Algorithm** that references the default workflow criteria algorithm type.

Workflow Process Template Specify the workflow process template to use to process incoming notifications identified with the notification upload type.

Fastpath:

Refer to [Designing Workflow Process Criteria](#) for more information.

Setting Up Notification Download Types

Every notification download staging record has a notification download type. This code controls the format of the record that is sent to a service provider. Open **Admin > Integration > Notification Download Type** to define your notification download types.

Fastpath:

Refer to [Designing Notification Download Types](#) for more information.

Every notification download staging record has a notification download type. This code controls the format of the record that is sent to a service provider. Open **Admin > Notification Download Type** to define your notification download types.

Description of Page

Enter a unique **Notification Download Type** and **Description**.

Specify the **XAI In Service Name** that will be called for this NDS type if the download profile formatting method indicates that this download type will be processed by XAI.

Enter a value for the **Download Type Condition Flag** when a system condition should trigger the creation of a notification record. Refer to [System Conditions May Trigger Notification and Workflow](#) for more information.

Note:

The values for this field are customizable using the Lookup table. This field name is NT_DWN_TY_COND_FLG.

Indicate the relative **Priority** for processing NDS records of this type with respect to other types. This value defaults to Priority 90 - Lowest.

Note:

The values for this field are customizable using the Lookup table. This field name is NT_DWN_TY_PRIO_FLG.

Notification Download Type - Context

If the notification download staging record is communicated to the external system through XAI, the NDS context is used to help build the XML document.

Description of Page

The context collection functionality allows you to define a collection of **Context Types** that should be defined for a notification download staging record of this type. When the NDS record is created, with its collection of these Context Types, the Context Values would correspond to system data related to this NDS record. In addition, you may specify a **Context Value** if this is a constant value for NDS records of this type.

The **XPATH** is used by XAI NDS Types. For each context type, use the XPATH to indicate the relative path in the XML document where the field value will be placed when building the XML document.

Where Used

A Notification Download Staging record must reference a notification download type. Refer to [Process X - Populate Notification Upload Staging](#) for more information.

A Notification Download Profile references one or more notification download types. Refer to [Setting Up Notification Download Profiles](#) for more information.

Setting Up Notification Download Profiles

A notification download profile controls how the system routes notifications to service providers. You associate a notification download profile with one or more service providers. Whenever a notification is sent to a service provider, the system uses the notification download profile to determine the interface method and the format of notifications.

Open **Admin > Notification Download Profile > Add** to define your notification download profiles.

Fastpath:

Refer to [Designing Notification Download Profiles](#) for more information.

Description of Page

Define a unique ID and **Description** for each **Download Profile**.

Use **NDS Extract Process** to define the background process that creates notification download records and interfaces them out of the system.

The information in the scroll controls how the **Extract Process** formats an interface record for each **Notification Download Type**. In addition to defining a **Description** and **Comments**, you must define the **Processing Method**.

If your processing method is Batch, you need to define the **Notification Format Algorithm** that actually formats the interface record. If you haven't done so already, you must set up this algorithm in the system. To do this:

- Create a new algorithm (refer to [Setting Up Algorithms](#)).
- On this algorithm, reference an Algorithm Type that is associated with workflow event failure. The system comes supplied with several sample algorithm types that should be used as a sample if you have to write a new algorithm type.

Defining Umbrella Agreement Options

Your organization may use umbrella agreement functionality to manage many situations, including (but not limited to) the following:

- Creating a "negotiated contract" with a large customer with many sites.
- Creating a "negotiated contract" with all customers in a common geographic area, for example a specific city or an apartment complex
- Grouping and managing the proposal service agreements created during the quoting process
- Managing the renewal process for special contracts
- Applying override rate terms to one or more service agreements for a given effective period
- more...

Note:

Separately module. The umbrella agreement functionality is part of the Contract Management module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

The Big Picture Of Umbrella Agreements

The topics in this section provide background information about how to configure the system to support your umbrella agreement requirements.

Renewable Umbrella Agreements

When defining your umbrella agreement types, you must determine if umbrella agreements of this type are renewable. If so, you must set the renewal flag on the UA type to Renewable and determine the number of days prior to the end date of the umbrella agreement that the renewal process should start.

In addition, you must decide on your renewal procedure and design an appropriate renewal [algorithm](#). You may use one of the sample renewal algorithms provided by the system.

- The sample algorithm URNW-TD creates a To Do entry. Using this algorithm you can direct the To Do entry to an appropriate role to determine if the umbrella agreement should be renewed. If the umbrella agreement is associated with an account management group, the To Do entry could be assigned to a role defined for that AMG.
- The sample algorithm URNW-CA creates a [case](#). Using this algorithm you can create an appropriate case to help track the steps required for renewing an umbrella agreement.

If the base algorithms do not provide the logic your organization needs, you may create a new algorithm.

**Note:**

It is the responsibility of the renewal algorithm to change the renewal date as per the business requirements. If renewal requires manual review, the algorithm should reset the date to blank. If the algorithm can determine a new renewal date, the date should be changed to the appropriate value.

Terms Of Service Covered Entities

For each terms of service type you design, consider whether or not a TOS created for this type should reference one or more entities in the system that are "covered" by the terms of service. Following are some examples of covered entities:

- A special contract is created for all the McDonalds franchises in your service area. When creating the terms of service record for the umbrella agreement used for this contract, you want the user to link the person record representing the McDonalds corporate entity as a covered entity for the TOS.
- An umbrella agreement is created for a large customer with several types of services. Perhaps you want to group the services in the contract based on type of service. The service type may be set up as a covered entity.

The covered entities could also be used to denote eligibility. Refer to [Linking To A UA For A Group Of Premises](#) for an example of using the covered entity collection for eligibility.

The covered entities are actually characteristics. You must define the desired characteristic types if they do not already exist. In this case, they would be foreign key characteristic types. The characteristic types that you want to use must reference a characteristic entity of TOS covered entity.

A terms of service record may only reference covered entity types that you designate on the Terms of Service type record. When designing the covered entities that are allowed for TOS records of a given type, you may also configure the Terms of Service type to indicate that one or more covered entity types are required.

Refer to [Terms Of Service Type - Main](#) for more information.

Overriding Rate Terms

If your organization has business rules that require a service agreement's rate terms to be overridden, you can accomplish this using umbrella agreements and terms of service records. There are two levels of overriding that are possible:

- Override rate schedule
- Override other terms on the rate, including contract riders, contract terms and tax exemptions

To override any rate terms, the service agreement must be linked to a terms of service record that references a template service agreement. In addition, you must configure settings in the system to indicate whether or not overriding of terms is allowed.

- The **SA type** for the customer's service agreement indicates whether or not the rate schedule may be overridden using the rate source flag.
 - If the rate source value is Check TOS First, then SA, when applying the rate, the system determines if the SA is linked to a TOS effective at the time of the bill with a template SA. If so, the rate schedule on the template SA is used.
 - If the rate source value is Check SA Only, when applying the rate, the always uses the rate schedule on the customer's SA (regardless of whether or not the SA is linked to a TOS effective at the time of the bill with a template SA).
- If any bill factor on one of calculation rule indicates that it is eligible for tax exemptions, contract terms or contract riders, the terms of service usage flag on the bill factor indicates where the system should look for the appropriate value. The flag tells the system to find applicable information either on the TOS's template SA only, on the customer's SA only or it should first check the TOS, then check the customer's SA.

The following table illustrates the different scenarios possible when configuring your bill factors and the resulting behavior. The term "standard behavior" in the tables below indicate that the standard behavior as described in [Defining Bill Factors](#) is followed.

| | TOS Usage | Template SA | Customer SA | BF Char Source |
|---|--------------------------|-------------------|-------------|---|
| Contract Rider Applicability is checked | Check TOS First, then SA | Found | Not checked | If source = SA, the template SA's characteristic collection is checked. If source \diamond SA, the standard behavior is followed. |
| | | Not Found | Found | If source = SA, the customer SA's characteristic collection is checked. If source \diamond SA, the standard behavior is followed |
| | Check TOS Only | Not Found | Not Found | N/A |
| | | Found | Not checked | If source = SA, the template SA's characteristic collection is checked. If source \diamond SA, the standard behavior is followed |
| | | Not Found | Not checked | N/A |
| Check SA Only | Not checked | Standard behavior | | |

| | TOS Usage | Template SA | Customer SA | BF Value Source | BF Char Source |
|-----------------------------------|--------------------------|-------------|-------------|--|--|
| Value in Contract Term is checked | Check TOS First, then SA | Found | Not checked | Template SA | N/A |
| | | Not Found | Found | Customer SA | N/A |
| | | Not Found | Not Found | Bill Factor Value (based on Char Source) | If source = SA, the template SA's characteristic collection is checked. If source \diamond SA, the standard behavior is followed |
| | Check TOS Only | Found | Not checked | Template SA | N/A |

| | | | | |
|---------------|-------------|-------------------|--|---|
| | Not Found | Not checked | Bill Factor Value (based on Char Source) | If source = SA, the template SA's characteristic collection is checked. If source <> SA, the standard behavior is followed |
| Check SA Only | Not checked | Standard behavior | | |

| | TOS Usage | Template SA | Customer SA | BF Value Source |
|-----------------------------|-----------------------------|---------------|-------------|-------------------|
| Tax Exemption is checked | Check TOS First, then SA | Found | Not checked | Template SA |
| | | Not Found | Found | Customer SA |
| | | Not Found | Not Found | No value |
| | Check TOS Only | Found | Not checked | Template SA |
| | | Not Found | Not checked | No value |
| | | Check SA Only | Not checked | Standard behavior |

Note that [proration](#) logic is followed for the above functionality as expected. For example, imagine that a bill factor with Value in Contract Terms is proratable and the TOS usage value is Check TOS First, then SA. If the template SA has a contract value that is only in effect for the first 10 days of a bill, that value is used for the first 10 days and the remaining days in the bill take the value from the SA (if applicable) or the bill factor value as per the table rules above.

Note:

When designing your terms of service type, you must indicate whether a template service agreement is optional, required or not allowed. When the template SA is required, the user setting up the TOS record for this TOS type must link the correct service agreement as the template SA. If a new template service agreement is required, the new SA must be created first.

Setting Up Umbrella Agreement Options

The topics in this section describe how to set up umbrella agreement options.

Configure SA Types for Umbrella Agreements

For each type of service agreement that may be linked to a terms of service record, you must configure the Rate Source for the [SA type](#) to indicate if the rate should always be taken from the service agreement (Check SA Only) or if the rate should be taken from the terms of service record for the service agreement, if any (Check TOS First, then SA).

Fastpath:

Refer to [Overriding Rate Terms](#) for more information.

Note:

The rate source is only visible on SA type if the Contract Management module is not [turned off](#).

Configure Bill Factors for Umbrella Agreements

For each bill factor that has a value in contract term, contract rider applicability or tax exemption applicability, you must indicate where the system should look for a value when a service agreement is linked to a terms of service with a template SA and where this bill factor is referenced by the rate being applied. Using the terms of service usage flag, tell the system to Check TOS Only, Check SA Only or Check TOS First, then SA.

Fastpath:

Refer to [Overriding Rate Terms](#) for more information.

Note:

The terms of service usage flag is only visible on bill factor if the Contract Management module is not [turned off](#).

Configure A Campaign To Link An SA To A Terms Of Service

The system provides a pair of column reference algorithm types that support linking a new service agreement to an existing terms of service record via an [order](#). The pair includes a validation algorithm type CRVL-SATOS and a posting algorithm type CRPS-SATOS.

In order to take advantage of this functionality, you must:

- Create an algorithm for each of the above algorithm types. Only one algorithm is needed for each algorithm type because there are no parameters for either one.
- Setup a unique [column reference](#) for the terms of service ID column reference code and plug in the new validation and posting algorithms on the record.
- For campaigns whose orders link a new service agreement to an existing umbrella agreement, make sure to define a [miscellaneous field](#) for the terms of service ID. Note, the miscellaneous field must reference the column reference that you setup above.

Based on your business practice, you may want to further configure your campaign / package for linking a service agreement to an existing terms of service. Refer to [Linking A Service Agreement To A TOS Through Orders](#) for more information.

Setting Up Umbrella Agreement Types

The umbrella agreement type transaction is used to maintain your UA types. The topics in this section describe how to use this transaction.

Umbrella Agreement Type - Main

Open **Admin > Umbrella Agreement > Umbrella Agreement Type > Add** to define basic information about an umbrella agreement type.

Description of Page

Enter a unique **Umbrella Agreement Type** code and **Description** for the UA type.

Use **Renewal** to indicate whether an umbrella agreement of this type is Renewable or Not Renewable. For renewable UA types, indicate the **Renewal Days Before Expiration**. The renewal date for umbrella agreements of this type are calculated based on this number of days before the end date.

Use the characteristics collection to define characteristics that can be defined for umbrella agreements of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on umbrella agreements of a given type. Turn on the **Default** switch to default the **Characteristic Type** when umbrella agreements of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

**Note:**

Characteristic Types. You can only choose characteristic types defined as permissible on an umbrella agreement record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Enter the valid **Terms of Service Types** that may be referenced for umbrella agreements of this type.

Umbrella Agreement Type - Algorithms

Open **Admin > Umbrella Agreement > Umbrella Agreement Type > Search** and navigate to the **Algorithms** page.

Description of Page

The grid contains **Algorithms** that control important functions in the system. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (descriptions of all possible events are provided below).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** for which you can define algorithms.

| System Event | Description |
|--------------|---|
| UA Renewal | Algorithms of this type are executed by the UARENEW background process when an umbrella agreement has reached its renewal date. Only one renewal algorithm is allowed for a given UA type. |

Setting Up Terms Of Service Types

The terms of service type transaction is used to maintain your Terms of Service types. The topics in this section describe how to use this transaction.

Terms Of Service Type - Main

Open **Admin > Umbrella Agreement > Terms of Service Type > Add** to define basic information about terms of service types.

Description of Page

Enter a unique **Terms of Service Type** code and **Description** for the TOS type.

Use **Template SA Usage** to indicate whether a template SA is Optional, Required or Not Allowed. Refer to [Overriding Rate Terms](#) for more information about using template SAs.

Use the characteristics collection to define characteristics that can be defined for terms of service records of a given type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on terms of service records of a given type. Turn on the **Default** switch to default the **Characteristic Type** when terms of service records of the given type are created. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

**Note:**

Characteristic Types. You can only choose characteristic types defined as permissible on a terms of service record. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Use the **Covered Entities** collection to define the types of entities that are "covered" by terms of service records of this type. Refer to [Terms Of Service Covered Entities](#) for more information

Note:

Characteristic Types. You can only choose characteristic types defined as permissible for TOS covered entity. Refer to [Setting Up Characteristic Types & Their Values](#) for more information.

Terms Of Service Type - UA Types

Open **Admin > Umbrella Agreement > Terms of Service Type > Add** and navigate to the **UA Types** page.

Description of Page

Enter the valid **Umbrella Agreement Types** that may reference this terms of service type.

Setting Up Terms of Service Cancel Reasons

Whenever a terms of service record is canceled, a cancel reason must be specified. Open **Admin > Terms of Service Cancel Reason** to specify such cancellation reasons.

Description of Page

Enter an easily recognizable **Terms of Service Cancel Reason** and **Description** for the terms of service cancellation reason.

Umbrella Agreements Configuration Examples

This section provides examples of how you would configure the system to support various business scenarios.

Linking A Service Agreement To A TOS Through Orders

As described in [Configure A Campaign To Link An SA To A Terms Of Service](#), the system has provided a pair of column reference algorithms to enable your users to link a new service agreement to an existing terms of service record (and its umbrella agreement) when starting service via the order transaction.

When designing your campaign and packages to use this option, consider the scenarios where you may use this to determine whether or not you require additional configuration. The following topics describe some possible scenarios.

Linking To A UA For A Given Account

Imagine that you would use this logic when an important customer is starting additional service and has an existing umbrella agreement for other services that the new service should be added to. The user creating the order is probably the account manager for that account and would know the correct terms of service record to link the new service to.

For this scenario, you do not need to provide any "help" to the user to indicate that linking to a TOS is an option or to help select the correct TOS. You simply need to ensure that the campaign that would be used by this account manager to start service for the important customer simply includes a question / miscellaneous field to [link the SA to the terms of service](#).

Linking To A UA For A Group Of Premises

Imagine you have created an umbrella agreement for a group of premises that are not actively managed by a specific user. For example, perhaps there are several apartment complexes that have negotiated a special rate with your

company. When new customers sign up for service at a premise that belongs to one of these apartments, the user should be informed that there is a special contract for this premise. The user may also need help selecting the correct terms of service record. To accomplish this logic, you must define additional algorithms to help your users.

For example, perhaps your standard campaign for residential electric customers includes a package to be used by premises linked to one of these apartment buildings and should only be eligible to one of those premises. You must create an eligibility algorithm for this package. Its logic could be designed based on the following assumptions:

- The qualifying premises are linked to a parent premise
- The parent premise is linked to the appropriate terms of service record in its covered entity collection

The eligibility algorithm checks to see if the order's premise is linked to a parent premise that is referenced on a terms of service record for an umbrella agreement that is currently in effect. It could also be restricted to search for a specific umbrella agreement type or terms of service type if appropriate.

Note:

The campaign for this scenario must include a question / miscellaneous field to [link the SA to the terms of service](#). It should be configured with an applicability of only applicable on package. The package that is used to include the SA into the terms of service for the apartment complex would include this question / miscellaneous field.

Once the user chooses this package, user is prompted to provide the correct terms of service record via the question / miscellaneous field. To help the user, you should create a column reference retrieval algorithm to default the correct terms of service record for this premise. It would use the same logic as the eligibility algorithm described above. In other words, it would find the parent premise for this premise and then find the terms of service record covered entity collection includes this parent premise and whose umbrella agreement is currently in effect.

Reports Addendum

This chapter is an addendum to the general [Defining and Designing Reports](#) chapter.

Configuring the System to Invoke Oracle Analytics Publisher Enterprise Real-Time

In order to invoke Oracle Analytics Publisher Enterprise from within the system, it must be configured. This topic describes the steps at a high level that are required to configure your system to enable BI Publisher.

Specify Reporting Tool Options

The following information should be defined on Reporting Tool Options table:

- **Reporting Server** is the web server URL where the reporting tool is installed.
- **Reporting Folder** defines the name of the directory on the Oracle BI Publisher server where reports are located. The system's reporting tool algorithm constructs the URL to open Oracle Analytics Publisher Enterprise based on the information provided on Reporting Options. The same folder name should be used as a report folder in Oracle Analytics Publisher Enterprise where reports are published.

Reporting Tool Algorithm

The base product provides an installation algorithm plug-in spot called Reporting Tool. This plug-in spot should contain an algorithm that invokes the reporting tool real-time. The corresponding algorithm type, called algorithm reference: F1-BIPR-INV, invokes Oracle Analytics Publisher Enterprise.

This algorithm relies on information defined in the Reporting Options table: the reporting server and folder names for accessing the reporting tool. The algorithm constructs several strings, for example, the URL of the Analytics Publisher, information about the report being requested and user info in the format expected by Oracle Analytics Publisher Enterprise. The Java program returns the correct URL to the browser. The browser then opens an Analytics Publisher Enterprise window with the appropriate URL.

To use the algorithm reference: F1-BIPR-INV algorithm type to invoke Oracle Analytics Publisher Enterprise, perform the following steps:

1. Create an algorithm for this algorithm type.
2. In the installation options, add an entry to the algorithm collection with an algorithm entity of Reporting Tool and indicate the algorithm created in the previous step.

Interface with Oracle Analytics Publisher Enterprise Batch Scheduler

Presently the base product does not provide support for batch jobs with Oracle Analytics Publisher. Please use Oracle Analytics Publisher directly in order to schedule reports to run in batch.

Configuring the System for Batch Bill Print

This section describes the steps for configuring the applications to print bills in batch.

Configure Oracle BI Publisher for Batch Bill Print

1. Configure the Oracle BI Publisher Scheduler to allow report job submission.

Note:

Refer to the Oracle Fusion Middleware Administrator's Guide for Oracle Business Intelligence Publisher for more information.

2. Ensure that the CI_BILLPR report artifacts (CI_BILLPR.rtf, CI_BILLPR.xdo, CI_BILLPR.xdm) are deployed to corresponding BI Publisher catalog folder:

Configure Oracle Utilities Customer Care and Billing for Batch Bill Print

1. Go to **Admin > Reporting > Reporting Options** and configure the following values:
 - **Reporting Server from Browser** should point to the correct BI Publisher Server URL; for example, `http://<hostname>:port`
 - **Reporting Folder** is the name as the Catalog Folder in BI Publisher where CI_BILLPR is located; for example, CCB
 - **Reporting Engine User ID** is the BI Publisher User ID.
 - **Reporting Engine Password** is the BI Publisher Password.
2. Create a custom Bill Route Type Extract Algorithm using the C1-BLEX-BIP Algorithm Type. Ensure that the following algorithm soft parameters are set:
 - **Output Directory** is the directory in BI Publisher server where the generated output files will be placed, for example, `/tmp/`
 - **Report Absolute Path** is the path where CI_BILLPR.xdo is located in the BI Publisher Catalog, for example, `/CCB/CI_BILLPR/CI_BILLPR.xdo`
 - **Report Format** is the format of the generated output files; for example, `pdf`
 - **Report Code** is the CI_BILLPR report code; for example, `CI_BILLPR`
3. Go to **Admin Menu, B, Bill Route Type** and configure the corresponding Bill Route Type (such as, `POSTAL`) to use the RTTYPOST Batch Control and the custom Bill Route Type Extract Algorithm.

Description of Sample Reports

This section provides an overview of each sample report supplied with Oracle Utilities Customer Care and Billing that may be found in the demonstration database. They may be used by your organization as they are or as a starting point for creating a [new report](#).

Note:

Account Security. The sample reports provided with the product do NOT incorporate account security. If a user has been given security to view the report, then all the data in the report is available for viewing.

Active Severance Processes - CI_ACSVPR

Parameters

| Parameter | Parameter Code | Description |
|------------|----------------|--|
| Start Date | P_FROM_DT | Start date to use for reporting severance processes. If not defined, start date is set to 1900-01-01. |
| End Date | P_TO_DT | End date to use for reporting active severance processes. If not defined to date is set to the current date. |

Report Description

This report is used to aid in the monitoring of active severance processes. The report details are used to review how the company is doing as far as the collection of outstanding debt, as well as to monitor the progress of currently active severance processes.

The report selects active severance processes whose creation date is between the input start and end dates.

Bill Print in BI Publisher - CI_BILLPR**Parameters**

| Parameter | Parameter Code | Description |
|-------------------|----------------|--|
| CC&B user | P_USER_ID | No default value. Required. Returns an error message if user ID is null, empty or does not exist in database. |
| Batch Switch | P_BATCH_SW | For a single bill print, Batch Switch is 'No' and for multiple bill print, Batch Switch is 'Yes'. |
| First Bill | P_FROM_BILL_ID | First Bill Id to print for the Bill Range. |
| Last Bill | P_TO_BILL_ID | Last Bill Id to print for the Bill Range. |
| Batch Code | P_BATCH_CD | Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch code are selected. |
| Batch Number | P_BATCH_NBR | Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch number are selected. |
| Extract Algorithm | P_EXTRACT_ALG | Passed in by the system the report is submitted in batch. Only bills with a Bill Routing whose bill route type references this extract algorithm are selected. |

Report Description

This report is used with BI Publisher to display all the information that appears on the customer's printed bill for the bill ID entered in the input parameters. Refer to the description of the parameters above. The bill is only displayed if the bill is complete.

See below for details of the information extracted for the report. In addition, the sample report layout provided for the base product includes:

- Payment coupon.
- Form for change of address.
- A graph of consumption for current charges.

The following sections highlight the data that is extracted for this report.

Bill Information

| Field Name | Format | Source/Value/Description |
|-----------------|--------|---|
| SORT_KEY | A12 | Primary sort for the report - currently sorted by Bill Id |
| BILL_ID | A12 | CI_BILL |

| SIBLING_ID | A12 | CI_FT |
| FT_ID | A12 | CI_FT |
| CUR_AMT | S15.2 | CI_FT |
| TOT_AMT | S15.2 | CI_FT |
| FT_TYPE_FLG | A2 | Adjustment or Adjustment Cancel ('AD' or 'AX') |
| SHOW_ON_BILL_SW | A1 | CI_FT |
| CURRENCY_CD | A3 | CI_FT |
| XFERRED_OUT_SW | A1 | CI_FT |
| ADJ_TYPE_CD | A8 | CI_ADJ |
| CAN_RSN_CD | A4 | CI_ADJ |
| SA_ID | A10 | CI_ADJ |
| CHAR_PREM_ID | A10 | CI_SA |

| | | |
|-------------------|------|---|
| DESCR_ON_BILL | A254 | CI_ADJ_TYPE_L |
| ADJ_CAN_RSN_DESCR | A60 | Description of cancel reason code. (Note that this is retrieved in a special stored procedure that retrieves all the cancel reason codes and descriptions.) |

Bill Message Information

One record for every bill message linked to the bill.

| Field Name | Format | Source/Value/Description |
|------------------|--------|--------------------------|
| MSG_PRIORITY_FLG | A12 | CI_BILL_SA or CI_FT |
| INSERT_CD | S15.2 | CI_BILL_SA or CI_FT |
| MSG_ON_BILL | S15.2 | CI_BILL_SA or CI_FT |

Billed Revenues by Rate - CI_BILREV

Parameters

| Parameter | Parameter Code | Description |
|-----------------------------|------------------|---|
| Accounting Period | P_ACCT_PERIOD | Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided. |
| Account Type Characteristic | P_CHAR_TYPE | Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. |
| Account Type | P_REV_ACCTY_CHAR | Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts. |

Report Description

This is an analysis report for the billed revenues for an accounting period according to the various rates, which were in effect in the system. The information in this report helps to adjust rates in order to achieve better financial results and comply with regulations and market trends.

This report selects all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within input accounting period (parameter 1)
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 2 & 3)

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Case Statistics By Case Type - CI_CSESTS

Parameters

| Parameter | Parameter Code | Description |
|-------------------------------|----------------|---|
| Start Date | P_FROM_DT | See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date. |
| End Date | P_TO_DT | See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date. |
| Case Condition (Open, Closed) | P_COND_FLG | If specified, only cases in this condition are included in the report. If left blank, the reports produces statistics for both open and closed cases. |

Report Description

This report provides two types of statistics:

1. Open cases whose creation date falls between the input Start Date and End Date (inclusive)
2. Closed cases whose closing date falls between the input Start Date and End Date (inclusive)

The third parameter is only used if you want to restrict the statistics to only open or closed cases. If you leave this parameter blank, both open and closed statistics will be produced.

The following information is provided in graphical format:

- Number of cases by case type
- Percentage of cases by case type

Case Statistics for a Given Status - CI_CSESGS

Parameters

| Parameter | Parameter Code | Description |
|--------------------------|------------------|---|
| Start Date | P_FROM_DT | See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date. |
| End Date | P_TO_DT | See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date. |
| Case Type/Status | P_CASE_STATUS_CD | This is the desired Case Type and Status that will be reported on. |
| Responsible User | P_CASE_OWNER | If specified, only cases with this responsible user are included in the report. |
| First Bucket High Limit | P_B1_LIMIT | Cases that took <= this number of days to reach the given status will be grouped together for statistical reporting. |
| Second Bucket High Limit | P_B2_LIMIT | Cases that took <= this number of days but more than the first bucket high limit to reach the given status will be grouped together for statistics reporting. |
| Third Bucket High Limit | P_B3_LIMIT | Cases that took <= this number of days but more than the second bucket high limit to reach the given status will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group. |

Report Description

This report shows cases of a given case type that transitioned to a given status during a given date range.

Graphs are printed to show the number and percentage of cases grouped by the time it took to reach the status. These statistics are grouped into age buckets whose size is controlled by the last 3 parameters.

Summary statistics are also printed showing the minimum, maximum, average and median times for these cases.

Collection Summary - CI_CLLSUM

Parameters

| Parameter | Parameter Code | Description |
|-----------|----------------|-------------|
|-----------|----------------|-------------|

| | | |
|------------|-----------|---|
| Start Date | P_FROM_DT | If from date is not set, the default is one month prior to the current date. |
| End Date | P_TO_DT | End date of the date range. If not defined by user, it is set to one month after the current date |

Report Description

This report provides detailed monthly summary information of all collection activities. The report is typically used by a collection department for resource planning and performance review purposes.

This report selects pending and completed collection events whose event trigger date falls between the input start and end dates.

Customer Contacts by Type - CI_CUSTCN

Parameters

| Parameter | Parameter Code | Description |
|-------------------------------|----------------|--|
| Start Date | P_FROM_DT | Start date to use for reporting customer contacts. If not defined, the start date is set to the current date minus 7 days. |
| End Date | P_TO_DT | End date to use for reporting customer contacts. If not defined, End Date is set to the current date. |
| Customer Contact Class / Type | P_CC_TYPE_CD | Specify a Customer Contact Class / Type to restrict the report output to a specific class / type. |

Report Description

This report lists all customer contacts in the system created within the input date range. You may optionally restrict the report to customer contacts for a given Customer Contact Class / Type (parameter 3).

Note:

Graphs. The information on this report is shown in both textual and graphical formats.

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_CC table on CC_DTTM to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Customers with Life-Support / Sensitive-Load - CI_PMLSSL

Parameters

| Parameter | Parameter Code | Description |
|-----------|----------------|-------------|
|-----------|----------------|-------------|

| | | |
|--------------|----------------|--|
| Service Type | P_SERVICE_TYPE | Service type used to restrict the report to premises with services of this type. |
|--------------|----------------|--|

Report Description

This reports displays a detailed list of premises that are coded with Life-Support (LS) or Sensitive-Load (SL) information. It may optionally restrict the output to premises with service points for input service type.

This information is used by a company to make sure that customers at these premises are dealt with appropriately in the case of an outage (planned and unplanned) or service cut due to non-payment.

The report provides detailed information about the premise and the related facility elements providing service to that premise (e.g. substation, feeder and node for electric service).

Note:

If ANY person connected to an account has an LS/SL indication in the Person record, then all the premises connected to this account will be treated as LS/SL. This means, for example, that a premise connected to an account that has a 3rd party guarantor with LS/SL is treated as a premise with LS/SL.

Field Order Print in BI Publisher- CI_FOPRNT

Note:

Field Order Print in batch for BI Publisher is not supported yet.

Parameters

| Parameter | Parameter Code | Description |
|--------------|----------------|---|
| CC&B user | P_USER_ID | No default value. Required. Returns an error message if user ID is null, empty or does not exist in database. |
| Batch Switch | P_BATCH_SW | For a single FO print, Batch Switch is 'No' and for multiple FO print, Batch Switch is 'Yes'. |
| First FO | P_FROM_FO_ID | First FO ID to print for the FO Range. |
| Last FO | P_TO_FO_ID | Last FO ID to print for the FO Range. |
| Batch Code | P_BATCH_CD | Batch Code passed in by the system the report is submitted in batch. Only field orders that reference this batch code are selected. |
| Batch Number | P_BATCH_NBR | Batch Code passed in by the system the report is submitted in batch. Only field orders that reference this batch number are selected. |

Extract Algorithm

P_EXTRACT_ALG

Passed in by the system the report is submitted in batch. Only field orders whose dispatch groups reference this FO extract algorithm are selected.

Report Description

This report is used with BI Publisher to display the Field Order information for the field order ID entered in the input parameters. Refer to the description of the parameters above. The field order will only be displayed if the field order's status is dispatched.

The following sections highlight the data that is extracted for this report.

GL Accounting Summary - CI_GLACSM

Parameters

| Parameter | Parameter Code | Description |
|-----------------------------|----------------|---|
| Accounting Period | P_ACCT_PERIOD | Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided. |
| Account Type Characteristic | P_CHAR_TYPE | Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. The account types for the GL accounts are used for grouping the output to the report. |

Report Description

This is a financial audit report used to check the financial details in Oracle Utilities Customer Care and Billing for an accounting period against the GL system. The report summarizes all financial transaction (FT) information for a given accounting period according to the different operating and GL divisions and according to various levels of the account GL information.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Letter Print - BI Publisher Sample Welcome Letters - CI_LTRGN_ENG REPORT

**Note:**

Generating letters in batch is not supported yet.

Parameters

| Parameter | Parameter Code | Description |
|------------------|----------------|--|
| Batch Switch | P_BATCH_SW | For reports accessed online, set the switch to 'No'. Otherwise, it should be set to 'Yes'. |
| Customer Contact | P_CC_ID | References the customer contact associated with the main customer linked to the account. |

Report Description

This sample report template for BI Publisher produces letters that are not associated with any other object (i.e., the template does not have to extract information from another object to merge into a letter). You can use this template as a welcome letter for a new customer.

By default, the English versions of the report templates are provided with the base product. If multilingual report templates are required, your implementation should provide reports for each language. When a letter is generated, the system uses the report template based on the customer's language.

The address and name for the company are extracted from the [installation options](#). The text for the letter is defined in the report layout and not provided by Oracle Utilities Customer Care and Billing. Reports are printed according to the customer's language definition and not based on the user's language definition.

This sample report uses the following text:

Welcome to %1. You have been filed with ID Number %2.

We hope to provide you with our best possible service. If you experience any problems or have any questions, please contact one of our customer service representatives at (800)1234567.

%1 is the company name stored as a message on the [installation options](#).

%2 is Person Id stored on the Customer Contact.

Meter Reads Performance - CI_MTREAD**Parameters**

| Parameter | Parameter Code | Description |
|-------------------|----------------|--|
| Accounting Period | P_ACCT_PERIOD | Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided. |

Report Description

This report selects bill segments for the input accounting period and displays the total number of read meters and unread meters for these bill segments grouped by route type.

Meters that are considered read are meters whose register reads have a status of Regular or Verified . Meters that are considered unread are meters whose register reads have a status of System Estimate, Office Estimate, System Prorate or Billing Force.

**Note:**

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Open Cases By Type - CI_CSEOPN**Parameters**

| Parameter | Parameter Code | Description |
|--------------------------|----------------|--|
| Start Date | P_FROM_DT | See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date. |
| End Date | P_TO_DT | See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date. |
| Case Type | P_CASE_TYPE_CD | If specified, only cases of this type are included in the report. |
| Responsible User | P_CASE_OWNER | If specified, only cases with this responsible user are included in the report. |
| First Bucket High Limit | P_B1_LIMIT | Cases that are open for less than or equal to this number of days will be grouped together for statistical reporting. |
| Second Bucket High Limit | P_B2_LIMIT | Cases that are open less than or equal to this number of days but more than the first bucket high limit will be grouped together for statistics reporting. |
| Third Bucket High Limit | P_B3_LIMIT | Cases that are open less than or equal to this number of days but more than the second bucket high limit will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group. |

Report Description

This is a report on open cases that were created between a given date range.

The report can be limited to a specific type and/or responsible user.

For each case type, the report shows the following:

- Number of open cases by age bucket (the last 3 parameters control the size (in days) of each bucket)
- Percentage of open cases by age bucket
- Details of the open cases

Payments Balance - CI_PMTBAL

Parameters

| Parameter | Parameter Code | Description |
|------------|----------------|---|
| Start Date | P_FROM_DT | Report gets all the payments that have been received during a given date range (from and to date parameters). If start date is not defined by the user, it is set to 7 days prior to the current date. |
| End Date | P_TO_DT | End date of the date range. If not defined by user it is set to the current date |

Report Description

This report provides an overall view of all payments created within the input date range. It is typically used for financial control and audit purposes. The report provides summary information about valid payments received and about canceled payment. Data is summarized by the tender source and the type of payment.

Receivables Aging - CI_RCVAGA

Parameters

| Parameter | Parameter Code | Description |
|--------------------------|----------------|---|
| Cutoff Date | P_CUTOFF_DATE | The date from which the arrears buckets are calculated. If no value is entered, the default is the current date minus 7 days. |
| First Bucket High Limit | P_B1_LIMIT | High limit of first bucket. |
| Second Bucket High Limit | P_B2_LIMIT | High limit of second bucket. |
| Third Bucket High Limit | P_B3_LIMIT | High limit of third bucket. |

Report Description

This report lists all accounts and their arrears information as of the input cutoff date using a balance forward accounting method.

Outstanding debt is placed into the buckets provided as input using the age of the debt as of the cutoff date. Credits are applied to the oldest debt first. For each account a separate bucket is used to display new charges. In addition, the total accounts receivable balance is displayed for each account.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ARS_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Tax Payables Analysis - CI_TXPYBL

Parameters

| Parameter | Parameter Code | Description |
|-----------------------------|------------------|---|
| Start Date | P_FROM_DT | Show summary of the tax amounts starting from this date. If not specified, the system will default this value to the current date minus 7 days. |
| End Date | P_TO_DT | Show summary of the tax amounts up to this date. If not specified, the system will default this value to the current date. |
| Account Type Characteristic | P_CHAR_TYPE | Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. |
| Account Type | P_TAX_ACCTY_CHAR | Account Type Char Value for tax related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #3. The parameter value indicated for this parameter should be one that represents tax liability accounts. |

Report Description

This report displays a summary of the tax amounts that were levied by the company to customers within the input date range. It also includes the tax exemption information for that period.

This report select all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within the input date range
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 3 & 4)

The report also provides tax exemption information for bill segments whose financial transactions satisfy the above criteria. The tax exemption information is retrieved by looking at the bill calculation lines associated with the FT's bill segment.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

To Do Entries - CI_TDENTR

Parameters

| Parameter | Parameter Code | Description |
|-------------------|--------------------|--|
| ToDo Entry Status | P_ENTRY_STATUS_FLG | Defines if the To Do entries on the report should be limited to those with a given status value. If this parameter is left blank, the report will show all open and assigned To Do entries. |
| ToDo Type | P_TD_TYPE_CD | Defines if the To Do entries on the report should be limited to those of a given ToDo type. If this parameter is left blank, the report will show all ToDo type that have at least one open or assigned entry. |

Report Description

The report shows open and assigned To Do entries.

You can limit the report to entries in a given status by specifying the desired **To Do Status** (open or assigned). If you don't specify a status, all open and assigned To Do entries will appear on this report.

You can also limit the report to entries of a given To Do Type by specifying the desired To Do Type. If you don't specify a To Do Type, all To Do Types with at least one entry in the open / assigned state will appear on this report.

Note:

Graphs. The information on this report is shown in both textual and graphical formats.

Umbrella Agreement Summary - CI_UASUMM

Parameters

At least one parameter is required. If the umbrella agreement is entered, no other parameter value is allowed. The report definition uses the validation algorithm RPTV-UASUMM to check these conditions.

| Parameter | Parameter Code | Description |
|-----------|----------------|-------------|
|-----------|----------------|-------------|

| | | |
|---|--------------------|---|
| Umbrella Agreement | P_UA_ID | Specify the Umbrella Agreement to restrict the report to this umbrella agreement (regardless of its status). When this parameter is specified, all other parameters are not allowed. |
| Account Management Group | P_AMG | Specify a value for this parameter to restrict the report to umbrella agreements related to this Account Management Group. |
| Umbrella Agreement Characteristic Type | P_CHAR_TYPE | Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type and value (parameter 4). |
| Umbrella Agreement Characteristic Value | P_CHAR_VALUE | Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type (parameter 3) and value. |
| Number of Days Before Expiration | P_EXPIRE_IN_X_DAYS | Specify a value for this parameter to restrict the report to completed umbrella agreements whose End Date is on or before the current date less the Number of Days before Expiration. |

Report Description

This report provides summary information about one or more [umbrella agreements](#).

If the user does not supply an umbrella agreement ID, but enters one or more of the other parameters, the report only selects umbrella agreements that match the input criteria AND the match the following criteria:

- The status of the umbrella agreement is complete
- The start and end dates of the umbrella agreement include the current date

The report does not include canceled terms of service records or canceled service agreements linked to the above umbrella agreements.

For each umbrella agreement that is included in the report, the output includes information about the umbrella agreement, its collection of terms of service records and for each TOS record, its collection of service agreements.

In addition, the report includes the following graphs:

- Umbrella agreement summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all service agreements linked to the umbrella agreement's terms of service records.
- Terms of service summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all its service agreements

Unbilled Revenues - CI_UBLREV

Parameters

| Parameter | Parameter Code | Description |
|-----------------------------|------------------|---|
| Accounting Period | P_ACCT_PERIOD | Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided. |
| Account Type Characteristic | P_CHAR_TYPE | Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. |
| Account Type | P_REV_ACCTY_CHAR | Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts. |

Report Description

This report provides a simplified calculation of estimated unbilled revenue for a given month.

It processes frozen financial transactions associated with bill segments and canceled bill segments whose bill segment end date is within the **Accounting Period** (parameter 1). It determines the billed revenue for the FT and then uses this information to calculate the unbilled revenue.

To determine "revenue", the report summarizes amounts posted to any distribution code with a characteristic entry that matches the input **Account Type Characteristic** type and **Account Type** characteristic value (parameters 2 and 3).

The estimate for the unbilled portion is calculated as $(\text{Bill Amount} / \text{Number of Days in the Bill Period}) * \text{Number of Unbilled Days for the Accounting Period}$.

For example, consider a bill segment on a monthly-billed cycle for the period of 3/10/03 - 4/9/03, and for \$150 (revenue part of the bill). Assume we are in the April/03 accounting period, which covers 4/1/03 through 4/30/03. This means 21 days are unbilled for April. The unbilled revenue is calculated as $150/31*21 = \$101.61$.

The following are some points to note about this report.

- If the report runs for an historical date, it still estimates the unbilled revenue portion based on the above formula even if actual data exists. In other words, it will not try to find actual bills for subsequent months. As a result, this report always shows what would have been the estimated unbilled revenue for a particular month if that month is the most recent one.
- Services can be billed monthly bi-monthly, quarterly or in any desired frequency. This report only performs the revenue recognition estimation using actual bills that were created in the report's accounting period. As a result, it does not estimate unbilled revenue for accounts that were not billed in any portion of the input accounting period.
- Revenue recognition practices are unique and may vary from customer to customer. In a given month we can produce current bills (e.g. for electric service) or future bills (e.g. cable services). In addition in some cases we can have bills that started before the accounting period and ending after it (for example in a cancel-rebill situation). This report will only estimate unbilled revenues for bills with the accounting period equals to the report's accounting period.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_BSEG table on START_DT, END_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Vacant Premises with Consumption - CI_VACANT

Report Description

This report shows all premises that are considered vacant, and provides information about the level of consumption, the period of vacancy, and the service point and register information.

This report selects service points that are linked to a service agreement that is either canceled or closed. The report excludes any service points that have never been linked to a service agreement. If consumption has been registered at such a service point since the end date of the service agreement, the service point's details are displayed.

This report may be used by the utility to investigate sites where problems such as service theft or leakage may be occurring.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_SA_SP on STOP_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any effect on the production environment.

Active Severance Processes - CI_ACSVPR

Parameters

| Parameter | Parameter Code | Description |
|------------|----------------|--|
| Start Date | P_FROM_DT | Start date to use for reporting severance processes. If not defined, start date is set to 1900-01-01. |
| End Date | P_TO_DT | End date to use for reporting active severance processes. If not defined to date is set to the current date. |

Report Description

This report is used to aid in the monitoring of active severance processes. The report details are used to review how the company is doing as far as the collection of outstanding debt, as well as to monitor the progress of currently active severance processes.

The report selects active severance processes whose creation date is between the input start and end dates.

Bill Print in BI Publisher - CI_BILLPR

Parameters

| Parameter | Parameter Code | Description |
|-----------|----------------|-------------|
|-----------|----------------|-------------|

| | | |
|-------------------|----------------|--|
| CC&B user | P_USER_ID | No default value. Required. Returns an error message if user ID is null, empty or does not exist in database. |
| Batch Switch | P_BATCH_SW | For a single bill print, Batch Switch is 'No' and for multiple bill print, Batch Switch is 'Yes'. |
| First Bill | P_FROM_BILL_ID | First Bill Id to print for the Bill Range. |
| Last Bill | P_TO_BILL_ID | Last Bill Id to print for the Bill Range. |
| Batch Code | P_BATCH_CD | Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch code are selected. |
| Batch Number | P_BATCH_NBR | Passed in by the system the report is submitted in batch. Only bills with a Bill Routing that references this batch number are selected. |
| Extract Algorithm | P_EXTRACT_ALG | Passed in by the system the report is submitted in batch. Only bills with a Bill Routing whose bill route type references this extract algorithm are selected. |

Report Description

This report is used with BI Publisher to display all the information that appears on the customer's printed bill for the bill ID entered in the input parameters. Refer to the description of the parameters above. The bill is only displayed if the bill is complete.

See below for details of the information extracted for the report. In addition, the sample report layout provided for the base product includes:

- Payment coupon.
- Form for change of address.
- A graph of consumption for current charges.

The following sections highlight the data that is extracted for this report.

| DESCR_ON_BILL | A254 | CI_ADJ_TYPE_L |
| ADJ_CAN_RSN_DESCR | A60 | Description of cancel reason code. (Note that this is retrieved in a special stored procedure that retrieves all the cancel reason codes and descriptions.) |

Bill Message Information

One record for every bill message linked to the bill.

| Field Name | Format | Source/Value/Description |
|------------------|--------|--------------------------|
| MSG_PRIORITY_FLG | A12 | CI_BILL_SA or CI_FT |
| INSERT_CD | S15.2 | CI_BILL_SA or CI_FT |
| MSG_ON_BILL | S15.2 | CI_BILL_SA or CI_FT |

Billed Revenues by Rate - CI_BILREV

Parameters

| Parameter | Parameter Code | Description |
|-----------------------------|------------------|---|
| Accounting Period | P_ACCT_PERIOD | Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided. |
| Account Type Characteristic | P_CHAR_TYPE | Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. |
| Account Type | P_REV_ACCTY_CHAR | Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts. |

Report Description

This is an analysis report for the billed revenues for an accounting period according to the various rates, which were in effect in the system. The information in this report helps to adjust rates in order to achieve better financial results and comply with regulations and market trends.

This report selects all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within input accounting period (parameter 1)
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 2 & 3)

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Case Statistics By Case Type - CI_CSESTS

Parameters

| Parameter | Parameter Code | Description |
|-----------|----------------|-------------|
|-----------|----------------|-------------|

| | | |
|-------------------------------|------------|---|
| Start Date | P_FROM_DT | See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date. |
| End Date | P_TO_DT | See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date. |
| Case Condition (Open, Closed) | P_COND_FLG | If specified, only cases in this condition are included in the report. If left blank, the reports produces statistics for both open and closed cases. |

Report Description

This report provides two types of statistics:

1. Open cases whose creation date falls between the input Start Date and End Date (inclusive)
2. Closed cases whose closing date falls between the input Start Date and End Date (inclusive)

The third parameter is only used if you want to restrict the statistics to only open or closed cases. If you leave this parameter blank, both open and closed statistics will be produced.

The following information is provided in graphical format:

- Number of cases by case type
- Percentage of cases by case type

Case Statistics for a Given Status - CI_CSESGS

Parameters

| Parameter | Parameter Code | Description |
|------------------|------------------|--|
| Start Date | P_FROM_DT | See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date. |
| End Date | P_TO_DT | See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date. |
| Case Type/Status | P_CASE_STATUS_CD | This is the desired Case Type and Status that will be reported on. |

| | | |
|--------------------------|--------------|---|
| Responsible User | P_CASE_OWNER | If specified, only cases with this responsible user are included in the report. |
| First Bucket High Limit | P_B1_LIMIT | Cases that took <= this number of days to reach the given status will be grouped together for statistical reporting. |
| Second Bucket High Limit | P_B2_LIMIT | Cases that took <= this number of days but more than the first bucket high limit to reach the given status will be grouped together for statistics reporting. |
| Third Bucket High Limit | P_B3_LIMIT | Cases that took <= this number of days but more than the second bucket high limit to reach the given status will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group. |

Report Description

This report shows cases of a given case type that transitioned to a given status during a given date range.

Graphs are printed to show the number and percentage of cases grouped by the time it took to reach the status. These statistics are grouped into age buckets whose size is controlled by the last 3 parameters.

Summary statistics are also printed showing the minimum, maximum, average and median times for these cases.

Collection Summary - CI_CLLSUM

Parameters

| Parameter | Parameter Code | Description |
|------------|----------------|---|
| Start Date | P_FROM_DT | If from date is not set, the default is one month prior to the current date. |
| End Date | P_TO_DT | End date of the date range. If not defined by user, it is set to one month after the current date |

Report Description

This report provides detailed monthly summary information of all collection activities. The report is typically used by a collection department for resource planning and performance review purposes.

This report selects pending and completed collection events whose event trigger date falls between the input start and end dates.

Customer Contacts by Type - CI_CUSTCN

Parameters

| Parameter | Parameter Code | Description |
|-------------------------------|----------------|--|
| Start Date | P_FROM_DT | Start date to use for reporting customer contacts. If not defined, the start date is set to the current date minus 7 days. |
| End Date | P_TO_DT | End date to use for reporting customer contacts. If not defined, End Date is set to the current date. |
| Customer Contact Class / Type | P_CC_TYPE_CD | Specify a Customer Contact Class / Type to restrict the report output to a specific class / type. |

Report Description

This report lists all customer contacts in the system created within the input date range. You may optionally restrict the report to customer contacts for a given Customer Contact Class / Type (parameter 3).

Note:

Graphs. The information on this report is shown in both textual and graphical formats.

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_CC table on CC_DTTM to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Customers with Life-Support / Sensitive-Load - CI_PMLSSL

Parameters

| Parameter | Parameter Code | Description |
|--------------|----------------|--|
| Service Type | P_SERVICE_TYPE | Service type used to restrict the report to premises with services of this type. |

Report Description

This reports displays a detailed list of premises that are coded with Life-Support (LS) or Sensitive-Load (SL) information. It may optionally restrict the output to premises with service points for input service type.

This information is used by a company to make sure that customers at these premises are dealt with appropriately in the case of an outage (planned and unplanned) or service cut due to non-payment.

The report provides detailed information about the premise and the related facility elements providing service to that premise (e.g. substation, feeder and node for electric service).

Note:

If ANY person connected to an account has an LS/SL indication in the Person record, then all the premises connected to this account will be treated as LS/SL. This means, for example, that a premise connected to an account that has a 3rd party guarantor with LS/SL is treated as a premise with LS/SL.

Field Order Print in BI Publisher- CI_FOPRNT

Note:

Field Order Print in batch for BI Publisher is not supported yet.

Parameters

| Parameter | Parameter Code | Description |
|-------------------|----------------------|---|
| CC&B user | P_USER_ID | No default value. Required. Returns an error message if user ID is null, empty or does not exist in database. |
| Batch Switch | P_BATCH_SW | For a single FO print, Batch Switch is 'No' and for multiple FO print, Batch Switch is 'Yes'. |
| First FO | P_FROM_FO_ID | First FO ID to print for the FO Range. |
| Last FO | P_TO_FO_ID | Last FO ID to print for the FO Range. |
| Batch Code | P_BATCH_CD | Batch Code passed in by the system the report is submitted in batch. Only field orders that reference this batch code are selected. |
| Batch Number | P_BATCH_NBR | Batch Code passed in by the system the report is submitted in batch. Only field orders that reference this batch number are selected. |
| Extract Algorithm | P_EXTRACT_ALG | Passed in by the system the report is submitted in batch. Only field orders whose dispatch groups reference this FO extract algorithm are selected. |

Report Description

This report is used with BI Publisher to display the Field Order information for the field order ID entered in the input parameters. Refer to the description of the parameters above. The field order will only be displayed if the field order's status is dispatched.

The following sections highlight the data that is extracted for this report.

GL Accounting Summary - CI_GLACSM

Parameters

| Parameter | Parameter Code | Description |
|-----------------------------|----------------|---|
| Accounting Period | P_ACCT_PERIOD | Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided. |
| Account Type Characteristic | P_CHAR_TYPE | Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. The account types for the GL accounts are used for grouping the output to the report. |

Report Description

This is a financial audit report used to check the financial details in Oracle Utilities Customer Care and Billing for an accounting period against the GL system. The report summarizes all financial transaction (FT) information for a given accounting period according to the different operating and GL divisions and according to various levels of the account GL information.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Letter Print - BI Publisher Sample Welcome Letters - CI_LTRGN_ENG REPORT

Note:

Generating letters in batch is not supported yet.

Parameters

| Parameter | Parameter Code | Description |
|------------------|----------------|--|
| Batch Switch | P_BATCH_SW | For reports accessed online, set the switch to 'No'. Otherwise, it should be set to 'Yes'. |
| Customer Contact | P_CC_ID | References the customer contact associated with the main customer linked to the account. |

Report Description

This sample report template for BI Publisher produces letters that are not associated with any other object (i.e., the template does not have to extract information from another object to merge into a letter). You can use this template as a welcome letter for a new customer.

By default, the English versions of the report templates are provided with the base product. If multilingual report templates are required, your implementation should provide reports for each language. When a letter is generated, the system uses the report template based on the customer's language.

The address and name for the company are extracted from the [installation options](#). The text for the letter is defined in the report layout and not provided by Oracle Utilities Customer Care and Billing. Reports are printed according to the customer's language definition and not based on the user's language definition.

This sample report uses the following text:

Welcome to %1. You have been filed with ID Number %2.

We hope to provide you with our best possible service. If you experience any problems or have any questions, please contact one of our customer service representatives at (800)1234567.

%1 is the company name stored as a message on the [installation options](#).

%2 is Person Id stored on the Customer Contact.

Meter Reads Performance - CI_MTREAD

Parameters

| Parameter | Parameter Code | Description |
|-------------------|----------------|--|
| Accounting Period | P_ACCT_PERIOD | Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided. |

Report Description

This report selects bill segments for the input accounting period and displays the total number of read meters and unread meters for these bill segments grouped by route type.

Meters that are considered read are meters whose register reads have a status of Regular or Verified . Meters that are considered unread are meters whose register reads have a status of System Estimate, Office Estimate, System Prorate or Billing Force.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Open Cases By Type - CI_CSEOPN

Parameters

| Parameter | Parameter Code | Description |
|------------|----------------|--|
| Start Date | P_FROM_DT | See the report's description for how this field is used. If start date is not specified, it is defaulted to 7 days prior to the end date. |

| | | |
|--------------------------|----------------|--|
| End Date | P_TO_DT | See the report's description for how this field is used. If end date is not specified, it is defaulted to the current processing date. |
| Case Type | P_CASE_TYPE_CD | If specified, only cases of this type are included in the report. |
| Responsible User | P_CASE_OWNER | If specified, only cases with this responsible user are included in the report. |
| First Bucket High Limit | P_B1_LIMIT | Cases that are open for less than or equal to this number of days will be grouped together for statistical reporting. |
| Second Bucket High Limit | P_B2_LIMIT | Cases that are open less than or equal to this number of days but more than the first bucket high limit will be grouped together for statistics reporting. |
| Third Bucket High Limit | P_B3_LIMIT | Cases that are open less than or equal to this number of days but more than the second bucket high limit will be grouped together for statistics reporting. Cases that took more than this number of days are included in another group. |

Report Description

This is a report on open cases that were created between a given date range.

The report can be limited to a specific type and/or responsible user.

For each case type, the report shows the following:

- Number of open cases by age bucket (the last 3 parameters control the size (in days) of each bucket)
- Percentage of open cases by age bucket
- Details of the open cases

Payments Balance - CI_PMTBAL

Parameters

| Parameter | Parameter Code | Description |
|-----------|----------------|-------------|
|-----------|----------------|-------------|

| | | |
|------------|-----------|---|
| Start Date | P_FROM_DT | Report gets all the payments that have been received during a given date range (from and to date parameters). If start date is not defined by the user, it is set to 7 days prior to the current date. |
| End Date | P_TO_DT | End date of the date range. If not defined by user it is set to the current date |

Report Description

This report provides an overall view of all payments created within the input date range. It is typically used for financial control and audit purposes. The report provides summary information about valid payments received and about canceled payment. Data is summarized by the tender source and the type of payment.

Receivables Aging - CI_RCVAGA

Parameters

| Parameter | Parameter Code | Description |
|--------------------------|----------------|---|
| Cutoff Date | P_CUTOFF_DATE | The date from which the arrears buckets are calculated. If no value is entered, the default is the current date minus 7 days. |
| First Bucket High Limit | P_B1_LIMIT | High limit of first bucket. |
| Second Bucket High Limit | P_B2_LIMIT | High limit of second bucket. |
| Third Bucket High Limit | P_B3_LIMIT | High limit of third bucket. |

Report Description

This report lists all accounts and their arrears information as of the input cutoff date using a balance forward accounting method.

Outstanding debt is placed into the buckets provided as input using the age of the debt as of the cutoff date. Credits are applied to the oldest debt first. For each account a separate bucket is used to display new charges. In addition, the total accounts receivable balance is displayed for each account.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ARS_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Tax Payables Analysis - CI_TXPYBL

Parameters

| Parameter | Parameter Code | Description |
|-----------------------------|------------------|---|
| Start Date | P_FROM_DT | Show summary of the tax amounts starting from this date. If not specified, the system will default this value to the current date minus 7 days. |
| End Date | P_TO_DT | Show summary of the tax amounts up to this date. If not specified, the system will default this value to the current date. |
| Account Type Characteristic | P_CHAR_TYPE | Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. |
| Account Type | P_TAX_ACCTY_CHAR | Account Type Char Value for tax related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #3. The parameter value indicated for this parameter should be one that represents tax liability accounts. |

Report Description

This report displays a summary of the tax amounts that were levied by the company to customers within the input date range. It also includes the tax exemption information for that period.

This report select all records in the financial transaction GL collection that satisfy the following criteria:

- The financial transaction is frozen.
- The Accounting Date on the financial transaction within the input date range
- The distribution code associated with the GL entry has a characteristic type and value that matches the input Account Type Characteristic and Account Type (parameters 3 & 4)

The report also provides tax exemption information for bill segments whose financial transactions satisfy the above criteria. The tax exemption information is retrieved by looking at the bill calculation lines associated with the FT's bill segment.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_FT table on ACCOUNTING_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

To Do Entries - CI_TDENTR

Parameters

| Parameter | Parameter Code | Description |
|-----------|----------------|-------------|
|-----------|----------------|-------------|

| | | |
|-------------------|--------------------|--|
| ToDo Entry Status | P_ENTRY_STATUS_FLG | Defines if the To Do entries on the report should be limited to those with a given status value. If this parameter is left blank, the report will show all open and assigned To Do entries. |
| ToDo Type | P_TD_TYPE_CD | Defines if the To Do entries on the report should be limited to those of a given ToDo type. If this parameter is left blank, the report will show all ToDo type that have at least one open or assigned entry. |

Report Description

The report shows open and assigned To Do entries.

You can limit the report to entries in a given status by specifying the desired **To Do Status** (open or assigned). If you don't specify a status, all open and assigned To Do entries will appear on this report.

You can also limit the report to entries of a given To Do Type by specifying the desired To Do Type. If you don't specify a To Do Type, all To Do Types with at least one entry in the open / assigned state will appear on this report.

Note:

Graphs. The information on this report is shown in both textual and graphical formats.

Umbrella Agreement Summary - CI_UASUMM

Parameters

At least one parameter is required. If the umbrella agreement is entered, no other parameter value is allowed. The report definition uses the validation algorithm RPTV-UASUMM to check these conditions.

| Parameter | Parameter Code | Description |
|--|----------------|---|
| Umbrella Agreement | P_UA_ID | Specify the Umbrella Agreement to restrict the report to this umbrella agreement (regardless of its status). When this parameter is specified, all other parameters are not allowed. |
| Account Management Group | P_AMG | Specify a value for this parameter to restrict the report to umbrella agreements related to this Account Management Group. |
| Umbrella Agreement Characteristic Type | P_CHAR_TYPE | Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type and value (parameter 4). |

| | | |
|---|--------------------|---|
| Umbrella Agreement Characteristic Value | P_CHAR_VALUE | Specify a value for this parameter to restrict the report to completed umbrella agreements related to this Characteristic type (parameter 3) and value. |
| Number of Days Before Expiration | P_EXPIRE_IN_X_DAYS | Specify a value for this parameter to restrict the report to completed umbrella agreements whose End Date is on or before the current date less the Number of Days before Expiration. |

Report Description

This report provides summary information about one or more [umbrella agreements](#).

If the user does not supply an umbrella agreement ID, but enters one or more of the other parameters, the report only selects umbrella agreements that match the input criteria AND the match the following criteria:

- The status of the umbrella agreement is complete
- The start and end dates of the umbrella agreement include the current date

The report does not include canceled terms of service records or canceled service agreements linked to the above umbrella agreements.

For each umbrella agreement that is included in the report, the output includes information about the umbrella agreement, its collection of terms of service records and for each TOS record, its collection of service agreements.

In addition, the report includes the following graphs:

- Umbrella agreement summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all service agreements linked to the umbrella agreement's terms of service records.
- Terms of service summary graph showing billing history by accounting period for the effective dates of the umbrella agreement for all its service agreements

Unbilled Revenues - CI_UBLREV

Parameters

| Parameter | Parameter Code | Description |
|-----------------------------|----------------|--|
| Accounting Period | P_ACCT_PERIOD | Defines the accounting period used for the report. A valid fiscal year and accounting period for a valid accounting calendar must be provided. |
| Account Type Characteristic | P_CHAR_TYPE | Defines a Characteristic Type for a characteristic linked to the Distribution Code to define an Account Type. |

| | | |
|--------------|------------------|---|
| Account Type | P_REV_ACCTY_CHAR | Account Type Char Value for Revenue related GL Accounts. The char type defined for this parameter should match the Char Type code defined as parameter #2. The parameter value indicated for this parameter should be one that represents revenue accounts. |
|--------------|------------------|---|

Report Description

This report provides a simplified calculation of estimated unbilled revenue for a given month.

It processes frozen financial transactions associated with bill segments and canceled bill segments whose bill segment end date is within the **Accounting Period** (parameter 1). It determines the billed revenue for the FT and then uses this information to calculate the unbilled revenue.

To determine "revenue", the report summarizes amounts posted to any distribution code with a characteristic entry that matches the input **Account Type Characteristic** type and **Account Type** characteristic value (parameters 2 and 3).

The estimate for the unbilled portion is calculated as (Bill Amount / Number of Days in the Bill Period) * Number of Unbilled Days for the Accounting Period.

For example, consider a bill segment on a monthly-billed cycle for the period of 3/10/03 - 4/9/03, and for \$150 (revenue part of the bill). Assume we are in the April/03 accounting period, which covers 4/1/03 through 4/30/03. This means 21 days are unbilled for April. The unbilled revenue is calculated as $150/31 * 21 = \$101.61$.

The following are some points to note about this report.

- If the report runs for an historical date, it still estimates the unbilled revenue portion based on the above formula even if actual data exists. In other words, it will not try to find actual bills for subsequent months. As a result, this report always shows what would have been the estimated unbilled revenue for a particular month if that month is the most recent one.
- Services can be billed monthly bi-monthly, quarterly or in any desired frequency. This report only performs the revenue recognition estimation using actual bills that were created in the report's accounting period. As a result, it does not estimate unbilled revenue for accounts that were not billed in any portion of the input accounting period.
- Revenue recognition practices are unique and may vary from customer to customer. In a given month we can produce current bills (e.g. for electric service) or future bills (e.g. cable services). In addition in some cases we can have bills that started before the accounting period and ending after it (for example in a cancel-rebill situation). This report will only estimate unbilled revenues for bills with the accounting period equals to the report's accounting period.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_BSEG table on START_DT, END_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any affect on the production environment.

Vacant Premises with Consumption - CI_VACANT

Report Description

This report shows all premises that are considered vacant, and provides information about the level of consumption, the period of vacancy, and the service point and register information.

This report selects service points that are linked to a service agreement that is either canceled or closed. The report excludes any service points that have never been linked to a service agreement. If consumption has been registered at such a service point since the end date of the service agreement, the service point's details are displayed.

This report may be used by the utility to investigate sites where problems such as service theft or leakage may be occurring.

Note:

Performance Consideration. If your implementation chooses to use this report, you may consider adding an index to the CI_SA_SP on STOP_DT to aid in performance. When making this decision, carefully weigh the benefit of improving report performance against the possible degradation to the performance of day-to-day processing as a result of defining a new index. In addition, many companies opt to create a reporting database that is a shadow of production to ensure that indexes defined to benefit reports may be created without any effect on the production environment.

Defining Overdue Processing Options

The system periodically monitors how much your customers owe to ensure they haven't violated your collection rules. When a violation is detected, the system initiates the appropriate activities (e.g., letters, disconnect notices, collection agency referrals, and eventually write off). The topics in this section describe how to configure the system to manage your overdue processing requirements.

Note:

The overdue processing module has been designed to collect on virtually anything from an unpaid bill to an unmatched financial transaction. You tell the system what you collect on by configuring the various overdue processing control tables. In this release, the base-package is delivered with algorithms that support collecting on overdue bills. If your organization practices balance-forward accounting (i.e., collection is based on overdue service agreement balances), you will not use this functionality. Rather, you will use the functionality described under [Defining Credit & Collections Options](#).

