By default the schema of the underlying service (for example, service script, business object or business service) is also the schema for the REST inbound web service operation and acts as both its Request and the Response schema. The product provides the ability to define an explicit schema for a REST inbound web service (IWS) operation, allowing a user to adjust the schema for an external facing consumer. The IWS operation schema also supports some special configuration that allows additional features to be defined only for the IWS operation schema.

The operation schema supports the following capabilities:

- Declaring whether an element belongs only to the request schema, only to the response schema, both (default) or excluded altogether. This is used to establish a clear separation between request and response schema definitions.
- Assign a different element name to an internal element. This allows the internal service element name to more closely align to internal references to the element, if needed. The external facing element name can be different allowing for a more readable schema.
- Introduce specialized elements that support links and other types of structural standards in a way that does not impact internal service processing.

Refer to [Web Service Schema Nodes and Attributes](#) for more information.

The REST servlet uses the request and response schemas to map elements to and from the internal schema.

Note: While the caller should only provide elements defined by the request schema, the application does not filter out extraneous elements. Assumption is that the internal service is designed to ignore such elements. However, only elements defined by the response schema are included in the response.

Dynamic Links

There are use cases where the published API includes a "_self" element that contain the endpoint URL of the GET operation related to the data returned in the response. Additionally, response payloads may include foreign keys and for those entities, the response includes a "_link" element that contains the endpoint URL of the GET operation for that entity (if it exists).

Syntax is provided in the REST inbound web service operation schema to support building the runtime endpoint URL for the _self and _link elements. Besides dynamically building the static portion of the URL based on the current environment details, it also builds the dynamic portion of the URL, substituting the URL components for the operation and substituting the path parameters. The syntax allows you to define a specific IWS Operation or allows you to reference a maintenance object and at runtime, the system determines the GET operation for the maintenance object and builds the URL accordingly.

Example of the syntax:

```
<_link getOperation="mo:'TO DO ENTRY';pk1:todoEntryId;" />
```

Example of the runtime endpoint URL:

```
_link: "http://.../common/todos/todoEntries/28937296450934"
```

A GET operation may be associated with a maintenance object to denote that this is the default GET operation for the entity. A **GET Operation** option at the Maintenance Object and Business Object level may be used to override this default. If the entity is not associated with a business object or the latter is not associated with such option then the operation associated with the maintenance object (if any) is used.

API Specification Documentation

The following documentation information may be provided for an Inbound Web Service:

- Short and detailed description for each operation.
- Help text may be provided for individual elements. The same text can be shared across multiple elements across all operations of the Inbound Web Service. If an element is not associated with help text then its internal field's label is used instead.
- Sample request and response documents may be provided for each operation.
- Operations may be associated with a sequence number that controls the order in which they appear in the Open API Specification.

Note: Detailed descriptions and element related help text are not translated since the published catalogue for base product APIs is in English language only.

Inbound SOAP Web Services

For inbound SOAP web services, by default the system uses the Schema Name to dictate the Request and Response for the service. The API can be overridden with custom formats by specifying Request and Response XSLs to transform into the relevant schema formats. In addition, if desired, the Request and Response Schemas that document the expected message may be provided.

Note: The Request and Response Schema fields are not supported in a cloud implementation.

Note: The system supports defining the XSLs as a [managed content](#) record. For backward compatibility, the system supports defining the XSL as a file in the file system. This is a system wide setting, defined using a feature configuration option. The feature type is **External Messages** and the option type is **XSL Location**. Set the value to **F1FL** to support XSL in the file system. The file location is configured using a system property. To support the XSL in managed content, no option is needed as this is the default. You may explicitly define the value of **F1MC** if desired.

In addition, note that for business object based operations, when invoking the web service an action is required. This may be passed into the web service as part of the invocation or alternatively, the action may be defined when configuring the operation using the transaction type.

Note: Using the transaction type **Change** requires all values to be passed in. Using the transaction type **Update** allows the web service to pass only the primary key and the values to be updated. All other elements will retain their existing values.

Annotations Used for Security

When preparing to deploy inbound SOAP web services, the security aspects of the service must be decided. The product provides a default security policy that is applied when no other policy is defined:

@Policy(uri="policy:Wssp1.2-2007-Https-BasicAuth.xml", attachToWsd=true) which requires HTTP Basic over SSL and a WS-Security Timestamp.

If a different security policy is desired, the following options are available:

- Security policies may be attached to the Inbound Web Service via the Java Enterprise Edition (Java EE) Web Application Server. This allows for multiple policies to be attached as supported by the Java EE Web Application Server. In order to enable this capability, explicit system configuration is required so that the product does not assume the default security policy. See the subsequent bullets for more information.
- Define a system wide security policy using a feature configuration option. Find the [Feature Configuration](#) record for the **External Messages** feature type. (It may need to be defined if it does not exist). Choose the option type **Default security policy** and define an appropriate value. If your implementation wishes for the policies to be attached at the Java EE Web Application Server, define this option type with an option value of **<none>**.
- Attach a security policy to the IWS via a Web Service Annotation. The base product provides annotation types that support the standard WS-Policy (**F1POLICY**) and OWSM Security Policy (**F1-OWSM**). No base annotation is supplied by the product for either annotation type.

If your implementation wishes for the policy of a particular IWS to be attached at the Java EE Web Application Server, define a special annotation for the **F1POLICY** annotation type and configure the **uri** parameter value to **<none>**.