Warning:

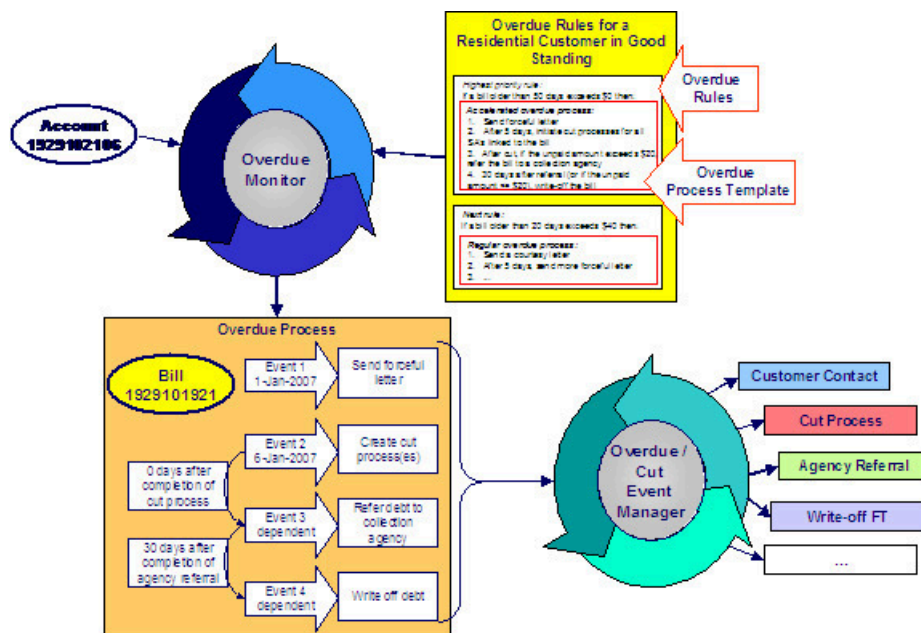

Setting up this module is as challenging as your organization's collection rules. If you have simple rules, the set up process will be straightforward. If your rules are complicated (e.g., they differ based on the type of customer, the age of debt, the type of service, etc.), your setup process will be more challenging.

Case Study - Collecting On Overdue Bills

The following topics introduce a case study that describes how overdue processing can be used to collect on overdue bills. This is just an example as virtually every aspect of overdue processing is configurable. Use this case study to familiarize yourself with the overdue processing core concepts.

Monitoring Overdue Bills

The following diagram illustrates the objects and processes involved with collecting overdue bills.

There are many important concepts illustrated above:

The Overdue Monitor checks if your accounts have bills that violate your overdue rules

The **Overdue Monitor** is a background process that periodically reviews your account's financial obligations.

Note well: every account belongs to a collection class. There are two types of collection classes: those whose accounts are monitored by the **Account Debt Monitor**, and those that are monitored by the Overdue Monitor. This chapter describes the Overdue Monitor.

Overdue rules define when and how unpaid bills are collected

An account's **collection class overdue rules** have algorithms that monitor an account's financial obligations. These algorithms are invoked by the Overdue Monitor when it's **time to review** an account's obligations.

These algorithms can contain any type of criteria. However, most are defined using a combination of a threshold age and monetary amount. For example, a classic algorithm would check if a bill has unpaid financial transactions more than 20 days old that exceed \$50.

In the case of bill-oriented collection, the monitoring algorithms look at each of the account's bills to determine if they are paid. Note, a bill is considered paid if its financial transactions (FTs) are linked to a balanced match event. If a monitoring algorithm finds an unpaid bill, it can check if it old enough (and large enough) to be considered a violation.

When you set up a monitoring algorithm, you define the type of overdue process that should be created when an overdue bill is detected. You do this by defining the appropriate "overdue process template".

An overdue process template defines how to handle an overdue bill

An [overdue process template](#) contains one or more [overdue event types](#). These define the number and type of events that are created to prod the customer to pay. For example, you might set up an overdue process template with event types to send a series of letters followed up by a call.

The overdue process template has contains the rules defining [when events are activated](#).

The specific action that's performed by an overdue event is controlled by the Activation algorithm defined on its event type. Refer to [Overdue Event Type - Main](#) for a list of the various Activation algorithms delivered with the base package.

Multiple objects can be associated with a single process

The above diagram shows a single bill linked to an overdue process. It should be noted that an overdue process is capable of referencing multiple bills (or other objects).

Note well: while a single overdue process can reference many overdue objects, all such objects must be of the same type. For example, you cannot commingle bills and service agreements under a single overdue process. The type of object managed by an overdue process is defined on its [overdue process template](#).

If a customer pays the bill, the overdue process is cancelled

If an overdue bill is paid, the [overdue process is canceled](#) real-time. You control if and how an overdue process is cancelled by setting up the appropriate rules on the [overdue process template](#).

The Overdue / Cut Event Manager activates and triggers overdue events

The [Overdue / Cut Event Manager](#) is a background process that activates overdue events on the appropriate date. On this date, the event's Activation algorithm(s) are called.

This Overdue / Cut Event Manager also has the responsibility of recursively activating later events that are dependent on the completion of earlier events.

Events can be activated real-time

[Overdue Process - Main](#) has a button that allows users to activate (and recursively trigger) overdue events online / real-time. This means you don't have to wait for a batch job to activate events.

Overdue events can wait for related activities to complete

As described above, an overdue event's Activation algorithm can create virtually any object. What wasn't explained is that the event can be set up to **wait** for the ancillary object to finish before it completes. For example, an event can create a To Do entry and wait for it to complete before the next event is triggered. You can introduce plug-ins to create and wait on virtually any object.

While an overdue event is in the Wait state, the Overdue / Cut Event Manager monitors the state of the related object(s). When the related object completes, the event is transitioned to the Complete state (thus triggering dependent overdue events). Please see [Some Events Wait For Something Before Completing](#) for more information.

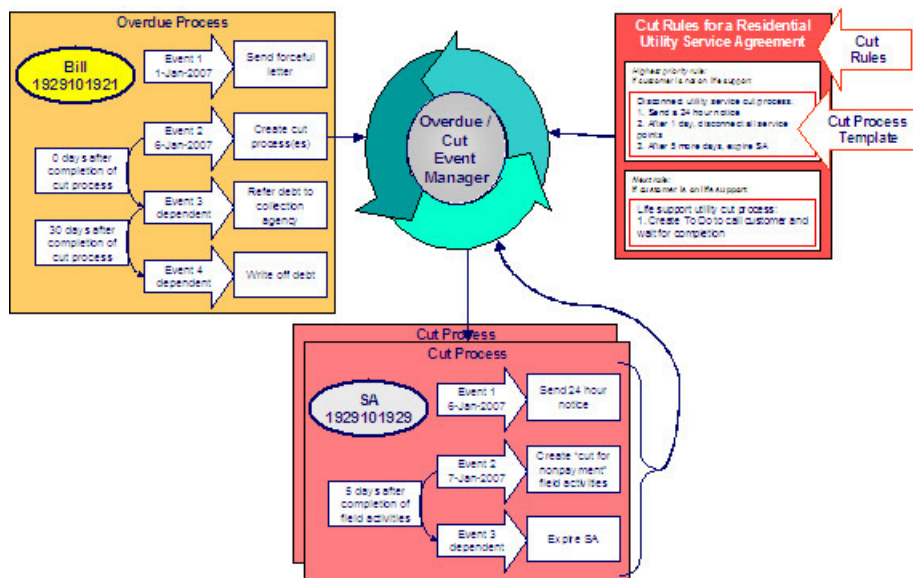

Cutting Service Agreements

An overdue process may contain an overdue event that creates a cut process(es). A cut process is used to cut (i.e., stop) a service agreement. The following diagram illustrates the objects and processes involved with cutting a service agreement.

Note:

Cut processes aren't required. It's quite conceivable to design an overdue process that doesn't cut service. For example, the overdue process may just contain an event that creates a case and the case manages the collection activities.

An overdue process may contain an overdue event that cuts (i.e., stops) service

If an overdue process's bill remains unpaid, one of the latter overdue events typically creates one or more **cut processes**. A cut process contains the activities to stop a service agreement (in the hopes that lack of service will inspire the customer to pay). It should be noted that a separate cut process is created for each service agreement.

Cut rules define how to sever service agreements

The system allows you to define rules to control the type of cut process created. For example, you may have a different cut process if the customer has life support equipment, or if it's winter, or ...

The cut rules are defined on the service agreement's [SA type](#). This allows different rules for different types of service agreements.

Overdue events can "wait" for related activities to complete

When an overdue event creates cut process(es), it typically enters the Wait state. It enters this state as it is waiting for the cut process(es) to complete before it can itself complete. While in the Wait state, the Overdue / Cut Event Manager monitors the state of the related cut process(es). When the cut process(es) complete, the system transitions the originating overdue event to the Complete state (thus triggering dependent events).

A cut process template defines how to cut a service agreement

Cut processes and events are created using a [cut process template](#). A cut process template defines the actions involved in cutting a given type of service agreement. A cut process template usually contains several cut events. These events are a series of letters and / or disconnection field activities that eventually result in the expiration of a service agreement if payment is not received.

An Activation algorithm controls the specific action associated with a cut event and therefore an event can do practically anything. Refer to [Cut Event Type - Main](#) for a list of the various Activation algorithms delivered with the base package.

Cut events are also managed by the Overdue / Cut Event Manager

The same [background process](#) that manages the activation of overdue events manages cut events. This means you only have to submit one batch job to activate and trigger both overdue and cut events.

Events can be activated real-time

[Cut Process - Main](#) has a button that allows users to activate (and recursively trigger) cut events online / real-time. This means you don't have to wait for a batch job to activate events.

Cut events can "wait" just like overdue events

Cut events support the ability to wait for something to complete just like overdue events. For example, if a cut event creates a field activity, it enters the Wait state. While in the Wait state, the Overdue / Cut Event Manager monitors the state of the related field activities. When the field activities complete, the system transitions the originating cut event to the Complete state.

And, just like for overdue events, the notion of a cut event creating something and then waiting for it to complete is not limited to field activities. For example, you could have a cut event create a To Do entry and wait for it to complete before the next event is triggered.

Please see [Some Events Wait For Something Before Completing](#) for more information.

After a service agreement is stopped, it will be final billed

Many cut processes are configured so their last cut event [expires the service agreement](#). What happens at expiration depends on the type of service agreement. However, eventually the service agreement is transitioned into the Stopped state.

When the last active service agreement linked to an account is stopped, the system changes the account's bill cycle to bill that evening. If only one of many SAs is stopped, the SA will only be final billed as per the account's original bill cycle schedule.

If a customer doesn't pay their final bill, the final bill will be processed using a different type of overdue process

Final bills only differ from ongoing bills in that the service agreements associated with the bill's FTs are not active. This means that there is nothing to cut. This means that the type of overdue process used to handle a "final" bill should differ from that used to handle "ongoing" bills.

As described above, overdue rules define how unpaid bills are handled (both ongoing and final). We recommend configuring your overdue rules to use different overdue process templates for final versus ongoing bills.

The last overdue event typically causes the debt to be written off

Ultimately, if the overdue and cut events fail to inspire payment, the debt will be written off. The method used to write-off a bill is controlled by an overdue event Activation algorithm.

How Does The Overdue Monitor Work?

This section describes how the Overdue Monitor background process (C1-ADMOV) uses your overdue rules to collect overdue debt.

This process has an optional input parameter for CIS Division. It can be used if your implementation requires processing of data by CIS Division. You will need to create a copy of this process's batch control for each CIS Division.

**Note:**

Recommendation. We recommend that you familiarize yourself with the concepts described in the [case studies](#) before reading this section.

Collecting overdue bills. The examples in the following section frequently refer to how the Overdue Monitor is configured for an organization that collects on unpaid bills. It should be noted that these are just examples as the Overdue Monitor can be used to collect on virtually anything (if you create the appropriate plug-in algorithms).

Different Overdue Rules For Different Customers

The Overdue Monitor uses rules to control how it monitors an account's debt. The system allows you to define different rules for different combinations of collection class, division and currency code. For example,

- You probably have different collection rules for different jurisdictions (i.e., CIS Divisions). For example, if you have customers in different states / provinces, you may have different rules applied to each jurisdiction's debt. The **CIS division on each customer's account** defines the jurisdictional rules applied to the account's debt.
- You probably have different collection rules for different customer segments. For example, bills for large customers might be overdue if they are more than 10 days late, whereas small customers might have 24 days. You differentiate your customers in respect of the overdue via the **collection class on the customers' accounts**. An account's initial collection class is defaulted from its customer class. You may override an account's collection class at will.
- You will have different criteria for every currency in which you work because the monitoring process always compares a customer's debt against some value and this value must be denominated in the customer's currency. A customer's currency is defined using a **currency code on the account**.

The above means that every combination of CIS division, collection class, and currency code can have different rules. The following matrix is used to illustrate a sample organization's rules (note, we assume a single currency and therefore avoid the third dimension):

| Account's Division | Account's Collection Class: | |
|--------------------|--|--|
| | Commercial Customer | Residential Customer |
| North | <p>Highest Priority: If a bill exists with unpaid FT's > \$0 that is older than 45 days, create the commercial 45 days late overdue process.</p> <p>Next Priority: If a bill exists with unpaid FT's > \$100 that is older than 30 days, create the commercial 30 days late overdue process.</p> | <p>Highest Priority: If a bill exists with unpaid FT's > \$0 that is older than 50 days, create the accelerated overdue process for residential customers.</p> <p>Lower Priority: If a bill exists with unpaid FT's > \$25 that is older than 25 days, create the courtesy reminder overdue process for residential customers.</p> |
| South | ... | ... |

Notice that there can be multiple criteria for each cell in the matrix. What differentiates one criteria from another is its priority. The higher priority criteria will be compared first. If the debt violates the criteria, the overdue process is initiated and no further comparisons are performed.

Overdue Rules Are Embodied In Algorithms

Your organization's overdue rules are defined in algorithms plugged in on [Collection Class Overdue Rules](#) (in the Overdue Monitor Rule system event). When the Overdue Monitor analyzes an account, it uses the rules associated

with the account's collection class, CIS division and currency code. To analyze an account, it simply invokes these algorithms in sequence order, i.e., the lower the sequence, the higher its priority.

An Overdue Monitor Rule algorithm has two responsibilities:

- it determines if an account violates its overdue rules,
- if so, it creates one or more overdue processes using an [overdue process template](#)

When Is An Account Monitored?

The Overdue Monitor determines if an account violates your overdue rules at least every X days, where X is defined on the [Customer Class - Controls](#) associated with the account's customer class and division (in the field Min Credit Review Freq (Days)).

In addition, the Overdue Monitor examines an account's debt as follows:

- X days after an account's bill due date (X is defined in the field Credit Review Grace Days on [customer class control](#)).
- If a payment is canceled with a cancellation reason that indicates non-sufficient funds.
- If a payment arrangement is broken (assuming you use the base package's break payment arrangement plug-in). Refer to [Breaking A Bill Oriented Payment Arrangement](#) for more information.
- If a pay plan is broken. Refer to [The Pay Plan Monitor](#) for more information.
- If a [match event](#) is added, changed or deleted.
- When a written off bill is [reversed](#).

Note:

Additional events. Your implementation can have other events trigger the analysis of an account by the Overdue Monitor. To do this, add logic to insert a row on the CI_ADM_RVW_SCH table when the event occurs. This row simply references the account ID to be reviewed and the desired review date.

Collection Class Defines If And How Accounts Are Monitored

As described above, every account references a collection class. The collection class defines if and how its accounts are monitored. There are three options:

- The accounts are monitored by the [Account Debt Monitor](#)
- The accounts are monitored by the Overdue Monitor (this is described in this chapter).
- The accounts are not monitored for overdue debt.

Note:

Migration. If you plan to migrate from the Account Debt Monitor (ADM) method of collection to the Overdue Monitor method, a special Overdue Monitor algorithm (C1-ACT-CSW) has been supplied that will skip accounts that are eligible for review by the Overdue Monitor if they have an active collection, severance or write-off process. This algorithm should be plugged in the applicable Collection Class Overdue Rules so that it will be invoked first. This allows accounts with active ADM-oriented collection activities to work themselves through the system. When an account no longer has any active ADM-oriented activities, monitoring responsibilities will be assumed by the Overdue Monitor.

The Big Picture Of Overdue Processes

As described above, the Overdue Monitor subjects your accounts to overdue rules. If a rule is violated, an overdue process is created. The topics in this section provide background information about overdue processes.

How Are Overdue Processes Created?

As described [above](#), the system creates an overdue process when an account violates your overdue rules. In addition, a user can manually create an overdue process at their discretion.

The Components Of An Overdue Process

The following topics describe the major components of an overdue process.

Overdue Objects

When an overdue process is created, the system links the overdue object(s) to the process. For example, if an overdue bill is detected, the bill is linked to the overdue process.

When you set up an [overdue process template](#), you define the type of object it collects on by defining the [foreign key characteristic type](#) used to reference the object. For example, when you set up an overdue process template to collect on bills, you define a foreign key characteristic type that references the bill object.

Overdue Events

An overdue process has one or more overdue events. These events are the actions designed to encourage the customer to pay. For example, you might set up overdue events that:

- Send letters (via the creation of a customer contact)
- Create To Do entries
- Impact the account's credit rating
- Create a case (e.g., to seize the customer's assets)
- ... (the list is only limited by your imagination as algorithms are used to perform the event's actions)

You define the number and type of events by configuring [overdue process templates](#). When the system creates an overdue process, it copies the events defined on the specified template.

It's important to note that all overdue events are created when the overdue process is created. A separate background process, the [Overdue / Cut Event Manager](#), is responsible for activating, monitoring, and triggering overdue events. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, start a cut process, refer debt to a collection agency, write-off debt, etc.).

Overdue Log

Every overdue process has a log holding its history. Entries are added to the log when meaningful events occur, for example:

- When the process is created, a log entry is created to describe why the process was started.
- When an overdue event is activated, a log entry is created. These entries frequently contain a foreign key to the object that the event created so that users can easily drill down to the object from the log. For example, if an event creates a To Do entry, the To Do entry's foreign key is placed on the log and this allows a user to drill down on the log entry to see the To Do entry.
- When a process is canceled, a log entry is created to describe the circumstances of the cancellation (e.g., manual versus automated).
- Users can manually add log entries (you might want to think of these as "diary" entries) as desired.
- ...

Many of the base-package algorithms involved in overdue processing insert log entries so that a thorough audit trail is maintained. These algorithms have been designed to allow you to control the verbiage in each log entry by defining the desired message number using an algorithm parameter.

The log is viewable on the [Overdue Process - Log](#) page.

**Note:**

More than just an audit trail. The log entries are more than just an audit trail. The system makes use of the log entries to know what it did. For example, when an overdue event needs to monitor the state of the To Do entries that it created, it uses the log to determine the identity of these To Do entries.

Experimenting With Alternative Overdue Process Templates

The system allows you to determine the efficacy of proposed overdue process templates using a small subset of customers before implementing the templates on the entire customer base. We use the term "champion / challenger" to reference this functionality.

We'll use an example to explain. Let's assume your prevailing overdue process template for residential customers starts with a "gentle reminder" letter followed 10 days later by a letter threatening collection agency referral if payment is not received. You may want to experiment with the impact of a change to this template. For example, you may want to change the "gentle reminder" to something more assertive and follow this up 5 days later with an even sterner warning. You can use the "champion / challenger" functionality to perform this experiment.

The following points describe how to implement "champion / challenger" functionality:

- Set up a "challenger" overdue process template for each template that you want to experiment with.
- Insert a new **Champion/Challenger** option on the Overdue Processing [Feature Configuration](#) for every champion template. Each option's value defines:
 - the "champion" overdue process template code
 - the "challenger" overdue process template code
 - the percentage of the time the system should use the "challenger" template
- Keep in mind that you can only experiment with one challenger template per champion template. For example, let's assume you have two prevailing overdue process templates - one for residential customers and another for commercial customers. You can experiment with different challenger templates for the residential and commercial templates. However, you cannot experiment with two different challenger templates for the residential champion template (i.e., a champion template can have 0 or 1 challenger template).

After setting up the above, your implementation's [Overdue Rule Plug-In](#) may include logic to use the challenger template X% of the time rather than the champion template. The sample plug-in provided in the base product, called C1-CB-CR-RAT, includes this logic.

If you are using the Oracle Utilities Analytics product, you can configure analytic zones in innumerable ways to compare the efficacy of the champion versus the challenger. For example,

- You can set up a graph to show the average duration of each type of process.
- You can set up a graph to show the average dollars that were successfully collected.
- You can set up a dimensional scorecard to show how each template performed in different regions (or customer classes or ...).
- Etc (the list is limited by your imagination)

Overdue Process Information Is Overridable

"Overdue process info" is the concatenated string of information that summarizes an overdue process throughout the user interface. The base-package logic constructs this string by concatenating the following information:

- The description of its overdue process template
- Its status
- For active processes, the number of days since it was created. For inactive processes, the number of days since it was inactivated.
- For active processes, the unpaid amount of the objects being collected

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your [overdue process templates](#). This design allows some / all overdue process templates to have an override info string.

Original and Unpaid Amounts

There are two amounts associated with each overdue object linked to an overdue process: its Original Amount and its Unpaid Amount. These amounts are used throughout overdue processing.

You control how these amounts are calculated by defining the appropriate algorithm on your [overdue process templates](#). For example, you can plug in a base-package algorithm (C1-CUAOA) if you collect on overdue bills and the original amount is the amount of financial transactions linked to the bill, and the unpaid amount is the sum of financial transactions that are not linked to balanced match events.

Overdue Processes Are Highlighted Elsewhere

The topics in this section describe how other parts of the system highlight the existence of overdue and cut processes.

Alert Zone

If you plug-in the appropriate alert algorithm (C1-OD-PROC) on the Installation record, alert(s) will be shown for active overdue processes in the Alert Zone that appears in the Sidebar and on Control Central - Account Information.

Credit and Collections Zone

The Credit and Collections zone on [Control Central - Account Information](#) shows active overdue and cut processes.

Account Activity History Zone

The Account Activity History Zone on [Control Central - Account Information](#) shows pending and waiting events and inactive processes.

How Are Overdue Processes Cancelled?

A user may cancel an overdue process at their discretion, online / real-time using [Overdue Process - Main](#).

The system will automatically cancel an overdue process when the object(s) associated with the overdue process are sufficiently paid. Exactly when the system checks if an overdue process should be cancelled is dependent on your organization's billing and accounting rules. For example, if you practice [open-item accounting](#), you'd want to analyze an account's active overdue processes whenever a match event is added, changed or deleted (as match events are the only objects that impact if debt is considered paid in an open-item world). The base-package supports this specific example. If you need additional events to check if an overdue process should be canceled (e.g., the creation of a pay plan), a base-package change MAY be necessary. Please check with customer support if you have questions.

Two algorithms plugged-in on the [overdue process template](#) handle the cancellation:

- The Cancel Criteria algorithm is responsible for determining if an overdue process should be canceled. Algorithms of this type analyze the outstanding debt on the objects linked to the overdue process and indicate whether a process can be cancelled.
- The Cancel Logic algorithm is responsible for actually canceling the process. The logic involved in cancellation can be quite sophisticated as canceling an overdue process can result in the cancellation of its pending events and cut processes.

Note:

Why two algorithms? The reason two algorithms are involved in cancellation is because we want the cancellation logic to be encapsulated in one place so it can be called during both manual and automated cancellation.

Different logic for different templates. Because both the Cancel Criteria and Cancel Logic algorithms are plugged-in on the overdue process's template, you can have different cancellation criteria and logic for different templates.

Overdue Processes Are Created From Templates

As described above, you set up [overdue process templates](#) to define the types of events and when they are executed. When an overdue process is created, its events are created by copying the event types from an overdue process template. The remaining topics in this section provide background information to assist you in setting up your templates.

The Big Picture Of Overdue Events

This section describes the various types of overdue events and their lifecycle.

How Are Overdue Events Created?

Overdue events are created as follows:

- The [Overdue Monitor](#) invokes Overdue Monitor Rules to periodically check your accounts (refer to [Overdue Rules Are Embodied In Algorithms](#) for how this works). An Overdue Monitor Rule creates an overdue process when an account violates your overdue rules. The overdue process has one or more overdue event(s). The number and type of events is controlled by the overdue process template specified on the Overdue Monitor Rule.
- Users can create an overdue process manually on [Overdue Process - Main](#). To do this, they specify an overdue process template. The number and type of overdue events is defaulted from the template.
- An overdue event may be manually added to an existing overdue process by a user on [Overdue Process - Events](#).

Note:

Bottom line. Most overdue events are created by the system when it creates an overdue process for delinquent obligations. If you need to create an ad hoc overdue event, you can either create an overdue process whose template contains the desired event OR link the desired event to an existing process.

Overdue Events Can Do Many Things

An overdue event can perform a wide number of activities as the logic is embodied in an algorithm. The following points describe how this works:

- Every overdue event references an [overdue event type](#).
- The overdue event type, in turn, references an Event Activation algorithm.
- The Event Activation algorithm is invoked when the event is [triggered](#).

Overdue Event Information Is Overridable

"Overdue event info" is the concatenated string of information that summarizes an overdue event throughout the system. The base-package logic constructs this string by concatenating the following information:

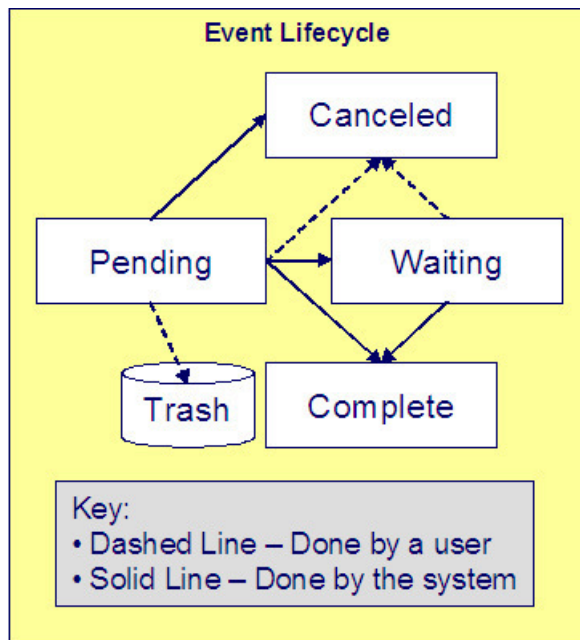

- The event type's description
- The event's status
- If it's pending:
 - If the event has a trigger date, the number of days until it's triggered plus the verbiage day(s) from today
 - Otherwise, the verbiage dependent on other events
- If it's waiting, the number of days, hours and minutes that it's been waiting
- If it's canceled, the cancel reason code's description

- If it's complete, the number of days, hours and minutes that it's been complete

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your event types. This design allows some / all event types to have an override info string.

Overdue Event Lifecycle

The following diagram shows the possible lifecycle of an overdue event:

Overdue events are initially created in the Pending state. An event can take myriad paths after it's created; it all depends on how you've configured the system. The following topics describe an event's lifecycle:

How and When Events Are Activated

An overdue event contains the date it should be activated; this is referred to as its trigger date. On this date, the Overdue / Cut Event Manager (a background process (C1-ODET)) invokes the Event Activation algorithm plugged-in on the event's event type. The Event Activation algorithm, in turn, will decide on the state in which to leave the overdue event (e.g., it may transition it to the Complete state or the Waiting state).

If a user can't wait for the Overdue / Cut Event Manager real-time, they can click a button on [Overdue Process - Main](#) to activate (and recursively trigger) events online / real-time.

You control how an event's trigger date is populated by configuring the [overdue process template](#). You are given two choices when you link an event type to an overdue process template:

- You can indicate the event should be assigned a trigger date when it is first created. You'd use this approach on the first event and events with no dependencies on earlier events. The following points describe how to configure the overdue process template to do this:
 - Indicate the event type is NOT dependent on other events, and
 - Define the number of days after the process's creation to use when calculating the trigger date.
- You can indicate the event should be assigned a trigger date only after earlier events are Complete. This technique should be used whenever you have an event that is only executed after other events are Complete. The following points describe how to configure the overdue process template to do this:
 - Indicate the event is dependent on other events, and

- Define the number of days after the completion / cancellation of all dependent event(s) that the trigger date should be set to. The Overdue / Cut Event Manager sets the trigger date on such an event when it detects that all of its dependent events are complete / canceled.

Note:

Calendar vs Workdays. When an overdue event is created by the system, its trigger date is set in accordance with your date arithmetic preferences. Refer to [Calendar vs. Work Days](#) for more information.

Activating Events Should Add a Log Entry

As described [above](#), an overdue process has a log holding a history of meaningful events in the process's life. Most Event Activation algorithms will add an entry to the process's log.

These log entries are more than just an audit trail as they also reference the objects that are created during activation. For example, if an activation algorithm creates a customer contact, the ID of the customer contact will be referenced on the log (and end-users will be able to drill down on the log entry to see the customer contact).

Holding Events

You can prevent a pending event with a trigger date on / before the current date from activating by plugging-in a Hold Event Activation plug-in on the overdue process template. This might prove useful, for example, if you want to suspend an overdue process while a [case](#) used to investigate the assertion of a customer is outstanding. Then, when the case closes, the overdue process can start up where it left off.

This technique would prove useful, for example, if your users can grant ad hoc suspend periods (e.g., if a customer wants a few extra days to pay before a cutoff). To do this, create a case type that has two states: Open and Close. Make sure to set up the Open state to have an automatic transition algorithm to close the case after X days. Then, all a user has to do is create a case of this type when they want to provide a suspend period. When the suspend period is over and payment isn't received, the case will close and the overdue process will start up where it left off.

Some Events Wait For Something Before They Activate

Consider this scenario - you want an overdue event to create a To Do entry so a user can authorize the next phase of an overdue process. When this event activates, the event's activation algorithm will create a To Do entry, but it will NOT transition the event to complete. Rather, the overdue event will exist in the waiting state. While in the waiting state, the Overdue / Cut Event Manager will monitor the state of the To Do entry. When the To Do entry completes, the original overdue event can transition to the complete state and then latter dependent events can be triggered. The following points describe how to configure the system to support this type of event:

- The event type's Event Activation algorithm should behave as follows:
 - It creates the object on which the overdue event waits.
 - It must link this object to the overdue process by creating a log entry where the prime-key of the related object is referenced (in a foreign-key characteristic). This log entry should also reference the event.
 - It should leave the overdue event in the waiting state.
- The event type must have a Monitor Waiting Event algorithm. This algorithm is invoked each time the [Overdue / Cut Event Manager](#) executes. If the related object has transitioned to a "final" state, the originating overdue event is transitioned to the complete state (and then latter dependent events are triggered).

Note:

Bottom line. Two algorithms must be set up on an overdue event type to implement waiting functionality: an Event Activation algorithm that creates the monitored object and a Monitor Waiting Event algorithm to check on the state of the monitored object. The Overdue / Cut Event Manager has the dual responsibility of activating the event and monitoring its related object for completion (and then triggering the dependent events when it completes).

While the above example illustrated how an overdue event could create and then monitor a To Do entry, you can use this functionality to create and monitor any object that has an initial and final state. If the base package does not contain the algorithms you need, simply develop new ones using the base-package algorithms as examples.

How Are Events Canceled

A pending event will be cancelled automatically by the system when the overdue process is canceled. Refer to [How Are Overdue Processes Cancelled](#) for more information.

A user may cancel a pending or waiting event at their discretion.

Regardless of what triggers the cancellation, the Cancel Logic algorithm plugged in on the overdue event type handles the cancellation. This allows you to introduce additional cancellation logic should the need arise. Please note that the base package cancel algorithms insert a [log entry](#) when a user manually cancels an event.

The Big Picture Of Cut Processes

While not required, many overdue processes will contain one or more events that will cut (i.e., stop) service. When such an event activates, it creates a "cut process". A cut process is very similar to an overdue process; the major difference is that a cut process is linked to a specific service agreement (the one being cut), whereas an overdue process is linked to the object(s) in arrears.

The topics in this section provide background information about cut processes.

How Are Cut Processes Created?

The activation of an overdue event can create one or more cut processes.

In addition, a user can manually create a cut process at their discretion using [Cut Process - Main](#).

Overdue Events Wait For The Cut Process To Conclude

Overdue events that create cut processes are perfect examples of events that [wait](#) for the object they create to complete before they, in turn, complete. After the cut process concludes, the originating overdue event will complete thus triggering its dependent events.

Cut Processes Exist Under An Overdue Process

It's important to note that a cut process exists in respect of an overdue process. In other words, you can't create a cut process without referencing a parent overdue process. There are two reasons why:

- A cut process's overdue process defines the objects in arrears. It is these objects that are monitored to determine if the cut process (and overdue process) can be cancelled.
- The [log](#) associated with a cut process's overdue process contains the history of the cut process(es) and their events; there is no log specific to a cut process.

The Components Of A Cut Process

Cut processes are simpler than overdue processes as they simply contain one or more "cut events". These events are the service agreement-specific actions designed to encourage the customer to pay. For example, you might set up cut events that:

- Create [field activities to cut service](#)
- Send letters (via the creation of a customer contact)
- Create To Do entries
- Impact the account's credit rating

- Create a case (e.g., to manage a customer with life support issues)
- ... (the list is only limited by your imagination as algorithms are used to perform the event's actions)

You define the number and type of events by configuring [cut process templates](#). When the system creates a cut process, it copies the events defined on the related template.

It's important to note that all cut events are created when the cut process is created. The Overdue / Cut Event Manager is responsible for activating the cut events at the appropriate time. Activation of an event causes the system to do whatever the event indicates (e.g., send a letter, send a To Do entry to a user, create a field activity, etc.)

Cut processes do not have their own log as their history is maintained on the parent overdue process's [log](#).

Cut Process Information Is Overridable

"Cut process info" is the concatenated string of information that summarizes a cut process throughout the system. The base-package logic constructs this string by concatenating the following information:

- Its cut process template's description
- Its status
- For active processes, the number of days since it was created. For inactive processes, the number of days since it was inactivated.
- For active processes, the unpaid amount of the objects being collected on the cut process's overdue process

If you'd prefer a different info string, you can develop a new algorithm and plug-it in on your cut process templates. This design allows some / all cut process templates to have an override info string.

How Are Cut Processes Cancelled?

A user may cancel a cut process at their discretion, online / real-time using [Cut Process - Main](#).

The system will automatically cancel a cut process when the overdue process is cancelled.

Regardless of what triggers the cancellation, the Cancel Cut Process algorithm plugged in on the cut process's [template](#) handles the cancellation.

If a cut process is canceled and the cut process's events created field activities, the cancel logic embodied in the algorithm can be quite sophisticated. Refer to [Field Activities To Cut And Reconnect Service](#) for an example.

Cut Processes and Events Are Created From Templates

When a cut process is created, its cut events are created by copying a cut process template's event types. Cut events follow the same lifecycle and possess the same behavior as [overdue events](#).

Cut Events Are Like Overdue Events

Cut events almost identical to [overdue events](#). The major difference is that cut events exists under a cut process and therefore are oriented towards the cut process's service agreement. The following topics describe other differences between cut events and overdue events.

Field Activities To Cut and Reconnect Service

A cut process that's created for a service agreement whose service can be severed will typically contain a cut event that creates field activity(s) to cut service. The base-package cut event activation algorithm will create field activities for the service points linked to the service agreement being cut. The type of activity is defined on the [field activity type profile](#) defined on each service point's SP type. Please see C1-CE-CR-FA for the exact details of the base-package algorithm.

If the cut process is canceled after field activity(s) are created and before the cut process completes, different activities can transpire. The specifics of what happens are controlled by a Cancel Logic algorithm plugged in on the [cut process template](#). The following points summarize how a base-package algorithm (C1-CP-DWFA) works:

- It assembles all Pending, Held and Complete cut for nonpayment field activities (FA) created by the cut process (these are defined in the overdue process's [log](#)).
- Each FA is processed as follows:
 - If the FA is Pending or Held and it is not linked to a field order (i.e., it hasn't been dispatched):
 - The FA is cancelled
 - An entry is added to the overdue process log to indicate the cancellation
 - If the FA is Pending or Held and it is linked to a field order (i.e., it has been dispatched):
 - A To Do entry is created (the To Do Type is defined on the algorithm)
 - If the FA is Complete and the Cut Process's SA is pending start or active (i.e., it hasn't been expired yet):
 - Reconnect field activity(s) are created for every service point that had a cut for non-payment field activity. The type of activity is defined on the [field activity type profile](#) defined on each service point's SP type.

A Cut Event Expires Service Agreements (and May Trigger Final Billing)

The last cut event is typically set up with an activation algorithm that expires the cut process's service agreement. If earlier cut events created "cut for non-payment" field activities, these field activities will be used as the basis for stopping service. Refer to [Finalizing Pending Stops](#) for how the system use the meter reads on these field activities as the "stop reads" on the service agreement. Note, you can see the field activities that are used to "cut" and "stop" service by viewing the Field Activities grid on [Service Agreement - Service Point](#).

Note:

Final billing. When the last service agreement linked to an account is expired, the system will schedule the account for billing (outside of its normal bill cycle schedule).

Write Offs Are Implemented Using Overdue Events

The system has been designed to allow overdue events on the original overdue process to write-off the objects being collected. Refer to [Writing Off Bills](#) for a case-study explaining how to do this.

Calendar vs. Work Days

When you set up your overdue and cut process templates, you supply information that controls how each event's trigger date is calculated. You have two options:

- You can say that an event's trigger date can only be populated after earlier, dependent events are complete. For example, the 2nd event (cut service) is triggered 2 days after the 1st event is complete (48 hour warning letter).
- You can say that an event's trigger date is populated when the process is first created. You simply define the number of days after the start of the process when each such event should be triggered. For example, the 2nd event (send cutoff warning) can be triggered 7 days after the start of the process.

In addition to the above, an option defined on the [Feature Configuration for Overdue Processing](#) plays a part in the calculation of an event's trigger date:

- If you set the option to use calendar days, the trigger date of events will be set to the first workday on / after the calculated date. For example, if you indicate that the 2nd event is triggered 7 days after the 1st event, the system will add 7 days to the 1st event's completion date. It then checks if this is a workday (and not a holiday); if so, this is the trigger date of the event; if not, it assigns the trigger date to the next workday.

- If you set the option to use workdays, the trigger date will be calculated by counting workdays. For example, if you indicate that the 2nd event is triggered 7 days after the 1st event, the system will count 7 workdays and set the trigger date accordingly.

Note:

Account's division controls the work calendar. The system uses the above information in conjunction with the [work calendar](#) associated with the account's division to determine workdays.

Bill-Oriented Collection - Advanced Topics

The topics in this section provide information on features designed to facilitate the collection of overdue bills.

Miscellaneous Bill-Oriented Collection Topics

The topics in this section provide background information about a variety of bill-oriented collection topics.

Highlights Of The Sample Overdue Monitor Rule Algorithm

A base-package Overdue Monitor Rule algorithm exists to support many different types of overdue rules (see C1-CB-CR-RAT). Keep in mind that multiple such algorithms can be plugged in on [Collection Class Overdue Rules](#). When the [Overdue Monitor](#) analyzes an account, it calls these algorithms until there are no more to invoke (or until an algorithm tells it that there is nothing more to check). The following points describe its various options:

- **Different rules based on credit ratings.** You can set up algorithms to only be applied to accounts with a credit rating \leq a given value. We anticipate such algorithms will be used in conjunction with other such algorithms to apply different rules based on the customer's credit rating.
- **Different rules based on an account or service agreement characteristic.** You can set up algorithms to only be applied if an account or one of its service agreements has a given characteristic type and value effective within the last X days. For example, you could set up an algorithm that would process an account if it had a broken payment arrangement service agreement within the last 365 days (broken payment arrangement service agreements are marked with a given char type and value). You could set up a different algorithm that treated strategic customers more leniently (given that the definition of "strategic" could be held in an account or service agreement characteristic).
- **Skipping a bill if it has a future postpone date.** You can set up algorithms to ignore an unpaid bill if it has a "postpone date" that's in the future. This date would be defined on the bill using an ad hoc characteristic. The characteristic type is defined as a parameter on the algorithm.
- **Special process for bills with disputed debt.** You can set up an algorithm to create a given type of overdue process if the bill has disputed debt. By "disputed debt", we mean a bill with a financial transaction that's linked to an unbalanced match event that's marked as Disputed.
- **Special process for bills with credit balances.** You can set up an algorithm to create a special overdue process if the bill's total charges are negative (i.e., a credit bill). Such bills should be very unusual as we strongly recommend that credit bills should have their credit balance applied to an overpayment service agreement during bill completion.
- **Different rules when all service agreements are inactive.** You can set up an algorithm that should only be applied if all service agreements are inactive. We anticipate this can be used to differ the type of overdue process as if an account does not have active service agreements; there is nothing to stop to encourage them to pay.
- **Different rules based on age and amount of a bill.** You can set up an algorithm to create different types of overdue processes based on the age and amount of the bills.

Note:

You are not limited by the base-package's rules. If your implementation requires options that are not supported by the base-package algorithm, simply develop your own.

Holding A Process's Events

Refer to [Holding Events](#) for a description of how to prevent the activation of an overdue / cut processes events while a given condition is true. The condition is defined in an algorithm so you can set up the system to prevent event activation for practically any condition. For example, you might want to hold event activation while the bill's account has an active case (e.g., a user might set up a case to conduct an ad hoc investigation of billing discrepancies). When the case closes, you'd want the process to start up where it left off.

Bill Info Shows Unpaid and Write-off Amounts

The base-package Bill Information algorithm (plugged in on the [Installation](#) record) is responsible for constructing a bill's summary information that appears throughout the system. This algorithm can be configured to show the unpaid and write-off amounts of each bill.

Writing Off Bills

The topics in this section provide background information on how to write off bills.

After Service Is Cut, Write-Off Oriented Events Can Commence

After the last service agreement has been stopped, overdue events to manage the write-off of the overdue process's bill(s) should be triggered. Please note that a separate overdue process is NOT created to manage write-offs. Rather, events associated with the original overdue process will handle the write-off activities.

Collection Agency Referrals

Before debt is written off, many implementations refer the unpaid bills to a collection agency. The following points describe how to implement this.

- Set up an overdue event type with an activation algorithm that refers an overdue process's bill(s) to a collection agency.
- When such an event is activated, the system creates a [Collection Referral](#) record for a collection agency. The specific agency to which the debt is referred is controlled by the event type's activation algorithm. The sample algorithm simply refers debt to the collection agency with the least amount of referred debt. If you prefer different logic, you must develop your own algorithm.
- A collection agency referral history record is linked to an account. It contains the amount of debt referred to the collection agency. It is the creation of this record that triggers the interface of information to the collection agency. The method used to interface the information to the agency is defined on the collection agency's record. Refer to [Setting Up Collection Agencies](#) for more information.
- If the collection agency is successful in obtaining the funds, a payment will be added. If the payment satisfies the cancel criteria defined on the overdue process template's cancellation plug-in, the overdue process will cancel. When an overdue process is cancelled, the cancel criteria on the overdue process's template are executed. We strongly recommend plugging in an algorithm that will cancel collection agency referrals when an overdue process is cancelled.
- If the collection agency is not successful in obtaining your funds after a given amount of time, you probably want to cancel the referral and write-off the debt. The cancellation of the referral will happen automatically if you set up your overdue process template to have an event that creates a collection agency cancellation X days after the referral. You can cancel a referral manually by simply creating a new collection agency referral history record (with a type of cancel).
- Collection agencies are notified of the cancellation of a referral by the creation of a new collection agency referral history record (with a type of cancel). This record will be interfaced to the agency in the same manner used to interface a new referral (see above).

**Note:**

Log entry. The base-package overdue event activation algorithms that make and cancel collection agency referrals insert rows in the overdue process's [log](#) to audit these events.

Writing Off Bills Will Create Write-Off Adjustments And Possibly A Match Event

Most overdue process templates will be configured to contain an event that writes-off the unpaid balance of bills.

**Note:**

Processing is redirected to another algorithm. The base-package overdue event activation algorithm that writes off bills simply redirects the call to the Write-Off Bill algorithm plugged in on the account's [Collection Class Overdue Rules](#). The reason for this redirection is because users can manually write-off a bill (using [Bill - Main](#)) and when they do this, we want to invoke the same logic as when an overdue process writes-off a bill.

The base-package Collection Class Overdue Rules - Write-Off Bill algorithm determines the amount that should be written off for each distribution code on each unpaid financial transaction. It then creates a separate adjustment for each service agreement where the lines on the adjustment contain the amount to be written off for each distribution code. If the unpaid financial transactions are not linked to a match event, the write-off adjustments plus the unpaid financial transactions will be linked to a new match event. If the unpaid financial transactions were linked to an unbalanced match event, the write-off adjustments will be added to the existing match event (thus making it balanced).

If partial payments were made against a bill, the amount written off will be prorated in light of the partial payments. For example, if 20% of a bill had been paid, 80% of each distribution code will be written off.

For example, assume the original bill's FT looked as follows (note, if the bill has multiple service agreements this will need to be done for each SA's FT's):

- Debit A/R \$110.00
- Credit Flat Charge Revenue (\$50)
- Credit Usage Revenue (\$50)
- Credit City Tax Payable (\$5)
- Credit State Tax Payable (\$5)

Assume the customer had made a partial payment of \$11 and it was matched to this FT. At write-off time, the system will create an adjustment whose adjustment lines will cause each distribution code to be written off by 90% (100% - \$11 / \$110). For example:

- Debit Flat Charge Revenue (or some W/O Expense) \$45
- Debit Usage Revenue \$45
- Debit City Tax Payable \$4.50
- Debit State Tax Payable \$4.50
- Credit A/R \$99

This adjustment will then be linked to the original match event on which the payment was linked (thus making it Balanced).

**Note:**

Log entry. The base-package overdue event activation algorithm that writes off bills inserts a row into the overdue process's [log](#) for each bill written off.

Small Amount Write-Downs

Many organizations will write-down a bill whose value is small early in an overdue process. The base-package overdue event activation algorithm has parameters to support this requirement (this algorithm allows you to write-off an overdue process's bill(s) if their value is less than a threshold amount).

If your organization writes-down small amounts differently than large amount, simply set up an overdue event type to reference such an activation algorithm and position it in the appropriate place in the overdue process template.

Bill Info Shows Written Off Amounts

The base-package Bill Information algorithm (plugged in on the [Installation](#) record) is responsible for constructing a bill's summary information that appears throughout the system. This algorithm can be configured to show the amount written-off for each bill.

Online Write Off Of Bills Is Performed On Bill-Main

If a bill's account is associated with a [Collection Class Overdue Rule](#) that has a Write Off Bill algorithm, a button appears on [Bill - Main](#) if the bill hasn't been written off. When clicked, the Write Off Bill algorithm is invoked to write-off the bill.

Online Reversal Of Written Off Bills Is Performed On Bill-Main

If a bill's account is associated with a [Collection Class Overdue Rule](#) that has a Write Off Bill algorithm, a button appears on [Bill - Main](#) if the bill has been written off. When clicked, the Write Off Bill algorithm is invoked (in reversal mode). The algorithm cancels the write-off adjustments (thus making the bill payable again). It also schedules the account for review by the [Overdue Monitor](#) the next time it runs.

Write Offs And Overdue Process Cancellation

It should be stressed that writing-off a bill may cause an overdue process to be canceled because the bill's FT will be linked to a balanced match event (note, the specific [cancel criteria](#) are in a plug-in so this is not a hard rule).

The following points highlight interesting aspects of bill write-off and overdue process cancellation:

- If a user writes off a bill [real time](#) and the bill has an Active overdue process, the process's cancel criteria will be invoked. This typically results in the cancellation of the overdue process.
- If an overdue event writes off a bill, the state of the process depends on your cancel criteria and where the overdue event is positioned in the overdue process. For example,
 - Imagine an overdue process that has an overdue event that writes off small amounts of debt early in the process. If such a process is applied against bill with a small amount of debt, the process will be canceled (when the event activates).
 - Contrast this to an overdue process where the last event writes off the bill. Because there are no other events to activate, the process will complete (i.e., it will not be canceled).

An Alert Can Show Written Off Bills

A base-package Control Central Alert algorithm (C1-WO-BILL) can be set up to highlight if the account in context has written off bills. This algorithm is plugged in on the [Installation](#) record.

Bill-Oriented Payment Arrangements

A payment arrangement is an agreement with a customer to payoff severely overdue debt in **billed** installments. Bills sent to customers with payment arrangements contain charges for both their current services and their payment arrangement installment amount.

Note:

Nomenclature. Some organizations refer to payment arrangements as "current bill plus" agreements because the customer's bills contain charges for both their current debt plus their installment amount. After the

customer has paid off their overdue debt, the payment arrangement closes and the customer's bills only contain charges for their current debt.

The topics in this section describe how to set up a payment arrangement and how the system monitors the ongoing arrangements.

Creating Payment Arrangements

When you create a payment arrangement, you are actually creating a service agreement. This service agreement is just like other service agreements in that:

- It holds debt.
- It is periodically billed (thus creating unmatched bill segment financial transactions).
- When a payment is received, the payment segment financial transactions are matched to the bill segment financial transactions.

Debt is transferred to a payment arrangement service agreement (PA SA) from the customer's delinquent bills at the inception of the payment arrangement.

When you transfer debt from the overdue bills to a PA SA, transfer adjustments are created to transfer debt from the delinquent SAs to the PA SA. Match events are created to link the "transfer from" adjustments to the original unpaid financial transactions (FT). When all FT's on a bill are linked to balanced match events, the bill is no longer considered overdue and any active overdue process (and its related cut processes) will be cancelled. Refer to [How Are Overdue Processes Canceled](#) for more information.

Note:

Use the Payment Arrangement Transaction. Use the [Payment Arrangement - Bill Oriented](#) to set up bill-oriented payment arrangements. This transaction creates a PA SA, transfers overdue bills to it, and sets up the installment amount. This transaction is also used if you need to break or cancel the payment arrangement.

Installment, Payoff and Current Amounts

Warning:

If you do not understand the difference between payoff balance and current balance, refer to [Current Amount versus Payoff Amount](#).

When you set up a payment arrangement service agreement (PA SA), you transfer delinquent debt to the PA SA using transfer adjustments. After moneys are transferred, the system sets the PA SA's current balance to zero. At this point, there will be no overdue bills. If the customer neglects to pay bills containing charges associated with the payment arrangement, an overdue process will ensue.

PA SAs start their life with a non-zero payoff balance (i.e., they have debt when first started). This debt is transferred from the bills whose outstanding debt necessitated the creation of the PA SA.

The installment amount that the customer is billed is determined by the number of installments used to payoff the debt. For example, if the customer owes \$500 and they want to pay this off in 10 installments, you'd set up the installment amount to be \$50. The installment amount is saved on the PA SA's recurring charge amount. If the customer again falls into arrears on their bills, you can transfer additional bills to the PA SA. You can also change the installment amount as needed.

A PA SA's payoff balance typically differs from its current balance. The payoff balance is the amount of debt remaining to be paid off under the terms of the payment arrangement. The current balance is the installment amount that has been billed but not paid. For example, a customer who is paying off \$500 with 10 installments of \$50 would have an initial payoff balance of \$500 and a current balance of \$0. After the first bill, the PA SA would still have a payoff balance of \$500, but its current balance would be \$50. When the customer pays, the PA SA's payoff balance would fall to \$450 and its current balance would return to \$0.

The following table contains a financial example of a customer who sets up a payment arrangement to payoff \$1,000 of debt in \$10 installments.

| Event | Normal SA's GL Accounting | PA SA's GL Accounting | Normal SA's Current Balance | Normal SA's Payoff Balance | PA SA's Current Balance | PA SA's Payoff Balance |
|---|---------------------------|----------------------------|-----------------------------|----------------------------|-------------------------|------------------------|
| Prior to creation of payment arrangement | N/A | N/A | 1000 | 1000 | N/A | N/A |
| Transfer debt from normal SA(s) to PA SA | Xfer 1000 A/R <1000> | PA A/R 1000 Xfer <1000> | 0 | 0 | 1000 | 1000 |
| Set current balance to zero on PA SA | N/A | N/A | 0 | 0 | 0 | 1000 |
| Customer is billed (\$50 for new debt and \$10 of payment arrangement debt) | A/R 50 Revenue <50> | N/A | 50 | 50 | 10 | 1000 |
| Customer pays \$60 | Cash 50 A/R <50> | Cash 10 PA A/R <10> | 0 | 0 | 0 | 990 |

When the customer pays off the payment arrangement debt, the system automatically closes the PA SA after it final bills (assuming the PA SA's SA type references a bill segment type that has a bill segment creation algorithm of Recurring Charge With Auto Stop).

Breaking A Bill-Oriented Payment Arrangement

If a customer neglects to pay a bill, an overdue process is created. If the bill contains charges from a payment arrangement, you'll want to "break" the payment arrangement. By "break", we mean cancel the arrangement and reinstate the debt under the originating bills. To do this, you must configure the [cut process template](#) used to cut the PA SA to contain a cut event that breaks the payment arrangement.

Note:

Processing is redirected to another algorithm. The base-package cut event activation algorithm that breaks a payment arrangement simply redirects the call to the Bill-Based Payment Arrangement algorithm plugged in on the account's [Collection Class Overdue Rules](#). The reason for this redirection is that users can manually break a payment arrangement (using [Payment Arrangement - Bill Oriented](#)). When they do this, we want to invoke the same logic as when a cut event activation algorithm breaks a payment arrangement.

The base-package Collection Class Overdue Rule - Bill-Based Payment Arrangement algorithm does the following:

- Creates "cancel adjustments" for all unpaid financial transactions associated with the payment arrangement (e.g., billed, but not paid installments).
- Cancels ALL adjustments that were used to transfer the debt to the payment arrangement. When these are cancelled, the original bills will become unpaid (and the debt will be rather old by this point).
- Syncs up current balance with payoff balance on the PA SA.
- Makes the PA SA pending stop and expires it (SA activation will stop the SA when it next runs).

- If there is a credit left on the PA SA (because payments were made against the arrangement), the credit will be distributed amongst the bills that contributed debt to it (the oldest bills are paid off first). This relief will occur via transfer adjustments from the PA SA to the original SAs.
- Note, if there is a debit left (e.g., because LPC were issued or some other type of adjustment was created by an operator), an error is issued as we don't handle new debit on a payment arrangement.
- Inserts a characteristic on the PA SA to indicate that it has been broken (you might want to use this to cause more strict overdue rules to be applied to accounts with broken payment arrangements).
- Marks the account so it will be reviewed by the [Overdue Monitor](#) the next time it runs.

Note:

The PA SA must final bill before it closes. It's important to note that the PA SA will only close after the PA SA is final billed. This is OK as it won't have any money left on it.

When the Overdue Monitor next runs, it will analyze the account's reinstated bills. We recommend setting up a Collection Class Overdue Rule - Overdue Monitor Rule algorithm that has more stringent rules if the account has a broken payment arrangement within the last X days. The base-package algorithm (C1-CB-CR-RAT) supports this type of processing.

Note:

Log entry. The base-package overdue event activation algorithm that breaks a payment arrangement SA inserts a row into the overdue process's [log](#).

Online Breaking

A user can click a button on the [Payment Arrangement - Bill Oriented](#) page to break a payment arrangement real time. When clicked, the Collection Class Overdue Rule - Bill-Based Payment Arrangement algorithm is called to break the payment arrangement. This is the same algorithm called when a cut event break a payment arrangement.

Online Canceling

A user can click a button on the [Payment Arrangement - Bill Oriented](#) page to cancel a payment arrangement real time. Cancellation should be used when you want to "logically delete" a PA SA because it shouldn't have been created.

The logic described above for breaking a payment arrangement is executed when a user cancels a payment arrangement; the only difference is that the PA SA is marked with a different characteristic type / value than when it is broken. The "broken" characteristic type / value can be used to apply stricter rules to the account when it's next reviewed by the [Overdue Monitor](#).

Creating Overdue and Cut Procedures

Your overdue procedures define how your organization collects overdue debt. Your cut procedures define how your organization cuts (i.e., stops) service agreements when collection attempts fail. In this section, we describe how to set up the data that controls these procedures.

Warning:

There are numerous ways to design your overdue and cut procedures. Some designs will result in easy long-term maintenance; others will result in maintenance headaches. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your overdue and cut procedures, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

Designing Your Overdue Procedures

The design of your overdue procedures is an iterative process. Over time, you will develop skills that will allow you to skip some steps. However, when you're starting out, we recommend you use the following matrix as your guide. When the matrix is complete, you're ready to set up the overdue processing control tables.

| Account's Division | Account's Collection Class: | Account's Collection Class: |
|---------------------------|------------------------------------|------------------------------------|
| | | |

The topics discussed below will gradually complete this matrix using a simple case study.

Fastpath:

For more information about how the information in this matrix is used to monitor your customers' debt, refer to [How Does The Overdue Monitor Work](#).

Your Divisions Are Frequently Preordained

An account's division defines the jurisdiction whose rules govern the account. For example, an account's division controls how its payments are distributed, if / how late payment charges are levied, etc. Divisions have typically been designed in advance of designing your overdue rules.

In our example, we assume you have two divisions: North and South.

| Account's Division | Account's Collection Class: | Account's Collection Class: |
|---------------------------|------------------------------------|------------------------------------|
| North | | |
| South | | |

Designing Your Collection Classes

Multiple collection classes are needed when your organization has different overdue rules and / or procedures based on the type of customer. If all customers are treated the same way, you'll have a single collection class (call it Generic). However, if you're like many organizations, you will have multiple collection classes.

For example, for commercial/industrial customers, you probably don't worry until they owe you more than, say, \$100 after 20 days. For residential customers, you probably don't worry until they owe you more than, say, \$5 after 20 days. In this situation, you will have at least two collection classes: one for commercial/industrial customers, the other for residential customers.

In our example, we assume you have two collection classes: Residential and Commercial/Industrial.

| Account's Division | Account's Collection Class: | Account's Collection Class: |
|---------------------------|------------------------------------|------------------------------------|
| | Residential | Commercial/Industrial |
| North | | |
| South | | |

Note:

There are two very different ways to monitor your accounts for overdue debt. This chapter describes the method referred to as Overdue Processing. Refer to [Collection / Severance / Write Off](#) for a description of the other method. We anticipate that most organizations will only use a single method. If your organization opts to use both methods, you will need to set up the corresponding collection classes.

Designing Overdue Monitoring Rules

At this point, we have the rows and columns defined in our matrix. Now it's time to work on the individual cells.

Note:

Single currency. We've assumed that your implementation works in a single currency. If this is not true, you will need to add a 3rd dimension that will have a value for each currency code.

Each cell will contain the rules that the [Overdue Monitor](#) uses to determine if an account has overdue debt. These rules will eventually be configured using one or more algorithms on [Collection Class Overdue Rules](#).

| Account's Division | Account's Collection Class: | Account's Collection Class: |
|---------------------------|------------------------------------|------------------------------------|
| | Residential | Commercial/Industrial |
| North | | |
| South | | |

Note:

If the Overdue Monitor encounters an account whose collection class and division does not have overdue rules set up, it will issue an error.

Determining the rules in each cell can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For residential debt (regardless of division) we have the following rules:
 - Highest priority. If a bill exists with unpaid FT's > \$0 that is older than 50 days, create the "accelerated overdue process" for residential customers. We'll talk more about this process later.
 - Medium priority. If the account's has a broken payment arrangement within the last 60 days with an unpaid bill > \$0 that is older than 20 days, create the "broken payment arrangement overdue process".
 - Lower priority. If a bill exists with unpaid FT's > \$25 that is older than 25 days, create the "courtesy reminder overdue process" for residential customers. We'll talk more about this overdue process later.
- For commercial-industrial debt (regardless of division) we have the following rules:
 - Highest priority. If a bill exists with unpaid FT's > \$0 that is older than 45 days, create the "commercial 45 days late overdue process". We'll talk more about this process later.
 - Medium priority. If the account's credit rating is < 550 and has an unpaid bill > \$0 that is older than 20 days, create the "risky commercial customer overdue process".
 - Lower priority. If a bill exists with unpaid FT's > \$100 that is older than 30 days, create the "commercial 30 days late overdue process". We'll talk more about this overdue process later.

Given the above, our matrix will look as follows:

| Account's Division | Account's Collection Class: | Account's Collection Class: |
|---------------------------|------------------------------------|------------------------------------|
| | Residential | Commercial/Industrial |

| | | |
|--------------|---|---|
| <p>North</p> | <p>Highest Priority: If a bill exists with unpaid FT's > \$0 that is older than 50 days, create the accelerated overdue process for residential customers.</p> <p>Medium Priority: If the account has a broken payment arrangement within the last 60 days with an unpaid bill > \$0 that is older than 20 days, create the broken payment arrangement overdue process.</p> <p>Lowest Priority: If a bill exists with unpaid FT's > \$25 that is older than 25 days, create the courtesy reminder overdue process for residential customers.</p> | <p>Highest Priority: If a bill exists with unpaid FT's > \$0 that is older than 45 days, create the commercial 45 days late overdue process.</p> <p>Medium priority: If the account's credit rating is < 550 and has an unpaid bill > \$0 that is older than 20 days, create the risky commercial customer overdue process.</p> <p>Lowest Priority: If a bill exists with unpaid FT's > \$100 that is older than 30 days, create the commercial 30 days late overdue process.</p> |
| <p>South</p> | <p>Same as above</p> | <p>Same as above</p> |

Note:

The rules are limited by your imagination (and business requirements). While the base-package Overdue Monitor Rule algorithm (C1-CB-CR-RAT) supports the above scenarios, we'd like to stress these are just examples. Your implementation can operate using very different rules by either configuring the base-package algorithm (it has many parameters that you can use to tailor your rules) OR by introducing a new algorithm. Refer to [Highlights Of The Sample Overdue Monitor Rule Algorithm](#) for the options delivered with the base-package.

Designing Overdue Process Templates and Event Types

The following table shows a sample overdue process template for one of the rules in the Residential / North cell in the previous section's matrix.

| Overdue Process Template | Overdue Event Type | When Triggered |
|--|---|--|
| <p>Accelerated overdue process for residential customers</p> | <p>Old debt letter</p> | <p>At inception of process</p> |
| | <p>Cut active service agreements</p> | <p>10 days after inception</p> |
| | <p>Reduce customer's credit rating</p> | <p>10 days after inception (i.e., at the same time the cut process is created)</p> |
| | <p>Write down small debt</p> | <p>0 days after completion of the cut process(es)</p> |
| | <p>Refer debt to collection agent</p> | <p>0 days after attempting the small write down (this means that either the small write-down or the agency referral will take place as if the write-down is successful, the bill's FTs will be matched to balanced match events and the overdue process will stop)</p> |
| | <p>Cancel collection agent referral</p> | <p>45 days after referral</p> |

| | |
|----------------|--|
| Write-off debt | 0 days after collection agent cancellation |
|----------------|--|

You should create a similar table for each of the distinct overdue process templates in your matrix.

At this point, you've designed the distinct overdue process templates. Next, you'll need to design the algorithms that control their overdue processes:

- A template's Calculate Unpaid and Original Amount algorithm calculates the original and unpaid amounts of the objects being collected by a process. These values are used throughout the overdue processing module.
- A template's Cancel Criteria algorithm is executed to determine if a process should be cancelled. Refer to [How Are Overdue Processes Cancelled](#) for the details.
- A template's Cancel Logic algorithm is executed to cancel a process. Refer to [How Are Overdue Processes Cancelled](#) for the details. Please note that the logic embodied in this type of algorithm can be sophisticated because it is responsible for stopping an ongoing process's activities (e.g., this could involve cancelling field activities or cases). Cancellation algorithms are also responsible for inserting log entry(s).
- A template's Hold Event Activation algorithm is invoked to determine if the [Overdue / Cut Event Manager](#) should [suspend the activation](#) of the process's events.
- A template's Information algorithm is invoked to construct the [override "info string"](#).

Next, extract each unique event type from the above table:

| Overdue Event Type | Action |
|----------------------------------|---|
| Old debt letter | Create a customer contact |
| Cut active service agreement(s) | Start a cut process for every active SA with an unpaid FT on the bill |
| Reduce customer's credit rating | Insert an account credit rating history record |
| Write down small debt | Create write-down adjustments if unpaid debt is less than \$x |
| Refer debt to collection agent | Create a collection agency referral |
| Cancel collection agent referral | Cancel the collection agency referral |
| Write off unpaid debt | Create adjustments to write-off unpaid debt |

At this point, you know the distinct event types. Next, you'll need to design the algorithms that control the lifecycle of each event type:

- The event type's Event Activation algorithm(s) are executed by the [Overdue / Cut Event Manager](#) on its trigger date. The following points describe the logic embodied in such an algorithm:
 - The activity that happens on the trigger date (e.g., creation of a customer contact, To Do, etc.). Refer to [Overdue Events Can Do Many Things](#) for the details.
 - Whether the event is transitioned into the Waiting or Complete state when it's triggered. Refer to [Some Events Can Wait](#) for the details.
 - How the log entry(s) associated with event activation will be constructed. The base-package algorithms allow you to control the verbiage in the log entry by defining the desired message number on the algorithm. This means that you may have to set up new messages. Refer to [Activating Events Should Add A Log Entry](#) for the details.

- The event type's Cancel Logic algorithm(s) are invoked when **an event is cancelled**. The following points describe the logic embodied in such an algorithm:
 - If the event is allowed to be canceled. This logic may be necessary if some conditions prevent events of this type from canceling. For example, you may want to prevent an event from canceling when there are later dependent events that aren't canceled.
 - Any ancillary actions that take place during cancellation.
 - How the **log entry(s)** associated with event cancellation will be constructed.
- The event type's Monitor Waiting Event algorithm(s) are invoked to **monitor a waiting event**. These algorithms are responsible for transitioning a Waiting event to Complete if the object on which it's waiting is complete.
- The event type's Event Information algorithm is invoked to construct the **override "info string"**.

Once you've designed each event type's algorithms, you're ready to design your cut processes.

Designing Cut Process Templates and Event Types

While not required, many overdue processes will contain an overdue event that cuts (i.e., stops) service (in the hopes that stopping service will inspire the customer to pay). When such an event activates, it creates one or more cut process(es).

The system allows you to control if and how service is cut by setting up Cut Process Rule algorithms on your SA types. This allows different rules for different types of service agreements. In addition, because these rules are embodied in algorithms, a given SA type can have conditional logic that controls the type of cut process created. For example, you may have a different cut process if the customer has life support equipment, or if it's winter, or ...

Note:

If a service agreements of a given type should never be cut. If you have certain SA types that should never be cut, do NOT define an algorithm in the SA type's Cut Process Rule .

Determining your Cut Process Rules can be straightforward or complicated; it depends on how your organization works. Our case study assumes the following:

- For service agreements associated with metered service, we have the following rules:
 - Highest priority. If the customer has life support requirements, create "cut process in light of life support" process.
 - Lowest priority. Otherwise, create a "metered service" cut process.
- For service agreements associated with charitable contributions, create an "expiration only" cut process.

Once you've determined if / how each SA type is cut, you need to design your cut process templates (you'll need one for each unique method of cutting a service agreement). The following table shows the cut process templates referenced above. Adjacent to each process are its events and an indication of when they are triggered.

| Cut Process Template | Event Number | Cut Event Type | Dependent On Event(s) | Trigger Date Set To X Days After Completion Of Dependent Events |
|----------------------|--------------|---|-----------------------|---|
| Metered service | 10 | Letter - 48 hour disconnect for non-payment warning | N/A - first event | 0 |
| | 20 | Field activity - disconnect for non-payment | 10 | 2 |
| | 30 | 'Service has been disconnected' letter | 20 | 0 |

| | | | | |
|--------------------------------------|----|--|-------------------|----|
| | 40 | Expire service agreement | 20 | 10 |
| Cut process in light of life support | 10 | Generate delinquent life support customer To Do entry (seeking approval for the cut) | N/A - first event | 0 |
| | 20 | Letter - 72 hour disconnect for non-payment warning | 10 | 0 |
| | 30 | Generate impending life support cutoff To Do entry to C&C rep | 20 | 3 |
| | 40 | Field activity - cut for non-payment | 30 | 0 |
| | 50 | Service has been disconnected letter | 40 | 0 |
| | 60 | Expire service agreement | 40 | 10 |
| Expiration only | 10 | Expire service agreement | N/A - first event | |

At this point, you've designed the distinct cut process templates. Next, you'll need to design the algorithms that control the lifecycle of their cut processes:

- A template's Cancel Logic algorithm is executed to cancel a process. In addition to cancelling the event, these algorithms are also responsible for inserting [log](#) entry(s).
- A template's Information algorithm is invoked to construct the [override "info string"](#).

Next, extract each unique event type from the above table:

| Cut Event Type | Action |
|---|--|
| 48-hour warning letter | Create a customer contact - 48-hour warning letter (letters are created via customer contacts) |
| 72-hour warning letter | Create a customer contact - 72-hour warning letter |
| Disconnect for non payment | Create a cut for non-payment field activity |
| Permission to start a cut process for a life support customer | Create To Do seeking permission to send 72 hour letter |
| Permission to create a cut field activity for a life support cutoff | Create To Do seeking permission to issue a cut field activity |
| Service has been disconnected letter | Create a customer contact - service cut letter |

Expire service agreement

Expire service agreement

At this point, you know the distinct event types. Next, you'll need to design the algorithms that control the lifecycle of their events:

- The event type's Event Activation algorithm(s) are executed by the [Overdue / Cut Event Manager](#) on its trigger date. The following points describe the logic embodied in such an algorithm:
 - The activity that happens on the trigger date (e.g., creation of a customer contact, To Do, etc.). Refer to [Cut Events Can Do Many Things](#) for the details.
 - Whether the event is transitioned into the Waiting or Complete state when it's triggered. Refer to [Some Events Can Wait](#) for the details.
 - How the log entry(s) associated with event activation will be constructed. The base-package algorithms allow you to control the verbiage in the log entry by defining the desired message number on the algorithm. This means that you may have to set up new messages. Refer to [Activating Events Should Add A Log Entry](#) for the details.
- The event type's Cancel Logic algorithm(s) are invoked when [an event is cancelled](#). The following points describe the logic embodied in such an algorithm:
 - If the event is allowed to be canceled. This logic may be necessary if some conditions prevent events of this type from canceling. For example, you may want to prevent an event from canceling when there are later dependent events that aren't canceled.
 - Any ancillary actions that take place during cancellation.
 - How the [log entry\(s\)](#) associated with event cancellation will be constructed.
- The event type's Monitor Waiting Event algorithm(s) are invoked to [monitor a waiting event](#). These algorithms are responsible for transitioning a Waiting event to Complete if the object on which it's waiting is complete.
- The event type's Event Information algorithm is invoked to construct the [override "info string"](#).

Set Up Tasks

The above topics provided background information about how overdue processing works. The following discussion summarizes the various set up tasks.

Cut Event Types

You will find that most of the time spent setting up your cut event types is spent setting up the objects that are referenced on the cut event type algorithms. For example, if you use the base-package algorithms, you may need to set up the following:

- The various "types" for the objects created by the plug-ins. For example, if a cut event type creates a To Do entry, you must supply the desired To Do type.
- [Foreign key characteristic types](#) that are used to reference the ancillary objects in the [log entries](#) (e.g., if an event creates a customer contact, the log references this customer contact using a FK characteristic type). Note, many of these will exist in the base-package.
- [Messages](#) that are used to define the verbiage in the [log entries](#). For example, if you use the base-package algorithm that creates a customer contact, you must supply the desired message category and number that contains the verbiage that appears in the log when customer contacts are created. Note, messages have been set up for all base-package algorithms (this means you should not have to set up new messages).
- Etc.

The only way to compile the complete list is to design the parameters for each cut event type algorithm. Refer to [Cut Event Type - Main](#) for the supported plug-in spots.

After you've set up the objects referenced on the algorithms, you can then set up the algorithms. Only then can you set up the cut event types.

Cut Process Templates

After your cut event types exist, you can set up your cut process templates. You will find that most of the time spent setting up your cut process templates is spent setting up the objects that are referenced on the cut process template algorithms. Refer to [Cut Process Template - Main](#) for the supported system events.

SA Type - Cut Process Rules

After you've created your cut process templates, you can set up the algorithms that hold your [cut process rules](#). These are plugged-in on [SA Type - Algorithm](#) in the Cut Process Rule system event.

Overdue Event Types

You will find that most of the time spent setting up your overdue event types is spent setting up the objects that are referenced on the overdue event type algorithms. For example, if you use the base-package algorithms, you will set up the following:

- The various "types" for the objects created by the plug-ins. For example,
 - If an overdue event type creates a To Do entry, you must set up the To Do type.
 - If an overdue event type creates a customer contact, you must set up the customer contact type.
 - If an overdue event type writes off debt, you must set up the adjustment types.
 - Etc.
- [Foreign key characteristic types](#) that are used to reference the ancillary objects in the [log entries](#) (e.g., if an event creates a customer contact, the log references this customer contact using a FK characteristic type). Note, many of these will exist in the base-package.
- [Messages](#) that are used to define the verbiage in the [log entries](#). For example, if you use the base-package algorithm that creates a customer contact, you must supply the desired message category and number that contains the verbiage that appears in the log when customer contacts are created. Note, messages have been set up for all base-package algorithms (this means you should not have to set up new messages).
- Etc.

The only way to compile the complete list is to design the parameters for each overdue event type algorithm. Refer to [Overdue Event Type - Main](#) for the supported plug-in spots.

After you've set up the objects referenced on the algorithms, you can then set up the algorithms. Only then can you set up the overdue event types.

Overdue Process Templates

After your overdue event types exist, you can set up your overdue process templates. You will find that most of the time spent setting up your overdue process templates is spent setting up the objects that are referenced on the overdue process template algorithms. Refer to [Overdue Process Template - Main](#) for the supported system events.

Collection Classes

Set up [collection classes](#) as per your [overdue procedures](#). Make sure to indicate that these collection classes use the Overdue collection method (only accounts linked to collection classes designated as using the Overdue collection method or processed by the Overdue Monitor).

Collection Class Overdue Monitor Rules

After your overdue process templates exist, you can set up your Overdue Monitor Rules. These rules are algorithms plugged in on [Collection Class Overdue Rules](#). You will find most of the time spent setting up these algorithms is spent setting up the objects referenced on the base-package algorithm.

Feature Configuration

You must set up a [Feature Configuration](#) to define parameters that control various overdue processing options.

The following points describe the various **Option Types** that must be defined:

- Trigger Date: Y-Workdays, N-Calendar Days. This option controls how the system computes the trigger dates on overdue and cut events. Enter Y if the system should use workdays. Enter N if the system should use calendar days. Refer to [Calendar vs Work Days](#) for the details.
- Payment Arrangement Type (B/S/A). This option indicates whether your implementation uses the [Balance-Oriented Payment Arrangements](#) (value **S**), [Bill-oriented Payment Arrangements](#) (value **B**) or both (value **A**). The value governs the navigation path for the payment arrangement lines in the [Account History](#) and [Credit & Collection](#) zones.
- Champion Template\$Challenger Template\$Percentage(1-100). You need only set up options of this type if your implementation implements [Champion / Challenger](#) functionality. Options of this type are entered in the format A\$B\$nnn where A is the overdue process template of the champion template, B is the overdue process template of the challenger template, and C is the percent of the time that the system should create the challenger template. The overdue monitor uses this option to override the champion overdue process template X% of the time with the challenger template. You may enter any number of these options (but only one per Champion Template).

Overdue and Cut Event Cancellation Reasons

Overdue events can be cancelled automatically and manually (at the discretion of a user). Regardless of the method of cancellation, a cancellation reason must be supplied. You set up your overdue event cancellation reasons using [Overdue Event Cancellation Reason - Main](#) and [Cut Event Cancellation Reason - Main](#).

Collection Agencies

If you refer debt to collection agents, you must set up your [collection agencies](#).

Alert To Highlight Active Overdue Processes

If you want an alert to appear if the account has active overdue processes, you must configure an appropriate Control Central Alert algorithm (C1-OD-PROC). This algorithm is plugged in on the [Installation](#) record.

Bill-Oriented Collection - Additional Set Up

The topics in this section provide information on additional set up requirements if you collect on unpaid bills.

One Bill Per Match Event

As mentioned earlier, a bill is considered paid if its financial transactions (FTs) are linked to a balanced match event. To determine a bill's outstanding amount, FTs from different bills cannot be commingled on the same match event (but it's OK for a bill's FTs to be on multiple match events). If you stick by the rule of "just one bill per match event" you will then be able to determine the outstanding balance of a partially paid bill. However, if you mix more than one bill under a match event, a particular bill's balance may become indeterminate.

The following Open-Item algorithm types have been provided by the base package to help enforce this rule:

- The Distribute by Bill Due Date Payment Distribution algorithm (C1-PYDS-BDU).
- The match by Bill ID Payment Distribution Override algorithm (C1-PDOV-PYBL).

- The FT cancellation FT Freeze algorithm (C1-CFTZ-COFT).

If any of your customized plug-ins and processes create match events, it is important that these too enforce this rule. You may want to refer to the base package algorithms as an example of how to do this.

Bill-Based Payment Arrangements

If you set up [payment arrangements for unpaid bills](#), you must configure the Bill-Based Payment Arrangement algorithm and plug it in on your [Collection Class Overdue Rules](#).

It's important to set up the adjustment types used during payment arrangement creation to NOT print on bills. This is because the base-package algorithm will match the adjustments used to transfer debt to the payment arrangement with the adjustment used to reduce the payment arrangement's current amount by the amount of the transfer if all adjustment types are set up to not print.

Bill-Based Write-off

If you [write-off unpaid bills](#), you must set up the following:

- Set up the adjustment type that will be used to write-off an unpaid financial transaction. This adjustment type must be configured as follows:
 - **Adjustment Amount Type** must be Calculated Amount
 - Its distribution code is irrelevant as a separate calculation line will be created for each distribution code on the FT's that is written off and these lines will reference the appropriate distribution code.
 - It must reference an adjustment type char type / value that identifies it as one used to write-off a bill's FTs
 - The following algorithms must be defined on the adjustment type:
 - The Generate Adjustment system event must reference an algorithm that has the responsibility of determining how to write-off a FT. This algorithm should be determining the FT's GL details and creating a separate adjustment calculation line for each GL detail. The base package is supplied with a sample algorithm that does this (C1-ADJG-WO).
 - The Adjustment Financial Transaction system event should reference an algorithm that impacts current, payoff and the GL by the amount being written off.
 - The distribution codes referenced on the financial transactions must be set up with a characteristic that holds the distribution code used to write-off the original amounts. For example,
 - Distribution codes used to record tax liabilities will typically reference the same distribution code for write-off (most organizations reverse tax liabilities at write-off time)
 - Distribution codes used to record revenue will typically reference a write-off distribution code used to record a write-off expense.
 - Distribution codes used to record receivables will typically not reference a write-off distribution code because receivables are implicitly written off when revenue and tax liabilities are written off.
 - Set up an adjustment cancellation code used when a users reverses a written-off bill (reversal involves canceling the write off adjustments).
 - Set up a Write Off Bill algorithm and plug it in on your [Collection Class Overdue Rules](#). This algorithm will reference the adjustment type described in the previous point.

Alert To Highlight Written Off Bills

If you want an alert to appear if the account has bills with written-off debt, you must configure an appropriate Control Central Alert algorithm (C1-WO-BILL). This algorithm is plugged in on the [Installation](#) record.

Open-Item Bill Amount Plug-In

You must set up the algorithm that computes the original, unpaid, and write-off amounts of your open-item bills. This algorithm is called by other algorithms when these amounts are needed. This algorithm is plugged-in on [Installation](#) in the Determine Open Item Bill Amounts spot.

Setting Up Overdue Processing

The topics in this section describe how to set up the control tables to implement your overdue processing.

Setting Up Overdue Event Types

An overdue event type encapsulates the business rules that govern a given type of overdue event. Open **Admin > Credit & Collection > Overdue Event Type > Add** to set up overdue event types.

Note:

Recommendation. Before using this transaction, we strongly recommend that you review [The Big Picture Of Overdue Events](#).

Description of Page

Enter a unique **Overdue Event Type** code and **Description** for the overdue event type.

Use **Long Description** to provide a more detailed explanation of the purpose of the overdue event type.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

| System Event | Optional / Required | Description |
|------------------------|---|--|
| Cancel Logic | Required | This algorithm is executed to cancel an overdue event. Refer to How Are Events Canceled for the details. |
| Event Activation | Required | This algorithm is executed to activate an overdue event on its trigger date. Refer to Overdue Events Can Do Many Things and How and When Events Are Activated for the details. |
| Event Information | Optional - only used if you want to override an overdue event's info string | This algorithm is executed to construct an overdue event's override info string. Refer to Overdue Event Information Is Overridable for the details. |
| Monitor Waiting Events | Optional - only used if events of this type can enter the Waiting state | This algorithm is invoked by the Overdue / Cut Event Manager for events in the Waiting state. Refer to Some Events Wait For Something Before Completing for the details. |

Setting Up Overdue Process Templates

An overdue process template encapsulates the business rules that govern a given type of overdue process. Open **Admin > Credit & Collection > Overdue Process Template > Add** to set up overdue process templates.

Note:

Recommendation. Before using this transaction, we strongly recommend that you review [The Big Picture Of Overdue Processes](#).

Description of Page

Enter a unique **Overdue Process Template** and **Description** for the overdue process template.

Collecting On Object defines the type of object managed by this overdue process. This field actually references a [foreign key characteristic type](#) that references the managed object. For example, if this overdue process template manages overdue bills, you'd reference a foreign key characteristic that references the bill object.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event** (note, all system event's are optional and you can define an unlimited number of algorithms for each event).

| System Event | Optional / Required | Description |
|------------------------------------|--|---|
| Calculate Unpaid & Original Amount | Required | This algorithm is executed to calculate the unpaid and original amounts of the objects associated with the overdue process. These amounts are shown on the overdue process page and in the base-package overdue info string . |
| Cancel Criteria | Required | This algorithm is executed to determine if an overdue process can be cancelled. Refer to How Are Overdue Processes Cancelled for the details. |
| Cancel Logic | Required | This algorithm is executed to cancel an overdue process. Refer to How Are Overdue Processes Cancelled for the details. |
| Hold Event Activation Criteria | Optional - only used if overdue processes of this type can be suspended while some condition is true | This algorithm is executed to determine if the activation of overdue and cut events should be suspended. Refer to Holding Events for the details. |

| | | |
|-----------------------------|---|---|
| Overdue Process Information | Optional - only used if you want to override an overdue process's info string | This algorithm is executed to construct an overdue process's override info string. Refer to Overdue Process Information Is Overridable for the details. |
|-----------------------------|---|---|

The **Event Types** control the number and type of overdue events linked to an overdue process when it is first created. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event type:

- **Event Sequence.** Sequence controls the order in which the overdue event types appear in the scroll.
- **Overdue Event Type.** Specify the type of overdue event to be created.
- **Days After.** If **Dependent on Other Events** is on, events will be triggered this many days after the completion of the dependent events (specified in the grid). Set this value to 0 (zero) if you want the event triggered immediately after the completion of the dependent events. If **Dependent on Other Events** is off, events will be triggered this many days after the creation of the overdue process. Refer to [How and When Events Are Activated](#) for the details.
- If **Dependent on Other Events** is on, define the events that must be completed or cancelled before the event will be triggered.
 - **Sequence** is system-assigned and cannot be specified or changed.
 - **Dependent on Sequence** is the sequence of the dependent event.

Setting Up Cut Event Types

A cut event type encapsulates the business rules that govern a given type of cut event. Open **Admin > Credit & Collection > Cut Event Type > Add** to set up cut event types.

Note:

Recommendation. Before using this transaction, we strongly recommend that you review [Cut Events Are Like Overdue Events](#).

Description of Page

Enter a unique **Cut Event Type** code and **Description** for the cut event type.

Use **Long Description** to provide a more detailed explanation of the purpose of the cut event type.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|------------------|---------------------|--|
| Cancel Logic | Required | This algorithm is executed to cancel a cut event. Refer to How Are Events Canceled for the details. |
| Event Activation | Required | This algorithm is executed to activate a cut event on its trigger date. How and When Events Are Activated for the details. |

| | | |
|------------------------|---|--|
| Event Information | Optional - only used if you want to override a cut event's info string | This algorithm is executed to construct a cut event's override info string. Refer to Cut Event Information Is Overridable for the details. |
| Monitor Waiting Events | Optional - only used if events of this type can enter the Waiting state | This algorithm is invoked by the Cut / Cut Event Manager for events in the Waiting state. Refer to Some Events Wait For Something Before Completing for the details. |

Setting Up Cut Process Templates

A cut process template encapsulates the business rules that govern a given type of cut process. Open **Admin > Credit & Collection > Cut Process Template > Add** to set up cut process templates.

Note:

Recommendation. Before using this transaction, we strongly recommend that you review [The Big Picture Of Cut Processes](#).

Description of Page

Enter a unique **Cut Process Template** and **Description** for the cut process template.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|-------------------------|--|--|
| Cancel Logic | Required | This algorithm is executed to cancel a cut process. Refer to How Are Cut Processes Cancelled for the details. |
| Cut Process Information | Optional - only used if you want to override a cut process's info string | This algorithm is executed to construct a cut process's override info string. Refer to Cut Process Information Is Overridable for the details. |

The **Event Types** control the number and type of events linked to a cut process when it is first created. The information in the scroll defines these events and the date on which they will be triggered. The following fields are required for each event type:

- **Event Sequence.** Sequence controls the order in which the cut event types appear in the scroll.
- **Cut Event Type.** Specify the type of cut event to be created.
- **Days After.** If **Dependent on Other Events** is on, events will be triggered this many days after the completion of the dependent events (specified in the grid). Set this value to 0 (zero) if you want the event triggered immediately

after the completion of the dependent events. If **Dependent on Other Events** is off, events will be triggered this many days after the creation of the cut process. Refer to [How and When Events Are Activated](#) for the details.

- If **Dependent on Other Events** is on, define the events that must be completed or cancelled before the event will be triggered.
 - **Sequence** is system-assigned and cannot be specified or changed.
 - **Dependent on Sequence** is the sequence of the dependent event.

Setting Up Collection Class Overdue Rules

Collection class overdue rules contain algorithms that impact accounts associated with a given collection class, division and currency code are managed. Open **Admin > Credit & Collection > Collection Class Overdue Rules > Add** to set up collection class overdue rules.

Note:

Recommendation. Before using this transaction, we strongly recommend that you review [Different Overdue Rules For Different Customers](#).

Description of Page

Enter the **Collection Class**, **CIS Division** and **Currency Code** to which the rules apply.

The **Algorithms** grid contains algorithms that control important functions. You must define the following for each algorithm:

- Specify the algorithm's **System Event** (see the following table for a description of all possible events).
- Specify the **Algorithm** to be executed when the System Event executes. Set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

| System Event | Optional / Required | Description |
|--------------------------------|--|--|
| Bill-Based Payment Arrangement | Optional - only specified if your implementation uses bill-oriented payment arrangements | This algorithm is executed to handle the creation, breaking and canceling of a Bill-Oriented Payment Arrangements . |
| Overdue Monitor Rule | Required | This algorithm is invoked by the Overdue Monitor to analyze an account's debt. Refer to How Does The Overdue Monitor Work for the details. If you have multiple rules (and therefore multiple algorithms), please take care when assigning the sequence number, as the Overdue Monitor will invoke these rules in sequence order. |
| Write Off Bill | Option - only specified if your implementation writes-off bills | This algorithm is executed to handle the write-off and write-off reversal of a bill. Refer to Writing Off Bills . |

Setting Up Overdue Event Cancellation Reasons

An overdue event cancel reason must be supplied before an overdue event can be canceled. Open **Admin > Credit & Collection > Overdue Event Cancel Reason** to define overdue event cancellation reasons.

Description of Page

Enter an easily recognizable **Overdue Event Cancel Reason** and **Description** for each cancellation reason.

Setting Up Cut Event Cancellation Reasons

A cut event cancel reason must be supplied before a cut event can be canceled. Open **Admin > Credit & Collection > Cut Event Cancel Reason** to define cut event cancellation reasons.

Description of Page

Enter an easily recognizable **Cut Event Cancel Reason** and **Description** for each cancellation reason.

Defining Interval Billing Options

Note:

The transactions described in this section are only available if the interval billing module is turned on. This Customer Care and Billing functionality has essentially been deprecated and should be performed within a Meter Data Management system. This functional area remains within Customer Care and Billing exclusively for upgrading customers who currently use Interval Billing within an earlier version of this system.

Note:

The interval rating and billing functionality described in this chapter was designed and developed prior to the big data requirements of the smart grid. Implementations should use a meter data management application, such as Oracle Utilities Meter Data Management, for smart grid requirements.

The system provides capability to bill complex customers who measure usage in small intervals, such as one hour, thirty minutes, fifteen minutes, etc. The "Interval Billing" subsystem covers a variety of functionality including:

- Capturing billable interval data quantities linked to a service agreement
- Capturing "raw" interval data quantities linked to service points, which may be later aggregated to create billable quantities for the service agreement
- Application of contract-based modifications to produce interval data quantities
- Apply interval prices to interval quantities. (Sometimes this is known as "direct billing")
- Support time of use mapping, including override maps created for certain special periods, such as interruptions
- Support time of use pricing and time of use contract values
- Support special contract options under which certain calculations supporting a contract's rate may be overridden or altered occasionally for specific periods of time

Note:

The ability to capture and maintain interval prices and TOU prices is officially part of the Rates subsystem. Although we will refer to them here, the main documentation is in the Rates administration guide.

Warning:

Setting up the interval billing control tables is as challenging as your organization's interval billing rules. If you have simple rules then your setup process will be straightforward. If your interval billing rules are complicated (e.g., specific prices for each customer, complicated TOU Mapping rules etc.), then your setup process will be more challenging.

Note:

Separate modules. Interval billing functionality is associated with separate modules, Complex Billing and Meter Data Management. If these modules are not applicable to your business you may turn them off. Refer to [Turn Off A Function Module](#) for more information.

Interval Billing Table Setup Sequence

The following table defines the table setup sequence required if your company has purchased the interval billing component.

| Function | Path |
|------------------------------------|---|
| General Environment | |
| Seasonal Time Shift | Admin, Seasonal Time Shift |
| Time Zone | Admin, Time Zone |
| Installation - Framework | Admin, Installation Options - Framework Indicate whether Seasonal Time Shift is required. |
| Installation | Admin, Installation Options Set Base Time and Start Day Option. |
| Interval Billing Environment | |
| Bill Factor | Menu, Rates, Bill Factor Note: earlier, you may have created bill factors for your general Rates environment. At this point, you may need to add more bill factors to satisfy your interval billing needs. |
| Interval Profile Relationship Type | Admin, Interval Profile Relationship Type [Note - you won't be able to define the collection of valid Interval Profile Types until after you define the Interval Profile Types.] |
| Interval Profile Type | Admin, Interval Profile Type [Note - you may need to define new algorithm types and algorithms if your interval profile type requires creation or validation algorithms.] |
| Algorithm | Admin, Algorithm. You will need to set up the creation and validation algorithms needed for an Interval Profile Type. |
| Shared Profiles | Menu, Interval Billing, Interval Profile Note: this is needed at this time if you want to create Start Options, which reference shared profiles. |
| Interval Registers | |
| Interval Register Type | Admin, Interval Register Type |

| | |
|---------------------------|--|
| Meter Configuration Type | Admin, Meter Configuration Type Note: earlier, you may have created meter configuration types for your general meter environment. At this point, you may need to add more meter configuration types for registers, which are used for interval or index channels. |
| Meter Type | Admin, Meter Type Note: earlier, you may have created meter types for your general meter environment. At this point, you may need to add more meter types for meters, which are used for interval or index channels. |
| Time of Use Billing | |
| Time of Use | Admin, Time of Use Note: earlier, you may have created time of use codes for your meter environment. At this point, you may need to add more time of use codes to satisfy your time of use mapping. |
| TOU Group | Admin, TOU Group |
| Bill Factor | Menu, Rates, Bill Factor At this point you may need to set up bill factors that are specifically for time of use pricing. |
| TOU Map Relationship Type | Admin, TOU Map Relationship Type [Note - you won't be able to define the collection of valid TOU Map Types until after you define the TOU Map Types.] |
| TOU Map Type | Admin, TOU Map Type |
| Algorithm | Admin, Algorithm. You will need to set up any creation algorithms needed for your TOU map types. |
| TOU Map Templates | Admin, TOU Map Template Note: this is not required, but will help to set up data for your TOU Maps. |
| Shared TOU Maps | Menu, Interval Billing, TOU Map Note: this is needed at this time if you want to create Start Options, which reference shared TOU maps. |
| Contract Options | |
| Contract Option Type | Admin, Contract Option Type |
| Algorithm | Admin, Algorithm. You will need to set up any validation algorithms needed for your contract option types. |

| | |
|--------------------------------------|---|
| Contract Option Event Type | Admin, Contract Option Event Type |
| SA Interval Billing Rate Environment | |
| Rate | At this point, you are ready to set up your interval billing and time of use rates and calculation rules. Refer to the Rate Environment section in the Control Table Setup Sequence . |
| SA Interval Billing Controls | |
| SA Type | Admin, SA Type Note: earlier you may have created your SA Types. At this point you may need to modify interval related SA Types to add valid interval information. Refer to the SA Type section in the Control Table Setup Sequence . |
| Start Option | Admin, SA Type Start Option Note: earlier you may have created your SA Type Start Options. At this point you may need to modify interval related SA Type Start Options to add valid interval information. Refer to the SA Type section in the Control Table Setup Sequence . |

**Note:**

You may have customers with interval billing, time of use billing and contract options all required for their rate. For simplification of the table, these control tables were listed in separate sections.

The Big Picture of Interval Billing

This section provides an overview of important Interval Billing concepts with which you should be familiar before you set up your Interval Billing control tables.

Interval Pricing

This section provides an overview of concepts related to setting up interval pricing options for your rates. Applying interval prices to interval quantities is sometimes referred to as 'direct billing'.

Interval Pricing Rate Application

Interval Pricing is the term used to describe applying interval prices to interval quantities to arrive at a bill calculation line item.

What data is needed in order to apply a rate component for an interval pricing scenario and how is this data defined?

- You need prices that vary at a given interval. Interval prices are stored for a **Bill Factor**/characteristic. Refer to [Bill Factor Interval Values](#) for more information.
- You need consumption values for each corresponding interval. The consumption values are stored for an Interval Profile linked to a service agreement. Refer to [Billable Interval Quantities for a Service Agreement](#) for more information. In order to find the correct interval profile for the service agreement, the rate component will reference a **Profile Relationship Type**. Refer to [Physical Attributes of Interval Data vs. Its Role](#) and [Interval Data Serves a Role for a Service Agreement](#) for more information.
- You need an algorithm in order to know how to apply the prices correctly. The rate component will reference a **Calculation Algorithm**, which will be executed to apply the prices to the quantities.

Refer to [Designing Your Interval Rate Components](#) for help in designing rate components of this type. Refer to [Setting Up Interval Pricing Rate Components](#) for more information.

Physical Attributes of Interval Data vs. Its Role

You will see, as you learn more about the design of interval billing, that there are two control tables that are important for defining billable interval data:

- Profile Type - this defines the physical attributes of the interval data
- Profile Relationship Type - this defines the role that the interval data is playing for a particular contract. You can also think of this as defining the business purpose of the data.

Interval Data Physical Attributes

When defining a collection of billable data, there are basic attributes, which need to be defined:

- Unit of Measure
- Minutes per Interval
- Service Quantity Identifier
- Is this data owned by a service agreement or is it common data?

These are physical attributes of the data and have nothing to do with the business purpose of the data. This information is defined on the Profile Type.

The profile type may also include algorithms related to its data:

- Validation algorithms may be used to check and correct various conditions related to the interval data. Refer to [Validation of Profile Data](#) for more information.
- A creation algorithm may be used to derive data for a profile. Refer to [Creation of Profile Data through Data Derivation](#) for more information.

Refer to [Designing Interval Profile Types](#) for more information.

You will see later that classic TOU Maps also have a classic TOU Map Type. Refer to [Physical Attributes of a classic TOU Map](#) for more information.

Business Role of Interval Data

The Profile Relationship Type is used by the system to indicate the "role" that a collection of billable interval data is playing. The following are some examples of roles that interval data may play:

- Measured Demand
- Contract Demand
- Aggregated Heating Demand
- Hedge Cover
- Excess Demand
- Reactive Energy

The profile relationship type is used by the rate component to indicate the data being billed. For example, the rate is billing "excess demand". When applying the rate, the system will determine which data is playing the role of "excess demand" for the service agreement. Refer to [Billable Interval Quantities for a Service Agreement](#) and [Interval Data Serves a Role for a Service Agreement](#) for more information.

You will see later that classic TOU Maps also have a "role". Refer to [Business Role of a TOU Map](#) for more information.

The Business Role Defines Interval Data Physical Attributes

To enable proper setup, you will need to define the valid [profile types](#) for each profile relationship type.

Raw Data Collection and Aggregation

This section provides an overview of concepts related to setting up your control tables to support the capturing of raw interval data.

Fastpath:

Refer to [The Big Picture of Raw Data Collection and Aggregation](#) for more information.

Note:

If your company uses an external system for collecting, adjusting and aggregating raw interval data, then you may skip this section.

Physical Attributes of Raw Interval Data

Raw interval data is available for use by algorithms in the system to create billable data for the service agreement. This data will not have any 'business' role, as with the billable interval data, described above.

As a result only 'physical' attributes of the raw interval data need to be defined, such as:

- Unit of Measure
- Minutes per Interval
- Service Quantity Identifier

This information is defined on the Interval Register Type.

The [interval register type](#) may also include algorithms related to its data:

- Validation algorithms may be used to check and correct various conditions related to the interval data. Refer to [Validation of Register Data](#) for more information.

Time of Use Billing

This section provides an overview of concepts related to setting up your control tables to support time of use billing.

Defining Time of Use Periods

Many customers choose not to price their interval data using interval prices. Time of Use Mapping enables a customer to map out time of use periods for their usage. This option for interval data might be preferred because:

- Typically it involves fixed prices for the use periods
- It is more manageable than direct billing
- It is easier for a customer to forecast and budget

A classic TOU Map holds the collection of time period definitions. The TOU Map has a TOU Map Type, which defines the minutes per interval. This is similar to the interval profile and profile type.

The time period definitions for a classic TOU Map indicate the TOU code for a given date and time.

| Map #123 (TOU Group 2) | |
|------------------------|-----------------|
| Effective 1 Jan 2000 | |
| Interval Date/Time | |
| 30/Apr/00 16:30 | On Peak/Winter |
| 30/Apr/00 16:45 | On Peak/Winter |
| 30/Apr/00 17:00 | Off Peak/Winter |
| 30/Apr/00 17:15 | Off Peak/Winter |
| --- | |
| 01/May/00 7:45 | Off Peak/Summer |
| 02/May/00 8:00 | On Peak/Summer |
| 02/May/00 8:15 | On Peak/Summer |
| --- | |

All the possible time of use codes for a given map are grouped together in a TOU group. Refer to [Grouping of TOU Codes](#) for more information.

Grouping of TOU Codes

Overview

The time of use map's purpose is to define time of use codes for given time periods. For example:

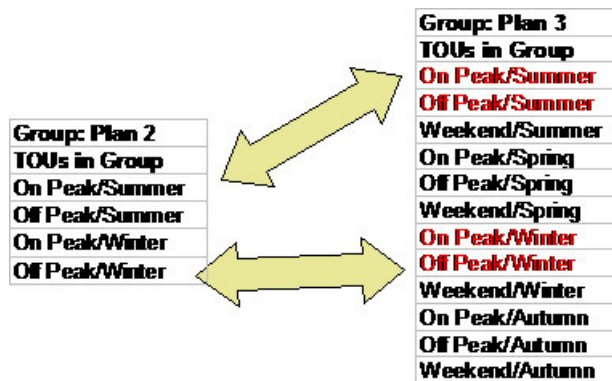

1/Jan/2001 05:00:000 is Off Peak, Winter

1/July/2001 13:00:000 is Weekend, Summer

5/July/2001 12:30:000 is On Peak, Summer

The time of use codes of "Off Peak, Winter" and "Weekend, Summer" are user-defined and use the same [TOU code](#) available for defining TOU for simple metering.

The set of time of use codes that make up a certain classic TOU map, are grouped together using the TOU group. The TOU group is a logical grouping of time of use codes. A TOU can exist on more than one TOU group.

The TOU group is used to define the collection of time of use codes available for a classic TOU map. In addition, you will see TOU group used in other areas of interval billing where a collection of time of use codes is required.

TOU Sequence

If desired, you may use sequence number to indicate the relative position or relative priority of each TOU code within a TOU group. This sequence number is not used by any system functionality, but is available for you to use in a plug-in algorithm.

For example, assume that your customer's contract states that if the usage for the time period "ON" is below a certain contract limit, they will be charged the "ON" price. However, if the usage exceeds this contract limit, they will be charged a higher price for this usage. Let's assume the same is true for "OFF". You may choose to implement this as follows:

- Besides TOU codes of "ON" and "OFF", create additional TOU codes called "ONEXCESS" and "OFFEXCESS"
- Define the TOU codes within the TOU group with sequences values as follows:

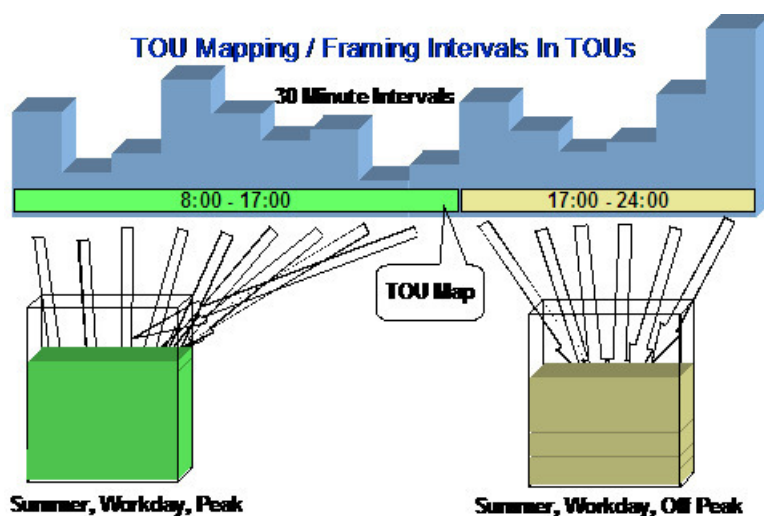

| Time of Use | TOU Sequence |
|-------------|--------------|
| ON | 1 |
| ONEXCESS | 2 |
| OFF | 3 |
| OFFEXCESS | 4 |

- Your classic TOU map will only define time periods for ON and OFF, but you will have TOU prices for all four time of use values.
- Design your TOU pricing algorithm so that if the usage for a given TOU is within the contract limit, the price for this TOU is used. However, if the usage exceeds the contract limit, then it will find the TOU with the next highest sequence and use the price for that TOU.

Time of Use Mapping and Pricing

The following section describes the logic used by the system to map interval quantities to time of use codes using a TOU map, and subsequently apply prices to these mapped quantities.

At some point during billing, the system will take interval quantities linked to the service agreement and map them to time of use quantities based on a TOU Map.

For simple billing, this type of data manipulation is typically handled using an SQ rule. Keep in mind that SQ Rules are processed before applying the rate components and therefore they do not have knowledge of system breaks that may cause price proration.

Proration occurs when a given price covers a period smaller than the billing period AND the system does not have readings for the period covered by the price. When this occurs, the system will prorate the usage to apply the correct price. Refer to [Effective Dates & Price Proration](#) for more information about proration.

If you read carefully the price proration information, you'll see that if the service quantities are peak quantities, the quantities are not prorated but the charges are prorated. For other cases, the system prorates the service quantities.

When your interval quantities are peak quantities, the same should apply. The mapping should occur prior to price breaks, for example, using an SQ rule. Then, the TOU pricing rate components would apply prices to the mapped SQ quantities.

For non-peak interval quantities, readings exist for any price break situation. As a result, no service quantity proration is necessary. The mapping simply needs to occur after all price breaks are determined - at the rate component level.

TOU Pricing Rate Component

A special rate component exists to perform time of use mapping and time of use pricing. In fact, this rate component uses a calculation algorithm, so the algorithm can be written to perform whatever logic you need it to perform. The system is shipped with an algorithm, which performs mapping only and another algorithm, which may perform mapping and pricing, or just pricing.

- The mapping algorithms populate the read details collection by default because this collection can contain the quantities for each UOM/TOU/SQI along with a date range (This is important for [price breaks](#).) In addition, you may configure the algorithm to also produce SQ quantities, which would represent the total quantities for each UOM/TOU/SQI.
- The pricing algorithm may be configured to apply prices to the SQ collection (for measures peak scenarios) or the read details collection (for non-measures peak scenarios).

Refer to [Designing Your Time of Use Rate Components](#) for help in designing rate components of this type. Refer to [Setting Up TOU Pricing Rate Components](#) for more information about setting up this type of rate component.

The TOU pricing rate component may reference a [TOU bill factor](#), which contains prices that differ for each time of use code or a regular bill factor, which contains a single price to apply to all mapped quantities.

Classic TOU Map Used For Mapping & Pricing

The classic TOU map used by the rate component for mapping is defined either directly on the rate component or it is linked to the service agreement.

- If ALL service agreements linked to the rate component's rate should use the same classic TOU map, then link the classic TOU Map to the rate component
- If some service agreements use different TOU maps than others, the TOU map must be linked to the service agreement. In this case, you must indicate a TOU Map Relationship Type on the rate component. The TOU map relationship type defines the [business role of TOU map](#).

Refer to [Sharing TOU Map Data](#) for more information.

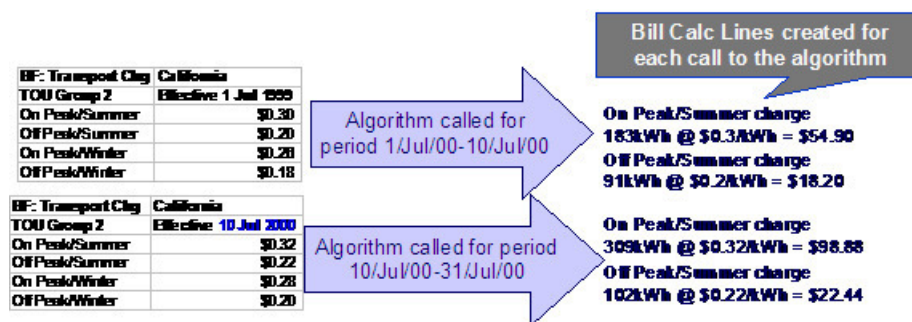

TOU Price Breaks

This section describes functionality related to price changes for time of use bill factor values. This logic is only applicable when the interval quantities do not measure peak quantities.

- [Algorithms are Called for Each TOU Price Break](#)
- [Algorithms Are Responsible for Storing Calculation Details](#)

Algorithms are Called for Each TOU Price Break

Rate application logic understands how to determine price breaks for the bill factor referenced on your rate component and calls the calculation algorithm for each price break. The TOU pricing algorithm will be passed the appropriate date/time range to handle mapping and pricing and will produce separated bill calculation lines for each time period.

Note:

Single TOU Group. If your rate component references a TOU bill factor, the price breaks for the bill factor are determined using a single TOU group. If multiple classic TOU maps are applicable for the billing period and each refers to a different TOU group (via its [TOU map type](#)), the system uses the SA type's rate selection date to select the appropriate TOU group to use to determine the collection of prices to apply.

[Top of Page](#)

Algorithms Are Responsible for Storing Calculation Details

When the TOU mapping algorithms calculate the mapped quantities for a given date/time range, the results are stored in the [calculation/audit read details](#) collection on the bill segment. This collection enables the system to record the mapped quantities along with period represented by each quantity.

Your algorithms may opt to additionally capture the total quantity for each time of use in the SQ Details collection as an audit.

Read Details

| | | |
|--------|---------------------|--------|
| OnSum | 01/Jul/00-10/Jul/00 | 183kWh |
| OffSum | 01/Jul/00-10/Jul/00 | 91kWh |
| OnSum | 10/Jul/00-31/Jul/00 | 309kWh |
| OffSum | 10/Jul/00-31/Jul/00 | 102kWh |

Algorithms use the read detail collection to store interim UOM/TOU/SQI details with date and time

SQ Details

| | |
|--------|--------|
| OnSum | 492kWh |
| OffSum | 193kWh |

The base algorithms also provide the option of populating the SQ collection with the total quantity for each UOM/TOU/SQI

Note:

Bill Factor prices have effective dates only. There is no effective time. When a price break occurs, the algorithm will determine the time for the price breaks in the same manner that billing time is determined. Refer to [Start and End Times for Billing](#) for more information.

The system provides one sample algorithm RCTMS that performs TOU mapping and another algorithm RCTMPS that performs TOU mapping and pricing or pricing alone. These algorithms support TOU price break logic as follows:

- The mapping functions for both algorithms populate the calculation/audit read details collection and allow you to set a parameter to indicate whether SQ entries should also be created.
- Based on a parameter, the pricing portion of RCTMPS applies the appropriate TOU prices to the mapped quantities stored in the calculation/audit read details collection.

If RCTMPS has been configured to perform mapping and pricing, it will perform the two functions as separate steps: first it maps the quantities and populates the read details, then it applies TOU prices to the read details. It does this for the following reasons:

- You may have a rate that requires manipulation of mapped quantities prior to applying prices. For example, perhaps you must add service quantities from a non-interval meter to your mapped quantities prior to applying prices.
- You may need to [override the mapped quantities](#) when recalculating a bill. The base algorithms will not re-map the quantities if the details were overridden. The pricing portion applies the prices to the overridden quantities.

Overriding Mapped Quantities

The mapping algorithms provided with the base product record the mapped quantities in the [calculation/audit read details](#) collection on the bill segment. When regenerating a bill segment, it is possible that circumstance requires you to override the details in this collection rather than allowing the system to map the interval quantities again.

Refer to [How To Override Service Quantities On A Specific Bill Segment](#) for more information.

The pricing functionality in the algorithms provided by the base product detect when mapped quantities have been overridden and apply the TOU prices to the overridden quantities.

Physical Attributes of TOU Map vs. Its Role

You will see, as you learn more about the design of TOU mapping, that there are two control tables that are important for defining TOU maps:

- TOU Map Type - this defines the physical attributes of the TOU Map
- TOU Map Relationship Type - this is needed for TOU maps that are linked to a service agreement. It defines the role that the TOU Map is playing for that service agreement. You can also think of this as defining the business purpose of the data.

Physical Attributes of a Classic TOU Map

When defining a classic TOU map, there are basic attributes, which need to be defined:

- The collection of possible time of use codes to which the data will be mapped. These are grouped together into a [TOU group](#).
- Minutes per Interval
- Is this data owned by a service agreement or is it common data?

These are physical attributes of the data and have nothing to do with the business purpose of the data. This information is defined on the classic TOU Map Type.

The [classic TOU map type](#) may also include an algorithm used to [automatically create data for the classic TOU map](#).

This is the same model used for interval profile data. Refer to [Physical Attributes of Interval Data](#) for more information.

Business Role of a Classic TOU Map

The TOU Map Relationship Type is used for TOU maps that are linked to the service agreement. It indicates the "role" that a classic TOU Map is playing for a particular service agreement. The following are some examples of roles that a classic TOU Map may play:

- Map for Measured Demand
- Map for Contract Demand
- Map for Excess Demand
- Map for Reactive Energy

If your rate component requires a classic TOU map but the TOU map is not common to all service agreements for the rate, then the rate component must indicate a TOU Map Relationship Type. The rate component algorithm uses this information to find the appropriate classic TOU map linked to the service agreement. Refer to [Classic TOU Maps Serve a Role for a Service Agreement](#) for more information.

This is the same model used for interval profile data. Refer to [Business Role of Interval Data](#) for more information.

The Business Role Defines Valid Physical Attributes for a Classic TOU Map

To enable proper setup, you will need to define the valid [classic TOU map types](#) for each TOU map relationship type.

Fastpath:

For more information about defining classic TOU maps and recording the time period data, refer to [Time of Use Mapping Background Topics](#).

Designing Interval Billing Options

Your interval billing options control how interval data may be maintained and billed for your customers with this capability.

Fastpath:

For more information about interval billing, see [The Big Picture Of Interval Billing](#).

Warning:

There are many ways to design your interval billing options. The flexibility of the system may add to the challenge of determining the best way to set up your control tables. In this section, we provide information to help you understand the ramifications of the various options. Before you set up your production data, we encourage you to gain an intuitive understanding of these options by using the system to prototype the alternatives.

The design of your interval billing options is an iterative process. Over time, you will develop intuitive skills that will allow you to skip some iterations. We recommend using the various steps in this section as a guide. When you are finished with this guide, you will be able to set up your interval billing options.

Designing Your Interval Billing Rate Options

This section assumes that you are familiar with the Rates subsystem and especially with the section [Understanding Calculation Groups and Rules](#). Your interval billing rate components will likely contain a combination of standard rate components and interval billing rate components. The focus in this section will be on designing rate components for interval billing and time of use mapping.

Designing Your Interval Rate Components

Although your rates will likely contain a combination of interval pricing and time of use pricing, we have separated these topics with respect to walking you through the control table setup.

To set up the rate components that support interval billing, we recommend using the following table as your guide.

| RC Type | Bill Factor | Interval Profile Relationship Type | Algorithm | TOU Map Relationship Type |
|---------|-------------|------------------------------------|-----------|---------------------------|
|---------|-------------|------------------------------------|-----------|---------------------------|

Obtain copies of existing bills that use the rate in question. If the rate is new, then write up EXACTLY how the information should appear on the customers' printed bills.

- Next, try to identify the components of the bill that are related to interval billing.
 - Are any of the lines produced as a result of direct billing? In other words, were interval prices applied to interval quantities?
 - Are any of the lines produced using interval quantities applied to a fixed price?

Start filling out the table with descriptions of what is needed to produce each line.

- Any line that is produced as a result of taking interval quantities and applying prices will be defined with the "Interval Pricing" rate component type.
 - This rate component type will require an Interval Profile Relationship Type (which is used to define the source data to price).
 - A bill factor will need to be defined. This bill factor may contain interval quantities or simple values.
 - An algorithm, which knows how to apply the prices to the quantities, is needed. The system provides the following rate component algorithms as examples.
- Rate Components related to time of use mapping and pricing are discussed below. Refer to [Designing Your Time Of Use Rate Components](#).

| RC Type | Bill Factor | Interval Profile Relationship Type | Algorithm | TOU Map Relationship Type |
|------------------|--------------------|------------------------------------|--|---------------------------|
| Interval Pricing | Strike Price | Hedge Cover | Apply prices to quantities assuming a continuous curve | N/a |
| Interval Pricing | Spot Market Prices | Amount in Excess of Hedge Cover | Apply prices only to positive quantities assuming a continuous curve | N/a |

Designing Your Billing Factors

To apply prices to interval quantities, bill factors are recommended. In fact, to be able to handle interval prices, you will need to use bill factors.

Fastpath:

To design and set up your bill factors, refer to [Setting Up Bill Factors](#) for more information.

Designing Your Interval Billing Controls

Designing Interval Profile Relationship Types

Recall that the interval profile relationship type can be thought of as the role that interval data will play. You can also think of it as the business description of the interval data.

The starting point for designing your interval profile relationship types is the rate. First, identify the relationship types that your rate needs in order to produce a bill

Using the above rate as an example, two profile relationship types have been identified

| Profile Relationship Type | Description |
|---------------------------|--------------------------|
| HEDGECOVER | Hedge cover |
| OVRHEDGE | Amount over hedge cover. |

Now, you must think about what other relationship types are required to produce the above relationship types needed by rates. In our above example, we will need to define a profile relationship type whose data is compared to the hedge cover data to produce the OVRHEDGE data. Let's assume that this new profile relationship type is related to measured demand.

| Profile Relationship Type | Description |
|---------------------------|--------------------------|
| HEDGECOVER | Hedge cover |
| OVRHEDGE | Amount over hedge cover. |
| MEASDMD | Measured Demand |

In this manner, you will be able to successfully define your profile relationship types.

Designing Interval Profile Types

Now that you have your profile relationship types defined, you need to begin defining profile types. The interval profile type defines the physical attributes of the interval data.

The essential attributes of any profile type are the UOM/SQI, the minutes per interval and the associated algorithms. The easiest way to start defining your interval profile types is to start with the profile relationship type and determine what type of data each customer may have for the same profile relationship type.

Let's start with our profile relationship types and make some assumptions regarding the physical attributes of the data that a customer may have for each of these roles:

- Let's assume that a customer's demand may be measured in either 30-minute intervals or 60-minute intervals. In either case, the UOM is kW and SQI is not applicable. Let's also assume that the measured data may be interfaced from an external source or may be aggregated from interval register data.
- Let's assume that the hedge cover is common, but that these values may also be in 30-minute intervals or 60-minute intervals.
- Finally, let's assume that our spot market prices are at 60-minute intervals and that the algorithm, which rates uses to apply the interval prices, expects the "amount in excess of the hedge cover" to be in 60-minute intervals. This means that we need two different algorithms for our OVRHEDGE data. One algorithm is used for a customer with 60-minute intervals and simply subtracts the two curves and produces the resulting data. The second algorithm is used for a customer with 30-minute intervals. It performs two steps. It subtracts the hedge from the measured demand and adds together each resulting 30-minute pair to produce a 60-minute OVRHEDGE curve.

We will assume that all of our profile data will follow the same seasonal time shift as our base time zone. Refer to [Time Zone and Time Changes](#) and [Designing Your Time Options](#) for more information.

| Prof. Rel. Type | Profile Type | Common/SA Owned | UOM/ SQI | Min/ Interval | Seasonal Time Shift | Algorithm |
|-----------------|--------------|-----------------|----------|---------------|---------------------|--|
| MEASDMD | DMDKW60 | SA Owned | KW | 60 | USShift | N/a |
| | DMDKW30 | SA Owned | KW | 30 | USShift | N/a |
| | DMDKW60AG | SA Owned | KW | 60 | USShift | Aggregate interval register data |
| | DMDKW30AG | SA Owned | KW | 30 | USShift | Aggregate interval register data |
| HEDGECVR | HEDGE60 | Common | KW/ HG | 60 | USShift | N/a |
| | HEDGE30 | Common | KW/ HG | 30 | USShift | N/a |
| OVRHEDGE | OVRHG60 | SA Owned | KW/ OVR | 60 | USShift | Compare MEASDMD to HEDGECVR to produce 60-minute over hedge curve |
| | OVRHG30 | SA Owned | KW/ OVR | 30 | USShift | Compare MEASDMD to HEDGECVR and add 30-min interval pairs to produce 60-min 'over-hedge' curve |

Note:

The above table accomplishes two steps: defining profile types and defining the valid profile types for a profile relationship type. When setting up this data, you will need to define your profile types first and then link them to the appropriate profile relationship type.

As with most of your control table design, this is an iterative process. As you design your profile types, you may see the need for new profile relationship types. You may find that a profile type will be valid for more than one profile relationship type.

Fastpath:

During your definition of the profile types, you may determine that new UOMs need to be defined. Refer to [Setting Up Unit Of Measure Codes](#) for more information.

During your definition of the profile types, you may determine that new pre-processing calculation groups that need to be defined. Refer to [Understanding Calculation Groups and Rules](#) for more information about defining SQI values.

Note:

Now that you have designed the control table values required to support your rate, we recommend that you set up [start options](#) for your SA types to assist a CSR in setting up a customer for this rate.

All of the above steps will need to be repeated for each interval billing rate that your company offers. For each rate, you need to define your rate components, your billing factors, your profile relationship types and then the appropriate profile types.

Designing Your Raw Data Options

Note:

If your company uses an external system for collecting, adjusting and aggregating raw interval data, then you may skip this section.

The term "Channel" is often used for devices that may store interval data. A physical channel may hold interval data or index readings.

- Interval channels will contain collections of interval data
- Index channels are a collection of time of use registers and readings for these registers are no different than standard register readings

In either case, a "channel" is represented in the system by a register and a meter will represent a logical grouping of channels (index or interval). Refer to [The Structure Of A Meter](#) for more information.

Designing Your Interval Register Types

Each register, which will record raw interval data will require an interval register type.

The essential attributes of an interval register type are the UOM/SQI, the minutes per interval and any validation algorithms.

- For our examples, let's assume that raw interval data may be measured in kilowatts or megawatts and may be measured in either 30-minute intervals or 60-minute intervals.
- For our examples, let's assume that the data may be standard recorded data or it may be calculated excess data. We will use an SQI to further label the excess demand.
- For each register type in our example, we will use a validation algorithm, which will verify that the intervals are correct according to the interval size on the interval register type.

We will assume that all of our raw interval data will follow the same seasonal time shift as our base time zone. Refer to [Time Zone and Time Changes](#) and [Designing Your Time Options](#) for more information.

| Interval Register Type | UOM/ SQI | Min/ Interval | Seasonal Time Shift | Validation Algorithm |
|------------------------|-----------|---------------|---------------------|------------------------|
| KW60 | KW | 60 | USShift | Validate interval size |
| KW60EXC | KW/EXCESS | 60 | USShift | Validate interval size |
| KW30 | KW | 30 | USShift | Validate interval size |
| KW30EXC | KW/EXCESS | 30 | USShift | Validate interval size |
| MW60 | MW | 60 | USShift | Validate interval size |
| MW60EXC | MW/EXCESS | 60 | USShift | Validate interval size |
| MW30 | MW | 30 | USShift | Validate interval size |
| MW30EXC | MW/EXCESS | 30 | USShift | Validate interval size |

We expect that you will need more algorithms than we supply. Your algorithms will be based on any number of factors. Be aware that new algorithms may require programming. See [How To Add A New Algorithm](#) for more information.

Designing Your Raw Data TOU Groups

In addition to designing TOU groups to be used by time of use maps, you may also set up [TOU groups](#) to define a valid collection of time of use values for a given meter configuration.

Designing Your Meter Configuration Types

You must define a meter configuration type for each valid collection of interval and index registers. For meter configuration types with index registers, you may indicate a TOU group, which contains the valid collection of time of use codes for the registers. For each interval register, you must check the Interval switch and indicate the appropriate Interval Register Type. A meter configuration may contain

- A single interval register
- Multiple interval registers
- A collection of index registers
- A combination of interval registers and index registers

Refer to [Setting Up Meter Configuration Types](#) for more information.

Designing Your Meter Types

You will need to set up appropriate [meter type codes](#) for the meters, which will be used to define or group index and interval channels. You must turn on the **Allow Interval Registers** switch for any meter type used by a meter, which will contain interval registers. Indicate the valid meter configuration types for this meter type.

Note:

If a meter type will only be used for meters linked to index channels, nothing special is required. Their behavior is similar to standard non-interval meters.

Designing Your Time of Use Options

Designing Your Time Of Use Rate Components

As you know from the rates chapter, the system can handle billing of quantities with different time of use periods using the SQ calculation rule type. Refer to [How To Set Up Service Quantity Calculation Rule](#) for more information. A more sophisticated rate component type is available, which can map interval profile data into time of use definitions and then apply prices based on time of use to produce multiple bill lines.

Obtain copies of existing bills that use the rate in question. If the rate is new, then write up EXACTLY how the information should appear on the customers' printed bills.

- Identify all the lines that represent charges for individual time of use periods.
- Determine how the quantities for the time of use periods are calculated. For example, what is the source data? Which time of use map is used to define the time periods? A TOU Pricing rate component type may be used to map each curve to its time of use quantities, apply time of use prices to mapped quantities or do both mapping and pricing. It all depends on how your algorithm is written.
 - In order to perform mapping, this rate component type needs to know where to get the interval data. You must indicate an Interval Profile Relationship Type (which is used to define the source data to map). Refer to [Billable Interval Quantities for a Service Agreement](#) for more information.
 - In order to perform mapping or pricing, this rate component type needs to know the classic TOU map. If the TOU map is common to ALL service agreements for the rate, you must indicate the appropriate TOU map. If the TOU map differs for different service agreements, you must indicate a TOU Map Relationship Type. The algorithms use this to find the appropriate [classic TOU map linked to the service agreement](#).
 - In order to perform pricing, this rate component type requires either a regular [bill factor](#) or a [TOU bill factor](#). The bill factor may contain the collection of prices directly, or may indicate that the prices are customer specific and can be found as contract quantities for the service agreement.
 - A calculation algorithm to map and / or price the quantities is needed. For mapping, this algorithm must apply the classic TOU map to the quantity curve and produce entries in the [calculation/audit read details](#) collection. For pricing, the algorithm will need to use the appropriate bill factor to apply prices to the quantities in the read details collection. If this bill factor is a TOU bill factor, a separate price exists for each time of use.

For our example, let's assume that curves exist for both active demand and reactive demand and assume each curve is mapped with a different classic TOU map. In addition, let's assume that excess demand used during a specific curtailment period will be priced at a different rate.

- For active demand, we have four time periods: on-peak winter, off-peak winter, on-peak summer and off-peak summer.
- For reactive demand, there are no charges in the winter so we have only two time periods: on-peak summer, off-peak summer. This classic TOU map is common to ALL service agreements for the rate.
- The curtailment charge will only appear if there is a curtailment event and the customer used more than their maximum demand defined for the period.

| RC Type | UOM/TOU | Bill Factor | Interval Profile Relationship Type | Algorithm | TOU Map Relationship Type | TOU Map ID |
|-------------|---------|-------------|------------------------------------|---|---------------------------|------------|
| TOU Pricing | N/a | DMDTOU | Active Demand | Map quantities to time of use periods; apply prices | Active Demand Map | |
| TOU Pricing | N/a | RCTVTOU | Reactive Demand | Map quantities to time of use periods; apply prices | | 13849374 |

| | | | | | |
|-------------|-----|---------|---------------------|--|--------------|
| TOU Pricing | N/a | CURTAIL | Curtailement charge | Map quantities to time of use periods, compare with maximum demand; apply prices to excess | Curtailement |
|-------------|-----|---------|---------------------|--|--------------|

Resulting bill calculation lines from the above TOU mappings (assuming this bill crosses the summer and winter seasons and a curtailment event occurred).

| |
|---|
| Charge for active kW On peak winter nn kW @ \$0.0353/kW: \$nn.nn |
| Charge for active kW Off peak winter nn kW @ \$0.0298/kW: \$nn.nn |
| Charge for active kW On peak summer nn kW @ \$0.0483/kW: \$nn.nn |
| Charge for active kW Off peak summer nn kW @ \$0.0327/kW: \$nn.nn |
| Charge for reactive kV On peak summer nn kV @ \$0.0293/Kv: \$nn.nn |
| Charge for reactive kV Off peak summer nn kV @ \$0.0231/Kv: \$nn.nn |
| Charge for curtailment excess nn kW @ \$0.0593/kW: \$nn.nn |

Once you have your rate components designed, you will be able to design the other control tables needed to set up your time of use billing customer.

Note:

Your time of use rate also requires interval profile relationship types. Refer to [Designing Interval Profile Relationship Types](#) and to [Designing Interval Profile Types](#).

Designing Your Time of Use Codes

The next most logical step in designing your time of use mapping controls is to define your time of use codes. To do this, look at the time of use periods to which your usage needs to be mapped. These values will likely correspond to the time of use quantities that your rate bills for. (Although it's possible that you are not billing for every time of use period.) Be sure to consider special time periods in your contracts such as holidays, curtailment days and interruption days.

Building on the above example, we have the following time of use codes defined:

| Time of Use | Description |
|-------------|---------------------|
| ONWIN | On Peak Winter |
| OFFWIN | Off Peak Winter |
| ONSUM | On Peak Summer |
| OFFSUM | Off Peak Summer |
| CURTAIL | Curtailement period |

For more information about time of use, refer to [UOM versus TOU versus SQL](#).

Designing Your TOU Groups

To further aid in designing time of use mapping, the TOU Group enables you to group together all the time of use codes that are used in a single map. In our above example, we will have two TOU Groups because the active and reactive energy quantities are mapped to different sets of time periods. You must also decide if you want to use a sequence number to define the relative order of a TOU within a TOU group.

Fastpath:

Refer to [Grouping of TOU Codes](#) for more information.

| TOU Group | Description | Time of Use | TOU Sequence |
|-----------|---|-------------|--------------|
| 4PARTS | Group for a 4-part map including On and Off Peak for Winter and Summer. | ONWIN | 0 |
| | | OFFWIN | 0 |
| | | ONSUM | 0 |
| | | OFFSUM | 0 |
| 2PARTS | Group for a 2-part map including On and Off Peak for Summer | ONSUM | 0 |
| | | OFFSUM | 0 |
| CURTAIL | Curtailment group, contains only one time of use | CURTAIL | 0 |

Designing Your Classic TOU Map Relationship Types

The starting point for designing your TOU map relationship types is the rate. First, identify the relationship types that your rate needs in order to successfully map quantities.

Using the above rate as an example, only two TOU map relationship types are required because the Reactive Demand map is linked directly to the rate component. However, let's add a relationship type for reactive demand also in case it is needed in the future.

| TOU Map Relationship Type | Description |
|---------------------------|-----------------|
| ACTVDMD | Active Demand |
| RACTVDMD | Reactive Demand |
| CURTAIL | Curtailment |

Now you must think of other types of maps that may need to be linked to the service agreement in order to successfully produce a bill. For example, are there any data derivation algorithms that require a classic TOU Map? If so, you need to define an appropriate classic TOU map relationship type to define the role for this map.

Designing Your Classic TOU Map Types

Now that you have your TOU map relationship types and your TOU groups defined, you can begin defining classic TOU map types. Recall that the classic TOU map type defines the physical attributes of the classic TOU map.

The essential attributes of any profile type are the TOU Group and the minutes per interval and the associated TOU map data creation algorithms.

The easiest way to start defining your classic TOU map types is to start with the classic TOU map relationship type and determine what type of classic TOU map each customer may have for the same TOU map relationship type.

Let's start with our TOU map relationship types and make some assumptions regarding the physical attributes of the data that a customer may have for each of these roles:

- For Active demand, the quantities may be recorded in 15-minute or 30-minute intervals. To facilitate efficiency in processing the data, we recommend that the TOU map data is stored in the same minutes per interval as the interval data being mapped. We'll assume that this is a common TOU map type.
- For Reactive demand, the quantities are recorded in 60-minute intervals. This is linked directly to the rate and is therefore a common TOU map type.
- For curtailment, we will assume that the override map will be in 15-minute, 30-minute or 60-minute intervals, based on the interval size of the actual demand data. In addition, we require a TOU map creation algorithm. This algorithm will produce a data for the curtailment TOU map based on the existence of a contract option event. It will generate the time of use data based on a [classic TOU map template](#). Refer to [Contract Option Background Topics](#) for more information. This will be an SA owned classic TOU map type.

Note:

We said above that we don't need a classic TOU map relationship type for Reactive Demand for our rate example. However, classic TOU map types must be defined. The table below includes the TOU map relationship type because we said we would add it just in case.

We will assume that all of our TOU data will not follow any seasonal time shifting. It will always be displayed in standard time. Refer to [Time Zone and Time Changes](#) and [Designing Your Time Options](#) for more information.

| TOU Map Rel. Type | TOU Map Type, Classic | Common/ SA Owned | TOU Group | Min/ Interval | Seasonal Time Shift | Creation Algorithm |
|-------------------|-----------------------|------------------|-----------|---------------|---------------------|--|
| ACTVDMD | 4PART15 | Common | 4PART | 15 | NoShift | N/a |
| | 4PART30 | Common | 4PART | 30 | NoShift | N/a |
| RACTVDMD | 2PART60 | Common | 2PART | 60 | NoShift | N/a |
| CURTAIL | CURT15 | SA Owned | CURTAIL | 15 | NoShift | Create based on events for 'curtail' contract option type. |
| | CURT30 | SA Owned | CURTAIL | 30 | NoShift | Create based on events for 'curtail' contract option type. |
| | CURT60 | SA Owned | CURTAIL | 60 | NoShift | Create based on events for 'curtail' contract option type. |

Now, you're ready to set up your interval billing options.

Note:

The above table accomplishes two steps: defining TOU map types and defining the valid classic TOU map types for a TOU map relationship type. When setting up this data, you will need to define your classic TOU map types first and then link them to the appropriate classic TOU map relationship type.

Designing Your Classic TOU Map Templates

In order to help your users to create and maintain data for classic TOU maps, you may define classic TOU map templates, which can be used to generate data for a classic TOU map. The templates may be used to define standard data for a TOU map as well as data for special periods, such as interruptions and holidays. The classic TOU map templates will reference a classic TOU map type. The system will use the TOU group and the minutes per interval from the map type to verify the setup of the template.

For our example, let us first design templates for the 15 minutes active demand TOU map type. Let's assume:

- On Peak for both winter and summer is from Monday to Friday, from 9am to 5pm, inclusive
- Off Peak for both winter and summer is all day Saturday and Sunday and from Monday through Friday, Off Peak is from 12AM to 8:45AM, inclusive and from 5:15pm to 11:45pm inclusive.

We'll worry about the season definitions for winter and summer later.

In addition, let's design the curtailment map template. Assume:

- Curtailment covers 9am to 5pm inclusive on the given curtailment day.

Designing Daily Templates

We need to define four daily templates: one for summer weekdays, one for summer weekend days, one for winter weekdays and one for winter weekend days.

Before defining the template, take note of some points about defining template components:

- For our winter weekday, we can define the off peak period with one entry covering 5:15pm through 8:45am using the Start and End Sequence Numbers to indicate that the end of the time period is on the second day.
- The classic TOU map generator will create intervals for the first period AFTER the start time up to and including the end time. As a result, our Start Time must be the interval before the first interval covered by the time of use code.

| TOU Map Template, Classic | TOU Map Type, Classic | Template Type | Start Seq | Start Time | End Seq | End Time | Time of Use |
|---------------------------|-----------------------|---------------|-----------|------------|---------|----------|-------------|
| 15MinWntrDay4PART15 | 15 | Daily | 1 | 8:45AM | 1 | 5PM | ONWIN |
| | | | 1 | 5PM | 2 | 8:45AM | OFFWIN |
| 15MinWntrWknd4PART15 | 15 | Daily | 1 | 12AM | 2 | 12AM | OFFWIN |
| 15MinSmrDay4PART15 | 15 | Daily | 1 | 8:45AM | 1 | 5PM | ONSUM |
| | | | 1 | 5PM | 2 | 8:45AM | OFFSUM |
| 15MinSmrWknd4PART15 | 15 | Daily | 1 | 12AM | 2 | 12AM | OFFSUM |
| 15MinCurtail CURT15 | CURT15 | Daily | 1 | 8:45AM | 1 | 5PM | CURTAIL |

Designing Weekly Templates

Now that we have our daily templates defined, we can define our weekly templates. For our example, we will need two weekly templates: one for a typical winter week and one for a typical summer week. For weekly templates, you must indicate the start day of the week.

We do not need a weekly template for the curtailment option.

| TOU Map Template, Classic | TOU Map Type, Classic | Template Type | Week Start | Start Seq | Start Day | Start Time | End Seq | End Day | End Time | Template |
|---------------------------|-----------------------|---------------|------------|-----------|-----------|------------|---------|---------|----------|---------------|
| 15MinWntr | OFFWIN | 15 Weekly | Mon | 1 | Mon | 12AM | 1 | Sat | 12AM | 15MinWntrDay |
| | | | | 1 | Sat | 12AM | 2 | Mon | 12AM | 15MinWntrWknd |
| 15MinSmr | OFFSUM | 15 Weekly | Mon | 1 | Mon | 12AM | 1 | Sat | 12AM | 15MinSmrDay |
| | | | | 1 | Sat | 12AM | 2 | Mon | 12AM | 15MinSmrWknd |

Finally, we need to decide if we want to create a Calendar template for our example. The decision of whether or not to create a calendar template will be based on a few factors:

- How many different seasons exist in the TOU map, where each season has different weekly templates?
- How do your holidays behave?

First, let's consider holiday behavior.

Designing Holiday Templates

When designing your classic TOU map templates, a special consideration should be made for holidays that occur throughout the year. Look at your classic TOU map contracts and ask the following questions:

- Are special prices applicable on holidays? Do these special prices require new time of use codes?
- If holidays do not get special prices, does the daily template look like the daily template for other days for this classic TOU map, for example like a weekend day?
- Do your holidays all have the same time period definitions as each other?

For our example, let's assume that our holidays use the Off Peak time of use for the season that it is in. In other words, winter holidays will use OFFWIN for every interval in that day and summer holidays will use OFFSUM for every interval in that day. As a result, we will not need to create a new template just for holidays. Instead, we can use the 15MinWntrWknd daily template for winter holidays and the 15MinSmrWknd daily template for summer holidays.

Designing Calendar Templates

The calendar template is used to define daily and weekly templates for month and day ranges. The map components may represent dates within a single year or may cross into the following year.

Remember that a main reason for creating templates is for use on the [TOU Map Generation](#) page to create data for a classic TOU map. On that page, you will specify the dates you want to generate data for. In addition you must keep in mind that you can specify one holiday template for the time period you are generating.

In our example, we have two seasons and our holiday template is different in each season. Creating a calendar template to define the seasons will not help us, because on the TOU map generation page, we wouldn't be able to indicate a single holiday template for the whole year. For our example, rather than creating a calendar template, we could simply go to the classic TOU map generation page and indicate:

- 1st Nov <year> through 30th April <year>, use the 15MinWntrWk template. For holiday overrides, use the 15MinWntrWknd daily template
- 1st May <year> through 31st October <year>, use the 15MinSmrWk template. For holiday overrides, use the 15MinSmrWknd daily template

In fact, in our example, even if our holiday template would not vary by season, one would have to weigh the advantage of creating a calendar template to define 2 seasons vs. running the TOU map generation twice. If you have a very small number of customers using the same templates, then a calendar template may not be worth creating. However, if you have many customers using the same template, it may be worth it.

Here is a possible guideline to follow for deciding whether or not to create calendar templates:

- If the same holiday template may be used for all holidays, and your customer's contracted time period definitions contain more than one season, then creating a calendar to define the seasons is recommended.
- If the holiday template changes throughout the year based on the season, then you must weigh the advantages of your possibilities:
 - You may just create weekly templates for each season and define the dates and the holiday template when using the classic TOU map generation page. This option is recommended when the templates apply to a very small number of classic TOU maps. The time taken to generate the data based on the weekly templates would be less than the time you would have spent on defining the calendar.
 - You may define your calendar to explicitly indicate your seasons and your holidays. Then when generating the data for this template, you would not indicate an override holiday template. This option is recommended when the template applies to a larger number of customers. The time taken to define the calendar would be less than that spent on generating multiple seasons for each TOU map.

Let's go ahead and design a calendar template using our weekly templates to understand the setup. For this purpose, let's assume our holiday template would be the same all year round.

Assume the seasons are defined as follows: Winter is 1st Nov. through 30th April, Summer is 1st May through 31st October. This template shows that the summer schedule includes the interval 12 AM on 01, November. This means that summer's last interval is the one that covers from 11:46 PM on the 31st of October through 12 AM on the 1st of November. The first interval in winter is 12:15 AM on the 1st of November, which covers the period from 12:01 AM through 12:15 AM. The similar setup is true for the end of winter / beginning of summer.

| TOU Map Template, Classic | TOU Map Type, Classic | Template Type | Start Seq | Start Date | Start Time | End Seq | End Date | End Time | Template |
|---------------------------|-----------------------|---------------|-----------|------------|------------|---------|----------|----------|-------------|
| 15MinClnd | 4PART15 | Calendar | 1 | 01May | 12AM | 1 | 01Nov | 12AM | 15MinSmrWk |
| | | | 1 | 01Nov | 12AM | 2 | 01May | 12AM | 15MinWntrWk |

Designing Your Contract Options

Designing Your Contract Option Types

Contract options are used for service agreements, which may be subject to special overrides or alterations in their rate for certain temporary periods. Contract options are used to define the possible special situations and to record the actual override events. Your contract option type is a high level categorization of the possible special situation applicable to a customer or group of customers.

To design your contract option types, you will need to review each rate for your interval customers and determine whether or not there are special options. Some examples of special options are:

- Interruptions. Perhaps you warn your customers of interruption periods and any usage incurred during that period will be subject to special prices.

- Curtailment. Perhaps you define periods where you ask a customer to shed their load below a certain subscribed demand and any demand, which exceeds this subscribed demand during that period, will be subject to a special charge.

Next, must determine whether or not a given option behaves differently under different circumstances. For example, perhaps you have different types of interruptions. If these different types of interruptions are applicable to the same customer, then you will require a single contract option type and multiple contract option event types for that option type. If these different types of interruptions are not applicable to the same customer, then you would probably want to define separate contract option type values.

You need to also consider whether or not contract option events for this type of contract option may overlap in their effective periods. If you do allow overlap, then you must be sure that any algorithm, which may process the contract option events, must know how to process the overlaps.

Your next step is to determine whether or not characteristic values will be needed for each contract option of this type. The characteristic values are available for use by the algorithms, when processing the contract options. For example, perhaps subscribed demand is defined at the contract option level. On the contract option type, you must define the possible characteristic types for contract options of this type. You may also define a default value, if applicable.

Finally, you will need to determine whether or not you wish to create validation algorithms to validate your contract option event data. Algorithms may be created to be executed upon add or change of the data, where the status is Pending, Frozen or Canceled.

For our purposes, let us assume that we have only two contract option types: Interruption and Curtailment. Neither one allows overlap. The Curtailment option type will define subscribed demand as a required characteristic and will define a validation algorithm to ensure that the value of the demand falls within an appropriate range. This algorithm program will be executed for pending and frozen events.

Note:

Because there are different algorithm entities, more than one algorithm type and algorithm are required, but both algorithm types may use the same program.

We will assume that both contract option types will follow the same seasonal time shift as our base time zone. Refer to [Time Zone and Time Changes](#) and [Designing Your Time Options](#) for more information.

| Contract Option Type | Descr | Allow Overlap | Seasonal Time Shift | Char Type | Algorithm |
|----------------------|---------------|---------------|---------------------|---------------------------------------|---|
| INTERRUPT | Interruptions | No | USShift | N/a | N/a |
| CURTAIL | Curtailments | No | USShift | SubscrDmd, required, no default value | <p>Pending: SbscrDmdPV (subscribed demand pending validation)</p> <p>Frozen: SbscrDmdFV (subscribed demand frozen validation)</p> <p>Canceled: n/a</p> |

Note:

Once you have the contract option types required to support your rate and derivation algorithms, we recommend that you set up Start Options for your SA Types to assist a CSR in setting up a customer for this rate. Refer to [Designing Your Start Options](#).

Designing Your Contract Option Event Types

When you designed your contract option types, you were already considering the possible contract option event types. You will need to define a different contract option event type for each different type of event that may occur for the same contract option type.

Your next step is to determine whether or not characteristic values will be needed for each contract option event of this type. The characteristic values are available for use by the algorithms, when processing the contract option events. On the contract option event type, you must define the possible characteristic types for contract option events of this type. You may also define a default value, if applicable.

For our example, we will define two types of interruptions, which may be applicable for customers on the same rate. We will define only one type of curtailment event. None of the event types require characteristic values.

| Contract Option Event Type | Descr | Contract Option Type | Char Type |
|----------------------------|-----------------------|----------------------|-----------|
| InterruptA | Interruptions, type A | Interrupt | N/a |
| InterruptB | Interruptions, type B | Interrupt | N/a |
| Curtail | Curtailments | Curtail | N/a |

Designing Your SA Interval Billing Options

Designing Your SA Types

Your interval service agreements will require special data to be set up, such as special rates, interval profiles, TOU maps and contract options. In addition, it will need to define a cutoff time and start day option. The system requires you to indicate a special role of Interval for SA types defined for interval billing service agreements.

Refer to [Defining Service Agreement Types](#) to help you design the standard fields required for all SA Types. Additionally, for interval SA Types, you will need to define the valid Profile Relationship Types, the valid Map Relationship Types and the valid Contract Option Types for this SA Type.

Let's assume that we set up only one SA Type for all interval billing customers. As a result, all the relationship types defined in our sample are valid.

| CIS Division / SA Type | Special Role | Profile Relationship Type | Map Relationship Type | Contract Option Type |
|------------------------|--------------|---------------------------|-----------------------|----------------------|
| CA / E-INTBIL | Interval | HEDGECVR | ACTVDMD | INTERRUPT |
| | | OVRHEDGE | CURTAIL | CURTAIL |
| | | MEASDMD | | |
| | | ACTVDMD | | |
| | | RACTVDMD | | |

Note:

that this setup does not provide any link between the profile relationship types, the map relationship types and the contract option types. These are just a list of valid entries for the SA Type.

Although we created a TOU map relationship type for RACTVDMD above, it is not needed for the TOU mapping rate so it is not linked to the SA Type as a valid value.

Refer to [Setting Up SA Types](#) for more information.

Designing Your Start Options

Once you have your rates defined and your SA Type defined, you should design Start Options to aid your customer service representatives in setting up these service agreements.

You will first need to design your [start options](#) with regard to standard SA information. Note that there may be other setup required before you can add your interval billing start options:

- To link common profiles to a start option you will need to create the appropriate [profile](#) first.
- To link common classic TOU maps to a start option you will need to create the appropriate [TOU map](#) first. This is only applicable to common maps that should be linked to the service agreement. In our example, it applies to the active demand map. The reactive demand map is linked directly to the rate component so no start option information is needed.
- To link shared contract options to a start option you will need to create the appropriate [contract option](#) first.

Note that when designing our rate components above, we did not give names to their rate schedules. Let's call the interval pricing rate schedule "INTPRC" and let's call the TOU Map rate schedule "INTTOU".

Recall that the classic TOU Map rate component required profile relationship types that we did not define above. We will assume that profile relationship types are defined with the same names as the map relationship types. We will also assume that the profile types define the same interval size as the map types.

You may also use Start Options to define Cutoff Time and Start Day Option, if they are different from the values defined on the installation record. Let's assume that our TOU mapping customers use a different Cutoff Time from the installation record.

The following table shows the start option definitions with the rates and the cutoff time information.

| CIS Division / SA Type | Start Option | Rate Schedule | Cutoff Time | Start Day Option |
|------------------------|---------------------------------|---------------|-------------|------------------|
| CA / E-INTBIL | Interval Pricing Hedge - 30MIN | INTPRC | | |
| | Interval Pricing Hedge - 60 Min | INTPRC | | |
| | TOU Map - option 1 | INTTOU | 2:00 AM | Current |
| | TOU Map - option 2 | INTTOU | 2:00 AM | Current |

The following table shows the profile related start options.

| CIS Division / SA Type | Start Option | Rate Schedule | Profile Relationship Type | Profile Type | Profile (Profile Type) |
|------------------------|--------------------------------|---------------|---------------------------|--------------|------------------------|
| CA / E-INTBIL | Interval Pricing Hedge - 30MIN | INTPRC | HEDGECVR | | 12859302 (HEDGE30) |
| | | | OVRHEDGE | OVRHG30 | |
| | | | MEASDMD | DMDKW30 | |

| | | | | |
|---------------------------------|--------|----------|---------|-------------------|
| Interval Pricing Hedge - 60 Min | INTPRC | HEDGE60 | | 4922018 (HEDGE60) |
| | | OVRHEDGE | OVRHG60 | |
| | | MEASDMD | DMDKW60 | |
| TOU Map - option 1 | INTTOU | ACTVDMD | ACTV30 | |
| | | RACTVDMD | RACTV30 | |
| TOU Map - option 2 | INTTOU | ACTVDMD | ACTV15 | |
| | | RACTDMD | RACTV60 | |

The following table shows the classic TOU map related start options.

| CIS Division / SA Type | Start Option | Rate Schedule | Map Relationship Type | Map Type | TOU Map (Map Type) |
|------------------------|------------------------------------|---------------|-----------------------|----------|--------------------|
| CA / E-INTBIL | TOU Map - option 1; no curtailment | INTTOU | ACTVDMD | | 12859302 (4PART30) |
| | TOU Map - option 2; no curtailment | INTTOU | ACTVDMD | | 52829947 (4PART15) |
| CA / E-INTBIL | TOU Map - option 3; curtailment | INTTOU | ACTVDMD | | 12859302 (4PART15) |
| | | | CURTAIL | CURT15 | |

The following table shows the contract option related start options.

| CIS Division / SA Type | Start Option | Rate Schedule | Contract Option Type | Contract Option |
|------------------------|---------------------------------|---------------|----------------------|----------------------|
| CA / E-INTBIL | TOU Map - option 3; curtailment | INTTOU | | 48399239048 (CURT15) |

Let's summarize what these tables define:

- The INTPRC rate requires 2 SA Owned profiles and one Common profile. The Common Profile needs to be created and linked to the start option. (For clarification, the Profile Type used for the profile is displayed in parentheses.) For the SA Owned profile, you need to indicate the profile type.
- There are two possible configurations for the rate INTTOU. As a result, there are two start options, each with the correct configuration defined.
- For the rate INTTOU, the SA will need profiles, TOU maps and, if they use the curtailment option, contract options.
 - The profiles will be SA owned, so only the profile relationship type and profile types are indicated.
 - For the TOU maps, the active demand maps is common so the actual map is indicated, whereas the curtailment map will be SA owned so only the map type is indicated. (The reactive demand map is linked directly to the rate component.)

- The curtailment option will be shared by more than one service agreement, so the contract option itself is linked to the start option.

Refer to [Setting Up Start Options](#) to learn how to enter this information.

Setting Up Interval Billing Options

Setting Up Interval Billing Control Tables

Setting Up Profile Relationship Types

Profile Relationship Types define the role that a set of interval data will serve for a customer. Open **Admin** > **Interval Profile Rel Type** > **Add** to define your profile relationship types.

Note:

This page will not be available if Complex Billing module is [turned off](#).

Description of Page

Enter a unique **Interval Profile Relationship Type ID** and **Description** for the profile relationship type.

Enter the **Interval Profile Type** collection. This is a list of valid [interval profile types](#) whose collections of data can serve the role defined by the profile relationship type.

Note:

To aid in setup, the interval profile type is not a required field on this user interface. This will help you to define your high level interval relationship types first and then define the more detailed profile types. The valid profile types will need to be linked to the appropriate relationship types prior to creating service agreement interval profiles.

Setting Up Interval Profile Types

Interval Profile Types define values common to interval profiles of the same type. Open **Admin** > **Interval Profile Type** > **Add** to define your interval profile types.

Note:

This page will not be available if Complex Billing module is [turned off](#).

Description of Page

Enter a unique **Interval Profile Type ID** and **Description** for the interval profile type.

Indicate whether interval profiles of this type are SA Owned or Common by entering the appropriate value in the interval profile **Sub Type**.

The **Creation Priority** will be used by the [Interval Profile Derivation Process](#) to determine the order in which the data for profiles linked to an SA should be derived. The values range from 10, being the highest priority to 90 being the lowest priority.

Note:

The values for this field are customizable using the Lookup table. This field name is CRE_PRIO_FLG.

Enter the **Unit of Measure** (UOM) that data values stored for interval profiles of this type are captured in.

If a service quantity identifier is needed to further qualify data stored for interval profiles of this type, enter a valid **SQ Identifier**.

Enter the **Minutes per Interval** to define the number of minutes expected in between each row of data collected for interval profiles of this type.

If the [installation](#) record indicates that [seasonal time shift](#) is required, then you must enter the appropriate **Seasonal Time Shift** record applicable for the interval data. Please take special note of the issue described in the [Evenly Sized Intervals](#) section.

The grid contains **Algorithms** that may be used to create or validate interval data for profiles of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** number and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

We expect that you will need more algorithms than we supply. Your algorithms will be based on any number of factors. Be aware that new algorithms may require programming. See [How To Add A New Algorithm](#) for more information.

The following table describes each **System Event**.

| System Event | Description |
|--------------------------|---|
| Interval Data Creation | These types of algorithms are used to derive interval data for a profile. |
| Interval Data Validation | These types of algorithms are used to validate profile data . |

Setting Up Interval Pricing Rate Components

This section describes how to define your interval pricing rate components.

Note:

Define Rate Schedule, Rate Version and other Rate Components. Before creating your interval pricing rate component, you must set up a rate. During this process, you will also need to set up calculation groups and rules. Refer to [Rates](#) for more information.

When you are ready to set up your interval pricing rate component, open **Menu > Rates > Rate Version Classic > Search**. Choose the rate version that this component should belong to. Use the Rate Version context menu and select Go to Rate Component + to add a new rate component.

Description of Page

Refer to [Rate Component - Main Information](#) for information about the common fields on this page. When defining an Interval Pricing rate component additional fields become available to you. The following information will help you to set up your Interval Pricing rate components.

Indicate whether or not this is **FCPO**.

Select a **Value Type** of Unit Rate. This field will be gray when the rate component is referenced on another rate component. The **Value Source** will most likely be Billing Factor. Your bill factor will likely be one with a type of Interval.

Fastpath:

Refer to [Defining Interval Values](#) for more information about setting up bill factors with interval prices.

Indicate whether or not this rate component is **Seasonal**. Refer to [Rate Component - Main Information](#) for more information about seasonal rate components.

The **Error if No Value** field is available for you to use in the calculation algorithm.

Indicate the **Calc Algorithm** that the system will use to calculate the bill line that this rate component produces.

- The system provides an Algorithm Type that is available for use here. It is called RCIPRS.

If this algorithm does not provide you with the logic you require, you will need to create a new algorithm (refer to [Setting Up Algorithms](#)). The above existing algorithm should be used as a sample if you have to write a new algorithm type.

Note:

The calculation algorithm's main purpose is to create bill calculation lines. However, the algorithm may populate other information for the bill, for example, it may add to the SQ or register read collection or it may overwrite the description on bill.

Indicate the **Audit Algorithm** to be used when a CSR wants to drill down into the details of a bill line that was calculated using this Rate Component.

- The system provides an algorithm type that is available for use here. It is called RCIPRS-ADT.

If this algorithm does not provide you with the logic you require, you will need to create a new algorithm (refer to [Setting Up Algorithms](#)). The above existing algorithm should be used as a sample if you have to write a new algorithm type.

Note:

The audit algorithm should produce the same results as the Calc Algorithm. They are separated because they have different responsibilities. For example, the Calc Algorithm should produce bill lines, but the Audit Algorithm should not. They share common logic related to accessing and processing the appropriate interval data records. As a result, it is recommended that these two programs share a common code which accesses and processes the interval data. The above algorithms provided by the system behave this way and should be used as samples.

Refer to [Interval Billing Calculation Details](#) to understand where a CSR may view the calculation details for a bill calc line, using this algorithm.

Indicate the **Interval Profile Rel Type**. This indicates to the system the profile, linked to the SA, which contains the interval quantities to be processed. Refer to [Business Role of Interval Data](#) and [Setting Up Profile Relationship Types](#) for more information.

Turn on **GL Statistical Quantity** if GL journal lines generated for this rate component should also contain the service quantity amount as a statistical quantity. You would use this option if you keep track of both dollar amounts and consumption units in your general ledger.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [Rate Version - Bill Print Info](#) for more information about these fields.

Move to the [Rate Component - GL Distribution](#) window to define how to book moneys associated with this rate component in the general ledger.

Setting Up Channel Control Tables

Setting Up Interval Register Types

Fastpath:

Refer to [The Big Picture of Raw Data Collection and Aggregation](#) for more information.

Interval register types define values common to interval registers of the same type. Open **Admin > Interval Register Type > Add** to define your interval register types.

Note:

This page will not be available if Meter Data Management module is [turned off](#).

Description of Page

Enter a unique **Interval Register Type** and **Description** for the interval register type.

Enter the **Unit of Measure** (UOM) that data values stored for interval registers of this type are captured in.

If a service quantity identifier is needed to further qualify data stored for interval registers of this type, enter a valid **SQ Identifier**.

Enter the **Minutes per Interval** to define the number of minutes expected in between each row of data collected for interval registers of this type.

If the [installation](#) record indicates that [seasonal time shift](#) is required, then you must enter the appropriate **Seasonal Time Shift** record applicable for the interval data. Please take special note of the issue described in the [Evenly Sized Intervals](#) section.

The grid contains **Algorithms** that may be used to perform actions on interval data for registers of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** number and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

We expect that you will need more algorithms than we supply. Your algorithms will be based on any number of factors. Be aware that new algorithms may require programming. See [How To Add A New Algorithm](#) for more information.

The following table describes each **System Event**.

| System Event | Description |
|------------------------------|--|
| Interval Register Validation | These types of algorithms are used to validate register data . |

Setting Up Meter Configuration Types for Channels

You must set up [meter configuration types](#) for your interval channels and index channels.

Setting Up Meter Types

You must set up [meter types](#) to use for grouping together your index and interval registers. You must turn on the **Allow Interval Registers** switch for any meter type used by a meter, which will contain interval registers. Indicate the valid meter configuration types for this meter type.

Setting Up Time of Use Billing Control Tables

Setting Up Classic TOU Map Relationship Types

Classic TOU Map Relationship Types define the role that a classic TOU Map will serve for a customer. Open **Admin** > **Consumption** > **TOU Map Relationship Type** > **Add** to define your classic TOU map relationship types.

Note:

This page will not be available if Complex Billing module is [turned off](#).

Description of Page

Enter a unique **TOU Map Relationship Type ID** and **Description** for the TOU map relationship type.

Enter the **TOU Map Type** collection. This is a list of valid [TOU map types](#) whose collections of data can serve the role defined by the TOU map relationship type.

**Note:**

To aid in setup, the map type is not a required field on this user interface. This will help you to define your high level map relationship types first and then define the more detailed map types. The valid map types will need to be linked to the appropriate relationship types prior to creating service agreement TOU maps.

Setting Up TOU Pricing Rate Components

This section describes how to define your TOU Pricing rate components. Refer to [Time of Use Mapping and Pricing](#) for background information.

**Note:**

Define Rate Schedule, Rate Version and other Rate Components. Before creating your TOU pricing rate component, you must set up a Rate Schedule. Refer to [Setting Up A Rate Schedule](#) for more information. You will also need to set up a rate version and possibly set up other types of rate components. Refer to [Defining Rate Versions](#) and [Defining Rate Components](#) for more information.

When you are ready to set up your TOU pricing rate component, open **Menu > Rates > Rate Version Classic > Search**. Choose the rate schedule and version that this component should belong to. Open its context menu, and select **Go to Rate Component Classic > Add** to add a new rate component.

Description of Page

Refer to [Rate Component - Main Information](#) for information about the common fields on this page. When defining a TOU Pricing rate component, additional fields become available to you. The following information will help you to set up your TOU Pricing rate components.

If the algorithm used by this rate component, only performs mapping and does not produce bill lines, indicate that this is **FCPO**.

The **Value Type** and **Value Source** are optional. If your algorithm performs pricing logic, then you will probably need to define a bill factor here. If your calculation algorithm only performs mapping, than you may not require any value here.

Indicate whether or not this rate component is **Seasonal**. Refer to [Rate Component - Main Information](#) for more information about seasonal rate components.

The **UOM** is available for use by your calculation algorithm. It could be used, for example, by a mapping algorithm to produce SQ quantities with a different unit of measure, assuming that the algorithm knows how to convert from one UOM to another. Note that the algorithms provided with the system do not use this field.

The **SQI** is available for use by your calculation algorithm. It could be used, for example, by a mapping algorithm to produce SQ quantities with a different SQI. Note that the TOU mapping and pricing algorithms provided with the system will use this field, if populated, to produce SQI quantities with this SQI value.

Measures Peak Qty and **GL Statistical Qty** behave the same way they do for SQ quantity rate components. Refer to [How To Set Up Service Quantity Rate Components](#) for more information.

The **Error if No Value** field is available for you to use in the calculation algorithm.

Indicate the **Calc Algorithm** that the system will use to map the interval quantities to time of use values.

- The system provides the following classic TOU mapping/pricing algorithms that are available for use here: RCTMS performs mapping of time of use only and RCTMPS performs both mapping and pricing, producing the necessary bill calculation lines.

If these algorithms do not provide you with the logic you require, you will need to create a new algorithm (refer to [Setting Up Algorithms](#)). The above existing algorithms should be used as a sample if you have to write a new algorithm type.

**Note:**

The calculation algorithm's main purpose is to create bill calculation lines. However, the algorithm may populate other information for the bill, for example, it may add to the SQ or register read collection or it may overwrite the description on bill.

Indicate the **Audit Algorithm** to be used when a CSR wants to drill down into the details of a bill line that was calculated using this Rate Component.

- The system provides the following audit algorithm that is available for use here: RCTPRS-ADT.

If this algorithm does not provide you with the logic you require, you will need to create a new algorithm (refer to [Setting Up Algorithms](#)). The above existing algorithm should be used as a sample if you have to write a new algorithm type.

Note:

The audit algorithm should produce the same results as the Calc Algorithm. They are separated because they have different responsibilities. For example, the Calc Algorithm should produce bill lines, but the Audit Algorithm should not. They share common logic related to accessing and processing the appropriate interval data records. As a result, it is recommended that these two programs share a common code which accesses and processes the interval data. The above algorithms, provided by the system, behave this way and should be used as samples.

Refer to [Interval Billing Calculation Details](#) to understand where a CSR may view the calculation details for a bill calc line, using this algorithm.

Indicate the **Interval Profile Rel Type**. This indicates to the system the profile, linked to the SA, which contains the interval quantities to be mapped. Refer to [Business Role of Interval Data](#) and [Setting Up Profile Relationship Types](#) for more information.

If the classic TOU map differs for different service agreements, indicate the **TOU Map Relationship Type**. The system uses this information to find the correct classic TOU map linked to the SA. Refer to [Business Role of a TOU Map](#) and [Setting Up TOU Map Relationship Types](#) for more information.

If ALL service agreements linked to the rate use the same map, indicate the classic **TOU Map ID**.

Enter the verbiage to appear on the customer's bill in **Description On Bill** and turn on the **Print** switch. Refer to [Rate Version - Bill Print Info](#) for more information about these fields.

Setting Up Time of Use Codes

An important step in preparing for Time of Use billing is to define Time of Use codes. Refer to [Setting Up Time-Of-Use Codes](#) for more information.

Setting Up TOU Groups

Once you have your time of use codes defined, you will need to create your TOU groups to group the codes together. Refer to [Setting Up TOU Groups](#) for more information.

Setting Up Classic TOU Map Types

The Classic TOU Map Type defines characteristics that are common to classic TOU Maps of the same type. Open **Admin > TOU Map Type Classic > Add** to define your TOU map types.

Note: The Classic TOU Map Type portal describes TOU Map Types that are used with the classic rate engine. For information about the differences between the classic and new style rate engines, see [Rates](#). For details on setting up TOU Map Types for the new style rate engine, see [Creating TOU Map Types](#).

Note:

This page will not be available if Complex Billing module is [turned off](#).

Description of Page

Enter a unique **TOU Map Type ID** and **Description** for the classic TOU Map Type.

Indicate whether TOU maps of this type are SA Owned or Common by entering the appropriate value in the **Sub Type**.

The **Creation Priority** will be used by the [TOU map data creation](#) process to determine the order in which the data for classic TOU maps linked to an SA should be derived. The values range from 10, being the highest priority to 90 being the lowest priority.

Note:

The values for this field are customizable using the Lookup table. This field name is CRE_PRIO_FLG.

Enter the **TOU Group** that defines the collection of TOUs for this map type.

Enter the **Minutes Per Interval** to define the number of minutes expected in between each row of data collected for classic TOU maps of this type.

If the [installation](#) record indicates that [seasonal time shift](#) is required, then you must enter the appropriate **Seasonal Time Shift** record applicable for the interval data. Please take special note of the issue described in the [Evenly Sized Intervals](#) section.

The grid contains **Algorithms** that may be used to create classic TOU map data for TOU maps of this type. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** number and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

We expect that you will need more algorithms than we supply. Your algorithms will be based on any number of factors. Be aware that new algorithms may require programming. See [How To Add A New Algorithm](#) for more information.

The following table describes each **System Event**.

| System Event | Description |
|------------------|--|
| TOU Map Creation | These types of algorithms are used to create TOU map data automatically. |

Setting Up Classic TOU Map Templates

The TOU Map Template classic page enables you to define daily, weekly and calendar templates for use by TOU data generation and automatic TOU data creation. Open **Admin > TOU Map Template Classic > Add** to define your TOU map templates.

Note:

The classic TOU Map Template portal describes TOU Map Templates that are used with the classic rate engine. For information about the differences between the classic and new style rate engines, see [Rates](#). For details on setting up TOU Map Templates for the new style rate engine, see [Creating TOU Map Templates](#).

Note:

This page will not be available if Complex Billing module is [turned off](#).

Description of Page

Enter a unique **TOU Map Template** name and a **Description** for the classic TOU map template.

Enter a classic **TOU Map Type**. Daily templates use the TOU map type to determine the TOU group whose TOU codes are valid for this template. All templates use the classic TOU map type to determine the interval size to ensure

that start and end times are valid for the interval size. For example, if your interval size is 60 minutes, then the amount of minutes between your start and end times must be a multiple of 60. For example, you would not be able to enter a start time of 10:00 and an end time of 10:15.

Use the **TOU Map Template Type** to indicate whether this template is Daily, Weekly, or Calendar.

The fields in the remaining portion of the page will depend on the classic TOU map template type.

A Daily template is used to define time of use periods applicable for hour/minute time ranges in an abstract day. Data in this template has no association with a specific day of the week or a specific calendar date. Each entry in the collection is used to define the time periods applicable for a given Time of Use code in this day. Enter the following information for your collection of time periods for the daily template.

Use the **Start Sequence Number** and the **End Sequence Number** to indicate whether the time period covered by this entry starts and ends on the same day or on different days. If the time period covered by the entry starts and ends on the same day, then the same number should be entered in both fields. If the time period ends on a different day (most likely one day later) than it starts, then the End sequence would be greater than the start sequence.

Enter the **Start Time** and **End Time** applicable for this **Time of Use** code. The valid time of use codes are limited to those belonging to the TOU group on the template's TOU map type.

Note:

The times on the TOU map components are in legal time. During the generation process the system will convert the time definitions into standard time, taking daylight savings into account. Time shifting is based upon the Seasonal Time Shift defined on the template's classic TOU Map Type. Refer to [Seasonal Time Shift](#) for more information.

When the TOU data is generated, intervals for this time of use code will be generated starting from the first time period AFTER the Start Time up to and including the End Time interval. Therefore, the end Time is inclusive and the start time is not inclusive.

A Weekly template is used to define the collection of daily templates that make up an abstract week. Data in this template has no association with specific calendar dates. You must indicate the **Week Start Day** to tell the system which day of the week is considered "day one".

Enter the following information for your collection of daily templates for the weekly template.

Use the **Start Sequence Number** and the **End Sequence Number** to indicate whether the time period covered by this entry starts and ends in the same week or in different weeks. If the days covered by the entry are in the same week, then the same number should be entered in both fields. If the time period ends in a different week (most likely one week later) than it starts, then the End sequence would be greater than the start sequence.

Enter the **Start Week Day** and **Start Time** and **End Week Day** and **End Time** applicable for this **Reference TOU Map Template**. The valid templates are limited to those that are daily and those whose TOU map type has the same TOU group and minutes per interval as this template's TOU map type.

Note:

The times on the TOU map components are in legal time. During the generation process the system will convert the time definitions into standard time, taking daylight savings into account. Time shifting is based upon the Seasonal Time Shift defined on the template's TOU Map Type. Refer to [Seasonal Time Shift](#) for more information.

When the TOU data is generated, intervals will be generated starting from the first time period AFTER the Start Time up to and including the End Time interval. Therefore, the end Time is inclusive and the start time is not inclusive.

A Calendar template is used to define the collection of weekly and daily templates that make up specific months and dates for a given calendar.

Enter the following information for your collection of daily and weekly templates for the calendar template.

Use the **Start Sequence Number** and the **End Sequence Number** to indicate whether the time period covered by this entry starts and ends in the same year or in different years. If the dates covered by the entry are in the same year,

then the same number should be entered in both fields. If the time period ends in a different year (most likely one year later) than it starts, then the End sequence would be greater than the start sequence.

Use the **Start Date** (month and day) and **Start Time** and the **End Date** (month and day) and **End Time** to indicate the time period applicable for this **Reference TOU Map Template**. The valid templates are limited to those that are daily and weekly and those whose TOU map type has the same TOU group and minutes per interval as this template's TOU map type.

Note:

The times on the TOU map components are in legal time. During the generation process the system will convert the time definitions into standard time, taking daylight savings into account. Time shifting is based upon the Seasonal Time Shift defined on the template's TOU Map Type. Refer to [Seasonal Time Shift](#) for more information.

When the TOU data is generated, intervals will be generated starting from the first time period AFTER the Start Time up to and including the End Time interval. Therefore, the end Time is inclusive and the start time is not inclusive.

Where Used

The [generate](#) button on the TOU map page allows you to specify a TOU map template and a holiday TOU map template to use for generating TOU data.

If you have a TOU map creation algorithm defined on a TOU map type, this algorithm will need to use a TOU map template to create TOU data. The mechanism for defining the TOU map template to use depends on how the algorithm is designed. The TOU map creation algorithm provided by the system ITMCCOPT expects the template to be defined as a characteristic of the service agreement.

Setting Up Contract Option Control Tables

This section describes the pages related to maintaining contract options.

Setting Up Contract Option Types

This section describes the pages related to maintaining a contract option type.

Contract Option Type - Main

Contract Option Type defines control information required for contract options. Open **Admin > Consumption > Contract Option Type > Add** to define your contract option types.

Note:

This page will not be available if Complex Billing module is [turned off](#).

Description of Page

Enter a unique **Contract Option Type ID** and **Description**.

Indicate whether you **Allow Overlap** of the effective period for contract events linked to contract options of this type.

If the [installation](#) record indicates that [Seasonal Time Shift](#) is required, then you must enter the appropriate **Seasonal Time Shift** record applicable for the contract option event data.

Select a **Characteristic Type** that may be used on contract options of this type. The characteristic type's Description appears adjacent.

The following fields should be defined for each characteristic type:

Sequence This field controls the order in which the characteristics appear on the [contract option](#) page.

Required Turn this switch on if this type of characteristic must be defined on all contract options of this type.

Default Turn this switch on if this characteristic type should automatically appear in the characteristic scroll area of contract options of this type.

Characteristic Value If a characteristic value can default for contract options of this type, specify the default value in this field.

Contract Option Type - Algorithms

To define validation algorithms for contract option events linked to contract options of this type. Open **Admin > Consumption > Contract Option Type > Search** and navigate to the **Algorithms** page to define validation algorithms for this contract option type.

Description of Page

The grid contains **Algorithms** that may be used to validate contract option event information. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** number and **Algorithm** for each system event. You can set the **Sequence Number** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the **Sequence** in which they should execute.

The following table describes each **System Event**.

| System Event | Description |
|-------------------------------|---|
| Contract Option Event Cancel | This algorithm is executed when a contract option event for a contract option of this type is canceled. |
| Contract Option Event Freeze | This algorithm is executed when a contract option event for a contract option of this type is frozen. |
| Contract Option Event Pending | This algorithm is executed when a contract option event for a contract option of this type is added or changed and the status is pending. |

Setting Up Contract Option Event Types

Contract Option Event Type defines control information required for contract option events. Open **Admin > Contract Option Event Type > Add** to define your contract option event types.

Note:

This page will not be available if Complex Billing module is [turned off](#).

Description of Page

Enter a unique **Contract Option Event Type** code and **Description**.

Indicate the **Contract Option Type** for this event type.

Use the **Characteristics** collection to define characteristics that can be defined for contract option events of this type. Use **Sequence** to control the order in which characteristics are defaulted. Turn on the **Required** switch if the **Characteristic Type** must be defined on contract option events of this type. Enter a **Characteristic Value** to use as the default for a given **Characteristic Type** when the **Default** switch is turned on.

Defining Prepaid Metering Options

The topics in this section describe how to set up the system to enable prepaid metering functionality.

Note:

Prepaid metering is optional. The system configuration requirements described in this section are only relevant if your organization offers prepaid metering service.

The Big Picture of Prepaid Metering

Prepaid metering allows customers to pay for energy before it is actually used.

How Does Prepaid Metering Work?

A traditional electronic prepaid metering system typically operates at three levels:

- Meters that are installed at the customer's home. These meters dispense energy up to the amount that the customer prepaid.
- Vending stations located at the utility's offices or designated payment agencies. These stations/agencies sell prepaid credits to customers.
- Master stations that group vending stations together for administration, reporting and control purposes. Master stations communicate information - e.g. customer information, tariff changes, etc - to the vending stations. The vending stations, in turn, report detailed customer sales and other transaction information to the master station.

A prepaid customer goes to a vendor and purchases credits for their meter to dispense energy. The vendor has knowledge of the customer and the rate that the customer is paying. The vendor issues the credits in any of the following forms: a prepaid card, a token (to be inserted into the meter) or a series of numbers (to be keyed into the meter).

Debit Meter vs. Credit Meter

Prepaid meters are commonly referred to as debit meters. Billed meter types are also called credit meters. A meter's state of being 'credit' or 'debit' translates to a specific meter configuration. Having this property set at the meter configuration level enables meters to be switched between 'credit' and 'debit' if needed.

Prepaid credits may be purchased for either new premises or existing premises. In the latter case, the existing premise could initially have a typical 'credit' meter. In this case, fieldwork may be involved in getting the meter switched from 'credit' to 'debit' (prepaid).

Prepaid Metering Transactions Result in Adjustments

There could be numerous types of prepaid transactions. But the most common types are prepaid sales and cancellations.

A sale or cancellation transaction includes a total amount that usually includes tax. In order to post to the general ledger, the prepaid transaction must result in a financial transaction. Moreover, separate GL entries must be created for the breakdown of revenue and tax. In some cases, it may also be necessary to calculate the usage from the revenue amount.

[Calculated Adjustments](#) are used to book revenue from these types of transactions. A base Generate Adjustment algorithm is available to let rate application generate the appropriate GL calculation lines and calculate the corresponding usage, if needed.

Prepaid adjustments do not affect a customer's balance.

Interfacing Prepaid Transactions

An adjustment upload batch process exists for uploading prepaid transactions that result in adjustments. Refer to [Interfacing Adjustments From External Sources](#) for more information.

Prepaid metering options need only be set up if your organization offers prepaid metering service to your customers. Refer to [Defining Prepaid Metering Options](#) for more information.

Prepaid Transactions Can Go Into Suspense

A prepaid transaction goes into suspense if a prepaid SA could not be determined for any of the following reasons:

- The badge number on the transaction is not a valid meter in the system
- The badge number on the transaction is a valid meter in the system, but is:
 - Not linked to a prepaid meter configuration type
 - Not linked to a non-closed, non-canceled prepaid SA

This can be a common occurrence because of the likelihood that transactions get uploaded prior to meter installation/exchange or service agreement information being updated in the system.

When this situation happens, you probably still want to recognize the revenue by posting an adjustment to a suspense SA that you designate. Refer to the base sample Get Prepaid SA Using Badge Number (C1-SABYBADGE) algorithm for an example of how the suspense SA is specified.

A batch process exists for automatically resolving suspense adjustments. Refer to [How Are Suspense Adjustments Resolved](#) for more information.

Setting Up The System To Enable Prepaid Metering

The following sections describe the steps in setting up control information for prepaid metering.

Meter Types

Prepaid meters are set up just like any other meter - i.e. the meter must reference a meter type and the meter's configuration must reference a meter configuration type.

To set up prepaid meter types you must do the following:

- Define the meter configuration types that will be used for recording prepaid usage. Mark each of these configuration types as Prepaid . Define one register with the appropriate UOM (e.g. kWh). See [Setting Up Meter Configuration Types](#) for more information.
- Define the meter types that will be used for prepaid metering. For each meter type, associate one of the Prepaid meter configuration types that you defined. You can also mark each meter type as Prepaid Capable. See [Setting Up Meter Types](#) for more information.

Note:

Base logic does not require the meter type to be marked as Prepaid Capable. The Prepaid indicator on the meter configuration type is used to identify prepaid meters.

Characteristic Types

The following characteristic types are needed if you are going to upload prepaid transactions as adjustments and need the system to determine the prepaid SA given a prepaid meter's badge number.

Refer to [Setting Up Characteristic Types](#) for more information.

Prepaid Entity Characteristic Type

Create a characteristic type that identifies whether an SA Type is used for prepaid metering. For example:

- Characteristic Type = <code>
- Description = Prepaid Entity
- Char Entities = SA Type
- Subclass = predefined list
- Values = Y, N

Badge Number Characteristic Type

Create a characteristic type for specifying a badge number. For example:

- <code>
- Description = Badge Number
- Char Entities = Adjustment, Adjustment Type
- Subclass = Adhoc

Algorithms

The following algorithms need to be set up in order to store prepaid transactions in the system.

Refer to [Setting Up Algorithms](#) for more information.

Note:

The following sections describe basic set up needed for uploading 'sale' and 'cancellation' types of prepaid transactions. Your implementation team may have to define additional specific algorithm types for any other prepaid transaction type that you need to upload into or store in the system.

Calculation Rule - Calculation Algorithm

Create an algorithm of type Determine Percent Given Total (C1-PCTGVNTOT) specifying your parameter values for UOM / TOU / SQL.

Create an algorithm of type Back Into Revenue (C1-BACKINREV) specifying your parameter values for UOM / TOU / SQL.

Adjustment Type - Generate Adjustment

Create an algorithm of type Adjustment Generation - Apply Rate (ADJG-RT), specifying your [prepaid rate](#) and parameter values for UOM / TOU / SQL.

Adjustment Type - Determine SA

Create an algorithm of type Get Prepaid SA Using Badge Number (C1-SABYBADGE), specifying your badge number characteristic type, prepaid characteristic type and suspense SA ID (i.e. SA to which the adjustment needs to post when a valid prepaid SA is not found).

Adjustment Type - Resolve Suspense

Create an algorithm of type Cancel Suspense Adjustment (C1-CANSUSADJ) specifying the following:

- [Badge number characteristic type](#)
- [Prepaid entity characteristic type](#)
- [Prepaid adjustment type](#)

- Adjustment cancel reason

If you want this algorithm to create to do entries for adjustments that have been in suspense for too long, specify additional parameter values for number of days and to do type and to do role (optional).

Adjustment Type - Adjustment Information

Specify the SUSPENSE_DESCR parameter on your adjustment information algorithm if you want the information to include an indication of suspense.

Installation - Adjustment Information

Specify the SUSPENSE_DESCR parameter on your adjustment information algorithm if you want the information to include an indication of suspense.

Rate

In order to generate separate calculation lines for the revenue and tax breakdown of the prepaid amount, you need to set up a prepaid rate with components that calculate revenue amount and tax amount given just a total amount.

Create a rate schedule with the following components:

- Tax Calculation Rule
 - Calculation Rule Type = Calculation Algorithm
 - Value Type = Percentage
 - Value Source = Bill Factor
 - Bill Factor = your tax bill factor
 - Calculation Algorithm = the one created for algorithm type C1-PCTGVNTOT. Refer to [Calculation Rule - Calculation Algorithm](#) for information.
 - Distribution Code = *your distribution code for tax liability*
- Revenue Calculation Rule
 - Calculation Rule Type = Calculation Algorithm
 - Derive SQ = checked
 - Value Type = Unit Charge
 - Value Source = Bill Factor
 - Bill Factor = your rate/kWh bill factor
 - UOM/TOD/SQI to use for the resulting calculated usage, for example kWh
 - RC Cross Reference = indicate the sequence for the tax calculation rule (above)
 - Calculation Algorithm = the one created for algorithm type C1-BACKINREV. Refer to [Calculation Rule - Calculation Algorithm](#) for information.
 - Distribution Code = your distribution code for revenue

Adjustment Types

You must define an adjustment type for each type of transaction that you want to store in the system. Refer to [Setting Up Adjustment Types](#) for more information.

For prepaid sales and cancellation transactions, you need to define [calculated adjustment types](#). In addition, plug-in the following algorithms:

- Adjustment FT Creation - GL Only algorithm - so that transaction amounts do not affect the customer's balance. Specify calc lines as the source for adjustment distribution codes.
- [Generate Adjustment](#)
- [Determine SA](#)

- [Resolve Suspense](#), if applicable.
- [Adjustment Information](#), if applicable

Adjustment Type Profiles

Create appropriate [adjustment type profiles](#) for your prepaid service agreements.

Service Agreement Types

You must create a prepaid [SA Type](#) for each unique CIS Division. Each SA Type must be set up as non-billable and requiring a characteristic premise. The SA Types must also indicate that they are used for prepaid by specifying a [prepaid entity characteristic](#) value.

Bill Cycle

Create at least one bill cycle that will be used for prepaid accounts. This bill cycle should not have a schedule defined.

Vendor Information

A vendor could be a vending station, payment agency or master station.

You must create a [person](#) for each of your vendors. Information about the vendor may include names, an address, phone numbers, etc.

Any other miscellaneous information about the vendor can be stored as characteristics on the person.

Hierarchical relationships between vendors can be established through characteristics. For instance, a vending station's person record may contain a foreign key characteristic that points to the master station that the vending station reports to.

Defining Conservation Program Options

Oracle Utilities Customer Care and Billing allows you to define conservation (or energy efficiency) programs and provide rebates to customers.

The Big Picture of Conservation Programs

The purpose of using conservation programs is to provide rebates to customers based on eligibility and verification of newly purchased appliances and hardware that are rated to conserve the demand for energy. To redeem their rebates, customers have to submit a rebate application to the utility with receipts, and the utility has to administer and report on the programs.

Admin and transaction objects are provided in the product to support the definition of conservation programs (admin data) and the subsequent rebate claims (transaction data). Portals and BPA scripts are used to maintain the conservation programs and rebate claims. Adjustments are used to recognize the expense and to process refunds.

The following sections discuss the maintenance objects that support this functionality.

Conservation Program Maintenance Object

A conservation program is an admin maintenance object (MO) used to support the definition of a conservation program. It holds rules that control how the claims for a conservation program are managed. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- A business object option Display Statistics Service Script is provided for business objects of this type. The script plugged into this option retrieves information displayed on the **Conservation Program Statistics Zone**.
- A business object option Display Statistics UI Map is provided for business objects of this type. This is the map used on the **Conservation Program Statistics Zone** to display statistics.
- A separate maintenance object is provided to capture rebate definitions for a conservation program
- Logs are not provided.
- The standard characteristics collection is provided.

Fastpath:

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin > Database > Maintenance Object > Search** and view the MO C1-CPROG.

Conservation Program Rebate Definition Maintenance Object

A conservation program has rebate definitions that define the rebate amounts and energy savings for different types of products. The superset of such lines is the "rebate matrix". Each row in the matrix defines the rebate and presumed energy savings for a product purchased by the consumer. If your organization wishes to use this maintenance object (MO), you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- The Rebate Definition table can be used to capture information for rebate claim lines such as, appliance type, refund amount, energy savings, and applicable manufacturers and models.
- Logs are not provided for the Rebate Definition.
- A characteristics collection is not provided.

Fastpath:

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin > Database > Maintenance Object > Search** and view the MO C1-RDEF.

Rebate Claim Maintenance Object

When a customer files a claim for a rebate, a rebate claim will be created. The rebate claim maintenance object (MO) is used to support the definition of a claim. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- Depending on the utility's requirements, you can specify single or multiple items on the Rebate Claim. A separate maintenance object is provided to capture rebate claim lines for a rebate claim.
- The standard characteristics collection is provided.
- A log is provided. This can be used to track approval information for the claim, to capture adjustments created as the claim is processed, etc.

Fastpath:

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin > Database > Maintenance Object > Search** and view the MO C1-RCLAIM.

Rebate Claim Line Maintenance Object

A rebate claim has a rebate claim line for each product eligible for a refund. You use the rebate claim line maintenance object (MO) to create a rebate line. If your organization wishes to use this MO, you can either use the business object (BO) supplied in the base product or configure your own BO.

This MO provides the following functionality:

- SA (service): The SA table is the real service SA. There is a separate SA under which the rebate adjustments are stored.
- Logs are not provided for Rebate Claim Line
- The standard characteristics collection is provided.

Fastpath:

For more information, about this MO and to review the business objects defined for this MO, navigate to **Admin > Database > Maintenance Object > Search** and view the MO C1-REBLN.

GL Accounting Example

The following table shows the financial transactions that are issued when processing energy conservation rebates. This example shows the financial transactions when a customer files a claim for a dishwasher and insulation.

Notice how the expense adjustments are atomized:

- Separate adjustments are created to expense each item individually.
- A single adjustment is created for the A/P check request.

| Event | GL Accounting |
|---|-------------------------------------|
| Rebate adjustment is created - dishwasher | Rebate Expense 35 A/P <35> |
| Rebate adjustment is created - insulation | Rebate Expense 45.45 A/P <45.45> |
| A/P check request issued | A/P 80.45 Cash <80.45> |

Setting Up Conservation Programs

Conservation Programs allow administrators to create and maintain conservation programs for which customer can submit rebate claims. To set up a conservation program, open **Admin > Customer > Conservation Program > Add**.

Fastpath:

For additional information on working with rebate claims, see [Rebate Claims](#).

The topics in this section describe the base-package zones that appear on the Conservation Program portal.

Conservation Program List Zone

The Conservation Program [List zone](#) lists every conservation program. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent conservation program.
- Click the Add link in the zone's title bar to add a new conservation program.

This zone displays the following for each conservation program defined in the system:

- Conservation Program Information (Description, Status, Start Date, End Date)
- The number of Complete Claims
- The total Complete Claims Amount

- The number of Incomplete Claims
- The Statistics Date/Time is the date that the statistics were last calculated

Use the following procedure to create a new conservation program:

- Select **Admin > Customer > Conservation Program > Add** or click **Add** on the title bar of the Conservation Program [List zone](#).
- Enter basic information about the conservation program in the **Main** section, including:
 - Conservation Program code
 - Description
 - Start Date/End Date
 - Statistic Update Frequency (in hours)
- Enter **Financial Information** about the conservation program, including:
 - CIS Division
 - SA Type
 - A/P Adjustment Type
 - A/P Taxable Adjustment Type
- Enter **Approval Information** about the conservation program, including:
 - Approval To Do Type
 - Duplicate Claim To Do Role
 - Approval Levels and Threshold Amounts
- Click **Save**. To return to the Conservation Program portal without saving the new program, click **Cancel**.

To view a specific conservation program, click the broadcast icon for the conservation program you wish to view. The remaining zones in the Conservation Program portal open displaying details about the selected conservation program.

Conservation Program Zone

You use the Conservation Program zone to view and maintain individual conservation program. The Conservation Program zone displays the following information about the selected conservation program:

- Basic information about the conservation program, including
 - Conservation Program
 - Description
 - Start Date/End Date
 - Statistic Update Frequency (in hours)
 - Status
- Financial Information about the conservation program, including
 - CIS Division
 - SA Type
 - A/P Adjustment Type
 - A/P Taxable Adjustment Type
- Approval Information about the conservation program, including
 - Approval To Do Type
 - Duplicate Claim To Do Role
 - Approval Levels and Threshold Amounts

Please see the zone's help text for information about this zone's fields.

Conservation Program Status

The Status of a conservation program indicates the current state of the program within the system. Valid statuses include:

- **Pending** indicates the program is pending. This is the initial state of a conservation program when first created.
- **Active** indicates the conservation program is currently active.
- **Inactive** indicates the conservation program is currently inactive.

Conservation Program Actions

You can perform a number of actions on a conservation program, including:

- **Edit:** Used to edit a conservation program
- **Delete:** Used to delete a conservation program
- **Activate:** Used to activate a pending or inactive conservation program
- **Refresh Statistics:** Used to refresh the statistics of an active conservation program
- **Deactivate:** Used to deactivate a pending or active conservation program
- **Pend:** Used to change the status of an active or inactive conservation program to Pending

The actions available are based on the current status of the conservation program. The table below summarizes the actions available at each status.

| Status | Valid Action |
|----------|--|
| Pending | Edit, Delete, Activate, Deactivate |
| Active | Edit, Refresh Statistics, Deactivate, Pend |
| Inactive | Activate, Pend |

Editing Conservation Programs

Use the following procedure to edit an active or pending conservation program:

- Click **Edit**.
- Edit the details of the conservation program as needed.
- Click **Save**.

Deleting Conservation Programs

Use the following procedure to delete a conservation program:

- Click **Pend** to change the status of the conservation program to Pending (if needed).
- Click **Delete**.
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the conservation program, click **Cancel**.

Activating Conservation Programs

To activate an inactive or pending conservation program, click **Activate**.

Deactivating Conservation Programs

To deactivate an active or pending conservation program, click **Deactivate**.

Setting the Status of Conservation Programs to Pending

To set the status of an active or inactive conservation program to Pending, click **Pend**.

Rebate Definition Zone

You use the Rebate Definition zone to add, view, and edit rebate definitions associated with a conservation program. A rebate definition defines the types of rebates allowed for a specific conservation program. The Rebate Definition zone displays the following details for each claim line:

- Rebate Definition
- Status (Active or Inactive)
- Rebate Amount per Unit
- Icons to Edit, Delete, and Activate/Deactivate rebate definitions

Adding Rebate Definitions

Use the following procedure to add a rebate definition:

- Click **Add** in the title bar of the Rebate Definition zone.
- Enter a Description of the rebate definition.
- Select the **Product** for the rebate definition from the dropdown list.
- Select the **Service Type** for the rebate definition from the dropdown list.
- Enter the **Rebate Per Unit Amount** for the rebate definition.
- Enter the **Rebate Unit of Measure** for the rebate definition.
- Select the **Expense Adjustment Type** for the rebate definition from the dropdown list.
- Enter the **Presumed Energy Savings** for the rebate definition.
- Select the **Presumed Energy Savings** Unit of Measure for the rebate definition from the dropdown list.
- Enter the **Manufacturer** and **Model** for each item eligible to be submitted as a rebate claim line.
- To upload manufacturer/model information from a comma-separated-values file, click **CSV File to Upload**.
 - Click **Browse** on the File Upload dialog, and browse to the file to be uploaded.
 - Click **Upload**.
- Click **Save**. To return to the Rebate Definition zone without adding the rebate definition, click **Cancel**.

Editing Rebate Definitions

Use the following procedure to edit a rebate definition:

- Click the edit icon for the rebate definition you wish to delete.
- Edit the details of the claim line as appropriate.
- Click **Save**. To return to the Rebate Definition zone without changing the rebate definition, click **Cancel**.

Note:

You can edit a rebate definition only when it is Active.

Deleting Rebate Definitions

Use the following procedure to delete a rebate definition:

- Click the delete icon for the rebate definition you wish to delete.
- Click **OK** on the Confirm Delete dialog. To close the dialog without deleting the rebate definition, click **Cancel**.

Activating Rebate Definitions

To activate an inactive rebate definition, click the **Activate** button for the rebate definition you wish to activate.

Note:

You can only activate rebate definition that is currently Inactive.

Deactivating Rebate Definitions

To deactivate an active rebate definition, click the **Deactivate** button for the rebate definition you wish to deactivate.

Note:

You can only deactivate rebate definition that is currently Active.

Rebate Claim Statistics Zone

You use the Rebate Claim Statistic zone to view statistics for submitted rebate claims based on the current conservation program. This zone displays the following:

- Conservation Program
- Statistics Date/Time
- Statistics Charts

Statistics Graphs

This zone displays statistics for submitted rebate claims using the following charts:

- **Statistics by Status:** A pie chart that displays the number and percentage of claims for each status.
- **Statistics by Month:** A line chart that displays the number of claims completed each month.
- **Statistics by Product:** A pie chart that displays the total value, percentage, and number of claim lines completed for each product.
- **Statistics by Claim Age:** A line and bar chart that displays the number of new claims per month (line graph) and the number of claims per age grouping (bar graph).

To refresh statistics, click **Refresh Statistics** on the title bar of the Rebate Claim Statistics zone.

Defining Open Market Options

Markets

Understanding Market

The Market object is used to define a deregulated market which is a geographical area operating with a set of rules to manage premises and/or customers for a service type. Separate market instances are created for each geographic area and service type, e.g. Gas New York (GNY), Electric New York (ENY), Electric United Kingdom (EUK).

Each deregulated market has participants (Service Providers) operating within that market. Different types of Service Providers are grouped into Market Relationship Types. There are Service Providers that manage the customer at a premise - e.g. Local Distribution Company, Energy Service Provider (Retailer, Supplier) and some that manage the meter at a premise (Meter Operator, Data Aggregator). Service Providers can operate across several deregulated markets (e.g. Retailers) and they can enter and exit markets independently. Start and End dates are provided to manage Service Providers entering and exiting markets.

Service Provider types can be managed by the market object and others can be managed by Market Provider Configuration. Recommended Market Relationship types managed by the Market object are Meter Owners, Meter Aggregators. There may be markets where no Service Providers are managed by the Market object, even where Meter Owners are present. For example when Meter Owners don't change.

Service Provider types managed by the Market Provider Configuration are recommended for Retailer and Distributor Market Relationship Types. This option provides greater flexibility for market transactions to be sent to service providers based on the market and billing options.

Note: Refer to Market Provider Configuration for Service Providers that are managed for each Market Billing Option.

Markets that manage a provider of last resort or fall back service provider will configure the market Fall Back Service Provider, the start and end dates allow a solution to determine who the current Fall Back Service Provider is. Not all markets have a Fall Back Service Provider.

Configuring Market

This portal is used to display and maintain a Market.

Refer to [Understanding Market](#) for more information.

To maintain markets, open **Admin > Open Market > Market**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Defining Consumer Contract Options

The topics in this section describe how to set up the system to enable consumer contract functionality.

Understanding Consumer Contracts

Consumer contracts record customer relationships. These relationships can encompass multiple services, multiple sites and multiple accounts. For example a consumer contract can be for a customer's gas and electricity supply at a single site or for a customer's water supply at multiple sites.

A consumer contract can relate to one or more consumer product versions. A consumer product version records values that are common to all consumer contracts related to that consumer product version. A consumer product version also records rules that are applied by customer service requests to set up a new consumer contract or change an existing consumer contract. These rules can for example create service agreements or stop service agreements. Refer to [Understanding Consumer Products](#) on page 1274 for more details. A consumer contract's consumer contract products record the links between the consumer contract and consumer product versions.

Note a consumer contract relates to consumer product versions not to consumer products. The consumer product version linked to a consumer contract is the version of the required consumer product that is applicable for that consumer contract. This could for example be the consumer product version that is effective for the date the consumer contract was agreed.

Consumer contracts group together service agreements. The relationship between a consumer contract and a service agreement is recorded in the service agreement by linking the service agreement to one of the contract's consumer contract products. A consumer contract can record details that are common for all of the related service agreements.

All consumer contracts have a consumer contract type. A consumer contract type limits which consumer products are valid for a consumer contract of that type. Note the consumer products that are eligible are further limited by the consumer product's eligibility criteria. Refer to [Understanding Consumer Products](#) on page 1274 for more details.

A consumer contract can have milestones where a milestone is a date that is significant to the contract. Milestones can optionally trigger an action. Refer to [Understanding Consumer Contract Milestones](#) on page 1273 for more details.

Understanding Consumer Contract Milestones

Dates that are significant to a consumer contract can be recorded as consumer contract milestones. A consumer contract milestone can optionally trigger an action. For example, a consumer contract milestone could record the date when a fixed-priced period ends and trigger a change to the consumer contract when this date is reached. Another example is a consumer contract milestone that sends a notification to the customer one month prior to the end of the fixed-priced period.

A consumer contract milestone can relate to one or more of the contract's consumer contract products. A contract's consumer contract products record the links between the consumer contract and consumer product versions. In the example above of a consumer contract milestone recording the date when a fixed price period ends, the consumer contract milestone would be related to the consumer contract period whose consumer product version has the fixed priced period.

Each milestone has a consumer contract milestone type. The consumer contract milestone type indicates whether or not a milestone is executable, that is whether or not it triggers an action. For executable milestones, the action to be performed is derived from the consumer contract milestone type.

A consumer contract milestone's executable status can be: Pending, Processed, Not Executable or Canceled. Not Executable indicates that the milestone does not have a related action and Canceled indicates that the milestone is no longer applicable.

The Perform Consumer Contract Milestone Actions (C1-CCMP) batch process executes a consumer contract milestone's actions. This batch process selects the consumer contract milestones whose milestone date is today or in the past and whose executable status is Pending. The batch process performs the **Perform Action** algorithms defined on the milestone's Consumer Contract Milestone Type business object. Once a consumer contract milestone's actions have been performed, the batch process changes its executable status to Processed.

Note:

This batch process is built using the [Plug-in Driven Background Processes](#) framework. Your implementation can introduce alternate logic, by duplicating this batch control and replacing the select and/or process records algorithms. Adjust the batch parameters according to your custom logic, if needed.

The base product provides a **Contract Milestone Type (BO) – Perform Action** algorithm that sends customer notification. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Contract Milestone Type (BO) – Perform Action** algorithm entity in the application.

Understanding Consumer Products

Consumer products record attributes and rules that are used for consumer contracts. A consumer product can for example record attributes for:

- The duration of a fixed-priced period
- The amount of a contractual change, such as an exit fee
- Prices

These attributes can be used when setting up a new consumer contract or changing an existing contract. They could also be used to display details when a product is being selected or to include details in correspondence with customers.

A consumer product's rules are used to set up new consumer contracts and to change existing consumer contracts.

A consumer product's attributes and rules are recorded in the consumer product's version. Refer to [Understanding Consumer Product Versions](#) on page 1275 for more details.

Consumer product eligibility criteria can be used to determine which consumer products that are eligible in particular circumstances. For example a consumer product could be eligible only when autopay is being used. Consumer product eligibility criteria are optional. If a consumer product has eligibility criteria then the consumer product is eligible or not depending on the criteria. If however a consumer product does not have eligibility criteria then the consumer product is always eligible. The next sections provide more information on this functionality.

Understanding Consumer Product Eligibility Criteria

A consumer product eligibility criteria rule requires the following components:

- Operand to be compared
- Comparison operator
- Comparison value
- Comparison results

The operands to be compared by consumer product eligibility criteria rules are identified using characteristic types. The characteristic types must have a characteristic entity of **Consumer Product Eligibility Operand**. The value of these characteristics are populated by the Operands algorithms that are defined on the related Consumer Contract Type's business object. The base product provides **Consumer Contract Type (BO) – Operands** algorithm that sets a characteristic value to indicate if the customer is or will be on autopay. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Contract Type (BO) – Operands** algorithm entity in the application.

The comparison operator can be one of the following: <, <=, <>, =, >, >=, Between, In or Is Blank.

The comparison value is recorded in the consumer product eligibility criteria rule.

The comparison results define what action should be taken when the criteria rule is applied. If the comparison is true or false, the result can be that the consumer product is eligible, the consumer product is not eligible or the next eligibility rule should be checked. If there is insufficient data, that is the operand to be compared was not found, the result can be that the consumer product is eligible, the consumer product is not eligible, the next eligibility rule should be checked or an error should be generated.

Understanding Consumer Product Versions

A consumer product version records the product attributes and rules that are applicable for consumer contracts related to the consumer product version.

Note: Consumer contracts relate to consumer product versions not to consumer products. The addition of a new consumer product version will not affect existing consumer contracts.

For a consumer contract that is created or changed using a customer service request, the consumer product version is determined using the Determine Version algorithm defined on the Consumer Product business object. The base package provides an algorithm type that determines the effective consumer product version by comparing the version's offer effective date and the date the new contract or contract change was agreed. Alternative custom algorithms could use one or more of the consumer product version's offer effective date, service effective date, offer end date, service end date and consumer product version selection. To see the list of available algorithm(s), search for algorithm types of the **Consumer Product (BO) – Determine Version** algorithm

Consumer products have two kinds of rules: consumer product rules and consumer contract rules. Consumer product rules are used to perform configurable services for a consumer product version. For example, a consumer product rule can determine the fallback product to use when a contract's product is no longer eligible. Consumer contract rules are used to set up new consumer contracts and make changes to existing consumer contracts. For example, a consumer contract rule can be used to create or stop a service agreement.

Consumer product rules relate directly to a consumer product version. Consumer contract rules are organized into groups using consumer product components. The consumer product components can be linked together into a hierarchy. The consumer product version records the consumer product component at the top of the hierarchy.

A consumer product version's attributes are recorded either as consumer product version characteristics or as consumer product component characteristics. Examples of attributes are: the duration of a fixed-price period and the amount of an exit fee.

Consumer product component eligibility criteria determine whether a consumer product component is applicable. The product attributes retrieved or consumer contract rules applied for a consumer product version will vary depending on the consumer product component eligibility criteria rules.

Understanding Consumer Product Rules

Consumer product rules are standard and custom rules that perform actions for a consumer product version. A consumer product rule class defines the type of action that is performed. A consumer product rule class is recorded in the consumer product version for each related consumer product rule. The base product provides the following consumer product rule classes:

- Determine Fallback Product
- Determine If Reapplication Required

A consumer product rule typically includes the following details:

- Basic information about the consumer product rule, including its name, description and detailed description. This is standard information for most consumer product rules.
- Specific parameters used by the consumer product rule.

The base product provides the following consumer product rules:

- **Determine Fallback Product:** A rule that determines the fallback product using a consumer product class recorded in the rule.
- **Determine if Product should be Reapplied:** A rule that determines if reapplication is necessary by deriving the current consumer product component eligibility criteria operands for the consumer product and comparing these with the previous operand values.

Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Product Rule (BO) – Apply Rule** algorithm entity in the application.

Understanding Consumer Product Components

Consumer product components group together product attributes and consumer contract rules.

Consumer product component eligibility criteria rules can be created for a consumer product component. These eligibility rules will determine if a consumer product component's product attributes are applicable and if a consumer product component's consumer contract rules are applied. A consumer product version could, for example, have one consumer product component that is eligible when a customer is on autopay and another consumer product component that is eligible when a customer is not on autopay.

A consumer product component can, optionally, have one or more child consumer product components. This allows consumer product components to be organized into a hierarchy. If a consumer product component is not eligible, any child consumer product components will also not be eligible.

Understanding Consumer Product Component Eligibility Criteria

A consumer product component eligibility criteria rule requires the following components:

- Operand to be compared
- Comparison operator
- Comparison value
- Comparison results

The operands to be compared by consumer product component eligibility criteria rules are identified using characteristic types. The characteristic types must have a characteristic entity of **Consumer Product Component Eligibility Operand**. The value of these characteristics are populated by the **Contract Operands** and **Location Operands** algorithms defined on the Consumer Product business object. The base product provides a **Consumer Product (BO) – Contract Operands** algorithm type that sets a characteristic value to indicate if the customer is or will be on autopay. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Product (BO) – Contract Operands** algorithm entity in the application.

The comparison operator can be one of the following: <, <=, <>, =, >, >=, Between, In or Is Blank.

The comparison value is recorded in the consumer product component eligibility criteria rule.

The comparison results define what action should be taken when the criteria rules is applied. If the comparison is true or false, the result can be that the consumer product component should be applied, the consumer product component should not be applied or the next eligibility rule should be checked. If there is insufficient data, that is the operand to be compared was not found, the result can be that the consumer product component should be applied, the consumer product component should not be applied, the next eligibility rule should be checked or an error should be generated.

Understanding Consumer Contract Rules

Consumer contract rules are standard and custom rules that perform actions to set up a new consumer contract or change an existing consumer contract which is related to the consumer product version. A consumer contract rule could for example create a new service agreement.

Consumer contract rules are grouped together by consumer product components. Consumer product components determine if and when a consumer contract rule will be applied. Refer to [Understanding Consumer Product Components](#) on page 1276 for more details.

Consumer contract rules are applied by a customer service request when a consumer contract is being created or changed. Different consumer product rules can be applied at different stages of the customer service request and for different changes. The consumer product component defines a consumer contract rule usage that determines when a consumer contract rule is applied.

The base product provides the following consumer contract rule usages:

- On Activation – Add: The consumer contract rules are applied during activation set up for the consumer product versions of consumer contract products that have been added.
- On Activation - Remove: The consumer contract rules are applied during activation set up for the consumer product versions of consumer contract products whose end date time has been set.
- On Completion – Add: The consumer contract rules are applied at completion for the consumer product versions of consumer contract products that have been added.
- On Completion – Remove: The consumer contract rules are applied at completion for the consumer product versions of consumer contract products whose end date time has been set.
- Service Location - Add: The consumer contract rules are performed when any action required to add a service point or registration point to a contract, such as field work or a market process, has been performed.
- Service Location – Remove: The consumer contract rules are performed when any action required to remove a service point or registration point from a contract, such as field work or a market process, has been performed.

The base product provides **Consumer Contract Rule (BO) – Apply Rule** algorithms that add a service agreement and that add a consumer contract milestone. Additional algorithms may exist for your implementation. To see the available algorithm(s), search for algorithm types of the **Consumer Contract Rule (BO) – Apply Rule** algorithm entity in the application.

Configuring Consumer Contract Type

This portal is used to display and maintain a Consumer Contract Type.

A Consumer Contract Type defines the Consumer Products that are valid for the type of contract. It also defines the information that is used in determining product eligibility.

Refer to [Understanding Consumer Contracts](#) for more information.

To maintain consumer contract types, open **Admin > Consumer Contract > Consumer Contract Type**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Configuring Consumer Contract Milestone Type

This portal is used to display and maintain a Consumer Contract Milestone Type.

A Consumer Contract Milestone Type defines milestone dates that can be recorded and whether an action should be performed for the type of milestone.

Refer to [Understanding Consumer Contract Milestones](#) for more information.

To maintain consumer contract milestone types, open **Admin > Consumer Contract > Consumer Contract Milestone Type**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Configuring Consumer Product

This portal is used to display and maintain a Consumer Product, including the consumer product's versions and eligibility rules.

Refer to [Understanding Consumer Products](#) for more information.

To maintain consumer products, open **Admin > Consumer Contract > Consumer Product**.

This is a standard [All-In-One Portal](#).

Refer to the Consumer Product zone's embedded help text for more information.

This portal also shows zones for Consumer Product Versions and Consumer Product Eligibility.

Configuring Consumer Product Version

This portal is used to display and maintain a Consumer Product Version.

Refer to [Understanding Consumer Product Versions](#) for more information.

To maintain consumer product versions, open **Admin > Consumer Contract > Consumer Product Version**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Configuring Consumer Product Rule

This portal is used to display and maintain a Consumer Product Rule.

Refer to [Understanding Consumer Product Rules](#) for more information.

To maintain consumer product rules, open **Admin > Consumer Contract > Consumer Product Rule**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Configuring Consumer Product Component

This portal is used to display and maintain a Consumer Product Component, including child consumer product components, eligibility rules and related consumer product versions.

Refer to [Understanding Consumer Product Components](#) for more information.

To maintain consumer product components, open **Admin > Consumer Contract > Consumer Product Component**.

This is a standard [All-In-One Portal](#).

Refer to the Consumer Product Component zone's embedded help text for more information.

This portal also shows zones for Consumer Product Component Eligibility and Related Consumer Product Versions.

Configuring Consumer Contract Rule

This portal is used to display and maintain a Consumer Contract Rule.

Refer to [Understanding Consumer Contract Rules](#) for more information.

To maintain consumer contract rules, open **Admin > Consumer Contract > Consumer Contract Rule**.

This is a standard [All-In-One Portal](#).

Refer to the embedded help text for more information.

Configuration

This section contains additional configuration topics for Oracle Utilities Customer to Meter and Oracle Utilities Customer Care and Billing.

Configuring Zones

Many zones in Oracle Utilities Customer Care and Billing do not require configuration by your implementation team. For example, the base package is shipped with the Account Financial History zone that appears on the Control Central - Account Information portal. This zone does not require configuration because its zone type has no configurable options (i.e., its behavior is static).

Other zones require configuration before they can be used because their behavior is dynamic. The topics in this section provide tips and techniques on how to configure zones in Oracle Utilities Customer Care and Billing.

Fastpath:

Refer to [The Big Picture of Portals and Zones](#) in the *Oracle Utilities Application Framework Administration Guide* for a description of portal and zone functionality.

Configuring Timeline Zones

A timeline zone is a zone that may be configured on the account or customer information tabs of Control Central. This type of zone contains one or more "lines" where each line shows when significant events have occurred. For example, you can set up a timeline zone that has two lines: one that shows when payments have been received from a customer, and another that shows when bills have been sent to the customer.

Fastpath: For a complete description of the numerous features available on a timeline zone, refer to [Timeline Zone](#).

Configuration is required to enable a timeline zone. A timeline zone is made up of one or more algorithms where each algorithm returns "events" for a certain type of record (payment or bill for example). The product delivers several algorithm types for the timeline zone to include "events" for many different transactions in the product. Each algorithm type uses the Account or Person in context to retrieve the related information.

- Refer to [Configuring Timeline Zones](#) in the framework portion of the administration guide for information about the type of detail each event may return. The base provided algorithm types include many parameters to allow the implementation to configure much of this information as desired.

Many of the algorithms support supplying a [BPA script](#) to launch when a user clicks on an event on a timeline. Be sure to review each algorithm type to see what types of events support a BPA script. For each event, determine if your business practice warrants the development of a BPA script.

After configuring the algorithms per your business needs, the following additional steps are needed:

- Set up a [zone](#) that references these algorithms. The zone will reference the **F1-TIMELINE** zone type.
- Link the zone to the appropriate portal(s) (e.g., [Control Central - Account Information](#) or [Control Central - Customer Information](#)).
- Update your users' [portal preferences](#) and [security rights](#) so they can see the zone in the desired location on the portal(s).

You can set up many timeline zones. For example,

- You might want different zones to appear on a portal depending on the type of user. For example, you might want one timeline for billing clerks, and a different one for customer service representatives.
- For aesthetic reasons, you might want multiple simple timeline zones to appear on a given portal rather than one complex timeline zone.
- You might want to set up context specific timeline zones. For example, you might want to have one timeline zone that is premise-oriented and another that is person-oriented.

Content Migration Assistant (CMA) Addendum

This section is an addendum to the general [Content Migration Assistant](#) section in the *Oracle Utilities Application Framework Administration Guide*. This section assumes that you are familiar with the concepts of Content Migration Assistant (CMA).

Note: CMA is designed to migrate configuration data only. Since base product data should be updated only through product patching mechanisms, CMA cannot currently be used to migrate master/transactional data that contains system-generated primary keys, such as customer account or billing information.

This addendum describes Content Migration Assistant (CMA) functionality that is specific to Oracle Utilities Customer Care and Billing.

The following sections provide information about what is provided in the C1-owned base package:

Base Package Migration Plans

The C1-owned base package provides a large number of migration plans to support migrating configuration and/or administration data from one environment to another.

Use the following procedure to access the base package migration plans:

1. Navigate to **Admin > Implementation Tools > Migration Plan > Search**.
2. Enter "C1" in the **Migration Plan** field.
3. **Click Refresh**.
4. Select a migration plan in the search results list. The details of the selected migration plan are displayed in the Migration Plan portal.

Note: The C1-owned base package plans can also be used as a basis for custom migration plans. To create a custom migration plan, select a plan to base the custom migration plan on, click the Duplicate button, and define the custom plan to meet the implementation's requirements as described in [Defining a Migration Plan](#) in the *Oracle Utilities Application Framework Administration Guide*.

Base Package Migration Request

The C1-owned base package provides two migration request to support migrating configuration and/or administration data from one environment to another.

Use the following procedure to access the base package migration requests:

1. Navigate to **Admin > Implementation Tools > Migration Request > Search**
2. Enter "C1" in the **Migration Request** field.
3. **Click Refresh**.
4. Click the **Copy and Sync Control Data** link in the search results list.

The details of the migration requests are outlined below. Please use the Migration Request portal to view additional details about this migration request.

Base Admin Data Migration Request

- **Migration Request:** C1-AdminBasic
- **Description:** Base Admin Data
- **Detailed Description:** Base Admin Data.
- **Migration Plans:** This migration request includes base package migration plans used by Oracle Utilities Customer Care and Billing.

Copy and Sync Control Data Migration Request

- **Migration Request:** C1-CopyControlTables
- **Description:** Copy and Sync Control Data
- **Detailed Description:** Copy and Sync Control Data.
- **Migration Plans:** This migration request includes base package migration plans used by Oracle Utilities Customer Care and Billing.

For additional information about these migration plans, see [Base Package Migration Plans](#) on page 1280.

Note: The C1-owned base package request can also be used as a basis for custom migration requests. To create a custom migration request, select the base package request, click the Duplicate button, and define the request as to meet the implementation's requirements as described in [Defining a Migration Request](#) in the *Oracle Utilities Application Framework Administration Guide*.

Wholesale and Piecemeal Migrations

There are two general types of migrations used with the Content Migration Assistant: wholesale migrations and piecemeal migrations.

Wholesale Migrations

Wholesale migrations are used when migrating all the configuration and/or administration data from one environment to another. For example, a wholesale migration might be used when migrating admin data from a development or test environment to a production environment. For more on this type of migration, see [Types of Migrations](#) in the *Oracle Utilities Application Framework Administration Guide*.

The following is a high-level overview of the steps involved when executing a wholesale migration.

1. Process the "F1-SchemaAdmin" (FW Foundation) migration request (This request contains migration plans for Field, Lookup, Char Type, Currency Code and FK Ref).
2. Process the "C1-AdminBasic" migration request. This includes copies of framework migration plans (including plans for Business Objects, Algorithms, and Feature Configurations) from the "F1-FrameworkAdmin" migration request, as well as independent base package C1-owned wholesale migration plans which can be run first.
3. Process any of the other delivered framework-based (F1-owned) migration requests as needed (except for the "F1-FrameworkAdmin" migration request which is already incorporated in #2)
4. Process the "C1-CopyControlTables" migration request. This includes base package C1-owned wholesale migration plans with dependency on "C1-AdminBasic" migration request.

Piecemeal Migrations

Piecemeal (or "non-wholesale" or "targeted") migrations are used when migrating a small portion (or piece) of configuration and/or administration data from one environment to another. For example, a piecemeal migration might be used when migrating groups and rules from a development or test environment to a production environment. For more on this type of migration, see [Types of Migrations](#) in the *Oracle Utilities Application Framework Administration Guide*.

The C1-owned base package does not contain piecemeal migration plans for Oracle Utilities Customer Care and Billing.

Processing Notes for Specific Objects

The following limitations apply to certain Oracle Utilities Customer Care and Billing objects when using Content Migration Assistant:

- An Issuing Center object references a User. If this user does not exist in the target system, Content Migration Assistant cannot apply the requested changes.
- A Case Type object references an Application Service. If this service does not exist in the target system, Content Migration Assistant cannot apply the requested changes.
- Collection Agency and Service Provider objects reference a Person. If this person does not exist in the target system, Content Migration Assistant cannot apply the requested changes.
- Service Provider and Tender Source objects reference a Service Agreement. If this service agreement does not exist in the target system, Content Migration Assistant cannot apply the requested changes.
- If your migrateable object includes log tables, you may add your log entity to the characteristic type F1-MGO. You should also mark the log table as a "Non-Migrateable Table" in the Maintenance Object options.
- Transactions are applied in an unspecified order (and probably in order numerically by a randomly generated ID value). CMA only looks at "hard" constraints when determining what to put into the same transaction. Any "soft" constraints such as characteristics and algorithm parameters that might have FK references to other objects are not processed by CMA. Unless the migration plan ensures that related items go into the same transaction, they will end up in different ones, and must need to apply again and again until eventually all gets applied.

To Do Lists Addendum

This section is an addendum to the general [To Do Lists](#) chapter. This addendum describes the To Do functionality that is specific to Oracle Utilities Customer Care and Billing.

Assigning A To Do Role

As described in [To Do Entries Reference A Role](#), each To Do entry requires a role. To Do entries created in Oracle Utilities Customer Care and Billing may attempt to assign a role based on an account management group or division if it is applicable to the type of data related to the To Do entry.

As described in [The Big Picture of To Do Lists](#), users are informed that something requires their attention by entries that appear in a To Do List. For example, consider what happens when billing can't find a reading (and it's not allowed to estimate):

- The billing process creates a bill segment that is in error (meter read cannot be found).
- This bill segment that's in error, in turn, triggers the creation of a To Do entry.
- The To Do entry is assigned a role. A role is one or more users who can look at / work on the entry.
- When users view a To Do List, they only see entries addressed to roles to which they belong.

You can optionally use account management groups (AMG) to define the respective role to be assigned to To Do entries that are associated with an account and To Do type. For example, you can create an AMG called Credit Risks and assign this to accounts with suspect credit. Then, whenever an account-oriented To Do entry is created for such an account, it will be assigned a role based on the Credit Risks AMG. Refer to [Setting Up Account Management Groups](#) for more information.

By assigning an AMG to an account, you are telling the system to address this account's To Do list entries to the roles defined on the AMG (note, each To Do type can have a different role defined for it on an AMG).

You can optionally use division to define the respective role to be assigned to To Do entries that are associated with an account and To Do type. For example, you may have a division called California Operations and assign this to accounts located in California. Then, whenever an account-oriented To Do entry is created for such an account, it will be assigned a role based on the California Operations division. Refer to [Setting Up CIS Divisions](#) on page 595 for more information.

A To Do Pre-Creation installation options plug-in is provided to determine the appropriate To Do Role for an account based on AMG and division setup. If plugged in, the logic to determine To Do role for an account is performed whenever a To Do entry is created. Refer to C1-TDCR-DFRL for further details on how this plug-in works.

Fastpath:

Refer to [To Do Entries Reference A Role](#) for the details of how an initial role is assigned to To Do entries.

Background Processes Addendum

This chapter is an addendum to the general [Defining Background Processes](#) chapter. This addendum describes the background processes that are provided with Oracle Utilities Customer Care and Billing .

Batch Process Dependencies

The contents of this section illustrate the periodicity and dependencies between the various background processes described above.

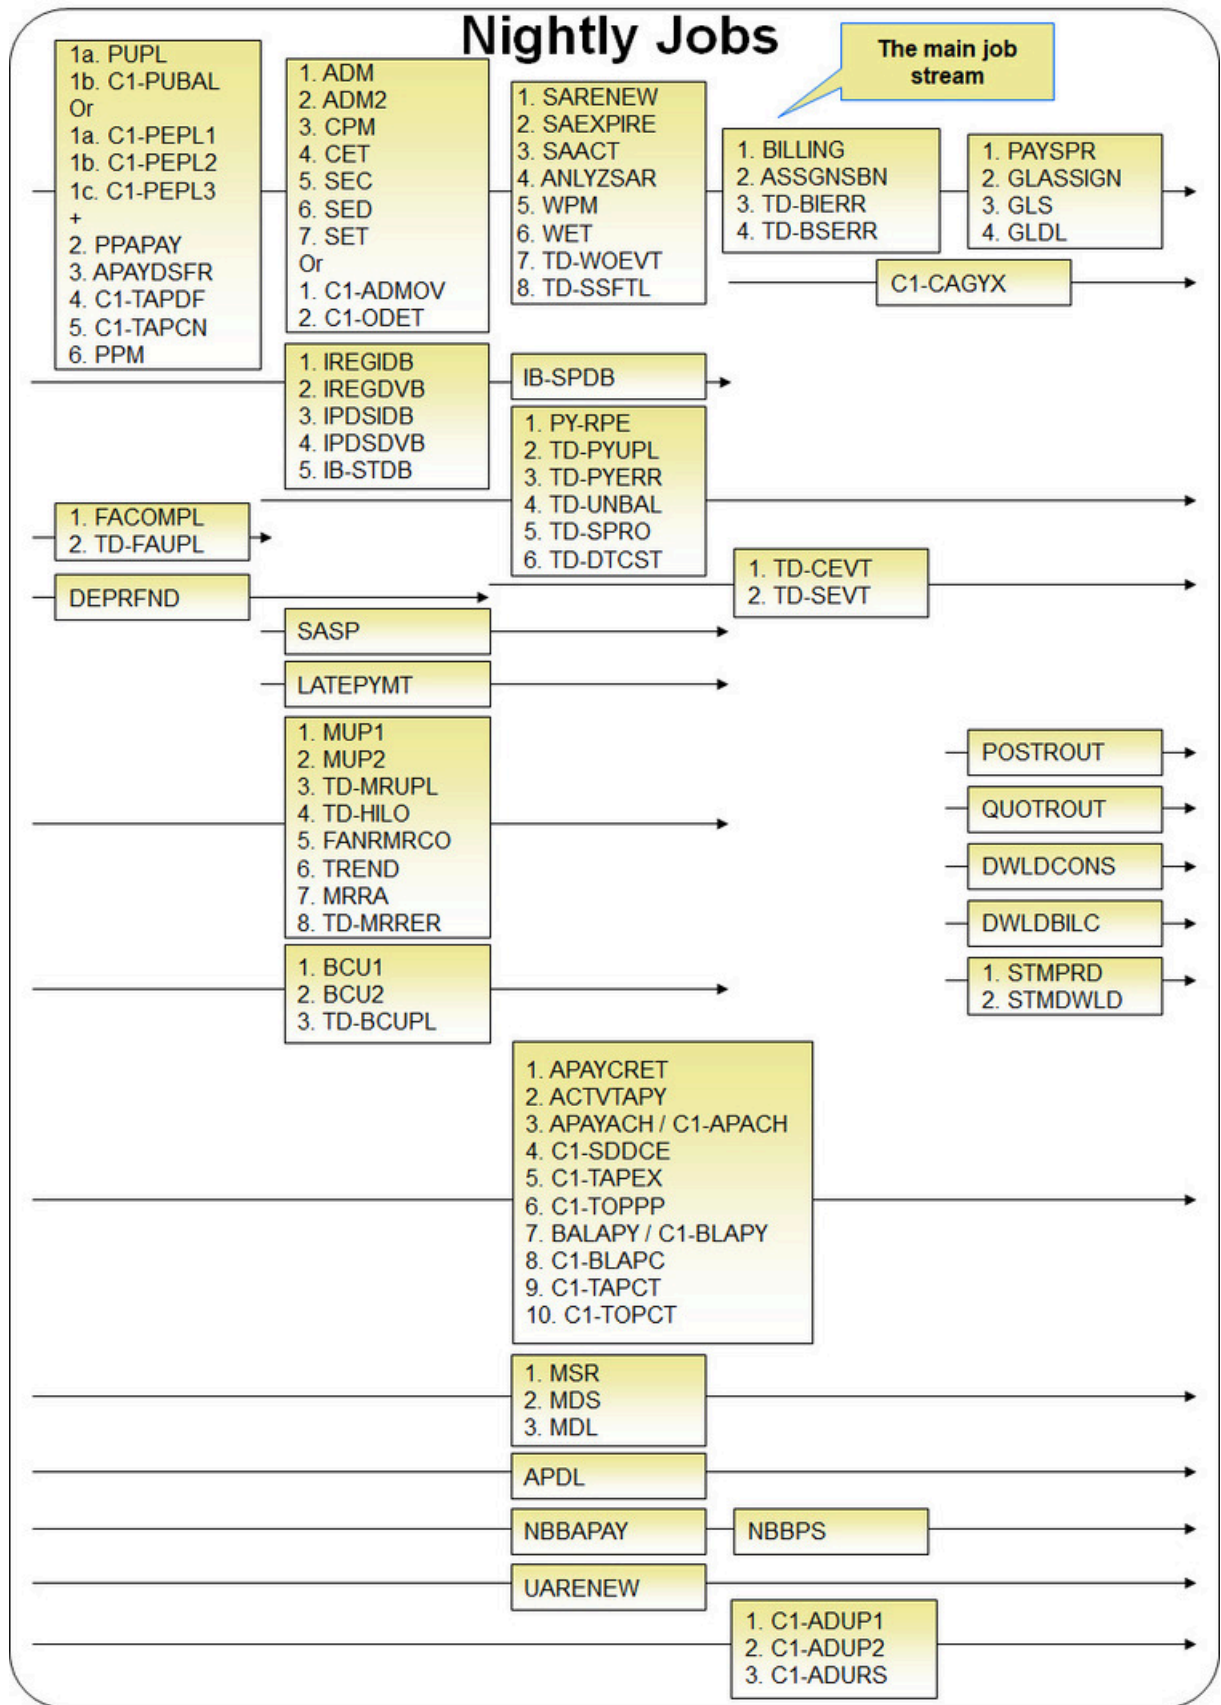

Batch Schedulers and Return Codes

If you use a batch scheduler (e.g., Control-M, Tivoli) to control the execution of your batch processes, it will be interested in the possible values of each process's return code. The return code is a number that indicates if the process ended successfully. All product processes will return one of the following return code values:

- 0 (zero). A value of zero means the batch process ended normally.
- 2. A value of 2 means the batch process detected a fatal error and aborted.

The Nightly Processes

The following diagram illustrates the dependencies between the batch processes.

The mnemonics in the boxes refer to the individual batch processes described above. When a box contains multiple processes, these processes must be run sequentially. When multiple boxes exist on a timeline, all processes in an earlier box must execute before the subsequent box is executed. Those timelines that appear beneath the Main Job Stream's timeline indicate when the timeline's respective processes can be executed in respect of the Main Job Stream.

The following diagram illustrates the daily batch processes for which there are no dependencies.

The mnemonics in the boxes refer to the individual batch processes described above.

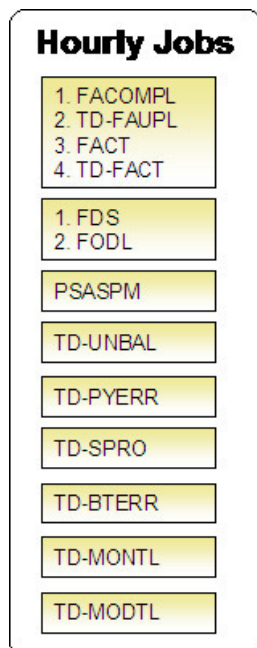

Note:

No dependencies exist. As you can see, there are no dependencies between the boxes (meaning they may be run in parallel).

The Ongoing or Hourly Processes

The following diagram illustrates the dependencies between the ongoing or hourly batch processes.

The mnemonics in the boxes refer to the individual batch processes described above. When a box contains multiple processes, these processes must be run sequentially.

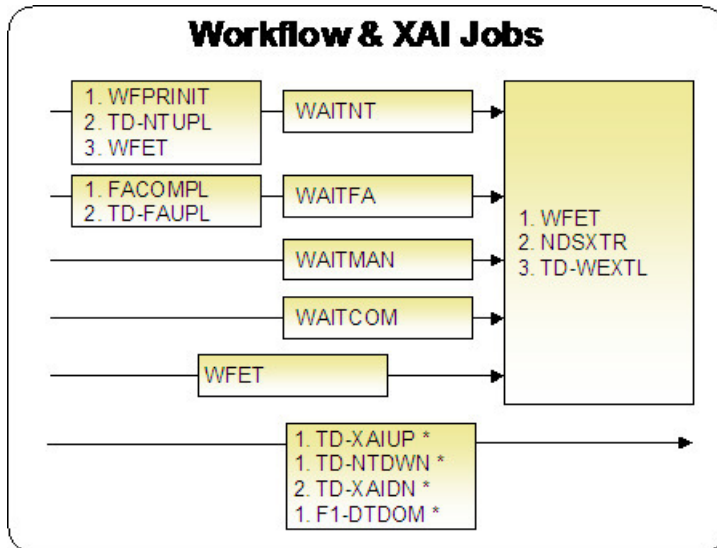

Note:

No dependencies exist. As you can see, there are no dependencies between the boxes (meaning they may be run in parallel).

The Workflow and XAI Processes

The following diagram illustrates the dependencies between the workflow and XAI background processes. While these processes should be run at least once a day, you may want to consider running them more frequently (depending on how frequently you interface notifications and field activities into the system).

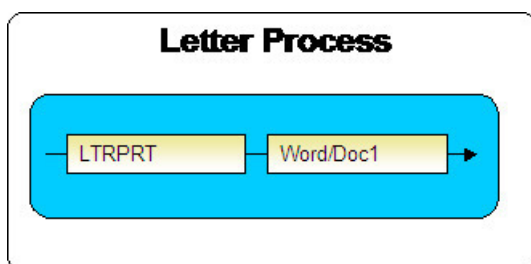

The mnemonics in the boxes refer to the individual batch processes described above. When a box contains multiple processes, these processes must be run sequentially. When multiple boxes exist on a timeline, all processes in an earlier box must execute before the subsequent box is executed.

* These processes create and/or clean up To Do entries for XAI upload staging, notification download staging, XAI download staging records or outbound messages in error. They are only applicable if your organization is using the XAI tool because only the XAI tool will mark one of these records in error.

The Letter Processes

To extract information for your various letters, only one background process, LTRPRT, is required regardless of the different types of letters you have. This process simply calls an algorithm plugged-in on the respective letter template to construct its flat-file content.

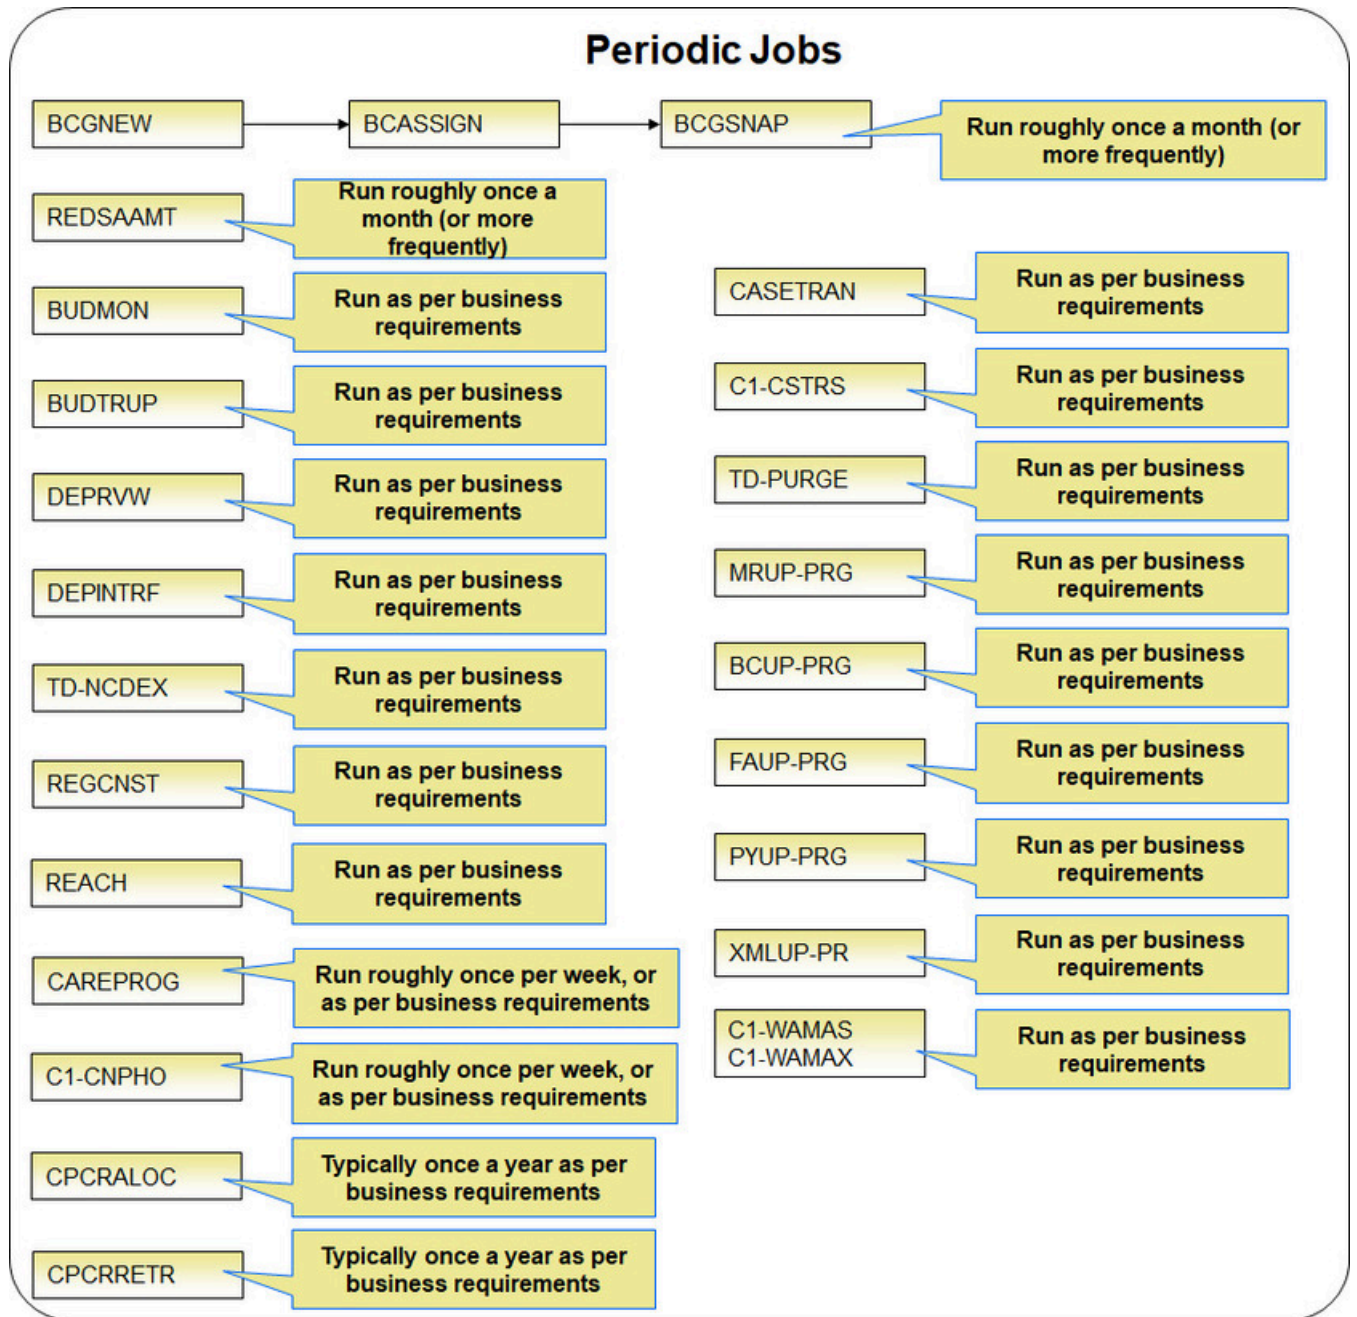

The following diagram illustrates the dependencies for the letter background process. While this process should be run at least on a daily basis, you may want to consider running it more frequently (depending on how frequently you produce letters).

The mnemonics in the boxes refer to the individual batch processes described above. When a box contains multiple processes, these processes must be run sequentially. When multiple boxes exist on a timeline, all processes in an earlier box must execute before the subsequent box is executed.

The Periodic Processes

The following diagram illustrates the dependencies between the periodic background processes. While many of these processes should be run at least on a monthly basis, you may want to consider running them more frequently (depending on business requirements).

The mnemonics in the boxes refer to the individual batch processes described above.

Note:

Few dependencies exist. As you can see, there are few dependencies between the boxes (meaning they may be run in parallel).

How To Set Up A New Extract Processes

Several background processes delivered with the system are used to interface information out of the system. The topics in this section describe when and how to introduce an additional extract process.

Setting Up Meter Read Extracts

You will need a meter read extract for every mechanism your company uses to route meter read requests to the software that handles your meter reading requests. For example:

- You will need a meter read extract to interface records to your handheld device software. The MDL process delivered with the system is intended to be used to handle this function. This process will have to be populated to format the output records in keeping with the needs of your meter reading software.
- If you interface some meter read requests to automatic meter reading software, you will need a new meter read extract process.

If you need additional meter read extract processes, set up the following information:

- Add a new [batch control](#) record. Populate the fields as follows:
- **ID.** Assign an easily recognizable unique ID for the meter read extract process.
- **Description.** Enter a description of the meter read extract process.
- **Accumulate All Instances.** Turn this switch on.
- Use [Route Type](#) to define the meter read extract process to be used for each route type.

Note:

Route types are defined for each route linked to every service cycle. Refer to [Setting Up Service Cycles And Routes](#) for more information.

- It may be necessary to register the process with your scheduler software.

Setting Up Automatic Payment Extracts

You will need an automatic payment extract for every mechanism your company uses to route automatic payment requests to a financial institution / clearing house. For example:

- You will need an automatic payment extract to interface records to the Automated Clearing House (ACH) if you allow customer to pay via credit card or direct debit from a checking account. The **APAYACH** and **C1-APACH** processes delivered with the system are intended to be used to handle this function.

If you need additional automatic payment extract processes, set up the following information:

- Add a new [batch control](#) record. Populate the fields as follows:
- **Batch Process.** Assign an easily recognizable unique ID for the automatic payment extract process.
- **Description.** Enter a description of the automatic payment extract process.
- **Accumulate All Instances.** Turn this switch on.
- Use [Auto Pay Route Type](#) to define the auto pay extract process to be used for each route type.

Choosing Which Records Are Selected

The system is delivered with some background processes that utilize the **Select Records** plug-in spot to select the records to be processed. It is important to note that these background processes do not utilize the Process Records plug-in spot. This logic is hardcoded as these background processes are some of the core system functions such as billing and collections. This functionality provides flexibility in choosing which records are processed, but not how they are processed.

The background processes delivered with the system optionally selects records based on CIS Division. One example is the batch control (BILLING) and algorithm (C1-BILL-SR). The background process and select records algorithm work as a pair. The batch control defines the parameter to be used by the select records algorithm. The algorithm defines the thread strategy, key fields, and makes the batch control parameter available to be used in the SQL algorithm parameter.

Customizing Which Records Are Selected

There are two ways to customize what is provided with the system.

If your organization processes records using the same criteria as the samples delivered in the system, in this case CIS Division, simply create a custom batch control for each CIS Division and specify the corresponding parameter value.

If your organization processes records using different criteria, the following points summarize the steps needed to implement a new background process using plug-ins for the specific functionality:

- Duplicate an existing batch control
- Remove the batch parameter not relevant to your organization and replace with the relevant batch parameter. Note: only the batch parameters associated with selecting records should be removed or updated. Parameters used to process records must remain.
- Duplicate the plug-in script associated with the select records algorithm type. Modify the script to pass the new batch parameter(s) to bind variables and remove those that are no longer batch parameters.
- Duplicate the select records algorithm type and associate with the new script.
- Create an algorithm for the new algorithm type. The SQL parameter value should be copied from the original algorithm type's algorithm parameter value and modified to make use of the newly added bind variables. (**Note:** Do not change the fields selected or their order.)
- Update the batch control to use the new select records algorithm.

The Big Picture of Sample & Submit

Sample and Submit refers to the ability to create Activity Requests. This is functionality that enables an implementer to design an ad-hoc batch process using the configuration tools.

Some examples of such processes are:

- Send a letter to customers that use credit cards for auto pay and the credit card expiration date is within 30 days of the current date.
- Stop auto pay for customers that use credit cards as the form of payment if the credit card has already expired. Notify the customer that their auto pay agreement has been terminated and that they need to call to reinstate.
- Select auto pay accounts that have more than X non-sufficient fund penalties, stop the auto pay agreement and notify the customer.

Note:

The terms *activity request* and *sample & submit request* may be used interchangeably.

Activity Request Type Defines Parameters

For each type of process that your implementation wants to implement, you must configure an activity request type to capture the appropriate parameters needed by the activity request.

Preview A Sample Prior To Submitting

To submit a new activity request, a user must select the appropriate activity request type and enter the desired parameter values, as applicable.

After entering the parameters, the following actions are possible

- Click **Preview** to see a sample of records that satisfy the selection criteria for this request. This information is displayed in a separate map. In addition, the map displays the total number of records that will be processed when the request is submitted. From this map you can **Save** to submit the request, go **Back** to adjust the parameters or **Cancel** the request.
- Click **Cancel** to cancel the request.
- Click **Save** to skip the preview step and submit the request.

When an activity request is saved, the job is not immediately submitted for real time processing. The record is save in the status Pending and a monitor process for this record's business object is responsible to transition the record to Complete.

As long as the record is still Pending, it may be edited to adjust the parameters. The preview logic described above may be repeated when editing a record.

The actual work of the activity request, such as generating customer contact records to send letters to a set of customers, is performed when transitioning to Complete (using an enter processing algorithm for the business object).

Credit Card Expiration Notice

The base product supplies a sample process to find customers that use credit cards for auto pay and their credit card expiration date is within *X* days of the current date.

To this functionality the following configuration tasks are needed:

- Define an appropriate [customer contact class](#) and [type](#) to use.
- Define appropriate activity request Cancellation Reasons. Cancellation reasons are defined using a customizable [lookup](#). The lookup field name is C1_AM_CANCEL_RSN_FLG.
- Define an activity request type for the business object C1-NotifyExpiringCreditCardTyp . You may define default parameter values for the number of days for expiration and customer contact class and type.

Defining a New Activity Request

To design a new ad-hoc batch job that users can submit via Sample and Submit, first create a new Activity Request Type business object. The base product BO for the activity type C1-NotifyExpiringCreditCardTyp may be used as a sample.

The business object for the activity request includes the functionality for selecting the records to process, displaying a preview map for the user to review and to perform the actual processing. The base product BO for the activity request C1-NotifyExpiringCreditCardReq may be used as a sample. The following points highlight the important configuration for this business object:

- Special BO options are available for the activity request BOs to support the [Preview Sample](#) functionality.
 - Activity Request Preview Service Script. This script is responsible for retrieving the information displayed when a user asks for a preview of a sample of records.
 - Activity Request Preview Map. This is the map that is invoked to display the preview sample results.
- The enter algorithm plugged into the Complete state is responsible for selecting all the records that satisfy the criteria and processing the records accordingly.

Setting Up Activity Request Types

Activity Request Types define the parameters to capture when submitting an activity request through Sample and Submit. To set up an activity request type, open **Admin > Customer > Activity Request Type > Add**.

The topics in this section describe the base-package zones that appear on the Activity Request Type portal.

Activity Request Type List

The Activity Request Type [List zone](#) lists every activity type. The following functions are available:

- Click a [broadcast](#) button to open other zones that contain more information about the adjacent activity type.
- Click the Add link in the zone's title bar to add a new activity type.

Activity Request Type

The Activity Request Type zone contains display-only information about an activity request type. This zone appears when an activity request type has been broadcast from the Activity Request Type List zone or if this portal is opened via a drill down from another page. The following functions are available:

- Click the **Edit** button to start a business process that updates the activity request type.
- Click the **Delete** button to start a business process that deletes the activity request type.
- Click the **Duplicate** button to start a business process that duplicates the activity request type.
- State transition buttons are available to transition the activity request type to an appropriate next state.

Please see the zone's help text for information about this zone's fields.

Maintaining Sample & Submit Requests

Use the Sample and Submit transaction to view and maintain pending or historic activity requests. Navigate using **Menu > Tools > Sample & Submit Request > Search**.

Sample & Submit Request Query

Use the [query portal](#) to search for an existing sample & submit request. Once a request is selected, you are brought to the maintenance portal to view and maintain the selected record.

Sample & Submit Request Portal

This portal appears when a sample & submit request has been selected from the Sample & Submit Request Query portal.

The topics in this section describe the base-package zones that appear on this portal.

Sample & Submit

The Sample & Submit zone contains display-only information about an activity (sample & submit) request. The following functions are available:

- Click the **Edit** button to modify the parameters. Refer to [Preview A Sample Prior to Submitting](#) for more information.
- If the activity request is in a state that has valid next states, buttons to transition to each appropriate next state are displayed.

Please see the zone's help text for information about this zone's fields.

Sample & Submit Log

This is a standard [log zone](#).

Defining Batch Schedule Options

The topics in this section describe how to set up the system to periodically execute batch job streams.

Note:

The batch scheduler is optional. Setting up the batch scheduler is only necessary if your organization uses the product's batch scheduler. If your organization uses a third party tool to manage the periodic execution of batch jobs, this section is not applicable.

Separate module. Batch scheduler functionality is associated with separate Workflow Scheduling module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

The Big Picture of Scheduling Batch Jobs

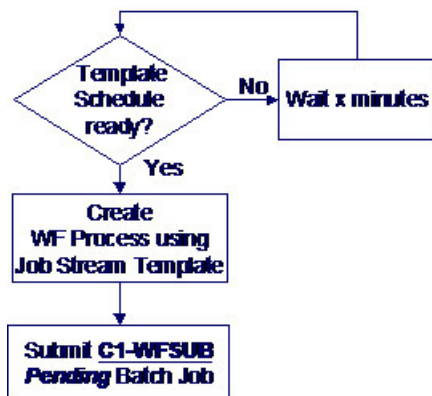

The following points provide an overview of how batch jobs are scheduled to run periodically.

Technical Implementation Of The Batch Scheduler

The topics in this section provide information about how your job streams are executed. This section is intended for your technical personnel who are responsible for configuring the program that periodically submits batch jobs.

A Program Determines If There's Work To Do

A program runs in the background looking for job stream (workflow process) templates whose [schedule](#) is ready to be processed. The following flowchart provides a schematic of its logic:

When C1-WFSUB executes, it causes the workflow events to activate. The activation plug-in on these workflow events creates Pending Batch Jobs

The following points summarize important concepts illustrated in the flowchart:

- When the job stream template [schedule](#) indicates it's time to start a job stream, a workflow process is created by copying the event types from the job stream (workflow process) template.
- In addition, a Pending batch job that activates the workflow process's events is created (i.e., the C1-WFSUB batch job is submitted).
- When C1-WFSUB executes, it activates the workflow process's events. The activation plug-in of these workflow events creates the job stream's Pending batch jobs. In addition, the activation algorithm transitions the workflow events into the Waiting state (they are waiting for the batch job to complete).

Note:

The identity of C1-WFSUB is not hard-coded. Rather, it's defined on the batch scheduler's [Feature Configuration](#).

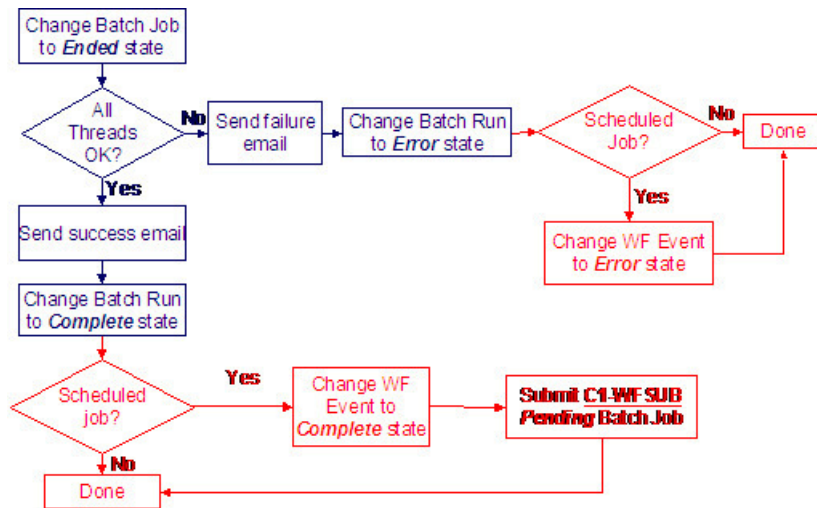

Note:

Number of Threads. For batch jobs related to a job stream, the number of parallel threads to execute is defined on a parameter on the workflow event's activation algorithm.

Completing A Batch Program That's Part Of A Job Stream

When a batch program completes, a common routine is called. The following flowchart provides a schematic of this routine's logic where the logic applicable to the batch scheduler is highlighted in red.

The following points summarize important concepts regarding the batch scheduler logic illustrated in the flowchart:

- If at least one thread fails and this batch job is one related to a scheduled job stream, the status of the corresponding workflow event is changed to Error.
- If all threads are successful, and this batch job is one related to a scheduled job stream,
 - The status of the corresponding workflow event is changed to Complete.
 - In addition, a Pending batch job is submitted to activate workflow events that are dependent on the completion of a batch job. When this job executes, the "downstream" batch jobs will be submitted (and then the logic shown above starts again).

Note:

Batch Run Number. The routine also creates a characteristic for the workflow event to capture the batch run number associated with this batch run. The characteristic type to use is defined on the [feature configuration](#).

Polling Frequency

Usage of the batch scheduler requires that your system administrator create a job in the operating system to periodically execute the program described above. It is important to schedule the execution of this program very frequently (e.g., every five minutes) in order to avoid lengthy time gaps between the completion of a batch job and the triggering of the dependent jobs.

Job Stream, a Definition

The term "job stream" refers to a suite of batch jobs that run periodically. Most organizations have multiple job streams. For example,

- You'll have a job stream that contains batch jobs that run nightly
- You'll have a different job stream that contains the hourly batch jobs
- You'll have a different job stream that contains the batch jobs that extract data for your data warehouse
- Etc.

Fastpath:

Refer to [Batch Process Dependencies](#) for a description of sample job streams.

A Workflow Process Is Created Each Time A Job Stream Executes

The system creates a [workflow process](#) each time a job stream executes. The workflow process has a separate workflow event for each batch job in the job stream. The batch jobs are submitted when the workflow process's events are activated (i.e., each workflow process event submits a specific batch job).

A Workflow Process Template Defines The Batch Jobs In A Job Stream

The system creates a job stream's workflow process using a [workflow process template](#). This means that a separate workflow process template exists for each job stream. For example, there is a workflow process template for the nightly job stream and another for the weekly job stream, etc.

There are typically dependencies between a job stream's batch jobs. For example, the billing batch job might be dependent on the successful execution of the payment upload batch job. Dependencies between batch jobs are defined by setting up workflow event dependencies on the workflow process. For example, if the billing batch job should only run after the payment upload batch job completes, you'd set up the workflow event that submits the billing job to be dependent on the completion of the event that submits the payment upload job. Note, you can define multiple dependencies between batch jobs (i.e., you can indicate that both the meter read upload and payment upload must complete before billing starts).

Once you define your job streams using workflow process templates, you indicate your job streams in the batch scheduler [feature configuration](#). The [job stream summary](#) page and the [job stream creation schedule](#) use this information to display the appropriate job stream templates.

How To Start A Job Stream

You can manually start a job stream using the [Job Stream Summary](#) page.

Optionally, you can [set up a schedule](#) defining when the system should start a job stream (i.e., create a workflow process). For example, you can set up a schedule for the "nightly" workflow process template to indicate that a workflow process should be created every night at 5:30 pm, Monday through Friday.

- You can monitor the status of your job streams on the [Job Stream Summary](#) page.
- You can monitor the status of a specific execution of a job stream on the [Job Stream Details](#) page. This page shows the status of the events on a workflow process and a summary of the execution status of each event's batch job.

Fastpath:

Refer to [Technical Implementation Of The Batch Scheduler](#) for more information.

Activating A Workflow Event Causes A Batch Run To Be Submitted

When a workflow event is activated, its activation algorithm creates a Pending batch run request. To be specific - the workflow event's Activation algorithm defines the batch process and the [number of parallel threads](#) that should be executed when the batch job is submitted. Please see the activation algorithm's parameters for a description of exactly how the Pending batch run request is created.

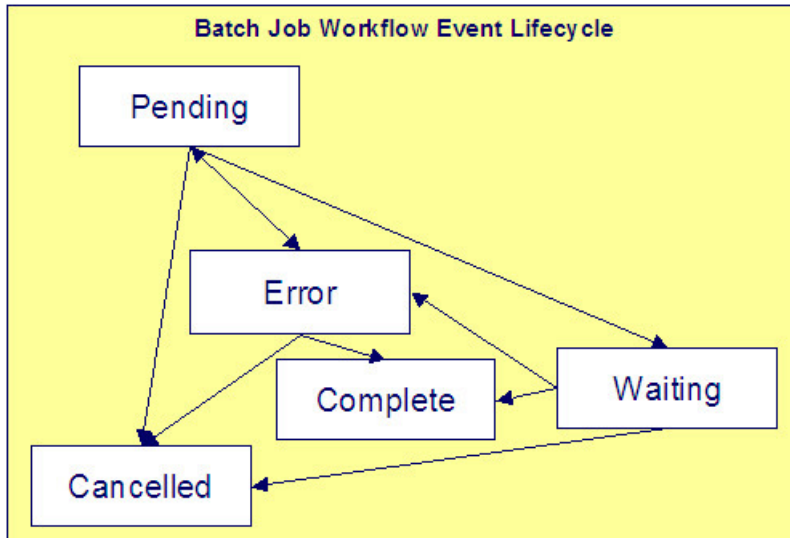

Note:

What activates workflow events? A batch process exists that is responsible for activating the workflow events associated with your job streams' workflow processes. This batch process is known as C1-WFSUB. In addition, when this process is submitted, it only activates the workflow events associated with a specific workflow process template (the workflow process template is identified by a parameter supplied to C1-WFSUB). You may wonder why the standard WFET batch process (i.e., the standard workflow event activator) doesn't process the batch scheduler workflow events. The reason is that C1-WFSUB is executed many times during the processing of your job streams and we didn't want to clutter up the run statistics for WFET with the myriad executions of C1-WFSUB.

Workflow Event Status Reflects The Status Of The Batch Run

The system creates a [workflow process](#) each time a job stream executes. The workflow process has a separate workflow event for each batch job in the job stream. The batch jobs are submitted when the workflow process's events are activated (i.e., each workflow process event submits a specific batch job). The following diagram shows the potential state of these workflow events:

Workflow Event Lifecycle

The following points explain the relationship between a workflow event's status and the state of the corresponding batch job that it submits:

- Workflow events are initially created in the Pending state. The event's batch job has not been submitted when it's in this state.
- When the workflow event is activated, its activation algorithm attempts to submit a request to execute a batch job:
 - If there is something wrong with the activation algorithm's parameters, the event will enter the Error state. If this happens, you can:
 - Resubmit the batch job by changing the event's state back to Pending.
 - Cancel the batch job by changing the event's status to Canceled .
 - Skip this batch job by changing the event's status to Complete . Do this if the subsequent dependent batch jobs should proceed despite these errors.
 - If the batch run is submitted successfully, the workflow event enters the Waiting state (it is waiting for the batch job to complete).
 - When the batch job completes, the workflow event transitions into either the Complete or Error state:
 - If the batch run aborts due to too many errors, it transitions into the Error state. If this happens, you can:
 - Restart a batch job that aborted by changing the event's status back to Pending.
 - Cancel the batch job by changing the event's status to Canceled .
 - Skip this batch job by changing the event's status to Complete . Do this if the subsequent dependent batch jobs should proceed despite these errors.
 - If the batch run doesn't abort, due to too many errors, it transitions to the Complete state.
 - You can Cancel a Pending event if you don't want the batch job to be submitted.
 - A Pending event will be Canceled automatically by the system if the workflow process is canceled by a user.
 - A Waiting event will be Canceled automatically by the system if the workflow process is canceled by a user.

**Note:**

You can monitor the status of a workflow process's events and their related batch jobs on the [Job Stream Details](#) page.

Setting Up The Batch Scheduler

The following topics summarize how to set up the system to enable the scheduling of job streams.

Create A Workflow Event Type - Activation Algorithm For Every Batch Job

As described under [The Big Picture of Scheduling Batch Jobs](#), the system creates a workflow process when a job stream is initiated. The workflow process's events cause Pending batch jobs to be created when the workflow events are activated.

A base-package Workflow Event Type - Activation algorithm exists that creates a Pending batch job (the identity of the batch job is defined as a parameter on the algorithm). This means that you need to set up a Workflow Event Type - Activation Algorithm for every batch job.

Besides defining the batch job's [batch control](#) code, the base-package algorithm, C1-WFAC-CRBJ also allows you to define the following values on each algorithm:

- **The number of parallel threads that should be submitted.** If this parameter is left blank, the batch job is submitted using a single thread. If a value greater than one is defined, the system automatically initiates this number of parallel threads. For example, if you want to kick the BILLING batch process using 20 parallel threads, specify a value of 20 in the respective algorithm's parameters. Refer to [Optimal Thread Count for Parallel Background Processes](#) for more information of executing a batch process in parallel threads.
- **The override email address used to inform that a batch job has finished.** If this parameter is specified, email is sent to this address when a batch job completes informing the recipient of its successful completion (or failure). Note, this address overrides the email address defined on the [Feature Configuration](#) for the batch scheduler (meaning that you need only populate this parameter if you want the email to be sent to someone other than the global email recipient defined on the Feature Configuration).
- **The value of all batch job-specific parameters.** Some batch jobs have job-specific parameters. For example, the Account Debt Monitor (ADM) batch process has a parameter that controls if calendar or workdays should be used when calculating dates. Values for the job-specific parameters may be defined on the batch code. In addition, override values may be defined on the algorithm's parameters. For example, you can define if calendar days or workdays are used when you set up the algorithm that submits the Account Debt Monitor batch process.

Create A Workflow Event Type For Every Batch Job

As described under [The Big Picture of Scheduling Batch Jobs](#), the system creates a workflow process when a job stream is initiated. The workflow process's events reference workflow event types. A separate workflow event type must be set up for every batch job (and you must reference the appropriate activation algorithm on each workflow event type).

Create A Workflow Process Template For Every Job Stream

As described under [The Big Picture of Scheduling Batch Jobs](#), the system creates a workflow process when a job stream is initiated. The system uses a workflow process template to create a workflow process. This means you must create a workflow process template for every batch job.

Set Up A Work Calendar

As described under [How To Start A Job Stream](#), you must set up a Job Stream Creation Schedule to define when each job stream should be started. You do this using the [Job Stream Creation Schedule](#) transaction. This transaction allows

you to create the submission dates and times using a "recurrence schedule" (i.e., you don't have to type in 52 entries for a weekly job stream, you can rather have the system create the 52 entries for you). This feature uses a given [work calendar](#) to know what days are workdays and holidays. You must set up a work calendar (or reuse an existing work calendar) if you intend to use this feature.

Set Up A Job Stream Creation Schedule For Each Job Stream

As described under [How To Start A Job Stream](#), you must set up a [Job Stream Creation Schedule](#) to define when each job stream should be initiated. For example, you can set up a schedule to have your "nightly" job stream run at 5pm, Monday through Friday.

Set Up Characteristic Types

When the system activates a workflow event that submits a Pending batch job, it updates the workflow event with information about the batch job. It does this by populating characteristics on the workflow event. In order for the system to do this, you must set up the following characteristic types:

- Batch Job ID. This must be FK characteristic to the Batch Job object.
- Batch Control Code. This must be a FK characteristic to the Batch Control object.
- Batch Run Number. This must be an ad hoc characteristic.

In addition to the above workflow event characteristics, you must also set up a workflow process characteristic:

- Business Date. This must be an ad hoc characteristic. It holds the business date that's passed to the job stream's batch jobs (all batch jobs in a job stream use the same business date).

Set Up A User ID For Batch Jobs

When batch jobs execute, they must reference a given user's information for the following:

- Batch jobs can cause "auditable" events to occur. These events have a user ID associated with them.
- Some batch jobs access language-specific data, the language used is defined on a given user.
- When batch jobs complete, an email message is sent to a user's email address.

When a batch job is submitted, it references a specific user ID; this user ID is used for the above points. We recommend setting up a "dummy" user for this purpose (e.g., user ID = BATCH).

Set Up A Feature Configuration

After completing the above set up tasks, you must set up a [Feature Configuration](#) to provide the batch scheduler with the information it needs to operate.

The following points describe the various **Option Types** that must be defined for the feature configuration:

- Active Job Stream (WF Template Code). Set up a separate option for every job stream. The option's value is the Workflow Process Template associated with the job stream. Note, only these job streams appear on the [Job Stream Summary](#) page and are available in the [Job Stream Creation Schedule](#) page.
- Batch Code FK Char Type. Set up a single option to define the foreign key characteristic type used to reference the batch code on the workflow events. Refer to [Set Up Characteristic Types](#) for more information.
- Batch Code of WF Event Activation Process. Set up a single option to define the batch code of the batch job that is responsible for [activating the workflow events](#) that cause Pending batch jobs to be created.
- Batch Job ID FK Char Type. Set up a single option to define the foreign key characteristic type used to reference the batch job on the workflow events. Refer to [Set Up Characteristic Types](#) for more information.
- Batch Run Number Ad hoc Char Type. Set up a single option to define the ad hoc characteristic type used to reference the batch run's run number on the workflow events. Refer to [Set Up Characteristic Types](#) for more information.

- **Business Date Ad hoc Char Type.** Set up a single option to define the ad hoc characteristic type used to reference the batch run's business date on the workflow process (a single business date is used for all batch jobs initiated by a job stream). Refer to [Set Up Characteristic Types](#) for more information.
- **Email Address on Batch Jobs.** Set up a single option to define the email address used to notify a user when a batch job completes (note, the Email's subject line indicates if the batch job failed or succeeded). Note, you can override the email address on a specific batch job using a parameter on the Workflow Event Activation algorithm used to create the Pending batch job. If you leave this field blank (and no override is defined for the batch job), no email will be sent.
- **SMTP Server Name and SMTP Port Number.** If you want email sent informing of the completion of a batch job, define the SMTP server and port number.
- **User ID on Batch Jobs.** Set up a single option to define the user ID controlling user-oriented functionality. Refer to [Set Up A User ID For Batch Jobs](#) for more information.
- **Work Calendar.** Set up a single option to define the work calendar used when Workflow Process Recurrence Schedules are created. Refer to [Set Up A Work Calendar](#) for more information.

Maintaining Job Stream Creation Schedules

As described under [How To Start A Job Stream](#), you can set up a job stream creation schedule to define when a job stream (workflow process) should be automatically created by the system. Open **Admin > System > Job Stream Creation Schedule** to set up a job stream creation schedule.

Description of Page

On this page, you define when the system should automatically create a workflow process for a job stream template. To do this:

- Enter the **Job Stream Template**.

Note:

Only job streams defined on the [Feature Configuration](#) for the Batch Scheduler appear on this page.

- Enter the **Dates and Times** on which the system should automatically create the workflow process.

When a schedule record is added, the system sets its status to Pending.

Click the **Hold** button to change a Pending schedule to Hold if you don't want the system to create a workflow process on the date and time. You'd hold a record rather than delete it if you intend to release the hold in the near future.

Click the **Release** button to change a Held schedule to Pending if you want to release the hold.

When the system creates a workflow process for a job stream schedule record, the schedule record's status is changed to Process Created. There is one exception to this statement - if multiple Pending schedule records exist for a given workflow process template, the system will create a single workflow process for the one with the latest date / time and mark all others as Skipped Due To Overlap.

Schedule records in the Process Created and Skipped Due To Overlap states are protected.

Rather than entering the individual Dates and Times, you can press the **Recurrence** button to have the system generate these for you. Pushing this button causes the **Recurrence Window - Daily Pattern** to open.

The **Range From** and **To** define the dates during which recurring entries will be created.

The **Pattern** defines the frequency of recurrence:

- The Daily pattern will create a schedule for every date in the range defined above (subject to exceptions defined below). You can define the following for this pattern:
 - Use **Repeat Every** to define if the schedule should be created every day (a value of 1), every other day (a value of 2), every third day (a value of 3), etc.
 - Enter the **Start Time** defined on the schedule records.
 - Turn on **Include Weekends** if schedule records should also be created on weekends.

- The Hourly pattern will create a schedule for every hour in the date range defined above (subject to exceptions defined below). You can define the following for this pattern:
 - Use **Repeat Every** to define if schedule records should be created every hour (a value of 1), every other hour (a value of 2), every third hour (a value of 3), etc.
 - Enter the **Between** start time and end time to restrict the hours during which schedule records are created.
 - Turn on **Include Weekends** if schedule records should also be created on weekends.
- The Weekly pattern will create a schedule for every week in the date range defined above (subject to exceptions defined below). You can define the following for this pattern:
 - Enter the **Start Time** defined on the schedule records.
 - Select the day(s) of the week that the schedule records should be created.

If You Work In A Non-English Language

The demonstration database is installed in English only. If you work in a non-English language, you must execute the [F1-LANG](#) background process on the demonstration database before using it as a Compare Source supporting environment. If you work in a supported language, you should apply the language package to the demonstration database as well.

If you don't execute F1-LANG on the demonstration database, any objects copied from the demonstration database will not have language rows for the language in which you work and therefore you won't be able to see the information in the target environment.

Security Addendum

This chapter is an addendum to the general [Defining Security and User Options](#) chapter. This addendum describes security functionality that is specific to Oracle Utilities Customer Care and Billing.

Implementing Account Security

CAUTION:

This section assumes you understand [The Big Picture of Row Security](#).

When you create an account, you must define which users can access the account's information. For example,

- If you have customers in two geographic territories, you may need to restrict access to accounts based on the office that manages each territory. For example, only users in the northern office may manage accounts in the northern territory.
- If you have industrial and residential customers, you may need to restrict access to these different customer segments based on the skill set of the users. For example, some users are skilled in dealing with industrial customers, while others are skilled in dealing with residential customers.

By granting a user access rights to an account, you are actually granting the user access rights to the account's bills, payment, adjustments, orders, etc.

Fastpath:

Refer to [If You Do Not Practice Account Security](#) for setup instructions if your organization doesn't practice account security.

Note:

Account security may also affect persons and premises. Refer to [Persons Can Also Be Secured](#) for how access to person information is also restricted by account security. Refer to [Premises Can Also Be Secured](#) for how access to premise information is also restricted by account security.

The topics in this section describe how to implement account security.

Persons Can Also Be Secured

It's important to be aware that persons can also be secured as a result of "account security". It works like this:

- If a person is linked to at least one account, users will not be allowed access to the person (or the person's related information) unless they have access to at least one of the person's accounts.
- If a person is not linked to any accounts (a rare situation), any user may access the person.

Note:

How are persons linked to accounts? A person is linked to an account when an account is created using the methods described under [How To Add A New Customer From Control Central](#) and [Order User Interface Flow](#). In addition, you may manually link and unlink persons from account using the [Account - Person](#) page.

Premises Can Also Be Secured

It's important to be aware that premises can also be secured as a result of "account security". It works like this:

- If a premise is linked to at least one account, users will not be allowed access to the premise (or the premise's related information) unless they have access to at least one of the premise's accounts.
- If a premise is not linked to an account (a rare situation), then all users may access the premise.

Note:

How are premises linked to accounts? A premise is indirectly linked to an account. For the purpose of access restriction, we deem a premise as being linked to an account if at least one of its service points is linked to at least one of the account's service agreements.

Data Becomes Invisible When Access Is Restricted

The following summarizes the impact of a user not having access to an account:

- [Account Security and Control Central](#) on page 1300
- [Account Security and Searches \(and Maintenance Pages\)](#) on page 1301
- [Account Security and To Do Lists](#) on page 1301

Account Security and Control Central

This section summarizes the impact of account security on [Control Central](#):

- Searches are affected as follows:
- An account will only be visible if a user has access to the account's access group.
- Persons that are not linked to accounts will be visible to all users.
- If a person is linked to an account, the person will only be visible if the user has access to at least one of the person's accounts.
- Premises that are not linked to accounts will be visible to all users.
- If a premise is linked to an account, the premise will only be visible if the user has access to at least one of the premise's accounts.
- The alerts that highlight the existence of "multiple relationships" are not impacted by account security. Specifically:
- The alert Person has multiple accounts will appear if the selected person is linked to multiple accounts, even if the user doesn't have access to every account. Note well, the person couldn't have been selected if the user didn't have access rights to at least one account.
- The alert Premise has multiple accounts will appear if the selected premise is linked to multiple account, even if the user doesn't have access to every account. Note well, the premise couldn't have been selected if the user didn't have access rights to at least one account.

- Only accounts to which the user has access will be displayed in the person tree.
- Only accounts to which the user has access will be displayed in the account tree.
- All other pages contain information related to Control Central's current account context. The current account context can never reference an inaccessible account and therefore these pages are not impacted by account security.

Note: If your implementation wishes to allow users to search for all accounts through Control Central without validating the user's access rights, this can be configured by setting up the **Search All Account** option type on the Customer Information Options [Feature Configuration](#) . If the user tries to select an account without having the required access, they will not be able to navigate to the Account Information tab on Control Central for the selected account.

Account Security and Searches (and Maintenance Pages)

Searches are the gateway to the information that appears on maintenance pages. In general, account-related information is suppressed when a user doesn't have access rights to the account. This suppression is true for rows that directly reference an account AND for rows that indirectly reference an account. For example:

- A user can only see bills associated with accounts to which they have access rights.
- A user can only see financial transactions associated with service agreements that are, in turn, associated with accounts to which they have access rights.

Note:

Person and premise searches are also impacted. Keep in mind that information will be suppressed from both person and premise-oriented searches if the person / premise is related to accounts. Refer to [Persons Can Also Be Secured](#) for how access to person information is also restricted by account security. Refer to [Premises Can Also Be Secured](#) for how access to premise information is also restricted by account security.

Account Security and To Do Lists

Account security does NOT impact the information that appears in a user's To Do list. Rather, we have assumed that your To Do roles (and the users assigned to these roles) are consistent with your account security requirements. This can result in anomalies. For example, it's possible for a supervisor to assign a bill segment error to a user who doesn't have access to the bill segment's account. This user will then see the related To Do entry in their Bill Segments In Error To Do list. However, when they drill down on the entry, account security will manifest itself (i.e., the user won't be able to display the bill segment that's in error). This happens because the drill down causes the bill segment search logic to execute. This logic inhibits the selection of bill segments if the user can't access the related account.

To minimize these anomalies, we recommend the following:

- Setup [To Do Roles](#) consistent with your Data Access Roles.
- Setup [Account Management Groups](#) that are consistent with your Access Groups.
- Setup default To Do Roles on your Account Management Groups for each [To Do type](#).

Restricted Transactions

The following table lists all transactions that have some type of account security. The following notation is used to describe the type of account security:

- **Account-oriented.** This notation is used if the respective transaction uses basic account security (i.e., the user must belong to at least one data access role that has access to the account's access group in order to see the information).
- **Person-oriented.** This notation is used if the respective transaction uses person-oriented account security. Refer to [Persons Can Also Be Secured](#) for more information.
- **Premise-oriented.** This notation is used if the respective transaction uses premise-oriented account security. Refer to [Premises Can Also Be Secured](#) for more information.

- None of the above. Some unusual transactions have unusual implementations of account security. These are described below.

| Transaction | Type of Account Security |
|---|--|
| Account | Account-oriented |
| Account Bill / Payment History | Account-oriented |
| Account Financial History | Account-oriented |
| Account Interval Info | Account-oriented |
| Account Payment History | Account-oriented |
| Account Person Replicator | Account-oriented |
| Account SAs for Debt Class | Account-oriented |
| Adjustment | Account-oriented |
| Adjustment Calculation Line Characteristics | Account-oriented |
| Appointment | Premise-oriented |
| Bill | Account-oriented |
| Bill Print Group | Person-oriented |
| Bill Segment | Account-oriented |
| Billable Charge | Account-oriented |
| Budget Review | Account-oriented |
| Case | Account-oriented, Person-oriented and Premise-oriented |
| Collection Agency Referral | Account-oriented |
| Collection Process | Account-oriented |
| Contract Option | Account-oriented |
| Control Central | Account-oriented, Person-oriented and Premise-oriented |
| Customer Contact | Person-oriented |
| Cut Process | Account-oriented |
| Declaration | Account-oriented |
| Deposit Review | Account-oriented |
| Field Activity | Premise-oriented |
| Field Order | Premise-oriented |

| | |
|------------------------------------|---|
| Financial Transaction | Account-oriented |
| Financial Transaction on a Bill | Account-oriented |
| Financial Transaction on a Payment | Account-oriented |
| Interval Profile | Account-oriented (for SA-specific profiles) |
| Landlord Agreement | Account-oriented |
| Loan | Account-oriented |
| Match Event | Account-oriented |
| Multi-Cancel/Rebill | Account-oriented |
| Non-Billed Budget | Account-oriented |
| Order | Account-oriented, Person-oriented and Premise-oriented |
| Overdue Process | Account-oriented |
| Pay Plan | Account-oriented |
| Payment | Account-oriented |
| Payment Arrangement | Account-oriented |
| Payment Arrangement for Bills | Account-oriented |
| Payment Event | The user must have access to ALL accounts linked to the payment event. |
| Payment Event Quick Add | The user must have access to ALL accounts linked to the payment event(s). |
| Payment Quick Add | Account-oriented |
| Payment / Tender Search | Account-oriented |
| Person | Person-oriented |
| Premise | Premise-oriented |
| Premise Management | Premise-oriented |
| Quote | Account-oriented |
| SA Billing History | Account-oriented |
| SA Cash Accounting Balance | Account-oriented |
| SA Financial History | Account-oriented |
| SA Relationship | Account-oriented |

| | |
|----------------------------------|--|
| Service Agreement | Account-oriented |
| Service Credit Event | The user must have access to ALL accounts linked to the service credit membership that has the service credit event. |
| Service Credit Membership | The user must have access to ALL accounts linked to the service credit membership. |
| Service Provider SA Relationship | Account-oriented |
| Severance Process | Account-oriented |
| Start/Stop | Account-oriented |
| Statement | The user can see the statement if they have access to at least one account on the statement's statement construct. |
| Statement Construct | The user can see the statement if they have access to at least one account on the statement construct. |
| Terms of Service | Account-oriented (User must have access to at least one account linked to the SA collection in the TOS.) |
| TOU Map | Account-oriented (for SA-specific TOU maps) |
| Umbrella Agreement | Account-oriented (User must have access to at least one account linked to the SA collection in the UA's TOS.) |
| Write Off | Account-oriented |
| Write Off Process | Account-oriented |

Account Security Case Studies

The topics in this section contain examples of how to implement account security. Use these examples to form an intuitive understanding of these objects. Once this intuition is obtained, you'll be ready to design the account security objects for your own company.

Securing Accounts Based On Customer Class

Assume the following security requirement exists:

- You have two broad groups of accounts:
 - Residential accounts.
 - Commercial / Industrial accounts.
- Users can be classified as have one of the following access rights:
 - May access all accounts.
 - May only access residential accounts.
 - May only access commercial / industrial accounts.

The following diagram illustrates the access groups and data access roles required to implement these requirements:

Notice the following about the above:

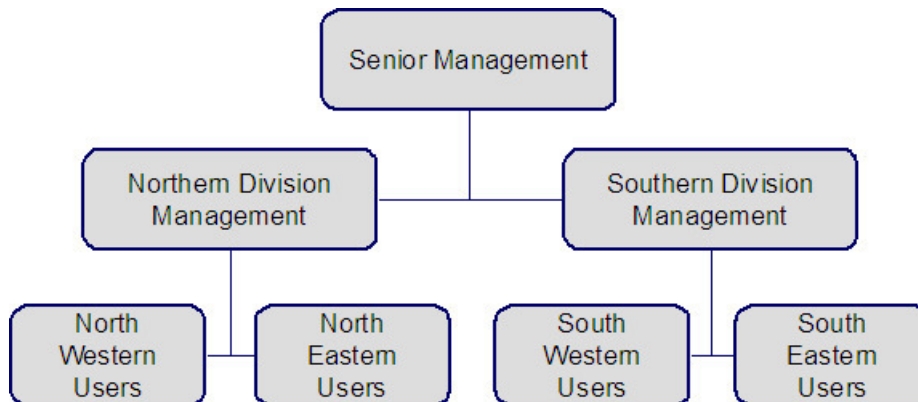

- There are 2 access groups because access to accounts is based on whether the account is considered to be residential or commercial/industrial.
- The Big Customers data access role is only linked to the C&I access group.
- The Small Customers data access role is only linked to the Residential access group.
- The All Customers access role is linked to both the C&I and Residential access groups. Users with this role can therefore access all accounts.

Securing Accounts Based On Region

Assume that accounts are classified as belonging to one of the following regions:

- Northwestern
- Northeastern
- Southwestern
- Southeastern

Assume the following company hierarchy exists:

- Senior Management has access to all customers
- Northern Division Management has access to all customers in the Northwestern and Northeastern divisions.

- Southern Division Management has access to all customers in the Southwestern and Southeastern divisions.
- Northwestern Users have access to all customers in the Northwestern division.
- Northeastern Users have access to all customers in the Northeastern division.
- Southwestern Users have access to all customers in the Southwestern division.
- Southeastern Users have access to all customers in the Southeastern division.

The following diagram illustrates the access groups and data access roles required to implement these requirements:

Notice the following about the above:

- There are 4 access groups because access to accounts is based on the region in which they are located (and there are 4 regions).
- There are 7 data access roles because each component of every layer of the access hierarchy requires a separate data access role.

The Default Access Group

There are two ways an access group can be assigned to an account:

- The base package will default an account's access group based on the user who adds the account. It uses the user's *default access group* to do this.
- If you can conceive of a rule to assign an appropriate access group to a newly added account, you can have your programming staff introduce a user exit to the account row program to implement this rule. For example, a user exit could be developed that assigns an access group to an account based on its customer class. The name of the user-exit is AFTER-MOVE-CORR-ADD and the name of the account row program is CIPCACCR.

Warning:

Regardless of the method used to assign an account's access group, please be aware that the user who adds an account must have access to this access group.

Note:

Subsequent changes to an account's access group. A user may change an account's access group to any access group to which they have access.

If You Do Not Practice Account Security

If you do not restrict access to accounts (i.e., all users can access all accounts), you must set up one access group and one data access role and then indicate all users are part of this role. You should also define the access group as the default access group on all of your users (so that new accounts are all labeled with this access group).

Masking Sensitive Data

Refer to [Masking Data](#) for instructions describing how to configure the system to mask sensitive data like a customer's social security number or bank account number. If your implementation intends to mask any of the information that appears in the [Customer Information Zone](#) please navigate to this zone's documentation for special instructions.

Encrypting Sensitive Data

The product provides support for encrypting certain sensitive data, which may be necessary if your implementation wants to meet security standards such as those for credit card transactions, as specified by the Payment Card Industry Security Standards Council.

Please be sure that you are familiar with the information documented in [Database Encryption and Masking](#) before reading further.

The remaining details in this section provide information about the fields in the product that support encryption along with the suggested configuration for the **Encryption** feature configuration entry if your implementation opts to encrypt the data.

External Account ID and Credit Card Number Encryption

If your implementation would like to encrypt credit card IDs, the following entry should be added to the Encryption feature configuration so that the data stored in the External ID column on the Account Automatic Payment table is encrypted:

table='CI_ACCT_APAY', field='EXT_ACCT_ID', encryptedField='ENCR_EXT_ACCT_ID'

Note:

- The External Account ID field also exists on other tables such as Auto Pay Clearing Staging table (CI_APAY_CLR_STG) and Payment Event Upload Staging table (CI_PEVT_DTL_ST) . Feature configuration options do not need to be configured for the External Account ID field on these tables as the field on these related tables is encrypted based on the feature configuration specified above for the Account Automatic Payment table (CI_ACCT_APAY).
- A customer's bank account ID or credit card number may also be stored in a column when an order is completed. A field encryption feature configuration for the Order Field table (CI_ENRL_FLD) does not need to be configured if the customer's bank account ID or credit card number is referenced on this table. The encryption for the field should be handled by a Column Reference - Preprocessing algorithm. The base product provides an Encrypt Account Auto Pay External Account Id Column Reference Value algorithm type for this purpose.
- A field encryption feature configuration option needs to be configured for each schema field to be encrypted that represents a customer's bank account ID or credit card number. If the value of an encrypted schema field will later be populated on or compared against an encrypted table field, the schema field and the table field must share the same key alias.

If your implementation is integrated with a self-service application and one time payment details are captured in Person Self-Service Payment Option (CI_PER_SS_PAYOPT) , the product supports encryption of the Credit Card Number and External Account ID fields on this table. In addition, the product supports a hash representation of this fields for searching purposes. To encrypt Credit Card Number and External Account ID, add the following entries to the Encryption feature configuration:

- `table='C1_PER_SS_PAYOPT', field='CREDIT_CARD_NBR', encryptedField='ENCR_CREDIT_CARD_NBR', hashField='HASH_CREDIT_CARD_NBR'`
- `table='C1_PER_SS_PAYOPT', field='EXT_ACCT_ID', encryptedField='ENCR_EXT_ACCT_ID', hashField='HASH_EXT_ACCT_ID'`

Bank Account Number Encryption

If your implementation would like to encrypt the bank account number stored on the bank account table, the following entry should be added to the Encryption feature configuration:

`table='CI_BANK_ACCOUNT', field='ACCOUNT_NBR', encryptedField='ENCR_ACCOUNT_NBR'`

MICR ID Encryption

The product provides support for encrypting MICR ID associated with payments. In addition, the product supports capturing a hash representation of this field for searching purposes. This field is captured on three tables and entries should be added to the Encryption feature configuration for each as follows:

- `table='CI_PEVT_DTL_ST', field='MICR_ID', encryptedField='ENCR_MICR_ID', hashField='HASH_MICR_ID'`
- `table='CI_PAY_TNDR_ST', field='MICR_ID', encryptedField='ENCR_MICR_ID', hashField='HASH_MICR_ID'`
- `table='CI_PAY_TNDR', field='MICR_ID', encryptedField='ENCR_MICR_ID', hashField='HASH_MICR_ID'`

Note: All configurations must share the same key alias.

Person ID Number Encryption

The product provides support for encrypting an identifier associated with a person. In addition, the product supports capturing a hash representation of this field for searching purposes. Because the ID collection on Person includes an ID type, your implementation may decide to encrypt all IDs captured for the person or may choose to only encrypt IDs of one or more specific ID types. If you want to encrypt multiple ID types, you must configure a field encryption option type for each ID type. The following shows an example of an encryption feature configuration entry for encrypting an ID with the type “SSN”:

`table='CI_PER_ID', field='PER_ID_NBR', encryptedField='ENCR_PER_ID_NBR', hashField='HASH_PER_ID_NBR', where='ID_TYPE_CD=SSN'`

Note:

- The Person ID Number also exists on the Order Person ID table (CI_ENRL_PER_ID) table. Feature configuration options do not need to be configured for the Person ID Number field on this table as the field is encrypted based on the feature configuration specified above for the Person Identifier table (CI_PER_ID).
- The Person ID Number may also be stored in a column when an order is completed. A field encryption feature configuration for the Order Field table (CI_ENRL_FLD) does not need to be configured if the Person ID Number is referenced on this table. The encryption for the field should be handled by a Column Reference - Preprocessing algorithm. The base package provides an Encrypt Column Reference Value algorithm type for this purpose.
- A field encryption feature configuration option needs to be configured for each schema field to be encrypted that represents a Person ID Number. If the value of an encrypted schema field will later be populated on or compared against an encrypted table field, the schema field and the table field must share the same key alias.

Company ID Encryption

The product provides support for encrypting the Company ID that is populated into automatic payment extract files. If your implementation would like to encrypt company IDs on the Auto Pay Route Type table (CI_APAY_RT_TYPE), the following entry should be added to the Encryption feature configuration:

```
table='CI_APAY_RT_TYPE', field='CO_ID', encryptedField='ENCR_CO_ID'
```

In addition, if your implementation allows Company ID overrides by CIS Division, the following entry should be added to the Encryption feature configuration so that the Company ID on the CIS Division Route Type table (C1_CIS_DIV_RTYP) is encrypted.

```
table='C1_CIS_DIV_TRYP', field='OVRD_CO_ID', encryptedField='ENCR_OVRD_CO_ID'
```

Encrypting Legacy Data

If you enable encryption in an existing implementation, you should run the encrypt legacy batch controls to encrypt legacy data that persists in the database:

- F1-ENCRT: Encrypt Legacy Table Field Data
- F1-ENCRS: Encrypt Legacy Schema Field Data
- C1-ECRVL: Encrypt Legacy Order Field Col Ref Value

Before executing the batch processes, you must have a keystore file in the system to hold the keys for encrypting data and define an encryption feature configuration that contains the details for the fields you want to encrypt.

Data Privacy Addendum

This section is an addendum to the general [Data Privacy](#) chapter. This addendum describes Object Erasure functionality that is specific to Oracle Utilities Customer Care and Billing .

Customer Erasure

A customer's personal information can be erased from the system under certain circumstances - the most common of which is when the information is no longer necessary for the original purposes of which it was collected and processed. This is usually the case when a customer's accounts have been closed for some time and there is no other activity for that customer.

Erasure can be triggered automatically (e.g. as service agreements go into a final state) or manually (e.g. when a customer calls in to request for erasure).

Automatic Trigger Of Customer Erasure

A person's eligibility for erasure can be automatically evaluated when key events occur on that person's accounts. These events include:

- Adding a service agreement
- Closing a service agreement
- Canceling a service agreement
- Reactivating a service agreement
- Accepting a proposal service agreement
- Declining a proposal service agreement
- Reopening a proposal service agreement
- Deleting a proposal service agreement

Monitoring SA Triggers For Customer Erasure

The base product provides an MO Audit algorithm, Monitor SA Manage Erasure Events (C1-SAMNGEREV) that implementations need to plug in on the Service Agreement (SA) MO to enable automatic triggering of erasure.

Note that this algorithm simply creates a General Process record for the Person. This technique allows the system to perform the erasure evaluation (i.e. in the Manage Erasure Schedule algorithm) in batch. This is to minimize the number of times that the Manage Erasure Schedule algorithm is executed for the same Person. For instance, if

the customer had one SA closed, another one canceled and another SA created, the erasure evaluation will only be executed once (i.e. when the C1-MNERP batch process runs) even if there were three SA events for that person.

The Manage Erasure Schedule for Person (C1-MNERP) plugin-driven batch process is provided to process the General Process records for managing person erasure. The Process Record algorithm on this batch process invokes the Manage Object Erasure (F1-ManageErasureScheduleDriver) business service. Refer to the C1-MNERP batch control in the application for more details.

Manual Trigger Of Customer Erasure

A customer may call in to request an agent to erase them from the system.

The base product provides a Trigger Customer Erasure (C1-TrgCustEr) BPA script that users can configure as a favorite script in their User Preferences.

This script assumes that the user retrieves the Person before running the script – meaning, the Person is already in the current context. The script pulls in the Person ID and renders the information on the map, which also captures Erasure Date, Erasure Reason and Comments as additional inputs.

A Confirm action will invoke the same Manage Erasure Schedule processing that is executed in automatically triggered person erasures. If the customer is eligible for erasure, the Person and its associated Account(s) and Service Agreement(s) will be scheduled for erasure on the designated Erasure Date. Otherwise, an error will be displayed, indicating ineligibility for erasure.

Refer to the Trigger Customer Erasure (C1-TrgCustEr) BPA script in the application for more details about this script.

The Person MO Controls Customer Erasure

A customer's eligibility for erasure is evaluated at the Person level. This means that only the Person maintenance object will specify a Manage Erasure Schedule algorithm. Eligibility criteria in this algorithm will check the status of the Person's Account(s) and Service Agreement(s) to determine whether or not these objects can be erased. Object Erasure Schedule records are added/updated/discarded, based on the outcome of the eligibility check.

Manage Erasure Schedule Algorithm: Person Erasure Evaluation

The base product supplies a Maintenance Object - Manage Erasure Schedule algorithm – i.e. Person Erasure Evaluation (C1-PEREREVAL) that determines Person Erasure eligibility based on the status of the service agreements (SAs). If all SAs are in some final state - e.g. Closed, Canceled - the Person is deemed eligible for erasure and the corresponding Object Erasure Schedule records are added. Otherwise, the Person is deemed ineligible for erasure. If a person that is already scheduled for erasure happens to have new activity - e.g. started a new SA, reactivated a Closed SA - any existing Object Erasure Schedule records for that Person and its Account(s) and SA(s) will be discarded.

Persons, Accounts And Service Agreements Are Obfuscated

The following sections describe the erasure processing for Person, Account and Service Agreement information.

Purge Versus Obfuscate

Purging involves physical deletion of a record. On the other hand, obfuscation involves updating certain fields in the table that are considered personally identifiable information (PII) – e.g. name, address, etc. The values of these fields are updated to blank or some value that is no longer identifiable to a person – e.g. the random-generated primary key of the Person record.

Base-supplied Person, Account and SA erasure logic performs obfuscation on the root tables of these maintenance objects (MOs). The reasons are:

- Purging could have impacts to external systems
- Purging might cause orphan data or invalid foreign key references within the system

However, base logic does purge most of the data in these MOs' child tables. The exceptions are characteristic tables and some SA child tables that do not contain PII.

Refer to the next sections for details on each object's obfuscation processing.

Person, Account and Service Agreement Erasure BOs

The base product provides the following Object Erasure Business Objects (BOs):

- Person Erasure: C1-ErasureSchedulePerson
- Account Erasure: C1-ErasureScheduleAccoun
- Service Agreement Erasure: C1-ErasureScheduleSA

All are child BOs of the Erasure Root parent BO - F1-ErasureScheduleRoot. These BOs are delivered plugged in on their corresponding maintenance objects.

Refer to the Business Object configuration in the application for more details.

Person, Account and Service Agreement Obfuscation Algorithms

The Person, Account and Service Agreement Erasure business objects include an Enter algorithm (on the Erased state) that is responsible for obfuscating data in the maintenance object's tables. The following sections describe each algorithm.

Person Obfuscation

The Person Erasure (C1-ErasureSchedulePerson) BO is delivered with an enter algorithm on the Erased state - C1-PEROBJERS.

This algorithm performs the following:

- On the Person root table, updates the Address1, City and Postal fields with the PER_ID value.

Note: These fields are search fields and are thus indexed.

- Deletes all records in the Person Seasonal Address table
- Deletes all records in the Person Identifier table
- In the Person Name table:
 - The primary name is retained and the name value is replaced with the PER_ID value.

Note: Deletion of the primary name makes the Person record and its Account and SA records unsearchable through the user interface - e.g. via Control Central search.

- All other names are deleted
- Deletes all records in the Person Phone table
- Deletes all records in the Person Contact table
- Deletes all records in the Person-to-Person table
- Deletes all records in the Person Self-Service Payment Option table

Note: The base algorithm does not obfuscate nor delete any Person Characteristics because this data is implementation-specific. Implementations that store any personally identifiable information (PII) in this table - e.g. in adhoc characteristic values should add their specific obfuscation/delete logic for these characteristics.

Account Obfuscation

The Account Erasure (C1-ErasureScheduleAccount) BO is delivered with an enter algorithm on the Erased state - C1-ACCTOBFS.

This algorithm performs the following:

- In the Account root table:
 - Removes the link to the Mailing Premise Id
 - Clears contents of the Account Data Area
- Deletes all Account Person records except the main Person.

Note: Deletion of the 'main' person makes the Account unsearchable through the user interface - e.g. via Control Central search.

- Updates the main Person's Address Source to Person
- Deletes all records in the Person Address Override table
- Deletes all records in the Account Auto Pay table

- Deletes all records in the Account Alerts table
- Deletes all records in the Account Messages table
- Deletes all records in the Account Credit Rating History table
- Deletes all records in the Account Debt Monitor Review Schedule table
- Deletes all records in the Non-Cash Deposit table
- Deletes all records in the Budget Review table
- Deletes all records in the Notification Preferences table and its child tables

Note: The base algorithm does not obfuscate nor delete any Account Characteristics because this data is implementation-specific. Implementations that store any personally identifiable information (PII) in this table - e.g. in adhoc characteristic values should add their specific obfuscation/delete logic for these characteristics.

Service Agreement Obfuscation

The Service Agreement Erasure (C1-ErasureScheduleSA) BO is delivered with an enter algorithm on the Erased state - C1-SAOBFSCFN.

This algorithm performs the following:

- On the SA root record, removes the link to the Characteristic Premise.
- Deletes all records in the SA/SP table and its child tables: SA/SP Field Activity and SA/SP Characteristics

Note: The base algorithm does not obfuscate nor delete any Service Agreement Characteristics because this data is implementation-specific. Implementations that store any personally identifiable information (PII) in this table - e.g. in adhoc characteristic values should add their specific obfuscation/delete logic for these characteristics.

Configuring The System For Customer Erasure

The following are the steps to enable Customer Erasure:

- Plug in the Manage Erasure Schedule - Person Erasure Evaluation algorithm on the Person MO.
- Configure the Erasure Period option on each of the Person, Account and SA MOs.

Note: Note: The values for all three MOs should be the same, to ensure the Erasure Dates are the same on the resulting Object Erasure Schedule records.

- Plug in the Monitor SA Manage Erasure Events (C1-SAMNGEREV) Audit algorithm on the SA MO.
- If using the Trigger Customer Erasure (C1-TrgCustEr) script to manually trigger person erasure:
 - Configure values for the Erasure Reason lookup field DP_CUST_ERS_RSN_FLG.
 - Configure the C1-TrgCustEr BPA script as a Favorite Script in User Preferences.

Notifying External Systems About Customer Erasure

When CCB is integrated with a meter data management system (such as Oracle Utilities Meter Data Management) and the Person and SA syncs are used to synchronize Contact and Usage Subscription information with corresponding Person and SA information, the meter data management needs to be notified when such information is already erased in CCB.

The following sync request BO schemas include a Customer Erased switch:

- MDM2 Person Sync Request: C1-MDM2PersonSyncRequest
- MDM2 SA Sync Request: C1-MDM2SASyncRequest

Logic on these BOs sets this switch to true if the related Person/SA has an Object Erasure Schedule record that is in the Erased state.

The meter data management system can use this switch to trigger its own erasure processing for Contact and Usage Subscription information. For an example, refer to the Data Privacy documentation for Oracle Utilities Meter Data Management.

Refer to the Business Object configuration in the application for more details.

Defining Converted COBOL Program Options

The topics in this section describe the transaction that allows you to define the metadata for converted COBOL programs within the current environment's database.

CAUTION: Updating converted COBOL Programs requires technical knowledge of the system. This is an implementation and delivery issue and should not be attempted if you do not have previous experience.

Converted COBOL Program - Main

Use this transaction to define converted COBOL program user exits for your system. Navigate to this page using **Admin > System > Converted COBOL Program > Search**.

Description of Page

The following describes fields that are relevant to defining the user exit code that a converted COBOL Program should use:

Program Component ID represents the internal ID that is given to the converted COBOL program component.

Program Com Name is the physical name of the converted COBOL program component.

Template is the template used to generate the converted COBOL program component.

Location ID (*for development purposes*)

Table (*for development purposes*)

User Exit Program. Specify if you have written user exit code for this converted COBOL program component.

Development Status Flag. Options include Note Generated and Not Regeneratable.

Short Comments provides a short description of the converted COBOL program component.

Long Comments provides more details of the converted COBOL program component.

The **Variable Information** grid (including Variable Name, Occurrence, Variable Sequence, Variable Value, and Variable Alternate Value) is *for development purposes only*.

Advanced Search Options

The product offers an option to perform expanded / fuzzy searching in [Control Central](#) Search by Name and Address. The option is only available if your implementation has appropriately configured your database for fuzzy searching.

Refer to the DBA guide in the installation guide for details on setting up the database to support fuzzy searching. Note that there are some implementations where fuzzy searching will not be possible. For example, it's only available for implementations using the Oracle database. Additionally, not all languages are supported. Refer to the Oracle Database documentation for more information about fuzzy searching.

If your implementation has configured its database to enable fuzzy searching, you must also set up a [Feature Configuration](#) to indicate that feature is supported. Find the Feature Configuration record for the **General System Configuration** feature type. (It may need to be defined if it does not exist). Choose the option type **Enable Expanded Results** and define a value of **Y**.

Integration

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration other systems. This section provides technical information needed by your implementers to accomplish this.

CTI-IVR Integration

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration with your Computer Telephony Integration/Interactive Voice Response (CTI/IVR) system. The interface provides the following functionality:

- The ability to launch Control Central for a particular account ID or phone number from an external application

- The ability to accept the next call, as dictated by the CTI software,
- The ability to perform an outbound phone call from within Oracle Utilities Customer Care and Billing

This document provides technical information needed by your implementers to fully integrate with your CTI/IVR system.

CTI-IVR Integration Configuration

The integration with your Computer Telephony Integration/Interactive Voice Response (CTI/IVR) system requires the setup of master configuration data that controls the Next Caller and Automated Dialer functions.

To set up the CTI/IVR integration master configuration, navigate using **Admin > General > Master Configuration**. You are brought to an all-in-one portal with options to add/edit the CTI/IVR Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

Launching The System From an External Application

The following section describes possible options to launch the system from an external system.

Launching The Application Using a URL

You launch the application using a URL. With this option you can set the system to launch a script upon startup. You can also indicate to the system to automatically load an appropriate page (if this information is not part of the script).

The application includes a simple sample html page that can launch CCB Control Central Search by Phone Number or by Central Search Account Id. The page is called CTISample.HTM and is located in /cm_templates.

Fastpath:

Refer to [Launching A Script When Starting The System](#) for further information.

Receiving the Next Caller in the Queue

If your CTI-IVR system allows users to request the next caller waiting in a queue, the system provides a mechanism to integrate with this functionality.

A BPA script called **Get Next Caller (C1-GtNxtClrC)** is available that can be used to request the next call waiting in an inbound queue managed by a CTI application.

When the **Get Next Caller** BPA is executed, it launches the **CTI Get Next Caller** and **Launch CTI** processing scripts that are defined in the CTI/IVR Integration master configuration. Your implementation creates the **CTI Get Next Caller** script that retrieves the next account in the queue. The base product supplies a sample **Launch CTI** BPA script that launches Control Central using the **C1-CCByAcct** BPA script and passing in the account that was returned by the **CTI Get Next Caller** script.

Customize Integration to Your Next Caller Function

Your implementation needs to create a **CTI Get Next Caller** processing script that will be responsible for getting the next account in the queue, based on your integrated CTI application. The base-supplied **Launch CTI** processing script can be used to navigate to Control Central with the next caller's account passed in.

In order to integrate the next caller functionality with your CTI-IVR system, perform the following steps:

- Create your custom **CTI Get Next Caller** service script that retrieves the next account from the queue.
- Create a **Launch CTI** BPA script if your business rules require additional logic and/or need to launch a different page in the system..
- Plug in the **CTI Get Next Caller** and **Launch CTI scripts** on the CTI/IVR Integration master configuration.

Initiating an External Call

This section describes the automated dialer functionality provided with the system as well as information about integrating with your own automated dialer.

Overview of Automated Dialer

In order to initiate a call to a customer from within the system, a context menu item **Go To Automated Dialer** is available on the Person context menu. To call a customer displayed in the current context, choose this option from the person context menu and a window appears, showing a list of phone numbers defined for that person.

Select the desired phone number and click **Dial**.

Note:

Context Entry Secured. The [navigation key](#) for this window `automatedDialer` refers to an application service to facilitate application security. If your installation does not support an integration with external dialer software, configure the security settings to ensure that users do not have access to the application service for this context entry.

Technical Implementation of Automated Dialer

The popup window is implemented as a BPA script (**C1-LAutoDial**) that calls a configurable **Automated Dialer** BPA script that is responsible for retrieving and displaying person contacts and phone numbers (i.e. if the installation option is set to Use Legacy Person Phone and Email feature configuration option is set to ‘Y’). The **C1-AutoDial** sample script provided with the system integrates to any soft phone protocol handler that launches a dialer based on overriding the “tel:” protocol from a browser, for example, Cisco IP Communicator. It launches a UI map to display the person contacts and phone numbers (i.e. if the feature option is set).

Phone Dialer Configuration

If your implementation chooses to use the functionality provided with the system and integrate with a soft-phone dialer, plug in the base-supplied **C1–AutoDial** script in the CTI/IVR Integration master configuration.

Customize Integration to Your Automated Dialer Software

In order to integrate with a different automated dialer software application, your implementers must create your own **Automated Dialer** BPA script, to call your specific dialer.

- Copy the **C1-AutoDial BPA** script and make the appropriate changes to integrate with your automated dialer (e.g. change the protocol from “tel:” to “callto:”.
- Plug in your custom Automated Dialer script on the CTI/IVR Integration master configuration.

Customize Automated Dialer User Interface

Your implementation may choose to display a different user interface for the **Go To Automated Dialer** function than the one provided with the system. For example, perhaps there is more information that you would like to display in addition to the person's name and phone numbers. In order to do this, your custom **Automated Dialer** script needs to invoke a custom UI map that you create as follows:

- Copy the base-supplied **C1-AutomatedDialer** UI map and make the necessary changes.
- Invoke your custom UI map from your custom **Automated Dialer** .

Analytics Integration Overview

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration with Oracle Utilities Analytics. Oracle Utilities Customer Care and Billing provides support for defining data load parameters, bucket configurations and characteristic mapping.

Analytics Configuration

This section describes functionality provided for integrating with Oracle Utilities Analytics (OUA).

- **Customer Analytics Configuration Portal**

Oracle Utilities Customer Care and Billing provides an Analytics Configuration portal that holds information on all the analytics-oriented configuration activities. This portal provides a summary of how much configuration has been set up, and also provides links and guidelines for the areas that need configuration, at the minimum, to successfully extract data from Oracle Utilities Customer Care and Billing to OUA. The following provides more information about this functionality.

1. **Analytics-Oriented Master Configuration Details** – These data load parameters are used to extract, load, and transform data from Oracle Utilities Customer Care and Billing to Oracle Utilities Analytics. These parameters are used to identify and/or filter data when loading them into the data warehouse. Refer to the *Oracle Utilities Customer Care and Billing* section in the **Configuring Oracle Utilities Analytics** chapter of the *Oracle Utilities Analytics Administration Guide* for detailed information on each extract parameter.
2. **Bucket Configuration List** – This is a summary of the bucket configurations that are needed to classify and group extracted data within Oracle Utilities Analytics. The bucket configurations provide the ability to readily report and analyze data by buckets, or groups. Refer to the *Oracle Utilities Customer Care and Billing* section in the **Configuring Oracle Utilities Analytics** chapter of the *Oracle Utilities Analytics Administration Guide* for detailed information on each bucket configuration supported by Oracle Utilities Customer Care and Billing.

- **Characteristic Mapping**

Oracle Utilities Customer Care and Billing has identified the objects for which characteristic extraction is supported. This includes mapping the source characteristic entity to the target dimension, and defining which target columns are allowed to be mapped for which target dimension. The following table shows the supported mapping.

| Object | Supported Target Dimension | Supported Target Columns |
|----------------------------------|-----------------------------|----------------------------|
| Account Characteristic | Account Dimension | User Defined Fields 6 - 15 |
| Person Characteristic | Person Dimension | User Defined Fields 1 - 6 |
| Premise Characteristic | Premise Dimension | User Defined Fields 6 - 18 |
| Premise Characteristic | Address Dimension | User Defined Fields 7 - 16 |
| Service Agreement Characteristic | Service Agreement Dimension | User Defined Fields 9 - 19 |

Self-Service Integration

The following sections describe functionality provided for the integration with self-service applications such as Oracle Utilities Customer Self Service and Oracle Utilities Digital Self Service.

Creating Self-Service Tasks

The customer self-service application invokes inbound web services to create self-service tasks. The system supplies an inbound web service for each supported self-service operation.

Note: For products that are continuing to use XAI for external messages, the product also includes XAI inbound services for most of the supported self-service task types. Note that the product recommendation is to discontinue use of XAI and use [inbound web services](#) instead.

Refer to the Oracle Utilities Customer Self-Service documentation or Oracle Utilities Digital Self Service documentation for more details on supplied inbound web services.

Each inbound web service references a service script that processes the specific self-service operation. Refer to the service script system data for processing details.

Self-Service Task Type Defines Self-Service Task Behavior

Each type of self-service operation has specific processing requirements.

Self-service task type controls how a self-service task is processed. It defines the business object to use when creating the self-service task record. The business object defines the lifecycle of self-service task record.

The self-service task type can also specify common configuration data, such as settings for error handling.

Creating Self-Service Tasks

The customer self-service application invokes inbound web services to create self-service tasks. The system supplies an inbound web service for each supported self-service operation.

Note: For products that are continuing to use XAI for external messages, the product also includes XAI inbound services for most of the supported self-service task types. Note that the product recommendation is to discontinue use of XAI and use [inbound web services](#) instead.

Refer to the Oracle Utilities Customer Self-Service documentation or Oracle Utilities Digital Self Service documentation for more details on supplied inbound web services.

Each inbound web service references a service script that processes the specific self-service operation. Refer to the service script system data for processing details.

Setting Up Self-Service Task Configuration

The following topics highlight the general configuration steps required to use self-service task functionality and to integrate with a self-service application such as Oracle Utilities Customer Self-Service (OUCSS).

Self-Service Integration Configuration

The integration with a self-service application such as Oracle Utilities Customer Self Service and Oracle Utilities Digital Self Service requires the setup of master configuration data that controls the processing of your self-service operations.

To set up self-service integration master configuration, select **Admin, General, Master Configuration**. You are brought to an all-in-one portal with options to add/edit the master configuration records. Add/edit the following master configuration:

- **CCB Self Service Integration:** This master configuration is used for the integration of customer data with a self service application.

Refer to the embedded help for more details on how each section in this record is configured.

Defining Self-Service Task Types

A self-service task type defines properties that control how a self-service task is processed.

Refer to [About Self-Service Tasks](#) for an overview of service task functionality.

To maintain the types applicable to your product, open **Menu > Self-Service > Self-Service Task Type**.

This is a standard [All-in-One portal](#).

The information captured on the self-service task type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Maintaining Self-Service Tasks

This section describes the functionality supported for viewing and maintaining self-service tasks.

Refer to [About Self-Service Tasks](#) for an overview of self-service task functionality.

Navigate using **Menu > Self-Service > Self-Service Task > Search**. You are brought to a query portal with options for searching for self-service tasks.

Once a self-service task record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Self-Service Task** zone provides basic information about a self-service task. Refer to the embedded help for more information.

Self-Service Start/Stop/Transfer Overview

Warning:

This topic is only applicable for the integration with Oracle Utilities Digital Self Service.

The Start Stop Transfer Tasks (C1-StartStopTransferTasks) inbound web service is used by the self-service application to support the following start/stop/transfer transactions:

- New Service
- Add Service
- Stop Service
- Transfer Service

Distinct action method roles represent each type of transaction:

- Self-Service New Service
- Self-Service Add Service
- Self-Service Stop Service
- Self-Service Transfer Service

At the beginning of the start/stop/transfer process, the action method role is used to identify the type of transaction. It is determined using the Request Mode (Start/Stop/Transfer), the New Customer indicator (Yes/No) and the New Account indicator (Yes/No):

- If Request Mode is 'Start', the Action Method Role is 'Self-Service New Service' if either the New Customer or the New Account indicator is 'Yes'. If both New Customer and New Account indicators are 'No', Action Method Role is 'Self-Service Add Service'.
- If Request Mode is 'Stop', the Action Method Role is 'Self-Service Stop Service'
- If Request Mode is 'Transfer', the Action Method Role is 'Self-Service Transfer Service'.

Configuration information are maintained using Self-Service Task Type and Customer Service Type. Self-Service Task Type defines the self-service task BO to be used. Customer Service Request Type defines the customer service request BOs used to persist data, and the controls used throughout the transaction. Refer to the "Enhanced Start, Stop, and Transfer Service Configuration Options" section of the digital self-service user guide for more about the controls.

At the beginning of the transaction, configuration information are determined and a self-service start/stop/transfer task is created. The same service task is used for the entire transaction. The service task is used to store the information received from the self-service application and operation processing results. It will remain in Pending status until the transaction is finalized. When the transaction is finalized, the service task is transitioned out of the Pending status and the collected information are persisted.

The following is the expected sequence of IWS operation calls per type of transaction:

New Service

1. [Retrieve Request Type Details](#)
2. [Retrieve Service-Related Customer Details](#) on page 1320 - operation is called if customer exists (Person ID is available).
3. [Service Eligibility](#) on page 1320
4. [Process Other Person](#) on page 1321
5. [Clear Other Person](#) on page 1321
6. [Determine Services To Start](#) on page 1321

7. [Validate Start SP Selection](#) on page 1322
8. [Service Questions](#) on page 1322
9. [Process Services To Start](#) on page 1322
10. [Deposit Assessment](#) on page 1322
11. [Start Service Finalization](#) on page 1323

Add Service

1. [Retrieve Request Type Details](#)
2. [Retrieve Service-Related Customer Details](#) on page 1320
3. [Service Eligibility](#) on page 1320
4. [Determine Services To Start](#) on page 1321
5. [Validate Start SP Selection](#) on page 1322
6. [Service Questions](#) on page 1322
7. [Process Services To Start](#) on page 1322
8. [Deposit Assessment](#) on page 1322
9. [Start Service Finalization](#) on page 1323

Stop Service

1. [Retrieve Request Type Details](#)
2. [Retrieve Service-Related Customer Details](#) on page 1320
3. [Determine Services To Stop](#) on page 1323
4. [Retrieve Services To Stop](#) on page 1323
5. [Validate Stop Service Agreement Selection](#) on page 1324
6. [Service Questions](#) on page 1322
7. [Process Services To Stop](#) on page 1324
8. [Stop Service Finalization](#) on page 1324

Transfer Service

1. [Retrieve Request Type Details](#)
2. [Retrieve Service-Related Customer Details](#) on page 1320
3. [Service Eligibility](#) on page 1320
4. [Determine Services To Start](#) on page 1321
5. [Validate Start SP Selection](#) on page 1322
6. [Service Questions](#) on page 1322 - operation is called with Question Placement Group is 'Start Service'
7. [Process Services To Start](#) on page 1322
8. [Deposit Assessment](#) on page 1322
9. [Determine Services To Stop](#) on page 1323
10. [Retrieve Services To Stop](#) on page 1323
11. [Validate Stop Service Agreement Selection](#) on page 1324
12. [Service Questions](#) on page 1322 - operation is called with Question Placement Group is 'Stop Service'
13. [Process Services To Stop](#) on page 1324
14. [Transfer Service Finalization](#) on page 1324

Self-Service Start/Stop/Transfer Operations

Warning:

This topic is only applicable for the integration with Oracle Utilities Digital Self Service.

Retrieve Request Type Details

This operation is used to retrieve the following configuration information at the beginning of the start, stop and transfer transaction:

- Action Method Role
- Action Method
- Self-Service Task Type
- Customer Service Request Type
- Person/Business Controls
- Start Service Controls
- Stop Service Controls

Action Method Role is determined based on the Request Mode, New Customer indicator and New Account indicator inputs. The Action Method Role is used to determine the Action Method. The Action Method defines the Self-Service Task Type and Customer Service Request Type configuration. Note that the Self-Service Task Type and Customer Service Request Type can differ by CIS Division and/or Customer Class. The Self-Service Task Type defines the self-service task BO to be used. The Customer Service Request Type defines the customer service request BOs used to persist data, and the controls used throughout the transaction. Controls determine the behavior of the self-service application UI, operations, and service task processing. Succeeding operations expect the Self-Service Task Type and Customer Service Request Type as inputs.

Person/Business Controls are based on the input person/business flag. Start Service Controls are returned if the input Request Mode is either 'Start' or 'Transfer'. Stop Service Controls are returned if the input Request Mode is either 'Stop' or 'Transfer'.

Time Zone is returned as part of the Start Service and Stop Service Controls. It comes from one of the following sources:

1. Customer Service Request Type
2. Premise - Input premise if available. Otherwise, premise linked to the input account's most recent service.
3. Installation Options

Retrieve Service-Related Customer Details

This operation is used to retrieve the following service-related information for the input account and/or person:

- Name
- Mailing Address
- Contact Details

If the input account is populated, the input person is either the account owner (main customer) or a guest who was invited by the owner. Name, Mailing Address and Contact Details are based on the account's main customer. If input account is not populated, Name, Mailing Address and Contact Details are based on the input person. Phone and email contact information are always returned. Other contact types are returned based on the corresponding control.

This operation also uses the Should Prompt For ID controls to determine if ID should be prompted for the input account and/or person. If the input account is populated, the account's main customer is used. Otherwise, the input person is used. If ID should be prompted, the valid ID Types controls are returned for input person.

Finally, this operation indicates if a non-final self-service start/stop/transfer task exists for the input account.

Service Eligibility

This operation determines if a customer is eligible to start service. It is used when starting new service, adding service, or transferring service. If the customer is eligible, a new self-service start/stop/transfer task is created where the input customer information and the results of processing performed throughout the transaction are persisted. The service task will remain in Pending status until it is transitioned by the finalize operation. Abandoned service tasks are discarded automatically via a monitor algorithm on the Pending status. The service task ID is returned as well as the customer's eligible and ineligible accounts.

The [Retrieve Request Type Details](#) on page 1319 operation that determines configuration information should be called before this operation can be used.

When starting new service for new customer (input person is not populated), the Check For Existing Person Algorithm control is used to determine if an existing person in the system matches the input name, ID, and contact information. If a match is found, the operation returns a match indicator, and no further processing is performed.

When starting new service or adding new service, person identity checks may be performed based on the ID check controls. The Should Prompt For ID controls are used to determine if ID should be prompted for the input person. This is the same step performed in the [Retrieve Service-Related Customer Details](#) on page 1320 operation and both should have the same result. It is necessary to do this step in this operation because the result from the [Retrieve Service-Related Customer Details](#) on page 1320 operation is not persisted.

The Start Service Eligibility Algorithms control determines eligibility. It uses the input information to this operation, the ID check results, and the ID prompt result. This control also determines the customer's eligible and ineligible accounts.

Process Other Person

This operation process additional persons when starting new service. The main customer's eligibility should be evaluated, and a pending self-service start/stop/transfer task already exists before this operation can be used. Eligible persons are persisted on the service task. Ineligible persons may be persisted based on the service task based on the Other Person Eligibility controls. Each person's eligibility is returned as output. Note that any additional persons that are currently in the self-service start/stop/transfer task are replaced with the input when this operation is called.

The Search For Person Algorithm control is used to find an existing person in the system that matches the input name, ID, and contact information. The search result (Match / No Match / Ambiguous Match) is returned as output. If the search resulted in an ambiguous match, the person is skipped. Person identity checks may be performed based on the ID check controls.

For new a new person, eligibility is based on ID check results. Note that if ID check is not performed, the person is considered eligible. Only eligible new persons are persisted on the service task. The Other Person Eligibility control determine the eligibility of an existing person. It is either based on ID check or a set of utility-specific eligibility algorithms. Eligibility based on ID check is evaluated the same way as a new person. Existing persons that are eligible are persisted on the service task. Existing persons that are ineligible are persisted on the service task if the Other Person Processing control is set to 'Review'.

Clear Other Person

This operation removes any additional persons that are currently in the pending self-service start/stop/transfer task.

Determine Services To Start

This operation determines the SP-based services to start at premise when starting new service, adding service, or transferring service. The main customer's eligibility should be evaluated, and a pending self-service start/stop/transfer task already exists before this operation can be used. It uses the Determine Services To Start Algorithm control to get a list of SA to start for SPs at the premise for the input start date. This information is stored in the service task's start service details. Note that SA and SP information currently in the service task are replaced when this operation is called. The operation returns the determined SPs along with badge number of the meter currently installed on the SP.

Note that the start date must be within the range defined by the start service controls. The range is calculated as follows:

- Start Date Low Limit = Current Date + Lead Days
- Start Date High Limit = Start Date Low Limit + Maximum Start Days in Future control

Lead Days is initially set to the Lead Days control. If the current time is past the Cutoff Time control, an extra day is added to it. Also, weekends and holidays based on the Work Calendar control are skipped when incrementing the Start Date Low Limit.

Validate Start SP Selection

This operation uses the Validate SPs To Start Algorithms controls to validate the selected SPs where service is being started if Start Level control is 'Individual Services'. It is used when starting new service, adding service, or transferring service. The SP-based services to start at the premise should be determined before this operation can be used.

Service Questions

This operation uses the Read Questions algorithm on the CS request type BO to retrieve the applicable service questions when starting new service, adding service, stopping service, or transferring service. The SP-based services to start at a premise and/or the SP-based services to stop for an account should be determined, and a pending self-service start/stop/transfer task already exist before this operation can be used.

Note that when transferring service, this operation is called for two scenarios - start service and stop service. The operation uses the input Question Placement Group to distinguish between these calls. Question Placement Group is used to logically group questions, based on where the questions are shown on the user interface.

- If Question Placement Group is 'Start Service', the questions are filtered using the input premise and SPs.
- If Question Placement Group is 'Stop Service', the questions are filtered using the input premise only. Any further filtering (e.g. SP Type) will be done by the calling system using the applicability list that is returned for each question.

When invoking the algorithm, the input account and SPs are used. If the input Question Placement Group is 'Stop Service' and Stop Level control is 'Account', all premises in the service task's stop details are used. Otherwise, the input premises are used.

Process Services To Start

This operation marks which of the SPs and SP-based SAs previously determined by the [Determine Services To Start](#) on page 1321 operation will be started based on the input premise or SPs when starting new service, adding service, or transferring service. If Start Level control is 'Premise' all SPs and SAs are marked. If Start Level control is 'Individual Services' only the input SPs and its SAs are marked.

This operation also process response to start service questions using Process Question Responses routine. In this operation, the routine may change which SAs are marked for start, set an SA's start option, or add non SP-based SAs to the services being started.

All services being started are validated using Validate Service To Start Algorithms control.

Deposit Assessment

This operation determines the deposit requirements when starting new service, adding service, or transferring service. The main customer's eligibility should be evaluated, and a pending self-service start/stop/transfer task already exists before this operation can be used. It uses the deposit controls and the customer information in the service task to determine if deposit is required. If deposit is required, the deposit amount is calculated using the Recommendation Algorithm associated with the Deposit SA Type control's deposit class. The deposit required indicator and deposit amount are persisted on the service task and returned as output. The Allow Pay In Full control is also returned as output.

If the deposit is required, the operation returns deposit installation options collection. Each entry has two attributes:

- Number of Installments
- Installment Amount

Number of Installments is based on the Number of Installments control. The corresponding Installment Amount is the deposit amount divided by the Number of Installments. Note that Installment Amount must be greater than or equal to the Minimum Installment Amount control an option to be included in the collection. If Allow Pay In Full control is 'true', the following entry is included in the collection:

- Number of Installments = 1

- $\text{Installment Amount} = \text{Deposit Amount}$

The operation will fail if deposit is required and not one deposit installation option can be determined.

Start Service Finalization

This is the final operation called when starting new service or adding service. It is used to update additional information on the self-service start/stop/transfer task and to nudge it out of the pending status. The additional information includes:

- Number of Installments
- Main customer's contact information
- Paperless Billing switch
- Auto Pay Information
- Web User Information

Algorithms in the service task's lifecycle are responsible for persisting the collected information to the appropriate objects (person, account, premise, SA and SP). Refer to the self-service task BO (C1-SSStartStopXferServiceTask) for more information.

The operation returns one of the following task statuses:

- In Progress – Service Task is in a non-final status.
- Complete – Service Task is in the completed status.
- Error – Service Task is in an error status.

Processing errors are returned as a list of messages. If service task processing resulted in a new account being added, the account ID is returned as an output.

Determine Services To Stop

This operation uses the Determine Services To Stop Algorithm control to determine the SP-based services to stop for an account at a given stop date when stopping service or transferring service. It returns number of premises that have stoppable services.

This operation can be called read-only mode. This mode is used by the self-service application to determine if stop service is available as an option to the user. When not in read-only mode, a self-service start/stop/transfer task containing the determined SP-based services is created if one doesn't exist (initial call when stopping service). The service task will remain in Pending status until it is transitioned by the finalize operation. The ID of the newly created service task is returned as output. If service task already exists (transferring service or stop date is changed when stopping service), the service task ID is passed to this operation and its stop details are replaced with the determined SP-based services.

Note that the stop date must be within the range defined by the stop service controls. The range is calculated as follows:

- $\text{Stop Date Low Limit} = \text{Current Date} + \text{Lead Days}$
- $\text{Stop Date High Limit} = \text{Stop Date Low Limit} + \text{Maximum Stop Days in Future control}$

Lead Days is initially set to the Lead Days control. If the current time is past the Cutoff Time control, an extra day is added to it. Note that weekends and holidays based on the Work Calendar control are skipped when incrementing the Stop Date Low Limit.

Retrieve Services To Stop

This operation retrieves the premises with stoppable service that were previously determined and persisted on the self-service start/stop/transfer task. A list of SAs is returned for each premise. Each entry has two attributes:

- Service Type
- Badge Number of the meters currently installed on the SPs associated with the SA

Pagination is applied to the returned premise list using the page offset and page limit input parameters.

Validate Stop Service Agreement Selection

This operation uses the Stop Level, Require SAs At Same SP To Behave Together, and Validate Services To Stop Algorithm controls to validate the selected SP-based services to stop. It is used when stopping service or transferring service. The SP-based services to stop for the account should be determined before this operation can be used.

Process Services To Stop

This operation marks which of the premises and SP-based SAs previously determined by the [Determine Services To Stop](#) on page 1323 operation will be stopped based on the input premises and SAs when stopping service or transferring service. If Stop Level control is 'Account' all premises and SAs are marked. If Stop Level control is 'Premise', all SAs for the selected premises are marked. If Stop Level control is 'SA', only the selected SAs are marked.

This operation also process response to stop service questions using Process Question Responses routine. In this operation, the routine may change which SAs are marked for stop or add non SP-based SAs to the services being stopped.

All services being stopped are validated using the Validate Services To Stop Algorithms control.

Stop Service Finalization

This is the final operation called when stopping or transferring service. It is used to update the self-service start/stop/transfer task with any additional contact information for the main customer and to transition it out of the pending status.

Algorithms in the service task's lifecycle are responsible for persisting the collected information to the appropriate objects (person, account, premise, SA and SP).

The operation returns one of the following task statuses:

- In Progress – Service Task is in a non-final status.
- Complete – Service Task is in the completed status.
- Error – Service Task is in an error status.

Processing errors are returned as a list of messages.

Transfer Service Finalization

This is the final operation called when transferring service. It is used to update additional information on the self-service start/stop/transfer task and to nudge it out of the pending status. The additional information includes:

- Number of Installments
- Main customer's contact information
- Paperless Billing switch
- Auto Pay Information
- Web User Information

Algorithms in the service task's lifecycle are responsible for persisting the collected information to the appropriate objects (person, account, premise, SA and SP).

The operation returns one of the following task statuses:

- In Progress – Service Task is in a non-final status.
- Complete – Service Task is in the completed status.
- Error – Service Task is in an error status.

Processing errors are returned as a list of messages. If service task processing resulted in a new account being added, the account ID is returned as an output.

Defining DataConnect Options

Oracle Utilities DataConnect facilitates data extraction from Oracle Utilities applications such as Oracle Utilities Customer to Meter and Oracle Utilities Customer Care and Billing for use in external applications; such as, analytics applications and energy management systems.

This section describes how Oracle Utilities DataConnect works and how to implement and configure the system to support data extract processing.

Note: There are two versions of DataConnect. The initial version is referred to as “Legacy DataConnect”. The current and recommended version is simply referred to as “DataConnect” or “Current DataConnect”. Implementations are recommended to use the current version. “Legacy DataConnect” remains available for implementations that used the initial version, but is not recommended for new implementations.

DataConnect Data Extracts

Oracle Utilities DataConnect can be used to extract two types of data:

- **Master Data**

(see [Customer and Premise Data Extracts](#) on page 1325 for more information)

- Service agreement, account, and person related information
- Service point and premise related information
- Service point / meter history related information

- **Billing Data**

(see [Billing Data Extracts](#) on page 1329 for more information)

The extraction processes used for each type of data can be run to produce separate extracts or combined into one.

If individual flat files are preferred, the data can be correlated in external systems through service agreement and/or service point data that is included in each type of extract. All data extracts contain the following data elements that can be used for this correlation:

- **Service Point ID:** The service point ID in Oracle Utilities Customer Care and Billing and/or
- **Service Agreement ID:** The service agreement ID in Oracle Utilities Customer Care and Billing

External systems receiving data extracted from the Oracle Utilities DataConnect facilities can use these IDs to associate billing data to extracted master data.

If a single flat file is preferred, meaning an extract that contains billing data and master data in one export file, the Billing Data extraction process can be configured to retrieve the associated master data of the bills and place the information in the same row as the billing data.

Note: There is a version 1 and version 1+ for the DataConnect extracts. In the following pages where a system object such as a batch control or data area is noted the objects are listed as (v1/v1+). When only a single object is noted it applies to both v1 and v1+.

Customer and Premise Data Extracts

Customer and premises data extracts are performed through the use of data synchronization, audit algorithms, business objects, and related batch processes.

Batch processes are used to create initial load extracts for service point/premise and meter master data, and service agreement / account / person related master data. The initial load includes the historical data in the system (either all or a subset, depending on how the batch process is configured). Following the initial load, data synchronization requests are created when master data is added or changed.

Customer and Premise Data Extracts: Maintenance Object Audit Algorithms

Detecting changes in customer and premise data can be identified by audit algorithms on the following maintenance objects:

- Service Agreement
- Account

- Person
- Service Point
- Premise
- SP/Meter History
- Meter

The Generic Change Data Capture algorithm type (F1-GCHG-CDCP), which is provided in the base package, can be used to create audit algorithms for following maintenance objects:

- Service Agreement
- Service Point
- SP/Meter History

In addition, the following audit algorithm types can be used to create audit algorithms for customer and premise data:

- Account Change Data Capture (Customer Data Extract) (C1-ACCECDCCU)
- Person Change Data Capture (Customer Data Extract) (C1-PERECDCCU)
- Account Mailing Address Change Data Capture (C1ACCMACDC)

The following algorithm types are used with v1 ONLY.

- An **Account Change Data Capture (SA-Based) – Include Reactivated SAs** algorithm type (C1-ACCCDCSAR) is provided in the base package. This algorithm type can be used to create an audit algorithm on the Account maintenance object to determine if a service agreement sync request record is to be created for each of the account's non-closed, non-canceled service agreement(s). A change in a related account's details will instantiate a Service Agreement Extract Sync Request (of the type defined for the SA Sync Request BO algorithm parameter) if one does not already exist in the initial state for the service agreement. The base package also contains an algorithm (C1-ACCEDCSA) that is based on this algorithm type.
- A **Person Change Data Capture (SA-Based) – Include Reactivated SAs** algorithm type (C1-ACCCDCSAR) is provided in the base package. This algorithm type can be used to create an audit algorithm on the Person maintenance object to determine if a service agreement sync request record is to be created for each of the person's non-closed, non-canceled service agreement(s). A change in the main person details linked to the service agreement's account will instantiate a Service Agreement Extract Sync Request (of the type defined for the SA Sync Request BO algorithm parameter) if one does not already exist in the initial state for the service agreement. The base package also contains an algorithm (C1-PERECDCSA) that is based on this algorithm type.
- A **Premise Change Data Capture (SP-Based)** algorithm type (C1-PREMCDCSP) is provided in the base package. This algorithm type can be used to create an audit algorithm on the Premise maintenance object to determine if a service point sync request record is to be created for each of the premise's service point. A change in the premise details will instantiate a Service Point Extract Sync Request (of the type defined for the SP Sync Request BO algorithm parameter) if one does not already exist in the initial state for the service point. The base package also contains an algorithm (C1-PREECDCSP) that is based on this algorithm type.
- A **Meter Change Data Capture (SP/Meter History-Based)** algorithm type (C1-MTRCDCSPH) is provided in the base package. This algorithm type can be used to create an audit algorithm on the Meter maintenance object to determine if a SP / Meter History sync request record is to be created for the meter's current installation. A change in the meter details will instantiate a SP / Meter History Extract Sync Request (of the type defined for the SP / Meter History Sync BO algorithm parameter) if one does not already exist in the initial state for the current meter installation. The base package also contains an algorithm (C1-MTRCDCSPH) that is based on this algorithm type.

Master Data Extracts: Business Objects and Algorithms

The maintenance object audit algorithms create data synchronization requests in the following manner:

- If the Generic Change Data Capture (F1-GCHG-CDCP) algorithm type (provided in the base package) is used, the synchronization requests are based on the Sync Request BO maintenance object options.
- Alternatively, if the base package supplied Maintenance Object – Audit algorithm types, which are outlined in the [Customer and Premise Data Extracts: Maintenance Object Audit Algorithms](#) on page 1325 section are used, the synchronization requests are based on the Sync Request BO defined in the algorithm parameters.

Extraction of service agreements, service points and SP/Meter History related information are supported by the following data synchronization business objects.

- **SA/Account/Person Sync for DataConnect (C1-ExternalRepoSASync/C1-ExternalRepoPlusCusDataSync):** used to extract service agreement / account / person related information. This business object should be defined as a value for the Sync Request BO option on the Service Agreement maintenance object.
- **SP/Premise Sync for DataConnect (C1-ExternalRepoSPSync/C1-ExternalRepoPlusSPMeterSync):** used to extract service point/premise related information. This business object should be defined as a value for the Sync Request BO option on the Service Point maintenance object.
- **SP/Meter History Sync for DataConnect (C1-ExternalRepoSPMtrHistSync/C1-ExternalRepoPlusSPMeterSync):** used to extract SP/meter history related information. This business object should be defined as a value for the Sync Request BO option on the SP/meter history maintenance object.

These business objects use the following Pre-Processing algorithms to take initial data snapshots, and define the batch control used to extract data and export to a flat file:

- Capture SA-Based Initial Snapshot for DataConnect (C1-CEXTRCSAI/C1-CEXTRCSAD)
- Capture SP-Based Initial Snapshot for DataConnect (C1-CEXTRCSPI/C1-CEXTRSPMI)
- Capture SP/Meter History Initial Snapshot for DataConnect (C1-CEXTRCSHI/C1-CEXTRSPMI)

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for other pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Enter algorithms on the Determine If Sync Needed states verify if a synchronization is needed by capturing the final snapshot of the data and comparing it against the initial snapshot. If changes are detected, the final snapshots of the data are stamped on the synchronization requests for export.

- Capture SA-Based Final Snapshot for DataConnect (C1-CEXTRCSAF/C1-CEXTRPSAF)
- Capture SP-Based Final Snapshot for DataConnect (C1-CEXTRCSPF/C1-CEXTRSPMF)
- Capture SP/Meter History Final Snapshot for DataConnect (C1-CEXTRCSHF/C1-CEXTRSPMF)

The Prepare Delimited Extract Data (Ignore Custom Sync Records) Enter algorithm (C1-PRPEXDNCU/C1-PRTBDEXDT) on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the batch control defined by the pre-processing algorithm).

Customer and Premise Data Extracts: Batch Controls

Customer Data

The customer data extraction process uses a set of batch processes to create data synchronization requests and extract files.

The following batch processes are used to create initial synchronization requests:

- Current DataConnect
 - **Customer Data Initial Load for DataConnect (C1-CDTIL):** This batch control creates initial synchronization requests for account data (service agreements/accounts/persons) and SA's SP data (SA/SP). The appropriate sync business objects for the two extracts should be plugged in as parameters to the batch job.
 - **Mail Address Initial Load DataConnect (C1-MADIL):** This batch control creates initial synchronization requests for accounts.
- Legacy DataConnect
 - **SA-Based Initial Load for Legacy DataConnect (C1-SAEIL):** This batch control creates initial synchronization requests for service agreements / accounts / persons.
 - **SP Initial Load for Legacy DataConnect (D1-SPEIL):** This batch control creates initial synchronization requests for service points.

The following batch processes are used to create extract files from synchronization requests.

Note: These batch processes should be run to create initial load data synchronization requests based on the Sync for DataConnect business objects.

- Current DataConnect

- **Customer Data Extract for DataConnect (C1-CUDTX):** This batch control creates extract file(s) for service agreements / accounts / persons related information.
- **SA/SP Data Extract for DataConnect (C1-SSDTX)**
- **Mailing Address Extract DataConnect (C1-MADTX):** This batch control creates extract file(s) that contain mailing address information.
- **SA-Based Extract for DataConnect (C1-CUDTX):** This batch control creates extract file(s) for service agreements / accounts / persons related information.
- Legacy DataConnect
 - **SP Extract for Legacy DataConnect (D1-SPE SR):** This batch control creates extract file(s) that contain service point information.

These batch controls are defined as values for the Batch Control for Extract algorithm parameters on the Pre-Processing algorithms on the Sync for DataConnect business objects (see above).

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Premise Data

The premise data extraction process uses a set of batch processes to create data synchronization requests and extract files.

The following batch processes are used to create initial synchronization requests:

- Current DataConnect
 - **SP/Meter Initial Load for DataConnect (D1-SPMIL):** This batch control creates initial synchronization requests for service points, device configurations, and devices.
- Legacy DataConnect
 - **Install Event Initial Load for Legacy DataConnect (D1-IEEIL):** This batch control creates initial synchronization requests for install events.

The following batch processes are used to create extract files from synchronization requests.

Note: These batch processes should be run to create initial load data synchronization requests based on the Sync for DataConnect business objects.

- Current DataConnect
 - **SP/Meter Extract for DataConnect (D1-SPMSR):** This batch control creates extract file(s) that contain service point, device configuration, and device information.
- Legacy DataConnect
 - **Install Event Extract for Legacy DataConnect (D1-IEESR):** This batch control creates extract file(s) that contain install event information.

These batch controls are defined as values for the Batch Control for Extract algorithm parameters on the Pre-Processing algorithms on the Sync for DataConnect business objects (see above).

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file.) for a delimited flat file containing extracted data.

Setting Up and Executing Master Data Extracts

Setting up master data extracts involves the following steps:

1. Add audit algorithms on the Service Agreement, Account, Person, Service Point, Premise, SP/Meter History and Meter maintenance objects.

- a) Add the Generic Change Data Capture algorithm as an audit algorithm on the Service Agreement, Service Point, and SP/Meter History maintenance objects.
 - b) Add the Account Change Data Capture (SA-Based) - Include Reactivated SAs algorithm as an audit algorithm on the Account maintenance object.
 - c) Add the Person Change Data Capture (SA-Based) - Include Reactivated SAs algorithm as an audit algorithm on the Person maintenance object.
 - d) Add the Premise Change Data Capture (SA-Based) algorithm as an audit algorithm on the Premise maintenance object.
 - e) Add the Meter Change Data Capture (SP/Meter History-Based) algorithm as an audit algorithm on the Meter maintenance object.
2. Add the DataConnect synchronization request business objects as Sync Request BO options on the Service Agreement, Service Point and SP/Meter History maintenance objects.
 3. Execute initial load batch processes related to service agreements and service points.
 4. Once the initial load synchronization has been executed, changes to service agreements, accounts, persons, service points, premises, SP/Meter History records or meters will trigger the creation of new synchronization requests and resulting extraction files.
 5. Execute the sync request monitor process.
 6. Execute the extract batch processes related to service agreements and service points.

Billing Data Extracts

When sending billing related data to an external system, both historical and current data needs to be extracted.

Historical data can be extracted as part of an initial load process, and only needs to be provided during initial setup of the integration. Historical data includes data history for all bill segments for a specified historical period that are:

- Linked to completed bills.
- Not linked to bills but are linked to frozen FTs that are linked to completed bills.

Current data should be extracted on a regular ongoing (or incremental) basis. However, in addition to sending current data, any billing corrections should be extracted as well.

Extraction of billing data is performed through use of data synchronization, post bill completion algorithms, business objects and related batch processes.

Billing Data Extracts: Business Objects and Algorithms

Billing generates synchronization requests when bills complete through a Customer Class – Post Bill Completion algorithm. The Change Data Capture of Billing Data for DataConnect (C1-CAPBILLEX) algorithm type provided in the base package can be used to create a Customer Class – Post Bill Completion algorithm that creates a billing synchronization request record for each of the bill's bill segments if one does not exist in the initial state.

Billing related information extracts are supported by the following data synchronization business objects.

- Current DataConnect
 - Bill Sync for DataConnect (C1-ExternalRepoPlusBillSync)
 - Bill Segment Sync for DataConnect (C1-ExternalRepoPlusBillSegSync)
- Legacy DataConnect
 - Billing Sync for Legacy DataConnect (Tab-delimited) (C1-ExternalRepoPlusBillingSync)
 - Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync)

These business objects should be defined as an algorithm parameter on the algorithm based on the Change Data Capture of Billing Data for DataConnect (C1-CAPBILLEX) algorithm type. These business object use the following Pre-Processing algorithms to take an initial data snapshot, and define the batch control used to extract data and export to a flat file. However, since billing data are always synched when it gets completed, no actual initial snapshot is taken. Instead, the parameters used for building the snapshots are taken and stored on the sync request record for later use when building the final snapshot.

Current DataConnect

| Business Object | Pre-Processing Algorithm |
|--|---|
| Bill Sync for DataConnect (C1-ExternalRepoPlusBillSync) | Capture Bill Data Initial Snapshot (C1EXTCBILLI) |
| Bill Segment Sync for DataConnect (C1-ExternalRepoPlusBillSegSync) | Capture Bill Segment Data Initial Snapshot (C1EXTRCBSI) |

Legacy DataConnect

| Business Object | Pre-Processing Algorithm |
|--|---|
| Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync) | Capture Billing Data Initial Snapshot for Legacy DataConnect (C1-EXTRCBLIP) |
| Billing Sync for Legacy DataConnect (Tab-delimited) (C1-ExternalRepoPlusBillingSync) | Billing Data Initial Snapshot for Legacy DataConnect (C1-EXTRCBLIP) |

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for pending related synchronization requests, and, if none, transitions them to the Determine if Sync Needed state.

Enter algorithms on the Determine If Sync Needed states extract a final snapshot of the data if the billing related data is to be extracted and exported. These include:

- Algorithms that check if there is a need to export the billing data. It will discard the synchronization request if one of the following is true:
 - The synchronization request is for a cancelled bill segment whose original usage has not been previously sent out.
 - The synchronization request has been marked for non-synchronization (such as, the bill segments related SA Type is not configured to be extracted on the Billing Data Configuration for DataConnect master configuration record).

| Business Object | Algorithm |
|--|--|
| Billing Sync for Legacy DataConnect (Tab—delimited) (C1-ExternalRepoPlusBillingSync) | Determine if the Billing Sync is Needed (C1-DSCANUSNS) |
| Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync) | Determine if the Billing Sync is Needed (C1-DSCANUSNS) |

- Algorithms that capture the billing data information and stores it on the synchronization request.

Current DataConnect

| Business Object | Algorithm |
|--|---|
| Bill Sync for DataConnect (C1-ExternalRepoPlusBillSync) | Capture Bill Data Final Snapshot (C1EXTCBILLF) |
| Bill Segment Sync for DataConnect (C1-ExternalRepoPlusBillSegSync) | Capture Bill Segment Data Final Snapshot (C1EXTRCBSF) |

Legacy DataConnect

| Business Object | Algorithm |
|--|---|
| Billing Sync for Legacy DataConnect (C1-ExternalRepoBillingSync) | Capture Billing Data Final Snapshot for Legacy DataConnect (C1-CAPBILUSN) |
| Billing Sync for Legacy DataConnect (Tab-delimited) (C1-ExternalRepoPlusBillingSync) | Capture Billing Data Final Snapshot for Legacy DataConnect (C1-CAPBILUSN) |

When using Legacy DataConnect, if a single extract file that combines both the billing and master data (customer and premise) information is preferred, the following algorithms can be used to capture the master data information of the bill. These algorithms should be plugged in on the Determine if Sync Needed state after the Capture Billing Data Final Snapshot for DataConnect algorithm.

- Capture Billing's SA Final Snapshot for DataConnect (C1-CEXTRCSA) - This is the algorithm that captures the service agreement, account and person information associated with the bill.
- Capture Billing's SP Final Snapshot for DataConnect (C1-CEXTRCSP) - This is the algorithm that captures the service point and premise information associated with the bill.
- Capture Billing's Meter History Final Snapshot for DataConnect (C1-CEXTRCSM) - This is the algorithm that captures the meter history associated with the bill.

When using DataConnect v1, the Prepare Delimited Extract Data (Process All) Enter algorithm (C1-PRPEXDCUS/C1-PRPTDEXDT) on the Send Request state prepares and formats the data for extraction, and creates a general process record for the synchronization request (based on the extract batch control defined by the pre-processing algorithm).

Billing Data Extracts: Batch Controls

The billing data extraction process uses a set of batch processes to create data synchronization requests and extract files.

Creating Initial Synchronization Requests

The following batch processes are used to create initial synchronization requests for bills:

- Current DataConnect
 - Bill Data Initial Load for DataConnect (C1-BLDIL)
 - Bill Segment Data Initial Load for DataConnect (C1-BSDIL)
- Legacy DataConnect
 - Billing Data Initial Load for Legacy DataConnect (C1-BLEIL)

These batch processes should be run to create initial load data synchronization requests based on the sync business objects described above.

Creating Extract Files

The following batch process is used to create extract files from synchronization requests for billing related information.

- Current DataConnect
 - Bill Data Extract for DataConnect (C1-BLDTX)
 - Bill Segment Data Extract for DataConnect (C1-BSDTX)
- Legacy DataConnect
 - Billing Data Extract for Legacy DataConnect (C1-BSYEX)

These batch controls are defined as values for the Batch Control for Extract algorithm parameters on the Pre-Processing algorithms on the sync business objects described above.

The following batch controls are used to extract bill segment lines and service quantities:

- Bill Seg Lines Extract - DataConnect (C1-BSLDX)
- Bill Segment SQ Extract - DataConnect (C1-BSSQX)

These should be run after bill segment extract has been run.

Use the **Batch Control** portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name for this file) for a delimited flat file containing extracted data.

Setting Up and Executing Billing Data Extracts

Setting up billing data extracts involves the following steps:

1. Configure the Billing Data Configuration for the DataConnect master configuration record. This is used to configure the UOM, TOU, and SQI of the SA Type's service quantity and charges that will be extracted. Additionally, you can also configure the UOM, TOU and SQI at the rate level.
2. Add the Capture Bill and Bill Segment Extract for DataConnect v1+ (C1CAPBILBSEG) related post bill completion algorithm to the applicable customer classes.
If using DataConnect v1, use the Capture Billing Data for DataConnect (Comma-delimited) (C1-CAPBILLEX) algorithm.
3. Execute initial load batch processes related to billing data.
4. Once the initial load synchronization has been executed, current data should be extracted on a regular ongoing (or incremental) basis. In addition to sending current data, any billing corrections will be extracted as well (data related to bill segments not linked to bills but are linked to frozen FTs that are linked to completed bills).
5. Execute the sync request monitor process.
6. Execute the extract batch processes related to billing.

Billing Data DataConnect Master Configurations

The master configuration business objects for billing data Configuration for DataConnect define general configuration details for the DataConnect functionality.

Billing Data Configuration for Legacy DataConnect

The Billing Data Configuration for Legacy DataConnect master configuration is used to configure the UOM, TOU, and SQI of the SA Type's service quantity and charges that will be extracted. Additionally, you can also configure the UOM, TOU and SQI at the rate level.

Billing Extract Master Configuration for DataConnect

The Billing Extract Master Configuration for DataConnect master configuration is used to define the configuration used to extract billing data. This includes the extraction types, including bill and bill segment sync request business objects, as well as CIS Divisions and SA Types for each, the number of historical periods for initial load, and the calculation line's category based on the rating engine used (billing extract assumes that only one rating engine is used by the system).

Navigate using **Admin**, then **General**, then **Master Configuration**. In the Master Configuration list, scroll to the appropriate master configuration and click the add icon if there is no record yet or the edit icon to modify an existing record.

For more information about specific fields in the master configuration, refer to the embedded help.

Extract Flat File Formats

This section outlines the format of output flat files created by master and billing data extracts.

External Fieldwork System Integration

The following section describes functionality provided for integrating your field activities with an external system.

Note:

Separate module. Field activity integration functionality is associated with separate Field Activity Integration module. If this module is not applicable to your business you may turn it off. Refer to [Turn Off A Function Module](#) for more information.

The Big Picture of External System Integration

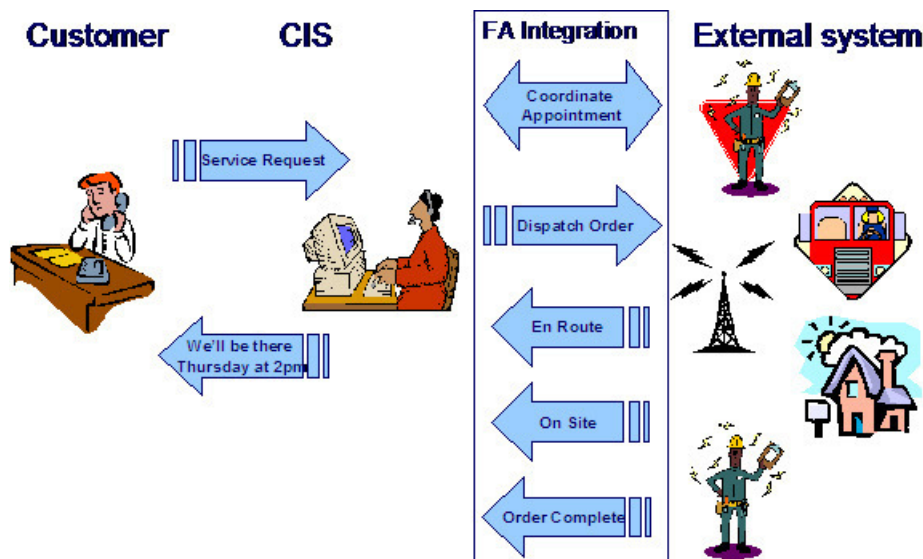

Many utilities use other systems to coordinate work that goes out to the field. The following are examples of functionality provided by fieldwork management systems:

- Defining crews, skills, availability for work
- Scheduling appointments
- Tracking individual field activities, usually utilizing handheld devices to get up-to-the-minute status
- Balancing the workload

Since Oracle Utilities Customer Care and Billing can generate many work orders, you can integrate it with your external systems. The most common type of external system used to coordinate fieldwork is a Workforce Management (WFM) system. However, some companies may set up their business such that certain field activities should be sent to other types of systems. For example,

- Maybe new meter installations are the responsibility of the Asset Management system. A field activity of this type originated in Oracle Utilities Customer Care and Billing should be sent to the asset management system. That type of system may support its own crew dispatching logic or perhaps it performs some simple processing for the field activity and then interfaces the field activity to the WFM system.
- Outage related field activities are typically sent to an outage management system. The outage management system uses information from several outage calls to determine the source of the outage problem. The outage system may support its own crew dispatching logic or it may integrate with a WFM system to dispatch a crew.

The following diagram illustrates the typical integration with an external system:

The following points describe the diagram:

- While speaking with the customer and entering information into the system, information about available appointments may be accessed from an external system and displayed on an Oracle Utilities Customer Care and Billing user interface. Information about the appointment that is booked with the customer is sent to the external system.
- Information about new field activities created in Oracle Utilities Customer Care and Billing is sent to the appropriate external system using XAI. The external system performs the dispatching and tracking for the field activity.
- Intermediate field activity states may be interfaced from the external system to Oracle Utilities Customer Care and Billing.

- Completion information is interfaced from the external system to Oracle Utilities Customer Care and Billing.

Mapping Field Activity Types to an External System

When integrating with an external system, you must determine how to map your field activity types in Oracle Utilities Customer Care and Billing to your related task identifier in the external system.

Decide whether Oracle Utilities Customer Care and Billing provides information on its field activity types that map to the task in the external system. For more information, see [Designing Your Field Activity Profiles & Types](#). You can leverage Oracle Utilities Customer Care and Billing field activity types and the messages sent from Oracle Utilities Customer Care and Billing to indicate the appropriate task in the external system. If tasks in the external system already have the information that maps to the field activity types in Oracle Utilities Customer Care and Billing, then the messages in Oracle Utilities Customer Care and Billing can pass the field activity types to the external system. You need to determine where your mappings will exist to decide how to map the field activity types and where.

In the sample integrations provided, it is assumed that the Oracle Utilities Customer Care and Billing field activity types map to the external system tasks using characteristics on the field activity type. You can use one or more characteristics on the field activity type to map it to the task in the external system.

Cancelling a Field Activity

Various business processes in the system create field activities (for example, start/stop, severance or cut process, device test selection). If the process that creates a field activity is canceled, the system attempts to automatically cancel the related field activity. If an implementation integrates with an external system, typically messages can be sent real-time to the external system AND to a field worker dispatched to work on the field activity to indicate that an FA is being canceled.

However, it's possible that there are situations where it is known ahead of time that a message cannot be successfully sent real-time. (For example, some field workers do not have real time communication with the dispatcher while in the field).

If this situation exists, you may configure the [external system feature configuration](#) to identify intermediate status values that should prevent a field activity from automatically completing. All processes that attempt to automatically cancel a field activity whose dispatch group references an external system will first check to see if it's in an intermediate status that should prevent auto-cancellation.

Note:

Each business process must define what should occur when a field activity is not allowed to be auto-canceled.

Field Activities Not Related to a Premise

There are often field activities generated that do not relate to a specific premise. Because Oracle Utilities Customer Care and Billing requires a service point for every field activity, implementations must define one or more premises to represent the "no address premise" to use for one of these field activities. The decision as to whether to use one premise or more than one premise depends on how you plan to interface this information to an external system. For example

- Maybe the external system expects the user to use the field activity instructions to describe the location of the problem. In this case only one "no address" premise is needed
- You may decide that the operations area on a field activity's service point is interfaced to the external system and that you want to create a different "no address" premise for each of your operations areas.

Regardless of how many "no address" premises you decide to define, you must create at least one service point to be able to create a field activity. You may choose to create a service point for each service type you support. You must also be sure that your users know how to find the correct premise and service point in the search when creating the field activity.

We recommend that you create a special [premise type](#) to use for these premises and reference that premise type in the No Address Premise Type option on the [feature configuration](#). The base product [Extract FA Information](#) service resets the Address fields if the premise linked to the field activity's service point is a "no address" premise type.

Override Phone Number

When entering field activity information for a customer, you may want to capture a specific contact phone number to interface to the external system. We recommend that you create a field activity characteristic type to capture the contact phone number and reference that characteristic type in the Phone Number Characteristic Type option on the [feature configuration](#). The base product [Extract FA Information](#) service overrides the Account's phone number if it finds a characteristic on the field activity with this characteristic type.

Integration Through XAI

The integration between Oracle Utilities Customer Care and Billing and the various external systems is through XAI.

- The XAI real time outgoing message engine is used to retrieve appointment information and book appointments.
- Information about field activities is interfaced to the external system using near real time NDS messages.
- When the system receives messages from the external system, records are received as inbound messages.

External System Feature Configuration Refers to a Service Provider

In order to communicate to the external system using XAI, the system must be able to identify a service provider related to the external system. The service provider associated with an external system is defined as an option on the [external system's feature configuration](#).

Dispatching Field Activities

When your implementation integrates with an external system, field activities are created in Oracle Utilities Customer Care and Billing and interfaced to the external system. The external system manages the assigning and dispatching of work associated with this field activity.

If your external system can supply interim status information, this can be passed to our system and logged with the field activity. For example, if the external system can indicate that the field worker is en route or on site, this can be logged for the field activity so that if the customer calls to inquire about the status, the user is able to communicate the information.

When work is completed, full completion information related to the field activities is interfaced from the external system back to the system.

Note:

that field activities are interfaced to the external system, not field orders. Field orders are not necessary because they are used to bundle field activities together, an activity now managed by the external system. You may still choose to create field orders for these types of field activities if you want to group field activities for your own purposes.

Integration with Multiple External Systems

Some organizations use more than one external system to manage different types of field activities. For example, line work may be handled in one system and meter service work in another. To achieve this the [external system's feature configuration](#) is defined at the dispatch group level. Field activities are interfaced to an external system based on their dispatch group information.

Algorithms Control FA Integration

The interaction between Oracle Utilities Customer Care and Billing and your external systems is handled entirely via algorithms that are plugged into the appropriate dispatch group. If your dispatch group indicates that it should interface with an external system, then you must specify one or more FA Integration algorithms. These algorithms are called when the following system events occur

- A field activity linked to the dispatch group is created, whether online or in batch
- A field activity linked to the dispatch group is canceled, whether online or in batch
- The "header" information for a field activity linked to the dispatch group is changed, whether online or in batch

Note:

Header information. "Header" information for a field activity refers to information on the field activity record. It does NOT include steps, characteristics, remarks or log records.

- The characteristics collection for a field activity changes online. Changing the characteristics via a batch routine will not trigger the FA integration algorithms.

Sample FA Integration Algorithm

The system provides a sample algorithm for FA integration called FWFM-FA-INT. This algorithm creates outbound messages (by creating NDS records) to notify an external system if any field activities are created or if any changes are made to existing FAs so that their corresponding orders are created or updated respectively. Refer to the algorithm type description for more detail about the algorithm's logic.

Note:

Alert For Problems With Message. The base product provides an alert algorithm (CCAL-FAERMSG) that may be plugged in to the [installation options](#). This algorithm displays an alert if there is an error associated with an outbound message for the field activity or if a response has not been received within a specified time limit.

Extract FA Information

When XAI processes the outgoing messages generated by the sample FA integration algorithm, it builds the XML request by calling the service referenced on the NDS type's XAI inbound service.

The base product provides a service, called CIPOEFIP, which extracts field activity information along with information related to the service point, meter, item, premise and account for the field activity (if applicable). If this service does not provide the functionality required by your implementation, you may create your own version using this one as a basis.

Note that this service defines an input parameter to exclude Financial Information. You can set this to Yes to avoid the account financial information (see below).

The following tables list the data that is extracted.

Cancel Reason and its Description

Incoming Messages from the External System

If your implementation requires general updates to the field activity from your external system, for example, updating the priority based on a change to the priority in the external system, the XAI Inbound Service that processes this message may reference the standard field activity service.

The base product supplies two additional services to handle special incoming messages from your external system.

- One service processes responses to outgoing messages initiated by Oracle Utilities Customer Care and Billing.
- One service processes field activity completion information.

FA Response

The sample integration is designed to expect a response, whether positive or negative, from the external system when an outgoing message is sent.

The base product provides a service, called CIPORFAP, which processes this response. Note that we also provide an XAI Inbound Service, FA Response, defined to invoke this service. This service provides the ability to do the following for positive responses:

- Update information about the field activity (refer to [Populating FA Response](#) for details)
- Create a [field activity log](#) entry

If the incoming message is a negative response to a message originally sent by Oracle Utilities Customer Care and Billing, the service supports the following functionality:

- Create a [field activity log](#) entry.
- Create a To Do Entry

For both the log entry and the To Do entry, if the external system has provided an external message category and code in the message that have been mapped to an internal message category and code on the feature configuration table, the system looks up the message text and includes it in the log message. Refer to [FA Log Entry Events](#) for more information.

The following topics provide some additional information.

Create a Log Entry

In order to create a log entry, the system needs to know the log type to use. The service accepts a log type as input and your XSL that maps data to this service may assign an appropriate log type.

If a log type is not provided, the system can try to default one of the base sample log types if information is provided about the type of base sample message that this is a response to. To do this, the service needs to identify the notification download condition of the original message.

Fastpath:

Refer to [Sample FA Integration Algorithm](#) for information about the notification download conditions used for the sample integration.

Your XSL may provide

- The notification download condition flag.
- The notification download type. Using the NDS type, the system can find the appropriate notification download condition flag.
- The external system and the message id that the system generated and sent to the external system. Using that information, the original outbound (NDS) message can be retrieved and the NDS type and its corresponding notification download condition flag can be determined.

Fastpath:

Refer to [Sample FA Integration Algorithm](#) for more information about creating the message ID.

Refer to [Field Activity Log](#) for a list of the base sample log types and the type of message they are generated for.

Create a To Do Entry

In order to create a To Do entry, the system needs to know the To Do type to use. The service accepts a To Do type as input and your XSL that maps data to this service may assign an appropriate To Do type. If you don't pass in a To Do type the system looks up the **To Do Type for FA Response** indicated on your [external system's feature configuration](#).

Populating FA Response

The following table lists the fields to populate for an FA response message.

| |
|---|
| General information |
| FA ID |
| Positive Switch (Y if response is positive, N if response is negative) |
| Outbound Message Information (used to identify the original outgoing message that this is a response to) |
| External System |
| Message ID |
| Notification Download Condition flag |
| NDS Type |
| Error Message Information Refer to FA Response for more information |
| Message Category |

FA Intermediate Status

Appointment Information

Field Activity Characteristics

Intermediate Status Updates

Oracle Utilities Customer Care and Billing supports receipt of intermediate status updates for a field activity from an external system. To process messages from the external system regarding status update changes, the system call the standard Field Activity service with a change action updating the intermediate status as provided.

If your organization's external system supports different intermediate status values for a [field activity](#), your implementers must customize the lookup value that defines the list of valid intermediate status values.

Field Activity Completion

The system provides a staging table to use to upload and complete field activities. However, this staging table has limitations as described in [field activity completion considerations](#). For these reasons and to enable to support [integration through XAI](#), the base product provides a sample service (called CIPOASTP) that can be invoked by XAI to support completion of the all step types, including the "generic" step types and the "standard" step types. We provide an XAI Inbound Service, C1FACompletionWithSteps, defined to invoke this service. The sample service:

- Creates field activity upload staging and FA step upload staging records
- If meter read information has been provided, it creates a meter read record and its corresponding register reads.
- For any of the "generic" steps, the process updates or creates the appropriate record(s) and populates the id of the record updated as the foreign key for the FA step record. For example, for the Change Meter step type, the process updates the meter record with the information provided through XAI and links the meter id to the FA step record.

- The process then performs the standard "complete step" logic. For the "generic" step types, the FA step should simply be marked as complete because the foreign key is already linked. For the "standard" step types, the completion logic described in [FACOMPL - Upload and Complete Field Activities](#) is performed.

Fastpath:

Refer to [Field Activity Completion Considerations](#) for the list of "generic" and "standard" step types.

- Creates an FA log entry with a log type of Order Completion to indicate that the field activity has been completed by an external system.
- Standard FA completion logic is also performed. For example, completion algorithms are executed, etc.

Note:

The sample service provided by the system may not provide all the functionality your implementation requires for completing every "generic" step. For example, not all service point, meter or item fields are included in the list of fields that may be updated. If the sample process does not satisfy your needs, your implementers should copy the sample process and modify the new process as needed.

Characteristic limitation. The sample service limits the number of field activity characteristics that may be uploaded to 100.

Error Handling. If any error is found during step completion, this sample service backs out all changes and issues an error indicating the problem.

Populating Field Activity Completion

The following table lists the fields to populate for a Field Activity Completion.

| |
|---|
| FA Upload Staging Information |
| FA ID |
| All fields in the FA Upload Staging table, FA upload characteristics, FA upload remarks and FA upload staging steps |
| "Generic" Step Type Information |
| Step Sequence Number |

Device Test Information

All fields for main Device Test table

External System. Used to record a test done by a third party.

Device Test Component / Result Extra Information.

This additional information is used to identify the meter readings that should be associated with component test results that are meter readings. Note. This FA completion service supports providing information for a single meter reading (in the FA upload staging info above). If your device test produces multiple readings, the assumption is that the readings are entered separately prior to this upload of completion information.

Component sequence. Indicate the sequence of the Device Test Component

Read Sequence for the register for that component. This should correspond to the register's relative sequence within the meter configuration.

Component Result sequence. Indicate the sequence of the Component Result

Read Date/Time. For each result that is related to a meter read, indicate the read date / time so that the system can find the associated meter read for this result.

Booking Appointments Via An External System

If your field activity requires an appointment, the user navigates to the [appointment](#) page to book the appointment. If the dispatch group for your field activity is associated with an [external system's feature configuration](#), the

appointment page includes a user exit to provide the ability to communicate with the external system for the following actions:

- Display available appointments
- Book an appointment
- Cancel an appointment

Note:

Implementation specific behavior. The actual behavior of your appointment integration is dependent on your external system behavior. For example, some systems store appointment booking, which may be done real time, independently from storing field activities, which are interfaced in near real time. Other systems may display available appointments real time but may book appointments as part of storing the field activity, which is near real time.

This section describes the tools provided to interface with your external system along with a description of sample integration of real time appointment interaction provided with the system.

Note:

Oracle Utilities Mobile Workforce Management integration. In addition to general FA integration logic, the system provides integration with Oracle Utilities Mobile Workforce Management. Refer to the documentation for integration for more information.

Configuring Appointment Options

There are several configuration options available to customize the interaction with your external system for appointments.

Manual Appointments

If your external system books appointment in real time, it's possible that there is a problem with the communication to the external system while the user is attempting to book an appointment. You may configure your [external system's feature configuration](#) options to allow manual booking of appointments so that the user is able to book appointments even if the system is down. If you set the option Allow Manual Appointments to Y,

- If the communication is available to show appointments, but the connection is down when you attempt to book one of the displayed appointments, you can click OK to book the appointment using a "near real time" message. This is applicable for systems that book appointments real-time via the appointment page.
- If the communication is unavailable while you are attempting to show appointments, you may add your own appointment period. When you click OK, a "near real time" message is created.

Fastpath:

Refer to [Book Appointment](#) for more information about the creation of "near real time" messages.

Note:

If the user has created an appointment or has chosen an appointment that is not available in the external system, it is possible that the manual appointment is not accepted and a negative response is received. You may configure your system to allow [forced appointments](#) to force the external system to accept the chosen appointment.

If there is a problem with the communication to your external system while attempting to cancel an appointment, you may configure your [external system's feature configuration](#) options to Allow Manual Appointment Cancellation. If this option is set to Y and the communication is unavailable while you are attempting to cancel an appointment, you can click OK to cancel the appointment using a "near real time" message.

Narrowing Appointment Window

If you have set the [external system's feature configuration](#) option Allow Narrowing Of Appointment Window to Y, then your users are able to enter a more granular appointment time than what is displayed. For example, if the list of available appointments shows an appointment period of 1pm to 4pm and this option is turned on, the user could enter an appointment period of 2pm to 2:30pm.

Forced Appointments

If your external system allows the user to choose appointment periods that are not available in the system, set the [external system's feature configuration](#) option Allow Forced Appointments to Y. When this option is turned on a Forced checkbox is visible on the search for an appointment page. The user should check this if the desired appointment is not available.

Note:

Forcing manual appointments. If your system allows [manual appointments](#) and allows forced appointments, the [book appointment](#) logic provided with the system automatically flags manual appointments as forced to ensure that they are accepted by the external system.

If an appointment is forced, the system populates a field activity characteristic indicating this. The characteristic type to use is defined as a [feature configuration](#) option.

User Defined Search and Result Fields

It is possible that your external system allows the user to provide additional information prior to searching for available appointments. For example, imagine that your customer wants the appointment to be in the afternoon and your external system allows you to request "afternoon" appointments only. To enable this functionality, you define a User Defined Search Criteria field on the [external system's feature configuration](#) options.

You may define up to 10 user defined search criteria fields. The information is passed to the message engine to [get available appointments](#). It is assumed that your XSL scripts correctly map the information into a format understood by the external system to determine the desired appointment periods.

The result grid for the available appointments displays the start date / time and end date / time. If your external system provides additional information for each appointment period that would help the user choose the best appointment, you may define a User Defined Result Field on the [external system's feature configuration](#) options.

You may define up to 10 user defined result fields. If you have configured the external system to define extra result fields, it is assumed that your response XSL correctly maps the information from the external system to the appropriate column in the available appointments collection so that it can be displayed to the user.

For any custom field that you want to include in the search or the results, you must define a [field](#) in the system to indicate the type of data and the label for this field.

Appointment Periods vs Reservations

When an external system is used for appointments, it is not necessary to set up [appointment period](#) records in Oracle Utilities Customer Care and Billing ahead of time. The external system is responsible for providing the available appointment periods. When a user books an appointment with an external system, Oracle Utilities Customer Care and Billing creates an appointment period as an audit. This enables the user to view the appointment information when viewing the field activity in the system.

If the external system creates a reservation record for the appointment in its system, the unique identifier of that reservation may be stored with the field activity in Oracle Utilities Customer Care and Billing as a characteristic. The characteristic type to use is defined as a [feature configuration](#) option. The sample integration provided with the system populates the field activity characteristic with a reservation number received.

Real Time Appointment Interaction

The appointment page communicates with the external system for appointments. This section describes some technical information related to the logic delivered with the system.

Appointment Page User Exit

The base product appointment page provides java user exit code that is invoked when the dispatch group is associated with an external system (i.e., it references a [feature configuration](#)). The user exit code does the following:

- It determines the [service provider](#)
- It finds the NDS types that are associated with the following notification download condition flags:
 - Get Available Appointments. This is passed to the engine to retrieve the available appointments
 - Appointment Book. This is passed to the engine to book an appointment real time.
 - Appointment Book - Near Real Time. This is passed to the engine to book an appointment in near real time.
 - Appointment Cancel. This is passed to the engine to cancel an appointment real time.
 - Appointment Cancel - Near Real Time. This is passed to the engine to cancel an appointment in near real time.
- It invokes the Appointment Java Class Interface defined on the [external system's feature configuration](#) options passing all the data available on the page service.

Note:

Implementation specific business logic. The intention is that any unique business logic required to interact with your implementation's external system is encapsulated in the appointment java class interface plugged in on your feature configuration options. However, if your implementation has unique logic that must be coded in the java user exit on the appointment page, that code may also be replaced by implementation specific appointment page user exit code.

Sample Appointment Java Class

The Appointment Java Class Interface referenced on your external system's feature configuration is responsible for interaction with the XAI real time outbound message engine to communicate with the external system for appointment logic.

The base product provides a default java class (called `com.splwg.wfmi.workforce.DefaultWFMSystem`) for appointment integration that may be used if it provides the logic your implementation needs.

Note:

Oracle Utilities Mobile Workforce Management. Refer to documentation on integration for information about the java class provided for integration with Oracle Utilities Mobile Workforce Management.

The default java class provided with the base product does the following:

- Extracts additional field activity information not provided by the appointment page service
- Converts the data in the page service and the additional FA information into an XML document
- Invokes the real time outgoing message engine.

Responses received from the engine are in the form of an XML document. The java class transforms the information into a format recognized by the page data model and sends it back to the user exit.

Note:

The `CILOAFTP.xml` found on the `xmlMetaInfo` directory describes the base structure of the Show Appointment, Book Appointment and Cancel Appointment request XML. The selected field activity to be booked or canceled has an additional `faExtraInfo` element. The `faExtraInfo` element follows the structure described by `CILOEFIP.xml`.

The following sections describe more detail about the logic provided by the sample base product appointment Java class interface.

- [Get Available Appointments](#)

- [Book Appointment](#)
- [Cancel Appointment](#)

Get Available Appointments

For obtaining available appointments, the user exit passes the NDS type that references the Get Available Appointments condition flag. All the data available on the page service is passed to the engine as an XML document including any [user defined search fields](#).

The user exit expects a response to this message to return a collection of records to display in the available appointments grid on the appointment page, including any [user defined result fields](#). Any errors received are communicated to the user.

Note:

Translate Message. Any error message received from the external system is translated from an external message to an appropriate system error message using the message information on the [external system's feature configuration](#).

[Top of the Page](#)

Book Appointment

Once the user has confirmed the desired appointment with the customer, the user attempts to book the appointment. The generic appointment integration java class provided with the system sends a message to books appointments real time. The user exit passes the NDS type that references the Appointment Book condition flag.

Note:

One FA at a time. The sample user exit provided by the system only supports booking appointments for one field activity at a time. As a result, if you want to use the sample user exit, your external systems should be configured with the option Allow Multiple Reservations set to N. If your organization would like to support booking appointments for multiple field activities at once, you may create your own user exit to provide this capability.

The sample user exit provided with the product expects either a positive or negative response to this message.

- If a positive response is received, the user exit expects to be passed a reservation number and an indication of whether or not the appointment was forced. It populates the field activity characteristics collection with these values using the **Reservation Characteristic Type** and **Appointment Forced Characteristic Type** defined as options on the [external system's feature configuration](#).
- If a negative response is received, an error message is displayed to the user.

Note:

Translate Message. Any error message received from the external system is translated from an external message to an appropriate system error message using the message information on the [external system's feature configuration](#).

If the message engine cannot communicate with the external system, it returns an indication to the user exit. The user exit proceeds as follows:

- If the external system indicates that Allow Manual Appointments is set to false an error is displayed to the user.
- If manual appointments are allowed, the user exit issues a warning to the user asking if the message should be logged and sent when the communication is up again. If the user agrees, the user exit invokes the java class asking it to post a near real time message [near real time message](#).
 - The user exit calculates a unique outgoing message ID for the external system. The message id is calculated using a database sequence whose name is referenced in the option **Message ID Database Sequence Name** on the [external system's feature configuration](#). This message id is passed to the real time message engine to be populated as an NDS context entry to support an [asynchronous response to the message](#).
 - The user exit passes the NDS type that references the Appointment Book - Near Real Time condition flag. The FA Id is also passed to the real time message engine to be posted as an NDS context entry. The system expects that the response to this message will create an XAI upload staging record and that this record will update the

field activity's characteristics with the reservation and forced appointment information (if applicable). Refer to [Near Real Time NDS Messages](#) for more information about responses to near real time messages and XAI upload staging.

- If the external system's configuration indicates that [forced appointments](#) are allowed, the message is sent to the external system with the forced indication set. If the external system does not allow forced appointments, it's possible that this manual appointment could be rejected by the external system.

If no error is received, the appointment page continues with the "change" action. An appointment period is created for the chosen appointment time if one doesn't already exist and the appointment period is linked to the field activity.

Note:

that the appointment period is created and linked to the field activity even if the message is sent to the external system in near real time and no confirmation has been received. This was done to record the requested appointment in our system to cater for the situations when the customer wants to change or cancel the appointment prior to receiving the acknowledgement from the external system.

[Top of the Page](#)

Cancel Appointment

If the customer wants to cancel the appointment, the user navigates to the appointment page. The generic appointment integration java class provided with the system sends a message to cancel an appointment real time. The user exit passes the NDS type that references the Appointment Cancel condition flag. The user exit expects either a positive or negative response to this message.

- If a positive response is received, the appointment page continues with the change action. (See below).
- If a negative response is received, an error message is displayed to the user.

Note:

Translate Message. Any error message received from the external system is translated from an external message to an appropriate system error message using the message information on the [external system's feature configuration](#).

If the message engine cannot communicate with the external system, it returns an indication to the user exit. The user exit proceeds as follows:

- If the external system indicates that Allow Manual Appointment Cancellation is set to false an error is displayed to the user.
- If manual appointments are allowed, the user exit issues a warning to the user asking if the message should be logged and sent when the communication is up again. If the user agrees, the user exit invokes the java class asking it to post a [near real time message](#).
 - The user exit calculates a unique outgoing message ID for the external system. The message id is calculated using a database sequence whose name is referenced in the external option **Message ID Database Sequence Name** on the external system table. This message id is passed to the real time message engine to be populated as an NDS context entry to support an [asynchronous response to the message](#).
 - The user exit passes the NDS type that references the Appointment Cancel - Near Real Time condition flag. The FA Id is also passed to the real time message engine to be posted as an NDS context entry. A response to this message will be an acknowledgement. No further updates to field activity data are expected.

If no error is received, the appointment page continues with the "change" action. The appointment period is unlinked from the field activity and if no other field activities are linked to this appointment period, the appointment period is deleted. In addition, the field activity characteristics for the reservation number and forced appointments are removed from the FA.

Note:

The above updates are performed even if the message is sent near real time and no response has been received. This was done to cancel the appointment in our system to cater for the situations when the customer wants to rebook the appointment prior to receiving the acknowledgement from the external system.

Validating Meter / Item Installations

Incoming Validate Meter / Item Message

When Oracle Utilities Customer Care and Billing receives the incoming message to validate a meter or item, the service, called CIPOVMIP, which processes the message, creates a pending notification download staging record (using the NDS type whose notification download condition is Validate Meter/Item). It creates context records for the Badge Number being validated along with an indication of whether the badge number is for a Meter or an Item.

Fastpath:

For more information about NDS types available in product integrations, refer to Oracle Utilities Mobile Workforce Management NDS Types and Oracle Utilities Work and Asset Management NDS Types listed in the documentation on integration.

The system provides an XAI Inbound Service, ValidateMeterItemRequest, defined to invoke this service. The following table lists the fields to populate for this service.

| |
|----------------------------|
| General Information |
| Message ID |
| FA ID |
| FA External ID |
| Meter / Item Flag (M or I) |
| Badge Number |

Outgoing Validate Meter / Item Message

The service provided with the product that processes the Validate Meter / Item notification download staging record does the work of validating the badge number. The service, called CIPOVRSP, does the following:

- Finds a unique device (meter or item) corresponding to the badge number provided.

Note:

The validation is only possible if the badge number is unique for a meter or item. If multiple values are found, a negative acknowledgement is returned.

- Verifies that the device is not retired
- Verifies that the Meter type or Item type of the device being verified is defined as valid for the SP Type associated with the field activity's service point.
- It verifies that the device is not already installed somewhere else.
- If the device is a meter, it verifies that there is an effective Meter Configuration for the meter on or before the message date/time.

Note:

Return Meter Configuration Type. The meter configuration type and the collection of the meter's registers are included in the output record returned to Oracle Utilities Mobile Workforce Management/Oracle Utilities Work and Asset Management.

- If the device is an item, it verifies that the item's receive date is on or before the message date.

The system provides an XAI Inbound Service, `ValidateMeterItemResponse`, defined to invoke this service. The following table lists the fields populated by this service.

| |
|--|
| General Information |
| Message ID |
| FA ID |
| FA External ID |
| Meter / Item Flag (M or I) |
| Badge Number |
| StatusFlag (Y - positive acknowledgement, F - negative acknowledgement.) |
| Meter Config Type (populated only for meters) |
| Collection of registers (populated only for meters) |
| ErrorCode (populated only for negative acknowledgement) |
| Error Message (populated only for negative acknowledgement) |

Setting Up The System To Enable FA Integration

The following section provides an overview of how to enable FA integration with an external system.

Service Provider Setup

In order to use XAI to interface with an external system, you must define a service provider. Once the service provider is defined, you must design your outbound messages.

Defining Characteristic Types For FA Integration

The following characteristic types must be defined to facilitate FA integration.

Fastpath: Refer to [Defining Characteristic Types](#) for information on how to set up characteristic types.

External System Task Characteristic Type

If you have decided to map the tasks on your external system to the Oracle Utilities Customer Care and Billing field activity types, then you need to define the characteristic types based on your decisions. It is possible to map a combination of fields from the external system to a field activity type in Oracle Utilities Customer Care and Billing.

- Refer to the following topics in the documentation on integration for more information about how you should define characteristics in product integrations:
 - Oracle Utilities Mobile Workforce Management Characteristic Types
 - Oracle Utilities Work and Asset Management Characteristic Types
- Include Field Activity Type in the characteristic entity collection

Forced Appointments Characteristic Type

If your implementation supports [forced appointments](#), the appointment booking logic attempts to store a characteristic on a field activity with a forced appointment.

- Create an ad hoc characteristic type.
- Include Field Activity in the characteristic entity collection

Reservation Characteristic Type

If your external system defines a separate reservation ID for appointments, the appointment booking logic attempts to store a characteristic on a field activity with the appointment reservation number.

- Create an ad hoc characteristic type.
- Include Field Activity in the characteristic entity collection

Override Phone Characteristic Type

Create a characteristic type for override phone if your implementation supports capturing a contact phone number on the field activity.

- Create an ad hoc characteristic type.
- Include Field Activity in the characteristic entity collection

Field Activity ID Characteristic Type

The sample FA integration algorithm may be configured to populate the field activity ID as a characteristic on any NDS records it creates. This facilitate in drilling down from the NDS record to the field activity. To support this logic,

- Create a foreign key characteristic type (if you don't already have one defined for Field Activity Id).
- Include Notification Download Staging in the characteristic entity collection

Setting Up Outbound Messages

The sample integration provided with the base product includes a predefined list of messages that are sent to an external system under various conditions. The messages are generated either from the sample FA integration algorithm or the sample real time appointment interaction. In each case, an NDS type is required to define properties of the message. Rather than hard-coding an NDS type, the integration algorithm and the user exit that manages the real time appointment interaction use a Notification Download Condition to reference the NDS type.

At implementation time, you should define an appropriate NDS type for each notification download condition listed below if it is applicable to your business.

The following download conditions are used in the [sample FA integration algorithm](#):

- FA Cancellation
- FA Creation
- FA Changed
- FA Rescheduled
- Appointment Cancel via FA Cancel

For each of the above NDS types, you must reference the following context types: Field Activity ID, Message ID. They should also reference an XAI inbound service that has been defined for the [Extract FA Info](#) service. The system provides an XAI inbound service called ExtractFAInfo, which you may use.

Note:

You can refer to the demonstration data provided with the system to view samples for pre-configured NDS types and their condition flags.

The following download conditions are used in the sample [real time appointment interaction](#):

- Get Available Appointments
- Appointment Book
- Appointment Cancel

The above NDS types do not need to reference a real XAI inbound service because the real time appointment interface is responsible for building the XML request.

Note:

You can refer to the demonstration data provided with the system to view samples for pre-configured NDS types and their associated XAI inbound services.

The following download conditions are used to send [real time appointment messages in near real time](#).

- Appointment Book - Near Real Time
- Appointment Cancel - Near Real Time

Because the XML request is built by the appointment interface prior to the creation of the NDS, these NDS types should reference a special XAI inbound service called CDxProcessXDS. This service basically tells the download staging sender that the XDS already exists and doesn't need to be created.

Designing Your External System Feature Configuration

For each external system, you must define a [feature configuration](#) with a feature type of FA Integration.

Note that it is also possible for you to define multiple entries in the feature configuration table for a single external system. You would do this if your external system may be configured in multiples ways for different dispatch groups. For example, maybe your service territory includes urban areas and rural areas. Perhaps your rules for scheduling appointments differ based on the location of the premise. You could define two separate feature configurations and define the appropriate appointment options for each one. When defining your dispatch groups, be sure to define separate dispatch groups based on the operations area and link the appropriate feature configuration accordingly.

If you define multiple feature configurations, consider whether they should all reference the same service provider. One consideration is whether or not the method of communication with the external system is the same for all feature configurations.

Configure the options for your external system interaction.

Note:

Your implementation may define additional options types. You do this by add new lookup values to the lookup field WFM_OPT_TYP_FLG.

| Option | Description |
|---------------------------------------|---|
| Account Rel. Type - Company Contact | Identify the account relationship type used to define a company's contact person. |
| Allow Forced Appointments | Use this option to indicate if forced appointments are supported. Possible values are Y and N. |
| Allow Manual Appointment | Use this option to indicate if a user is allowed to manually set up an appointment . Possible values are Y and N. |
| Allow Manual Appointment Cancellation | Use this option to indicate if a user is allowed to manually cancel an appointment . Possible values are Y and N. |
| Allow Multiple Reservations | Use this option to indicate if booking appointments for multiple field activities is allowed. Possible values are Y and N. |

| | |
|---|---|
| Allow Narrowing Of Appointment Window | Use this option to indicate if the user is allowed to further narrow down a selected appointment window . Possible values are Y and N. |
| Appointment Forced Characteristic Type | When an appointment reservation is forced, a characteristic of this type is added to the field activity. Note that the field activity's FA type must also define this as a valid characteristic type. |
| Appointment Java Class Interface | This is the java class implementation used to interface with the external system to support real time appointment interaction . |
| Default Days of Available Appointment | This option is used to determine the end date of the search period when choosing a dispatch group on the appointment page. |
| Hi-Low Review | Use this option to indicate if meter reads coming from the external system should be reviewed for Hi-Low failures and trended. Possible values are Y and N. |
| Intermediate Status to Prevent FA Cancel | This option is used to identify FA Intermediate Status values that should prevent the system from automatically canceling a Field Activity . The value entered here should correspond to a valid lookup value for the field FA_INT_STATUS_FLG. |
| Intermediate Status to Prevent FA Type Change | This option is used to identify FA Intermediate Status values that should prevent users from changing the FA Type. The value entered here should correspond to a valid lookup value for the field FA_INT_STATUS_FLG. |
| Intermediate Status to Skip Message | This option is used to identify FA Intermediate Status value used when a Field Activity is created by an external system or when other information for a field activity is updated by an external system. The base FA integration algorithm uses this information to ensure that messages sent to the external system to highlight new field activities or changes to field activities are only triggered when additions / changes are initiated in our system. The value entered here should correspond to a valid lookup value for the field FA_INT_STATUS_FLG. |

| | |
|-----------------------------------|---|
| Message ID Database Sequence Name | <p>The name of the database sequence to be used to get the next unique message ID for this external system. This is used to facilitate an asynchronous response to the message.</p> <p>If you interface with more than one external system, you may choose to use the same sequence name for all external systems or to define a separate sequence name for each external system. If you choose to define multiple feature configuration records for the same service provider, be sure that each feature configuration references the same sequence name because generated message IDs must be unique for the service provider.</p> <p>The base product provides the database sequence CI_WFM_MSGID_SEQ, which may be referenced here.</p> |
| No Address Premise Type | <p>Indicate the premise type used to identify a premise that is used for field activities that are not related to a specific premise.</p> |
| Phone Number Characteristic Type | <p>Indicate the characteristic type used to identify an override phone number on the field activity.</p> |
| Phone Type - Business | <p>Indicate the phone type used to identify a business phone number.</p> |
| Phone Type - Fax | <p>Indicate the phone type used to identify a fax number.</p> |
| Phone Type - Home | <p>Indicate the phone type used to identify a home phone number.</p> |
| Plant Source | <p>Some external systems require a reference to a Plant in our system. There are several options for where an implementation may define this value. This option is used to identify where the Plant is defined. - enter FECO if the plant field is defined in Feature Configuration - enter OPAR if the plant field is defined in the SP Operations Area - enter SPCH if the plant field is defined in the SP Characteristic</p> |
| Plant Value | <p>If the Plant Source is FECO enter the value of the Plant. If the Plant Source is OPAR enter the field service class used to identify the plant value on the SP operations area. If the Plant Source is SPCH enter the characteristic type used to identify the plant value on SP characteristic. Only one option value may be defined for a given feature configuration.</p> |
| Reservation Characteristic Type | <p>When an appointment is successfully booked for the field activity, the external system often assigns a unique reservation number to the appointment. This reservation number is linked to the field activity as a characteristic using this characteristic type. Note that the field activity's FA type must also define this as a valid characteristic type.</p> |

| | |
|-----------------------------|---|
| Service Provider | This is the service provider defined for your external system. |
| To Do Type for FA Response | Indicate the To Do type to use to create a To Do entry . The system supplies the To Do type TD-FARSP that may be plugged-in here. The program populates the To Do Entry with the sort keys, drill keys and message parameters as shown in this base package To Do. If you want to create your own To Do Type, you must set up the values to match those in the base To Do Type. |
| User Defined Criteria Field | This is used on the appointment page to add specific appointment selection criteria . The value of this option should reference a Field defined in the system metadata. The appointment page allows up to 10 user defined criteria fields. |
| User Defined Result Field | This is used on the appointment page to add specific appointment selection result information . The value of this option should reference a Field defined in the system metadata. The appointment page allows up to 10 user defined result fields. |

For each message that may be received from an external system, map the external system message to an internal system message. Refer to [Feature Configuration - Messages](#) for more information.

Designing Your External System Field Activity Types

For each type of field activity that is interfaced to an external system, create an appropriate FA type.

- Indicate that the FA type is eligible for dispatch.
- Configure the appropriate value for Appointment Booking based on your business requirements.
 - If you have decided to map your external system tasks to the Oracle Utilities Customer Care and Billing field activity type, then for each field activity type, create one or more characteristics to identify how it is mapped to the equivalent task in the external system.
- Indicate the FA characteristics that are valid for field activities of this type
 - If your external system allows [forced appointments](#), define the forced appointment characteristic type created above and referenced on your external system feature configuration.
 - If your external system defines a separate reservation ID for appointments and this FA type allows appointments, define the reservation characteristic type created above and referenced on your external system feature configuration.

Refer to the following topics in the documentation on integration for more information about how you should use characteristics in product integrations:

- Oracle Utilities Mobile Workforce Management Characteristic Types
- Oracle Utilities Work and Asset Management Characteristic Types

Designing Your Dispatch Groups

When a field activity is created, the system uses the [Field Service Control](#) to assign the field activity to a dispatch group based on the type of activity, the type of service point and the operations area that manages the service point.

If the dispatching for this service point is managed by an external system, the [dispatch group](#) should be configured to interface with the external system:

- The dispatch group references the appropriate external system feature configuration.
- You must indicate an appropriate [FA integration](#) algorithm.

Considerations When Switching To External System Integration

If your implementation is currently using the field order functionality and is planning to switch to interface field activities to an external system, here are some considerations.

Field orders are not required when integrating field activities to an external system. As a result you may choose to disable the field order related functionality:

- The automatic dispatch background process (FOD) and download field order background processes (FDS) no longer need to be scheduled. In addition, the printing processes FODL and DSGPFODL no longer need to be scheduled.
- The menu items [Field Order](#), [Group Premise FAs](#) and [Field Order Search](#) are no longer applicable. Consider disabling security for these pages.

When switching over to begin using an external system, you will undoubtedly have pending field activities that need to be interfaced to the external system. If you change the field activity's dispatch group from one that does not reference an external system to one that does, the sample [field activity integration algorithm](#) will generate an FA Creation message to the external system.

It is possible that your pending field activities are already linked to field orders. If that is the case, you will not be able to change the dispatch group on the field activity. The recommendation for switching to an external system for dispatching is to change your pending field activities to remove the link between the field activity and the field order. As mentioned above, the field order is no longer needed. Once you remove the link then you are able to change the dispatch group on the field activity.

If you prefer to leave the field order / field activity link in place then you must change the dispatch group on your field order to one that references the new external system.

Outage System Integration

The following section describes functionality provided for the integration between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.

The Big Picture of Outage System Integration

Oracle Utilities Customer Care and Billing is the central repository for customer information; for example, name, address, phone number, etc. Oracle Utilities Network Management System is the central repository for outage information; for example, outage calls, affected supply nodes, expected restoration time, etc.

In an integrated environment, each system provides information to the other system so that they can operate together seamlessly.

- The outage system uses the set of current customers to determine and manage outages to minimize their impact
- The outage system is informed of outages captured in Oracle Utilities Customer Care and Billing
- Oracle Utilities Customer Care and Billing uses the current status of an outage at a given premise for customer service

Customer Information Integration

The outage system needs information about current customers to determine and manage outages to minimize their impact. The current customer information must be made available in Oracle Utilities Network Management System. This can be done via data synchronization.

Depending on the specific edge application and version you are using, there are components of the integration that use Sync Request for the change data capture step. The following points highlight how to get more information:

- Refer to your products integration to Oracle Utilities Network Management System Implementation Guide to configure the Sync Request and change data capture functionality.
- Review the Sync Request Business Objects provided by your product for NMS integration.
- Refer to Data Synchronization for a high level understanding of the process.

Fastpath:

Refer to [The Big Picture of Sync Requests](#) for more information about synchronizing data.

Interfacing Outage Calls

The following points describe the integration:

- Oracle Utilities Customer Care and Billing is able to record trouble calls for a particular service point that exists in the system, as well as for an unknown service point, i.e. a fuzzy call. For a fuzzy call, the caller must provide either a street intersection, or a street segment.
- When an outage call is created and sent to the external system, an algorithm on the outage call business object is responsible for creating an outbound message that's sent to the external system. This is a real-time synchronous interface between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.
- Oracle Utilities Network Management System processes the Calls table and creates Incidents.

Fastpath:

Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage call integration.

Outage Inquiry

Oracle Utilities Customer Care and Billing provides query transactions that can be used to make real-time synchronous calls to NMS and inquire on one of the following:

- Job History for a particular customer, service point, location or call identifier
- Call History for a particular customer, service point, location or call identifier
- Planned Outage Jobs for a particular service point

Fastpath:

Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage query integration.

Setting Up The System To Enable Outage Integration

The following section provides an overview of how to enable the integration between Oracle Utilities Customer Care and Billing and Oracle Utilities Network Management System.

External System Setup

An external system must be setup in order integrate Oracle Utilities Network Management System. Define message senders for the following Outbound Message Types and associate them to the external system:

- NMS Outage Call (C1-NMSOUTCAL)
- NMS Job History Query (C1-NMSJOBHST)

- NMS Call History Query (C1-NMSCALHST)
- NMS Planned Outages Query (C1-NMSPLNOUT)

For synchronizing outage related notification preferences to NMS, define a message sender for the Outbound Message to Notify Edge Applications (C1-NTFOUTMSG) Outbound Message Type and associate it to the external system.

Once the external system is defined, configure the [NMS Outage Integration Master Configuration](#) so the system knows which external system to use for outage queries.

Define Characteristic Types

The following characteristic types must be defined to facilitate Outage integration:

Fastpath: Refer to [Defining Characteristic Types](#) for information on how to set up characteristic types.

Outage Group Code Characteristic Type

These characteristics are used to describe the outage problem.

- Create at least one pre-defined characteristic type
- For each characteristic type, define its list of valid values
- Include Service Task Type in the characteristic entity collection

Note:

Integration with Outage Management. The outage codes must be defined in both Oracle Utilities Customer Care and Billing and the outage management system. Refer to your Oracle Utilities Network Management System documentation for information about defining the outage codes there.

Contact Name Characteristic Type

This is used to link the contact name of the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the [Schema Constants Feature Configuration](#) using the Outage Call Contact Name Characteristic Type feature option

Contact Number Characteristic Type

This is used to link the contact number of the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the [Schema Constants Feature Configuration](#) using the Outage Call Contact Number Characteristic Type feature option

Call Identifier Characteristic Type

This is used to link the call identifier supplied by the caller associated with an outage call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the [Schema Constants Feature Configuration](#) using the Outage Call Identifier Characteristic Type feature option

Street Name Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the [Schema Constants Feature Configuration](#) using the Outage Call Street Name Characteristic Type feature option

Cross Street Name Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the [Schema Constants Feature Configuration](#) using the Outage Call Cross Street Name Characteristic Type feature option

Block Number Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the [Schema Constants Feature Configuration](#) using the Outage Call Block Number Characteristic Type feature option

City Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the [Schema Constants Feature Configuration](#) using the Outage Call City Characteristic Type feature option

State Characteristic Type

This is used to link location information supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call.

- Create an ad-hoc characteristic type
- Include Service Task Type in the characteristic entity collection
- Specify this characteristic type on the [Schema Constants Feature Configuration](#) using the Outage Call State Characteristic Type feature option

Schema Constants - Feature Configuration

Create a [feature configuration](#) with the type Schema Constants. Populate entries for all the options listed below.

Note:

Only one. The system expects only one Schema Constants feature configuration to be defined.

Configure the options for your interaction with the outage system.

Note:

Your implementation may define additional options types. You do this by adding new lookup values to the lookup field F1CN_OPT_TYP_FLG.

| Option | Description |
|--------|-------------|
|--------|-------------|

Outage Call Contact Name Characteristic Type

This is used to link the contact name of the caller associated with an outage call as a characteristic on the outage call. Refer to [Define Characteristic Types](#) for more information.

Only one value is allowed for this option.

Outage Call Contact Number Characteristic Type

This is used to link the contact number of the caller associated with an outage call as a characteristic on the outage call. Refer to [Define Characteristic Types](#) for more information.

Only one value is allowed for this option.

Outage Call Identifier Characteristic Type

This is used to link the call identifier supplied by the caller associated with an outage call as a characteristic on the outage call. Refer to [Define Characteristic Types](#) for more information.

Only one value is allowed for this option.

Outage Call Street Name Characteristic Type

This is used to link the street name supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to [Define Characteristic Types](#) for more information.

Only one value is allowed for this option.

Outage Call Cross Street Name Characteristic Type

This is used to link the cross street name supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to [Define Characteristic Types](#) for more information.

Only one value is allowed for this option.

Outage Call Block Number Characteristic Type

This is used to link the block number supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to [Define Characteristic Types](#) for more information.

Only one value is allowed for this option.

Outage Call City Characteristic Type

This is used to link the city supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to [Define Characteristic Types](#) for more information.

Only one value is allowed for this option.

Outage Call State Characteristic Type

This is used to link the state supplied by the caller associated with a fuzzy trouble call as a characteristic on the outage call. Refer to [Define Characteristic Types](#) for more information.

Only one value is allowed for this option.

NMS Outage Integration - Master Configuration

The integration with Oracle Utilities Network Management System (NMS) requires the setup of master configuration data that controls the processing of master data synchronization and outage management operations.

Navigate to **Admin > General > Master Configuration**

Set up the **NMS Outage Integration Master Config**: This master configuration relates to the outage call and outage query integration with NMS.

Refer to the embedded help for more details on how each section is configured.

Outage Notification Preferences

The system supports the ability to synchronize notification preferences that are owned by other edge applications. For example, during an outage event, Oracle Utilities Network Management System (NMS) is the system responsible for sending notifications to impacted customers that are subscribed or opted-in to receive notifications for these events. To support this functionality, notification preference statuses for outage related notification types that are updated under a customer's account must be synchronized to NMS.

To configure your system to synchronize outage related notification preferences to NMS, perform the following steps:

- Configure the outage notification types that are owned by NMS (e.g. Planned Outage, Unplanned Outage, Outage Started, Estimated Restoration Type, Outage Restored). Notification types can be configured as template based subscription, or template based parent/individual push. Refer to [Setting Up Notification Preference Options](#) on page 708 for more information.
- Configure the **Notification Preferences** master configuration. Under the master configuration's Edge Application Notification section, add the notification types along with the edge application (Network Management System) and External System/Outbound Message Type for each entry. Refer to the embedded help for more details.

Once configured, the **Notification Preference Sync Initial Load (C1–NCPIL)** batch process is used to create initial synchronization requests. This batch control creates initial synchronization requests for Notification Contact Preference data (Maintenance Object C1–NT–PREF). The maintenance object and sync business object (C1–NtfContactPreferenceSync) are plugged in as parameters to the batch job.

For ongoing synchronization requests, the **Sync Request Monitor batch control (F1–SYNRQ)** is responsible for monitoring synchronization requests in the Pending state and transitions them to the Determine if Sync Needed state. Use the following parameters when running the F1–SYNRQ batch job:

- Maintenance Object: F1–SYNC REQ
-
- Restrict By Business Object: C1–NtfContactPreferenceSync
- Restrict By Status Code: PENDING

Fastpath:

Refer to the *Oracle Utilities Customer Care and Billing - Network Management System Integration Implementation Guide* for information about outage notification integration.

Oracle Utilities Digital Asset Cloud Service

The Oracle Utilities Customer Cloud Service Integration to Oracle Utilities Digital Assets Cloud Service provides the following functionality:

- Initial and incremental extract of customer data including persons, service points, and service agreements from Oracle Utilities Customer Cloud Service (or Oracle Utilities Customer to Meter or Oracle Utilities Customer Care and Billing).
- Initial and incremental import of customer data into Oracle Utilities Digital Asset Cloud Service.

This section describes the customer data extract functionality within Oracle Utilities Customer Care and Billing (or Oracle Utilities Customer to Meter or Oracle Utilities Customer Care and Billing) used with this integration.

Customer Data Extract

Customer information including persons, service points and service agreements in Oracle Utilities Customer Cloud Service (or Oracle Utilities Customer to Meter or Oracle Utilities Customer Care and Billing) can be extracted and sent to Oracle Utilities Digital Asset Cloud Service (or Oracle Utilities Digital Asset Management) for use in enrolling customers in demand response programs.

- An initial extract is used to duplicate customer information data as of a given date in Oracle Utilities Customer Cloud Service in Oracle Utilities Digital Asset Cloud Service. This is typically done during initial set up of the Digital Asset Cloud Service implementation.
- Following the initial extract, audit algorithms track new data and changes to existing data and create data synchronization requests, which can be used to create incremental extract files via batch processing.

Extracted data is sent to Digital Asset Management in a delimited file, which is uploaded into the system via batch processing and data synchronization. See **Importing Customer-Related Data from a Customer Information System** in the *Oracle Utilities Digital Asset Cloud Service User Guides* for more information about the import process.

Extract Process Overview

This section provide an overview of the extract process and outlines the various system objects used for each type of data (contacts, service points, and service agreements). The overall process is as follows:

1. An initial "extract" batch process is used to extract customer data into files that can be imported into Digital Asset Cloud Service.
2. Audit algorithms on the Contact, Service Point, and Service Agreement maintenance objects create synchronization requests.
3. Sync requests are processed using the specific batch processes (a separate batch control is provided for contacts, service points, and service agreements) to create incremental extracts.

Initial Load vs. Incremental Downloads

Customer data can be extracted in one of two modes: Initial or Incremental.

Initial extracts are used when setting up the system to export contact, service point, and service agreement data from Oracle Utilities Customer Cloud Service.

Incremental extracts are used to update customer data in Digital Asset Cloud Service as customer data changes in Oracle Utilities Customer Cloud Service.

Initial Extract Batch Processes

Extract files are created using object-specific "extract" batch processes. See [Extract Process Object Summary](#) below for the specific "extract" batch process used for each type of customer data. These are used only for the initial extract.

These processes use the following parameters:

- **File Name:** The name of the extract file. File names can use wildcards (Required)
- **Flat Path:** The file location where the extract file is created. This can be a file location on a local server or a location in Object Storage. See [Referencing URIs](#) in the *Framework Administrative User Guide* for more information. (Required)
- **File Format:** The file format used for extract file. This should be FIXD. Each extract type has its own format.
- **Low SP Id Override Value:** A service point ID used to define the low value in a a range of IDs to limit the data extracted.
- **High SP Id Override Value:** A service point ID used to define the high value in a a range of IDs to limit the data extracted.

Use the **Batch Control** portal to learn more about these and other parameters used by these batch processes.

Audit Algorithms and Sync Request Business Objects

Sync requests are created by audit algorithms, and are based on data specific sync request business objects. See [Extract Process Object Summary](#) below for the specific audit algorithms and "Sync Request" business objects used for each type of customer data.

The table below outlines the stages of the sync request lifecycle. Use the **Business Object** portal to learn more about these business objects and the details of each lifecycle state.

| State | Notes |
|--------------------------|--|
| Pending | <p>Sync requests begin in this state.</p> <p>An Enter algorithms creates the initial snapshot of the Digital Asset Cloud Service (DACS) data (contact, service point, or service agreement).</p> <p>The Sync Request Monitor (F1-SYNRQ) batch process is used to transition sync requests in this state to the Determine if Sync Needed state.</p> |
| Determine if Sync Needed | <p>An Enter algorithms creates the final snapshot of the DACS data.</p> <p>An Enter algorithms compares the initial and final snapshots. If there is no difference, the sync request moves to the Discarded state. Otherwise, the request moves to the Send Request state,</p> |
| Discarded | <p>Sync requests for which there is no different between the initial snapshot and final snapshot are sent to this state.</p> |
| Send Request | <p>An Enter algorithm creates a General Process record for the sync request.</p> <p>The request then moves to the Awaiting Acknowledgement state.</p> |
| Awaiting Acknowledgement | <p>Requests remain in this state until the system receives an acknowledgement that DACS has received the data contained in the request.</p> |
| Synchronized | <p>Sync requests enter this state following the Awaiting Acknowledgement state when the system receives an acknowledgement that DACS has received the data contained in the request. If an error occurs, the request moves to the Synchronized with Error state.</p> |
| Error | <p>Sync requests enter this state if an error occurs while in the Awaiting Acknowledgement state.</p> <p>An Enter algorithm creates a To Do entry.</p> |
| Canceled | <p>Sync requests enter this state if canceled in either the Error or Synchronized with Error states.</p> |
| Synchronized with Error | <p>Sync requests enter this state if an error occurs while in the Synchronized state .</p> <p>An Enter algorithm creates a To Do entry.</p> |

Incremental Extract Batch Processes

Incremental extract files are created from General Process records using "Incremental Extract" batch processes. See below for the specific "Incremental Extract" batch processes used for each type of customer data. These should be run as needed for incremental updates.

Use the **Batch Control** portal to view the parameters used by these batch processes.

Extract Process Object Summary

The table below lists the batch controls, algorithms, and business objects used by each type of customer data.

| Object Type | Initial Extract Batch Process | Audit Algorithms | Sync Request Business Object | Incremental Extract Batch Process |
|-------------------|--|--|---|---|
| Person | Migrate Person to DACS Contact (C1-DCTIL) | Sync Person as DACS Contact (C1_DAPERSYNC) | Sync CCB Person to DACS Contact (C1-DACSCContactSyncRequest) | Contact Incremental Sync Batch Control (C1-DCTEX) |
| Service Point | Migrate CCB SP to DACS MSP (C1-DSPIL) | Sync Service Point as DACS Metered Service Point (C1_DASPSYNC) | Sync CCB SP to DACS Metered Service Point (C1-DACSMSPSyncRequest) | SP Incremental Sync Batch Control (C1-DSPEX) |
| Service Agreement | Migrates SA to DACS Metered Service (C1-DMSIL) | Sync Service Agreement as DACS Metered Service (C1_DASASYNC) | Sync CCB SA to DACS Metered Service (C1-DACSMSSyncRequest) | MS Incremental Sync Batch Control (C1-DMSEX) |

Acknowledgement Messages

When Digital Asset Cloud Service processes incremental updates, it can send an acknowledgement back to Customer Cloud Service.

Refer to the Oracle Utilities Customer Cloud Service Integration to Oracle Utilities Digital Assets Cloud Service documentation for more information about configuring Digital Asset Cloud Service to send acknowledgements.

Extracting Persons

This topic provides additional details related to extracting Persons from Oracle Utilities Customer Cloud Service for import into Oracle Utilities Digital Asset Cloud Service.

Note: Persons are converted to Contacts in Oracle Utilities Digital Asset Cloud Service.

Initial Extract Batch Process

Initial extract files for persons are created using the Migrate Person to DACS Contact (C1-DCTIL) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run only for the initial extract.

Maintenance Object Audit Algorithm

The Sync Person as DACS Contact (C1_DAPERSYNC) audit algorithm tracks new person data and changes to existing person data and creates data synchronization requests, which are used to create incremental extract files.

Sync Request Business Object

Person sync requests are based on the Sync CCB Person to DACS Contact (C1-DACSCContactSyncRequest) business object.

Incremental Extract Batch Process

Incremental person extract files are created from sync requests and General Process records using the Contact Incremental Sync Batch Control (C1-DCTEX) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run as needed for incremental updates.

Person (Contact) Extract File Format

Person (Contact) extract files use the following tab-separated values format:

| Field Name | Optional/Required | Notes |
|------------------------|-------------------|--|
| External Reference Id | Optional | The contact's reference ID in the CIS application |
| Change Date Time | Optional | The date and time on which the contact was changed. Applicable only for Incremental Uploads Will be used to sequence processing in case there are multiple changes to the same contact. |
| Initial Load Sync Flag | Required | A value that indicates the type of upload. Valid values are: <ul style="list-style-type: none"> • F1IL - Initial Load • F1IC - Incremental |
| External Id | Required | The contact's ID in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Contact External ID. |
| Contact Type | Required | The type of contact. When importing data from Customer to Meter or Customer Cloud Service this will be either Person or Business. If the provided contact type has not been defined as a Program Subscription Contact Type in Digital Asset Management / Digital Asset Cloud Service an extendable lookup is used to map this value to the Contact Type used in Digital Asset Management / Digital Asset Cloud Service. |
| Name | Required | The contact's name. For format for this is <FIRST_NAME> <LAST_NAME> (note the space between them). |
| Home Phone | Optional | A home phone number associated with person-type contacts. |

| Field Name | Optional/Required | Notes |
|---|-------------------|---|
| Mobile Phone | Optional | A mobile phone number associated with person-type contacts. |
| Phone | Optional | A phone number associated with business-type contacts. |
| Email | Optional | An email address for the contact. |
| Life Support Sensitive Load | Required | A flag that indicates if the contact requires a Life Support Sensitive Load. Valid values are "true" and "false" An extendable lookup is used to map this value to the Life Support Sensitive Load flag used in Digital Asset Management / Digital Asset Cloud Service |
| Life Support Sensitive Load Description | Optional | An optional description for Life Support Sensitive Load. |
| Is Erased | Optional | A flag that indicates if the contact has been obfuscated (if supported) in the CIS application. Valid values are Y/N (Default) Applicable only to Incremental Uploads This should be set to "N" if Object Erasure is not supported in the CIS application. |

Sample Record

Below is a sample file:

```
EXTREFCON11      2023-06-21T13:15:00-08:00      F1IC      EXTCONTACT1      P
      John Smith      (510)777-8888      (510)777-9090      (510)556-4556
      johnsmith@gmail.com      false      None      N
```

Extracting Service Points

This topic provides additional details related to extracting service points from Oracle Utilities Customer Cloud Service for import into Oracle Utilities Digital Asset Cloud Service.

Initial Extract Batch Process

Initial extract files for service points are created using the Migrate CCB SP to DACS MSP (C1-DSPIL) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run only for the initial extract.

Maintenance Object Audit Algorithm

The Sync Service Point as DACS Metered Service Point (C1_DASPSYNC) audit algorithm tracks new service point data and changes to existing service point data and creates data synchronization requests, which are used to create incremental extract files.

Sync Request Business Object

Service point sync requests are based on the Sync CCB SP to DACS Metered Service Point (C1-DACSMSPSyncRequest) business object.

Incremental Extract Batch Process

Incremental service point extract files are created from sync requests and General Process records using the SP Incremental Sync Batch Control (C1-DSPEX) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run as needed for incremental updates.

Service Point Extract File Format

Service point extract files use the following tab-separated values format:

| Field Name | Optional/Required | Notes |
|------------------------|-------------------|---|
| External Reference Id | Optional | The metered service point's reference ID in the CIS application. |
| Change Date Time | Optional | The date and time on which the metered service point was changed. Applicable only for Incremental Uploads Will be used to sequence processing in case there are multiple changes to the same metered service point. |
| Initial Load Sync Flag | Required | A value that indicates the type of upload. Valid values are: <ul style="list-style-type: none"> • F1IL - Initial Load • F1IC - Incremental |
| External Id | Required | The metered service point's ID in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Service Point External ID. |
| Metered SP Type | Required | The type of metered service point. When importing data from Customer to Meter or Customer Cloud Service this comes from the Service Point Type. If the provided metered service point type has not been defined as a Metered Service Point Type in Digital Asset Management / Digital Asset Cloud Service an extendable lookup is used to map this value to the Metered Service Point Type used in Digital Asset Management / Digital Asset Cloud Service. |

| Field Name | Optional/Required | Notes |
|---------------------|-------------------|---|
| SP Source Status | Required | The metered service point's source status. Valid values are values for the Source Status (SP_SRC_STAT_FLG) lookup, and include: <ul style="list-style-type: none"> • D1CN (Connected) • D1DC (Disconnected) |
| Division | Optional | The metered service point's division. If the provided division has not been defined as a Division in Digital Asset Management / Digital Asset Cloud Service an extendable lookup is used to map this value to the Division used in Digital Asset Management / Digital Asset Cloud Service. |
| External Premise Id | Optional | The ID of the premise associated with the metered service point in the CIS application. |
| Time Zone | Required | The time zone in which the metered service point is located. |
| Country | Optional | The country in which the metered service point is located. |
| Postal | Optional | The metered service point's postal code. |
| Address 1 | Optional | The metered service point's address. |
| Address 2 | Optional | Additional details regarding the metered service point's address (if applicable). |
| Address 3 | Optional | Additional details regarding the metered service point's address (if applicable). |
| Address 4 | Optional | Additional details regarding the metered service point's address (if applicable). |
| City | Optional | The city in which the metered service point is located. |
| County | Optional | The county in which the metered service point is located. |
| State | Optional | The state in which the metered service point is located. |
| Longitude | Optional | The metered service point's longitude. |
| Latitude | Optional | The metered service point's latitude. |

| Field Name | Optional/Required | Notes |
|---|-------------------|---|
| Life Support Sensitive Load Flag | Required | A flag that indicates if the metered service point requires a Life Support Sensitive Load. Valid values are "true" and "false" An extendable lookup is used to map this value to the Life Support Sensitive Load flag used in Digital Asset Management / Digital Asset Cloud Service |
| Life Support Sensitive Load Description | Optional | An optional description for Life Support Sensitive Load. |
| Status | Required | The current state of the metered service point. Valid values are "ACTIVE" and "INACTIVE". |
| Is OK to Enter? | Optional | |
| SP Warning | Optional | |
| SP Instructions | Optional | |
| SP Instructions Details | Optional | |
| Is Key | Optional | |
| Key Id | Optional | |
| Device Location | Optional | |
| Device Location Details | Optional | |

Sample Record

Below is a sample file:

```
EXTREFMSP11      2023-06-21T14:01:00-08:00      FLIC      EXTMSP1      ZZ-EXTMSPTYPE

  41.501120      false      ACTIVE
```

Extracting Service Agreements

This topic provides additional details related to extracting service agreements from Oracle Utilities Customer Cloud Service for import into Oracle Utilities Digital Asset Cloud Service.

Initial Extract Batch Process

Initial extract files for service agreements are created using the Migrates SA to DACS Metered Service (C1-DMSIL) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run only for the initial extract.

Maintenance Object Audit Algorithm

The Sync Service Agreement as DACS Metered Service (C1_DASASYNC) audit algorithm tracks new service agreement data and changes to existing service agreement data and creates data synchronization requests, which are used to create incremental extract files.

Sync Request Business Object

Service agreement sync requests are based on the Sync CCB SA to DACS Metered Service (C1-DACSMSSyncRequest) business object.

Incremental Extract Batch Process

Incremental service agreements extract files are created from sync requests and General Process records using the MS Incremental Sync Batch Control (C1-DMSEX) batch process. Use the **Batch Control** portal to view the parameters used by this batch process. This process should be run as needed for incremental updates.

Service Agreement Extract File Format

Service agreement extract files use the following tab-separated values format:

| Field Name | Optional/Required | Notes |
|------------------------|-------------------|---|
| External Reference Id | Optional | The metered service's reference ID in the CIS application. |
| Change Date Time | Optional | The date and time on which the metered service was changed. Applicable only for Incremental Uploads Will be used to sequence processing in case there are multiple changes to the same metered service point. |
| Initial Load Sync Flag | Required | A value that indicates the type of upload. Valid values are: <ul style="list-style-type: none"> • F1IL - Initial Load • F1IC - Incremental |
| External Id | Required | The metered service's ID in the CIS application. When importing data from Customer to Meter or Customer Cloud Service this is the Service Agreement External ID. |
| Metered Service Type | Required | The type of metered service. When importing data from Customer to Meter or Customer Cloud Service this comes from the Service Agreement Type. If the provided metered service point type has not been defined as a Metered Service Type in Digital Asset Management / Digital Asset Cloud Service an extendable lookup is used to map this value to the Metered Service Type used in Digital Asset Management / Digital Asset Cloud Service. |

| Field Name | Optional/Required | Notes |
|---------------------|-------------------|--|
| External Contact ID | Optional | <p>The ID of the contact associated with the metered service in the CIS application.</p> <p>When importing data from Customer to Meter or Customer Cloud Service this is the Contact External ID.</p> |
| External Account ID | Optional | <p>An ID used to identify the account associated with the metered service record in the CIS application.</p> |
| Start Date Time | Required | <p>The date and time on which the metered service record started.</p> |
| End Date Time | Optional | <p>The date and time on which the metered service record ended or will end (if applicable).</p> |
| Division | Optional | <p>The metered service's division.</p> <p>If the provided division has not been defined as a Division in Digital Asset Management / Digital Asset Cloud Service an extendable lookup is used to map this value to the Division used in Digital Asset Management / Digital Asset Cloud Service.</p> |
| SA Status | Optional | <p>The metered service's status.</p> <p>If the provided status has not been defined as a Division in Digital Asset Management / Digital Asset Cloud Service an extendable lookup is used to map this value to a Status defined in Digital Asset Management / Digital Asset Cloud Service.</p> |
| Rate Schedule List | Optional | <p>A concatenated list of rate schedules and effective dates associated with the metered service.</p> <p>Each row in this list is composed of the following:</p> <ul style="list-style-type: none"> • Rate Schedule • Effective Date <p>Each element in the row will be delimited by comma (,).</p> <p>Each row in the list will be delimited by semi-colon (;).</p> <p>For example:</p> <p>ERES-1,2022-01-01ERES-2,2021-01-01</p> |

| Field Name | Optional/Required | Notes |
|-----------------|-------------------|--|
| Metered SP List | Optional | <p>A concatenated list of metered service points associated with the metered service.</p> <p>Each row in this list is composed of the following:</p> <ul style="list-style-type: none"> • External Metered SP Id (Required) • Start Date Time (Required) • End Date Time (Optional) <p>Each element in the row will be delimited by comma (,).</p> <p>Each row in the list will be delimited by semi-colon (;).</p> <p>Example: 6800401571,2022-12-13T14:30:00-05:00,17033042</p> |
| Is Erased | Optional | <p>A flag that indicates if the customer has been obfuscated (if supported) in the CIS application. Valid values are Y/N (Default)</p> <p>Applicable only to Incremental Uploads</p> <p>This should be set to "N" if Object Erasure is not supported in the CIS application.</p> |

Sample Record

Below is a sample file:

```

Asset Management System Integration

The following section describes functionality provided for the integration with an asset management system, such as Oracle Utilities Work and Asset Management (OUWAM).

Interfacing Service Calls

Oracle Utilities Customer Care and Billing is able to record service calls for a particular service point in the system, as well as for an unknown service point, i.e. a fuzzy call. Service call information is sent to the asset management system that will process any work that may be required due to the service call.

When recording a service call, the system creates a service call process flow and assigns it a service call communication type. The process flow type and service call communication type are determined from the action method with Action Method Role of **Service Call**. See [Action Method](#) for more information about setting up action methods. Service call communication type defines the rules and controls for creating service call communication. It also defines the service call communication business object.

The system is delivered with the following objects that are used to record a service call:

- Process Flow Type **C1-SERVICECALL**
- Service Call Communication Type business object **C1-ServiceCallCommTaskType**
- Service Call Communication business object **C1-ServiceCallCommunication**

Refer to [Service Calls](#) for more details.

Setting Up The System To Enable Asset Management System Integration

The following section describes how to enable the integration between Oracle Utilities Customer Care and Billing and your asset management system.

External System Setup

An external system must be setup to integrate with Oracle Utilities Work and Asset Management (WAM).

For sending service call information to WAM, define message senders for the following outbound message types:

- **New Service Call Communication Request Outbound Message (C1-SVCCALNEW)**. This is used to send new service call information.
- **Update Service Call Communication Request Outbound Message (C1-SVCCALUPD)**. This is used to send service call comments and service call cancel request.

For retrieving service call information from WAM, define message senders for the following outbound message types:

- **Service Call Search (C1-SVCCLSRCH)**. This is used by the service call search panel to retrieve service calls from the external system.
- **Service Call Details (C1-SVCCALDTL)**. This is used in the service call details pop up window to retrieve details of a service call from external system.
- **Retrieve Work Documents (C1-RETWRKDOC)**. This is used in the service call details pop up window to retrieve work documents related to a service call.

Once the external system is defined, configure the WAM Integration Master Configuration so the system knows which external system and outbound message types to use.

WAM Integration Master Configuration

The integration with Oracle Utilities Work and Asset Management (WAM) requires the setup of master configuration data that controls the processing of service call information.

To maintain master configuration, open **Admin > General > Master Configuration**

Set up the **CC&B WAM Integration** master configuration, which defines the external system and outbound message types to send and receive service call information. It also defines the URL of the WAM environment. This is used by the service call details pop-up window to render the service call hyperlink. The hyperlink is available if the user has access to the **Go To WAM (C1-GOTOWAM)** application service. Note that the login user to WAM should have access to the service call transaction. This authorization needs to be done in WAM.

Business Flags

It is possible that information detected in one product may be useful or even critical to share with another product. The framework provides functionality for receiving information from an external system that acts as a type of flag or alert that may need investigation. This allows any system to store detected business flags in a common way and share that information with one or more other systems. See [Business Flags](#) on page 493 for more information.

This section provides further information about this.

Service Point Business Flags

Overview

This product has implemented business flags that represent situations that exist at a customer's service point that are shared across external applications; such as, meter data management, mobile work force management, and analytics

applications. The situations that a business flag can represent ranges from critical knowledge that requires manual analysis for resolution to purely informational notifications.

This sharing of information allows users of each system to quickly understand the status of a service point as it relates to situations that users of the system would benefit from. For example, the analytics system may identify potential theft situations that should be investigated prior to releasing the next bill.

The subsequent sections describe business flag functionality that is specific to the service point business flag as implemented by this product.

See [Understanding Business Flags](#) on page 493 in the *Oracle Utilities Framework Administration User Guide* for a detailed understanding of the components of business flags.

Business Flags Can Require Analysis

For more serious situations a business flag can require manual analysis from a user. These types of business flags will generate a To Do when they are received from the external application. To resolve the To Do a user will investigate the service point based on the type of business flag present. Generally this investigation will result in the business flag being either confirmed or rejected. To reach the conclusion of whether the business flag should be confirmed or denied the user can be provided with a set of available actions that can be performed on the business flag.

See the C1-BFANL algorithm type for more information.

Business Flag Available Actions

Allowed actions are implemented as BPA scripts that will guide the user through a particular method of investigating or resolving the business flag. The following actions are supported:

- **Create Field Activity** - This will initiate a field activity associated to the business flag's service point. The type of field activity will be selected by the user.
- **Create Case** - This will initiate a case associated to the business flag's service point. The type of case will be selected by the user.
- **Create Notification** - This will initiate communication with the customer for the business flag's service point. The type of communication will be determined by the notification type selected by the user.

Business Flag Adding Available Actions

To extend the actions that are available to the user for investigating a business flag the following steps can be taken:

1. A new BPA script should be developed that provides the functionality for your particular business use case
2. That BPA script will be added to the transactional business object for the business flag using the option type "Valid Action"
3. Edit the business flag type to include the newly created action in the "Allowed Actions" section of the business flag type

Making Allowed Actions Available

Allowed actions are only accessible on those business object statuses that have been configured to support them. To permit access to the available actions on a given status one must add a business object status option for the type "Execution of Valid Actions Permitted" with a value of "Y".

Business Flag Can Prevent Bills from Freezing

Some business flags, particularly those that require investigation, should place a hold on the billing process to prevent potentially incorrect bills from being issued to the customer. When certain types of business flags are present on a service point it indicates that there may be a problem with the reported usage that is underlying the bill and as such it may not be desirable to allow the billing process to complete until the investigation into that usage has been completed. For example, if the business flag indicated potential theft or abnormally high usage it may be preferable to delay issuing the bill until an investigation can be performed and the issue rejected or resolved.

This functionality can be enabled through configuration of the Prevent Bill Segment Freeze Due to Business Flag algorithm.

See the Prevent Bill Segment Freeze Due to Business Flag (C1-PRVBSFBB) algorithm type for more detail.

A Field Activity Can Determine Business Flag Confidence

When a business flag results in a field activity being issued and a field team is sent to investigate the service point the result of that field activity investigation will drive the resolution of the business flag. This is done through the field remarks left by the field team. The field activity remarks can either be defined as confirming the business flag or rejecting it. By selecting the appropriate field activity remark the field team will conclude the investigation into the business flag and the final confidence will be updated as appropriate.

For those field activity remarks that should either confirm or reject the business flag the Business Flag Confidence Update algorithm type should be provided for the field activity remark – activation plug-in spot.

Please refer to the Business Flag Confidence Update (C1-BSFLGCFUP) algorithm type for more detail.

Business Flags Can Create Alerts

Some business flags have a high enough importance that they should be highlighted to any user that is viewing data for the service point the business flag is related to. Whether a business flag should create an alert is controlled on the business flag type. Furthermore, the appropriate algorithm must be configured in the “Installation Options – Framework” “Algorithms” tab for the “Control Central Alert” system event.

The product delivers the algorithm type “Highlight Open Business Flags”

Please refer to the Business Flag Confidence Update (C1-BSFLGCFUP) algorithm type for more detail.

Customer Relationship Management Integration

Oracle Utilities Customer Care and Billing provides tools to facilitate the integration with customer relationship management applications such as Oracle Social Relationship Management (SRM).

The following sections describe this functionality.

About Customer Relationship Requests

A customer relationship request is used to process requests that are initiated from an external customer relationship management system.

The following sections highlight customer relationship request functionality.

Social Relationship Management Requests

Oracle Social Relationship Management (SRM) is an example of an external system that can initiate customer relationship requests.

Social network posts cover a vast range of topics, a number of which could be related to the users' concerns with their utility service. For example:

- A Facebook user could post on a community page about a power outage in a specific area.
- A Twitter user might post about specific problems with their utility service (*e.g.*, high bill complaints).

Social conversations of this nature can be monitored and managed via Oracle SRM. Oracle SRM’s Engage module allows its users to see all social conversations, identify customer-specific issues and route the messages to the appropriate systems/channels.

Requests from social relationship management systems typically include:

- Information about the original posting on the social network/community (*e.g.*, author’s identifier, link to the post, etc.).
- Information about the posting within the social relationship management system (*e.g.*, the user that sent the request to the utility, link to the post, etc.).
- Additional details that will help with processing/resolution (*e.g.*, customer/account numbers, address, bill IDs, etc.).

Creating Customer Relationship Requests

Most customer relationship requests will be initiated from an external system.

The base product provides an Add Customer Relationship Request (C1-AddCustRR) inbound web service that can be used in a customer relationship management integration to create customer relationship request records. This inbound web service invokes a processing script that is configured in Customer Relationship Integration master configuration. The base product supplies an example of this processing script. It maps the inbound service's input data into the customer relationship request record. Refer to the C1-CreCustRR service script system data for processing details.

Setting Up Customer Relationship Request Configuration

The following topics highlight the general configuration steps required to use customer relationship request functionality and to integrate with a customer relationship management application such as Oracle Social Relationship Management (SRM).

Customer Relationship Management Integration Configuration

The integration with a customer relationship management application such as Oracle Social Relationship Management (SRM) requires the setup of master configuration data that controls the processing of your customer relationship requests.

To set up customer relationship integration master configuration, navigate using **Admin > General > Master Configuration**. You are brought to an all-in-one portal with options to add/edit the Customer Relationship Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

Defining Customer Relationship Request Types

A customer relationship request type defines properties that control how a customer relationship request is processed.

Refer to [About Customer Relationship Requests](#) on page 1385 for an overview of customer relationship request functionality.

To maintain customer relationship request types, open **Admin > Integration > Customer Relationship Request Type > Search**.

This is a standard [All-In-One Portal](#).

The information captured on the customer relationship request type depends on the business objects supported by your implementation. Refer to the embedded help text for more information.

Maintaining Customer Relationship Requests

This section describes the functionality supported for viewing and maintaining customer relationship requests.

Refer to [About Customer Relationship Requests](#) on page 1385 for an overview of customer relationship request functionality.

Navigate using **Menu > Integration > Customer Relationship Request > Search**. You are brought to a query portal with options for searching for customer relationship requests.

Once a customer relationship request record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Customer Relationship Request** zone provides basic information about a customer relationship request. Refer to the embedded help for more information.

The **Notes** zone allows users to capture additional notes to the customer relationship request.

RightNow Knowledge Integration

Oracle Utilities Customer Care and Billing provides an integration with Oracle RightNow Knowledge that allows users to view frequently asked questions about business processes/functions that relate to the portal or page that they are currently viewing and/or working on.

The following sections describe this functionality.

Displaying Frequently Asked Questions

The Oracle RightNow Knowledge application can be used to develop content for frequently asked questions about business processes. It also functions within the Oracle Customer Care and Billing application. The RightNow KnowledgeSyndication widget defines the interface for the retrieval of this content.

The Oracle Customer Care and Billing application provides a **Frequently Asked Questions** sidebar zone that uses the RightNow KnowledgeSyndication widget to retrieve content from a RightNow Knowledge base instance. This zone is context-sensitive.

Configuration data controls how information is displayed in the **Frequently Asked Questions** sidebar zone. Refer to [RightNow Knowledge Integration Configuration](#) for more details.

RightNow Knowledge Integration Configuration

The integration with Oracle RightNow Knowledge requires the setup of master configuration data that controls how content from the RightNow Knowledge base is retrieved and presented on the **Frequently Asked Questions** sidebar zone. This configuration includes the following settings:

- The URL of the RightNow Knowledge base instance.
- The list of portals and pages for which the **Frequently Asked Questions** sidebar zone will display.
- Settings for each portal / page:
 - Search terms to pass to the RightNow KnowledgeSyndication widget. The base product supplies a number of common search term types. Implementation-specific search term types can be added.
 - Number of results/answers to display in the **Frequently Asked Questions** sidebar zone.

To set up the RightNow Knowledge Integration master configuration, navigate using **Admin > General > Master Configuration**. You are brought to an all-in-one portal with options to add/edit the RightNow Knowledge Integration master configuration record. Refer to the embedded help for more details on how each section in this record is configured.

Creating Application Links in External Applications

When integrating Oracle Utilities applications with other external applications, you can create links from external applications to specific portals and pages within the Oracle Utilities applications (also known as "deep linking"). These links typically leverage Business Process Assistant (BPA) scripts that direct the user to the appropriate target portal or page for a specific entity such as an account or service point. Refer to [Creating Application Links in External Applications](#) in the *Application Framework Administrative User Guide* for more information about creating links.

Note: When creating application links, the use of the following parameters will help speed up launching the target page

- **initNav=false**: skips launching the default home page for the user
- **minSidebar=true** minimizes the sidebar for the user

Go to Portal Script

The Framework provides a generic script (F1-GoToPrtl) that can be used to navigate to the maintenance portal for a specified maintenance object and entity. Refer to [Navigating to a Given Record's Maintenance Portal](#) in the *Application Framework Administrative User Guide* for more information about using this script.

Go To CCB Script

Oracle Utilities Customer Care and Billing includes the Go To CCB script (C1-GoToCCB) that can be used to navigate directly to a specific page on Control Central. This script uses the following syntax:

```
script=C1-GoToCCB&FLAG=<FLAG_VALUE>&PKVALUE1=<ID>
```

Where:

- <FLAG_VALUE>: A value from the C1_TARGET_PORTAL_FLG lookup that specifies which Control Central page to open.
- <ID>: The primary key value for the entity (such as a Account, Person, or Premise) you wish to view.

Examples:

| Script | Flag Value | ID | Example |
|------------|--|------------|--|
| C1-GoToCCB | FLAG=C1CC (Control Central Account) | Account ID | script=C1-GoToCCB&FLAG=C1CC&PKVALUE1=Account ID} |
| C1-GoToCCB | FLAG=C1CP (Control Central Person) | Person ID | script=C1-GoToCCB&FLAG=C1CP&PKVALUE1=Person ID} |
| C1-GoToCCB | FLAG=C1CR (Control Central Premise) | Premise ID | script=C1-GoToCCB&FLAG=C1CR&PKVALUE1=Premise ID} |

Full URL Example:

```
https://<ENV_BASE_URL>/ouaf/cis.jsp/?
minSidebar=true&initNav=false&script=C1-
GoToCCB&FLAG=C1CC&PKVALUE1={your Account ID}
```

Customer Care and Billing Control Table Setup Sequence

The topics in this section describe the order in which the control tables should be set up.

Core Control Table Setup Sequence

To implement the system, you must set up your organization's business rules in "control tables". Setting up these tables is time-consuming because we allow you to tailor many aspects of the system to meet your organization's requirements. We strongly recommend that you take the time to document how you plan to set up all of these tables before you use the following roadmap to enter the core control data. Time spent understanding the interrelationships between this data will reap the rewards of a clean system that meets your current and long term needs.

While we describe the transactions and options in more detail in other sections of this manual, use the following chart (and the remaining sections of this chapter) as your roadmap. Here we list the order in which you perform tasks and the pages you'll use to set up your system. The order is important because some information must exist before other information can be defined (i.e., many dependencies exist).

Note: Auto setup. The Auto Setup column in the following table contains suggestions to save you time. It also indicates if a control table contains information when the system is installed.

Note: You don't have to set up every control table. You need only set up those control tables that govern functions that are applicable to your organization.

| Function | Menu | Auto Setup |
|----------------|------|------------|
| Global Context | | |

| | | |
|----------------------------|--|--|
| Algorithm | Admin, Algorithm. You will need to set up an algorithm that populates global context values. The global context is used by various zones in the system to display relevant data. This algorithm is plugged-in on the installation record . | |
| Accounting Environment | | |
| Country & State | Admin, Country | |
| Currency Codes | Admin, Currency Code | USD is automatically populated |
| Accounting Calendar | Admin, Accounting Calendar | |
| GL Division | Admin, General Ledger Division | |
| Security Environment | | |
| Application Service | Admin, Application Service | All base package transactions are automatically populated |
| Security Type | Admin, Security Type | |
| User Group | Admin, User Group Note, you won't be able to set up users at this point | One user group, ALL_SERVICES, is automatically setup. It references all other application services and a single user called SYSUSER. |
| Language | Admin, Language | ENG is automatically populated |
| Display Profile | Admin, Display Profile | Two display profiles are automatically setup: NORTHAM displays currencies and dates in a classic American format; EURO displays information in a classic European format |
| Data Access Role | Admin, Data Access Role | |
| Access Group | Admin, Access Group | |
| User | Admin, User | SYSUSER is automatically set up. Note that you may import your users (and user groups) from an external source . |
| Return to User Group | You must return to your user groups and define all of their users | |
| Customer Class Environment | | |

| | |
|-----------------------------------|---|
| Customer Class | Admin, Customer Class. At this point, you'll only be able to set up your customer class codes. You will return to these customer classes throughout the setup process to populate additional information. |
| Financial Transaction Environment | |
| Work Calendar | Admin, Work Calendar |
| CIS Division | Admin, CIS Division |
| Revenue Class | Admin Revenue Class |
| Algorithm | Admin, Algorithm. You will need to set up the algorithm that constructs a distribution code's corresponding GL account when it is interfaced to the general ledger |
| Distribution Code | Admin, Distribution Code |
| Bank & Bank Accounts | Admin, Bank |
| Billable Charge Template | Admin, Billable Charge Template. Note, if you want the system to default service quantities onto billable charges created using this template, you must setup the appropriate unit of measure code, time-of-use code and/or service quantity identifier. |
| Billable Charge Upload Line Type | Admin, Billable Charge Line Type |
| Algorithm | Admin, Algorithm. You will need to set up several algorithms. These algorithms: 1) retrieve a bill segment's consumption, 2) calculate a bill segment's bill lines, 3) construct a bill segment's financial transaction, 4) cancel previously estimated bill segments |
| Bill Segment Type | Admin, Bill Segment Type |
| Algorithm | Admin, Algorithm. You may want to set up an algorithm that formats the Bill Segment information that is displayed throughout the system for a specific Bill Segment Type. This algorithm is plugged-in on the Bill Segment Type. |

| | |
|----------------------------|---|
| Algorithm | Admin, Algorithm. You will need to set up the algorithm that constructs a payment segment's financial transaction |
| Payment Segment Type | Admin, Payment Segment Type |
| Algorithm | Admin, Algorithm. You will need to set up the algorithm that constructs an adjustment's financial transaction |
| Algorithm | Admin, Algorithm. Several plug-in spots are available to perform additional logic when processing adjustments. For example, if you have the system calculate adjustments, you must set up an adjustment generation algorithm. Refer to Adjustment Type for other available plug-in spots that may be used by your implementation. |
| Algorithm | Admin, Algorithm. You may want to set up an algorithm that formats the Adjustment information that is displayed throughout the system for a specific Adjustment Type. This algorithm is plugged-in on the Adjustment Type . |
| Algorithm | Admin, Algorithm. You may want to set up an algorithm that formats the Adjustment information that is displayed throughout the system. This algorithm is plugged-in on the installation record . |
| Adjustment Type | Admin, Adjustment Type |
| Adjustment Type Profile | Admin, Adjustment Type Profile |
| Approval Profile | Admin, Approval Profile. Note, an approval profile references a To Do type and one or more To Do Roles; these must be set up before you can set up the approval profile. After the approval profile(s) are set up, they must be referenced on the adjustment types that they govern. |
| Cancel Reason - Bill | Admin, Bill Cancel Reason |
| Cancel Reason - Payment | Admin, Payment Cancel Reason |
| Cancel Reason - Adjustment | Admin, Adjustment Cancel Reason |

| | |
|------------------|--|
| Tender Type | Admin, Tender Type |
| Tender Source | Admin, Tender Source |
| A/P Request Type | Admin, A/P Request Type |
| Issuing Center | Admin, Issuing Center. You will need to set up issuing centers if your organization assigns document numbers to bills. |
| Installation | Admin, Installation Options - Framework and Admin, Installation Options. Many fields on the installation record impact the financial transaction environment. Refer to the description of the Billing and Financial Transaction pages and the Messages tab in the Framework page for more information. |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm that distributes payments. |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm that handles overpayment situations. |
| Algorithm | Admin, Algorithm. You may need to set up an algorithm if specific customers can have individual bill due dates. |
| Algorithm | Admin, Algorithm. You may need to set up an algorithm if you want the system to delete bills that contain only information about historical payments. |
| Algorithm | Admin, Algorithm. You may need to set up an algorithm if you want the system to levy a non-sufficient funds charge if a payment is canceled due to non-sufficient funds. |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm that formats the bill information that is displayed throughout the system. This algorithm is plugged-in on the installation record . |

| | |
|--------------------------|---|
| Algorithm | Admin, Algorithm. You will need to set up an algorithm that formats the payment information that is displayed throughout the system. This algorithm is plugged-in on the installation record . |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm that defaults the amount when a payment is manually added. This algorithm also calculates the amount of an automatic payment for a bill for an account with an active auto pay option. This algorithm is plugged-in on the installation record . |
| Algorithm | Admin, Algorithm. Refer to Customer Class for other available plug-in spots that may be used by your implementation to perform additional logic when processing payments and bills. |
| Return to Customer Class | Admin, Customer Class. You will need to plug-in the algorithms defined above on your customer classes. |
| Budget Environment | |
| Algorithm | Admin, Algorithm. You will need to set up several algorithms at this time: How To Calculated The Recommended Budget Amount, How To Periodically True Up A Customer's Budget Amount, The Circumstances When The System Should Highlight A Customer As Having An Anomalous Budget. |
| Budget Plan | Admin, Budget Plan |
| Algorithm | Admin, Algorithm. Budget eligibility is set at the SA type level. You will need to set up an override budget eligibility algorithm if some service agreements for an SA type are not eligible for budget based on certain conditions. |
| Customer Environment | |

| | |
|--------------------------|---|
| Account Management Group | Admin, Account Management Group. Note, you will probably have to set up To Do Type and To Do Roles before you can setup account management groups. Refer to Assigning A To Do Role for more information on how account management groups may be used to define an entry's role. |
| Account Relationship | Admin, Account Relationship Type |
| Alert Type | Admin, Alert Type |
| Bill Message | Admin, Bill Message |
| Algorithm | Admin, Algorithm. If you have software that's capable of reconstructing an image of a bill in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your bill image software. |
| Bill Route Type | Admin, Bill Route Type |
| Contract Quantity Type | Admin, Contract Quantity Type |
| Algorithm | Admin, Algorithm. If you have software that's capable of reconstructing an image of a letter in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your letter image software. |
| Letter Template | Admin, Letter Template |
| Customer Contact Class | Admin, Customer Contact Class |
| Customer Contact Type | Admin, Customer Contact Type |
| Conservation Programs | Admin, Conservation Program. You will need to set up conservation programs if your organization provides rebates to customers based on eligibility and verification of newly purchased appliances and hardware that are rated to conserve the demand for energy. |

| | |
|--------------------------|--|
| Algorithm | Admin, Algorithm. You may need to set up the algorithms that determine if person ID's are in a predefined format. |
| Person Identifier Type | Admin, Person Identifier Type |
| SICs | Admin, SIC Code |
| Tax Exempt Type | Admin, Tax Exempt Type |
| Algorithm | Admin, Algorithm. You may need to set up the algorithms that determine if phone numbers are in a predefined format. |
| Phone Type | Admin, Phone Type. |
| Person Relationship Type | Admin, Person Relationship Type. |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm that formats the person information that is displayed throughout the system. This algorithm is plugged-in on the installation record . |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm to validate a person's name. This algorithm is plugged-in on the installation record . |
| Algorithm | Admin, Algorithm. You can override the system's standard account information string by setting up an algorithm that produces this string of information. This algorithm is plugged-in on the installation record . |
| Algorithm | Admin, Algorithm. If you have software that's capable of reconstructing an image of a letter in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record . |

| | |
|-------------------------------------|---|
| Algorithm | Admin, Algorithm. If you have software that's capable of reconstructing an image of a bill in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record . |
| Installation | Admin, Installation Options. Many fields on the installation record impact the Customer Environment. Refer to the description of the Main , Person , and Account tabs for more information. |
| Statements | |
| Algorithm | Admin, Algorithm. If you have software that's capable of reconstructing an image of a statement in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your statement image software. |
| Statement Route Type | Admin, Statement Route Type |
| Statement Cycle | Admin, Statement Cycle |
| Algorithm | Admin, Algorithm. If you have software that's capable of reconstructing an image of a statement in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record . |
| Automatic Payment (EFT) Environment | |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm to create automatic payments. This algorithm is plugged-in on the installation record . |

| | |
|--------------------------|---|
| Tender Source | <p>Admin, Tender Source</p> <p>Note: earlier, you created tender sources for the remittance processor and your cash drawers. At this point, you'll need to add at least one tender source for automatic payments. Why? Because automatic payments get linked to a tender control (which, in turn, gets linked to a tender source) when they are interfaced out of the system.</p> |
| Algorithm | <p>Admin, Algorithm. You will need to set up the appropriate automatic payment date calculation algorithm to populate the extract, GL interface and payment dates on automatic payments.</p> |
| Auto Pay Route Type | <p>Admin, Auto Pay Route Type</p> |
| Tender Type | <p>Admin, Tender Type</p> <p>Note: earlier, you created tender types for things like cash, checks, etc. At this point, you'll need to add a tender type for each type of automatic payments (e.g., direct debt, credit card, etc.).</p> |
| Work Calendar | <p>Admin, Work Calendar. You need only set up additional work calendars if the auto pay sources (i.e., the financial institutions) have different working days than does your organization</p> |
| Algorithm | <p>Admin, Algorithm. If you need to validate the customer's bank account or credit card number, you will need to set up the appropriate validation algorithms.</p> |
| Auto Pay Source Type | <p>Admin, Auto Pay Source Type</p> |
| Algorithm | <p>Admin, Algorithm. You may need to set up an algorithm if your customers can define a maximum withdrawal limit on their autopay options.</p> |
| Return to Customer Class | <p>Admin, Customer Class. You should plug-in the Autopay Over Limit Algorithm in each appropriate customer class.</p> |

Deposit Environment

| | |
|--|--|
| Algorithm | Admin, Algorithm. You will need to set up several algorithms at this time: The Definition Of A Good Customer, When To Refund A Deposit To A Customer, When To Recommend An Additional Deposit, How / When To Calculate Interest, How To Generate The Recommended Deposit Amount. |
| Deposit Class | Admin, Deposit Class |
| Non Cash Deposit Type | Admin, Non Cash Deposit Type |
| Field Work Environment - Phase 1 | |
| Representative | Admin, Representative |
| Operation Area | Admin, Operation Area |
| Field Service Class | Admin, Field Service Class |
| Algorithm | Admin, Algorithm. You will need to set up the algorithms that execute special functions (if any) when a field activity is completed |
| Field Activity Type & Steps | Admin, Field Activity Type |
| Field Activity & Field Order Cancellation Reason | Admin, Fieldwork Cancel Reason |
| Field Activity & Field Order Reschedule Reason | Admin, Fieldwork Reschedule Reason |
| Algorithm | Admin, Algorithm. If you need anything special to happen when a remark is associated with a field activity (e.g., generate a To Do), you will need to set up an algorithm to do whatever you need to do and associate it with the respective Field Activity Remark. |
| Field Activity Remarks | Admin, Field Activity Remark |
| Algorithm | Admin, Algorithm. If you have software that's capable of reconstructing an image of a field order in a PDF (for the purpose of online display), you will need to create an algorithm that formats the extract records that are sent to your field order image software. |

| | |
|---|---|
| Dispatch Group | Admin, Dispatch Group |
| Disconnect Location | Admin, Disconnect Location |
| Field Activity Type Profiles | Admin, Field Activity Type Profile |
| Algorithm | Field activities for Start/Stop will only be created if the SA Type linked to the service point has a SASP field work creation algorithm. Refer to the SA Type section below. |
| Algorithm | Admin, Algorithm. If you have software that's capable of reconstructing an image of a field order in a PDF for the purpose of online display, you will need to create an algorithm that renders this PDF. This algorithm is plugged-in on the installation record . |
| Credit & Collections Environment (if you collect on overdue bills (as opposed to overdue debt), you will NOT set up these tables; refer to Overdue Processing - Set Up Tasks for the list of control tables required to collect on overdue bills) | |
| Algorithm | Admin, Algorithm. You may need to set up algorithms if you have non-standard collection events. |
| Collection Event Type | Admin, Collection Event Type |
| Algorithm | Admin, Algorithm. You may need to set up a collection process cancellation algorithm if your organization allows individual service agreements to be removed from a collection process if they are paid (rather than performing cancellation based on all SAs in a debt class). |
| Collection Process Template | Admin, Collection Process Template |
| Collection Class | Admin, Collection Class |
| Algorithm | Admin, Algorithm. You will need to set up several algorithms at this time: Collection process cancellation criteria, Severance process cancellation criteria, and Override arrears due to pay plans. |
| Debt Class | Admin, Debt Class |
| Write Off Debt Class | Admin, Write Off Debt Class |

| | |
|----------------------------|--|
| Algorithm | Admin, Algorithm. You will need to set up Collection Condition algorithms. |
| Collection Class Control | Admin, Collection Class Control |
| Algorithm | Admin, Algorithm. You may need to set up algorithms if you have non-standard severance events. |
| Severance Event Type | Admin, Severance Event Type |
| Algorithm | Admin, Algorithm. You may need to set up a severance process cancellation algorithm if your organization allows a severance process to be canceled when the related service agreement is paid (rather than performing cancellation based on all SAs in a debt class). |
| Severance Process Template | Admin, Severance Process Template |
| Algorithm | Admin, Algorithm. You will need to set up several algorithms at this time: How to refer debt to a collection agency, How to transfer debt to another active service agreement, How to write down small amounts of debt, and How to refund credit balances to a customer. |
| Algorithm | Admin, Algorithm. You may need to set up algorithms if you have non-standard write-off events. |
| Write Off Event Type | Admin, Write Off Event Type (Note, you'll have to wait until you have defined your SA Types before you can set up the Write Off Events because SA Type is a necessary parameter to write off debt). |
| Write Off Process Template | Admin, Write Off Process Template |
| Write Off Control | Admin, Write Off Control |
| Collection Agency | Admin, Collection Agency. Note, each collection agency references a person therefore you must set up a person for each agency before you can enter collection agency information. |

| | | |
|------------------------------|--|--|
| Algorithm | Admin, Algorithm. You may need to set up algorithms if you have special logic that should be executed when a pay plan is canceled. | |
| Pay Plan Type | Admin, Pay Plan Type | |
| Payment Method | Admin, Payment Method | |
| Third Party Payor | Admin, Third Party Payor. Note, you must create an account before you can create a third party payor. | |
| Installation | Admin, Installation. Several fields on the installation record impact the Credit & Collections Environment. | |
| Algorithm | Admin, Algorithm. You will need to setup an algorithm that's called when a user write-off debt real time. | |
| Return to Customer Class | Admin, Customer Class. You should plug-in the Autopay Over Limit Algorithm in each appropriate customer class. | |
| Services & Characteristics | | |
| Service Type | Admin, Service Type | |
| Algorithm | Admin, Algorithm. If you have ad hoc characteristic types, you may need to set up the algorithms that control how they are validated | |
| Foreign Key Reference | Admin, FK Reference. If you have foreign key characteristic types, you may need to set up foreign key references to control how the user selects the characteristic values (and how the foreign key values are validated). | All base package FK references are automatically populated |
| Characteristic Type & Values | Admin, Characteristic Type | |
| Device Testing Environment | | |
| Algorithm | Admin, Algorithm. If you need to validate a specific device test component result, you will need to set up the appropriate validation algorithms. | |
| Device Test Component Type | Admin, Device Test Component Type | |

| | |
|--------------------------|--|
| Algorithm | Admin, Algorithm. If you need the system to determine if a device test's results are considered "passing", you will need to set up an algorithm to perform this processing. |
| Device Test Type | Admin, Device Test Type |
| Algorithm | Admin, Algorithm. If you have the system select meters / items for testing, you will need to set up an algorithm to perform this processing. |
| Meter & Item Environment | |
| Meter Type | Admin, Meter Type [Note - you won't be able to define the collection of valid Equipment Types and Item Types until after you define the Item Types. You also will not be able to define the collection of Meter Configuration Types until after you define the Meter Configuration Types.] |
| Meter ID Type | Admin, Meter ID Type |
| Manufacturer / Model | Admin, Manufacturer |
| Unit of Measure | Admin, Unit of Measure |
| Time of Use | Admin, Time of Use |
| Meter Configuration Type | Admin, Meter Configuration Type |
| Retirement Reason | Admin, Retire Reason |
| Protocol | Admin, Protocol |
| Read Out Type | Admin, Read Out Type |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm to generate estimated consumption. |
| Trend Area | Admin, Trend Area |
| Trend Class | Admin, Trend Class |
| High / Low | Admin, High Low Factor |

| | |
|-------------------------------------|--|
| Algorithm | Admin, Algorithm. You will need to set up an algorithm that calculates the high / low limits used on meter reads. This algorithm is plugged-in on the installation record . |
| Meter Location | Admin, Meter Location |
| Meter Read Instructions | Admin, Meter Read Instruction |
| Algorithm | Admin, Algorithm. If you need anything special to happen when a meter read with a given remark is uploaded (e.g., generate a field activity), you will need to set up an algorithm to do whatever you need to do and associate it with the respective Meter Read Remark. |
| Meter Reader Remarks | Admin, Meter Reader Remark |
| Meter Read Source | Admin, Meter Read Source |
| Meter Read Warning | Admin, Meter Read Warning |
| Item Type | Admin, Item Type |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm to format the standard meter info that appears throughout the system. This algorithm is plugged-in on the installation record . |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm to format the standard item info that appears throughout the system. This algorithm is plugged-in on the installation record . |
| Premise & Service Point Environment | |
| Premise Type | Admin, Premise Type |
| Algorithm | Admin, Algorithm. You will need to set up an algorithm to format the standard premise info that appears throughout the system. This algorithm is plugged-in on the installation record . |

| | | |
|-----------------------------------|---|--|
| Algorithm | Admin, Algorithm. You will need to set up an algorithm that formats the service point information that is displayed throughout the system. This algorithm is plugged-in on the installation record . | |
| Algorithm | Admin, Algorithm. You may need to set up the algorithms that determine if geographic ID's are in a predefined format. | |
| Geographic Type | Admin, Geographic Type | |
| Service Point Type | Admin, SP Type. [Note - you won't be able to define the SP Type's SA Types until after you define the SA Types or the FA Type Profiles until after you define the Field Activity Type Profiles.] | |
| Facility Level 1 to 2 | Admin, Facility Level 1 to 2 | |
| Facility Level 2 to 3 | Admin, Facility Level 2 to 3 | |
| Field Work Environment - Phase 2 | | |
| Field Service Control | Admin, Field Service Control | |
| Bill & Service Cycle Environment | | |
| Bill Cycle, Bill Cycle Schedule | Admin, Bill Cycle | |
| Bill Period, Bill Period Schedule | Admin, Bill Period | |
| Route Type | Admin, Route Type | |
| Service Cycle / Route | Admin, Service Cycle | |
| Service Schedule | Admin, Service Schedule | |
| Rate Environment | | |
| Frequency | Admin, Frequency | |
| Service Quantity Identifier | Admin, Service Quantity Identifier | |
| Algorithm Type | Admin, Algorithm Type. If you create new pre-processing calculation rules, you must set up an algorithm type for each such rule (the algorithm type defines the types of parameters that are passed to the calculation rule). | All base package algorithm types are automatically populated |

| | | |
|-----------------------------|---|--|
| Bill Factor | Main, Rates, Bill Factor | |
| Algorithm Type | Admin, Algorithm Type. If you create new Register Rules you must set up an algorithm type for each such rule (the algorithm type defines the types of parameters that are passed to the register rule). | All base package algorithm types are automatically populated |
| Rate | Main, Rates, Rate Schedule | |
| Calculation Group | Main, Rates, Calculation Group | |
| Algorithm | Admin, Algorithm. If you use algorithms to dynamically change step boundaries, calculate prices, or implement calculation rule eligibility rules, you must set up these algorithms. | |
| Calculation Rule | Main, Rates, Calculation Rule | |
| Bill Factor Value | Main, Rates, Bill Factor Values | |
| Bill Factor Interval Values | Main, Rates, BF Interval Values | |
| Item Type SQ Estimate | Admin, Item Type SQ Estimate | |
| Degree Day | Admin, Degree Days | |
| Late Payment Environment | | |
| Algorithm | Admin, Algorithm. You will need to set up the algorithm that determine if customers in a customer class are eligible for late payment charges | |
| Algorithm | Admin, Algorithm. You will need to set up the algorithm that levies late payment charges for customers in a customer class | |
| Return to Customer Class | Admin, Customer Class. You will need to plug-in the late payment charge algorithms set up above. | |
| SA Configuration | | |

| | |
|------------------------|--|
| Algorithm | <p>Admin, Algorithm. You will need to set up the algorithms that determine:</p> <ul style="list-style-type: none"> • How to calculate the late payment charge amount for service agreements of a given type • Special criteria to be tested before a service agreement is severed. • How to create field activities for service agreements of a given type. • Special processing that should take place prior to the completion of a bill that references service agreements of a given type. • Special processing that should take place during completion of a bill that references service agreements of a given type. • Special processing that should take place when service agreements of a given type are created. • Special processing that should take place when a financial transaction is frozen for service agreements of a given type. |
| Algorithm | <p>Admin, Algorithm. You may want to set up an algorithm that formats the SA information that is displayed throughout the system. This algorithm is plugged-in on the installation record.</p> |
| Algorithm | <p>Admin, Algorithm. You may want to set up an algorithm that formats the SA information that is displayed throughout the system for a specific SA Type. This algorithm is plugged-in on the SA Type.</p> |
| Algorithm | <p>Admin, Algorithm. If you want a Control Central alert to highlight when the current account has any stopped service agreement(s), you will need to set up the algorithm that does this. This algorithm is plugged-in on the installation record.</p> |
| Service Agreement Type | Admin, SA Type |
| Terms and Conditions | Admin, Terms and Conditions |
| SA Type Start Options | Admin, SA Type Start Option |

| | |
|---|--|
| Update SP Types with initial SA types and with FA Type Profiles | Admin, SP Type |
| SA Relationships | |
| SA Relationship Type | Admin, SA Relationship Type |
| Service Provider | Admin, Service Provider. Note, you must create a person before you can create a service provider. If you have financial relationships (you bill for them or they bill for you), you must also create an account and a financial settlement service agreement before you can create the service provider. |
| SA Type / SA Relationship | Admin, SA Type SA Relationship Type |
| Notification and Workflow | |
| Workflow Event Type | Admin, Workflow Event Type |
| Workflow Process Template | Admin, Workflow Process Template |

| Notification External (Sender) ID's | Admin, Notification External ID |
| Notification Download Type | Admin, Notification Download Type |
| Service Provider. | Admin, Service Provider. Note, you must create a person before you can create a service provider. |
| Notification Download Profile | Admin, Notification Download Profile |
| Algorithm | Admin, Algorithm. If you want a Control Central alert to highlight when the current account and/or premise has active workflow processes, you will need to set up the algorithm that does this. This algorithm is plugged-in on the installation record . |
| Sales and Marketing | |
| Order Hold Reason | Admin, Order Hold Reason |
| Order Cancel Reason | Admin, Order Cancel Reason |

| | |
|--------------------------------|--|
| And more... | Refer to Campaign and Package Setup Sequence for additional setup requirements |
| Service Credit Membership | |
| Algorithm | Admin, Algorithm. You may need to set up algorithms for the service credit membership type and service credit event type to control behavior for the service credit membership and its events. |
| Credit Unit | Admin, Credit Unit. If your service credits record non-monetary units. |
| Service Credit Membership Type | Admin, Service Credit Membership Type |
| Service Credit Event Type | Admin, Service Credit Event Type |
| Membership Inactive Reasons | Admin, SC Membership Inactive Reason |
| Wrap Up | |
| Algorithm | Admin, Algorithm. You will need to set up the algorithms that determine: #x2022; Special alerts on Control Central (assuming you have special alerts) |
| Installation Options | Admin, Installation Options - Framework and Admin, Installation Options. At this point, it's a good idea to double-check everything on the installation record. |
| Postal Default | Admin, Postal Code Default |

If you have cash drawers you will also need to set up the following information:

- Create a person / account to which you will link your over / under service agreement. Refer [How To Get An Unbalanced Tender Control In Balance \(Fixing Over/Under\)](#) for more information.
- Create a service agreement to which your over/under payments will be linked. This service agreement will reference your over / under SA type. Refer to [Over / Under Cash Drawer Segmentation](#) for more information.

If you upload payments from an external source (e.g., a remittance processor or lock box), you must set up the following information:

- Create a person and account to which the system will link payments with invalid account. Refer to [Phase 3 - Create Payment Events, Tenders, Payments and Payment Segments](#) for information about the process that books invalid payments to this account. Refer to [How To Transfer A Payment From One Account To Another](#) for how a user transfers the payment from the invalid account to the correct account (once known).
- Create a service agreement for this account. This service agreement will reference your payment suspense SA type. The system needs this service agreement so that it can distribute the invalid account's payment (and

this is necessary so that cash will reflect the payment). Refer to [Payment Upload Error Segmentation](#) for more information.

- Update the tender source associated with the respective source of payments to indicate the service agreement created in the previous step should be used for payments with invalid accounts. Refer to [Setting Up Tender Sources](#) for more information.
- Because the payment upload process simply books payments that reference invalid accounts to the account associated with the suspense service agreement on the payment's tender source, this account should belong to a customer class with the appropriate payment distribution algorithms. This may entail creating a new customer class that will only be used on suspense accounts. This customer class would need the following algorithms:
 - We'd recommend using a simple payment distribution algorithm like PYDIST-PPRTY (distribute payment based on SA type's payment priority).
 - We'd recommend using an overpayment distribution algorithm like OVRPY-PPRTY (distribute overpayment to highest priority SA type).

The remaining sections describe additional control tables that must be set up for specific functional areas.

Cross-Reference To The Remaining Chapters

The table in the previous section describes the order in which you should enter your control tables. These tables are described at length in the following chapters.

- Refer to [Defining General Options Addendum](#) and [Defining General Framework Options](#) for a discussion of the control tables associated with general functionality (e.g., country codes, state codes, etc.).
- Refer to [Defining Financial Transaction Options](#) for a discussion of the tables affecting your financial transactions (e.g., bill segment types, payment segment types, etc.)
- Refer to [Defining Customer Options](#) for a discussion of the control tables affecting persons, accounts and service agreements.
- Refer to [Defining Fieldwork Options](#) for a discussion of the control tables affecting fieldwork.
- Refer to [Defining Credit and Collections Options](#) for a discussion of the control tables affecting your collection activities.
- Refer to [Defining Meter and Item Options](#) for a discussion of the control tables affecting your meters and items.
- Refer to [Defining Cycles and Schedules](#) for a discussion of the control tables affecting your cyclical processes.
- Refer to [Rates](#) for a discussion of the control tables affecting your rates.
- Refer to [Defining SA Type Options](#) for a discussion of the control tables affecting your service agreement types.
- Refer to [Defining Background Process](#) for a discussion of the control tables affecting your background processes.
- Refer to [Defining Algorithms](#) for a discussion of the control tables affecting the algorithms referenced on many control tables.
- Refer to [Defining SA Relationships](#) for a discussion of the control tables affecting the relationships between service providers.
- Refer to [Defining Workflow and Notification Options](#) for a discussion of the control tables affecting the processing of notifications to and from service providers.
- Refer to [Defining Interval Billing Options](#) for a discussion of the control tables affecting the interval billing options for your customers.
- Refer to [Statements](#) for a discussion of the tables affecting the statement setup options for your customers.
- Refer to [Defining Service Credit Options](#) for a discussion of the tables affecting the service credit membership setup options for your customers.

Open-Item Accounting Table Setup Sequence

Open-item accounting tables need only be set up if your organization practices [Open Item Accounting](#). Refer to [Setting Up The System To Enable Open Item Accounting](#) for a description of the tables that must be set up to enable this functionality.

Fund Accounting Table Setup Sequence

Fund accounting tables need only be set up if your organization practices [Fund Accounting](#). Refer to [Setting Up The System To Enable Fund Accounting](#) for a description of the tables that must be set up to enable this functionality.

Payment Event Distribution Table Setup Sequence

Payment event distribution tables need only be set up if your organization opted to use the distribution rules method to create payment events. Refer to [Setting Up The System To Use Distribution Rules](#) for a description of the tables that must be set up to enable this functionality.

Loans Table Setup Sequence

Loans need only be set up if your organization offers [loans](#) to your customers. Refer to [Setting Up The System To Enable Loans](#) for a description of the tables that must be set up to enable this functionality.

Quotes Table Setup Sequence

Quotes need only be set up if your organization sends quotes to customers or prospects. Refer to [Defining Quotation Options](#) for a description of the tables that must be set up to enable this functionality.

Non-Billed Budget Table Setup Sequence

[Non-Billed Budgets](#) need only be set up if your organization allows your customers to pay set amounts at specified intervals (e.g. every two weeks). Refer to [Setting Up The System To Enable Non-Billed Budgets](#) for a description of the tables that must be set up to enable this functionality.

Appointments Table Setup Sequence

[Appointments](#) need only be set up if your organization allows your customers to make appointments for field activities. Refer to [Enabling Appointments](#) for a description of the tables that must be set up to enable this functionality.

Scripting Table Setup Sequence

Scripts need only be set up if your organization opts to create [scripts](#) to step your users through business processes. Refer to [Defining Script Options](#) for information about scripting and the tables that must be set up to enable this functionality.

Reports Setup Sequence

In order to use the reporting tool, you will need to set up reporting options. Refer to [Configuring The System To Enable Reports](#) for more information.

External Messages Setup

To configure the system to communicate with an external system, refer to [External Messages](#).

Case Management Setup Sequence

Case management options need only be set up if your organization uses cases to manage issues. Refer to [Setting Up Case Types](#) for more information.

Workforce Management Setup Sequence

Workforce management options need only be set up if your organization interfaces with an external workforce management system. Refer to [Setting Up The System To Enable FA Integration](#) for more information.

Umbrella Agreement Management Setup Sequence

Umbrella agreement management options need only be set up if your organization uses umbrella agreements to manage contracts. Refer to the integration documentation for more information.

Outage Management Setup Sequence

Outage management options need only be set up if your organization interfaces with Oracle Utilities Network Management System. Refer to the integration documentation for more information.

Prepaid Metering Setup Sequence

Prepaid metering options need only be set up if your organization offers prepaid metering service to your customers. Refer to [Defining Prepaid Metering Options](#) for more information.

Batch Scheduler Setup Sequence

Batch scheduler options need only be set up if your organization uses the batch scheduling functionality provided by the system rather than a third party batch scheduling system. Refer to [Setting Up The Batch Scheduler](#) for more information.

Zone Set Up

Most zones are delivered with the base-package and do not require any configuration. However, some zones are only available if configured by your implementation. Refer to [Configuring Zones](#) for more information.

To Do Options Setup

Refer to [Setting Up To Do Options](#) for more information on how to configure the system to match your organization's To Do management needs.

Defining Dashboard Options

Configuring the Customer Operational Dashboard

This section describes the process for configuring the Customer Operational Dashboard.

Refer to the [Using the Customer Operational Dashboard](#) section of the *Oracle Utilities Customer Care & Billing Business User Guide*. for more information on this functionality.

Configuration for the Customer Operational Dashboard is performed by adding or changing a Master Configuration. You can access the portal from the **Admin > General > Master Configuration**.

Once the Master Configuration search screen returns, configure the **Customer Operational Dashboard Configuration** record. Use the Add button beside the record to configure for the first time. If a record has already been added, then click the Edit button instead. Use the embedded help to guide you through the meaning of each configuration field.

This dashboard also leverages a method of pre-staging data known as Statistics Snapshots. Refer to [About Statistics](#) in the *Oracle Utilities Application Framework Administrative User Guide* for more information.

A method for tracking Performance Targets (also known as Service Level Agreements) is also available in the Customer Operational Dashboard. To understand how to set up Performance Targets, refer to [About Performance Targets](#) in the *Oracle Utilities Application Framework Administrative User Guide*. The Performance Targets you configure will then be leveraged on the **Batch Performance** page of the Customer Operational Dashboard.