Note: Refer to WebLogic documentation for more information on supported security policies.

Note: In order to use the OWSM Policy, additional system configuration is necessary. Contact your system administrator to confirm if your implementation supports OWSM.

Inbound SOAP Web Service Deployment

A Inbound SOAP Web Service must be deployed to the Java EE Web Application Server in order for it to be available to the Web Service Clients to access the system. Refer to [Deploying SOAP Web Services](#) for more information.

Deploying XAI Inbound Service via IWS

For implementations using XAI inbound services for external messages, the product recommends moving to the inbound web service mechanism, which uses the Java EE Web Application Server to communicate with the product rather than the XAI servlet.

For XAI inbound services that use the **Business Adapter**, it is straight forward to move to IWS because the configuration is similar. In both cases, the service is configured to reference a business object, business service or service script. The associated WSDL for each record is similar. Changing the interface for the incoming message to use IWS instead of XAI inbound services is similar.

However, for XAI inbound services that use the **Core Adapter**, these services reference an underlying "page service" in the product. For these services, the Request and Response schemas for the XAI inbound service were created using the Schema Editor. In order to support calling an underlying "page service" in IWS, first a [business service](#) must be created to reference the page service (if one doesn't already exist). However, the resulting schema for the business service is different from the Request and Response schemas related to the XAI inbound service. Moving this functionality to IWS using business services requires changes to the format of the incoming messages.

Moving all incoming messages over to use IWS instead of XAI is the product recommendation. However, to aid in implementations that have many integrations in place using the XAI inbound services that use the **Core Adapter** (or any adapter whose message class is **BASEADA**), the product provides the ability to deploy these types of XAI inbound services to the Java EE Web Application Server along with the Inbound Web Services.

To take advantage of this capability, you must define a feature configuration option. Under the **External Messages** feature configuration type, the **Support XAI Services via IWS** is used to indicate if this feature is supported. Setting the value to **true** turns on the feature. If no option is defined for that option type, it is equivalent to setting the value to **false**.

When the system is configured to support XAI services via IWS, the [Inbound SOAP Web Service deployment](#) includes XAI inbound services (that are configured with an Adapter that references the **BASEADA** message class). The deployment portal will also include a zone showing the deployment status of these XAI Inbound Services.

Note: There is no support for XAI inbound services via REST, only via inbound SOAP web services.

Configuring Inbound Web Service Options

This topic describes the configuration needed for using inbound web services.

Configuring SOAP Inbound Web Service Options

This topics in this section describes the configuration needed for using inbound SOAP web services.

Technical Configuration

In order to use inbound web services, there are tasks a system administrator must perform.

Refer to the Server Administration Guide for technical details of each of these processes.

Maintaining Web Service Annotation Types

The product provides some base annotation types. Refer to the metadata for more information. If your implementation wishes to define additional annotation types, use the Web Service Annotation Type portal. Open this page using **Admin > External Message > Web Service Annotation Type**.

You are taken to the query portal where you can search for an existing web service annotation type. Once an annotation type is selected, you are brought to the maintenance portal to view and maintain the selected record.

Note: Use of custom policies should only be considered if the policies supplied by the Java EE Web Application Server are not sufficient for your implementation's needs.

CAUTION: Important! When adding new records, carefully consider the naming convention of the web service annotation type code. Refer to [System Data Naming Convention](#) for more information.

The **Web Service Annotation Type** zone provides basic information about the web service annotation type.

Please see the zone's help text for information about this zone's fields.

The system supports the ability for an IWS record to refer to multiple policies. In this situation, the annotation type for the policy should include a reference to a parent annotation type so that the system can properly build the array of annotations.

Maintaining Web Service Annotations

If your implementation wishes to define annotations, use the Web Service Annotation portal. Open this page using **Admin > Integration > Web Service Annotation**.

This is a standard [All-in-One portal](#).

CAUTION: Important! When adding new records, carefully consider the naming convention of the web service annotation code. Refer to [System Data Naming Convention](#) for more information.

Maintaining XAI Inbound Services

XAI Inbound Service is a legacy mechanism for exposing system services to external systems as web services. The current supported mechanism for defining web services is [Inbound Web Services](#), which should be used for any new web service.

Some framework based products and existing implementations may have existing XAI inbound services that may need to be viewed. For these services, the product supports deploying them as SOAP inbound web services for execution. Refer to [Deploying XAI Inbound Service via IWS](#).

The following sections describe basic information about the maintenance pages. Note that some of the information is related to legacy functionality that is no longer supported.

XAI Inbound Service - Main

To view an inbound service, open **Admin > XAI > XAI Inbound Service**.

Description of Page

XAI In Service Name is used in the system to identify the service. The service name is also the first XML element after the <Body> element in the XML request/response document. The **XAI Service ID** serves as the primary key.

Owner indicates if this XAI inbound service is owned by the base package or by your implementation (**Customer Modification**). This information is display-only.

The **Adapter** defines the interface with the target application server.

If adapter for this service invokes a system service, then the appropriate **Service Name** is visible.

If adapter is the **Business Adapter** then **Schema Type** and **Schema Name** reference the object to invoke.

Web Service Category is visible if the XAI inbound service is linked to one or more [web service categories](#).

Use the **Description** and **Long Description** to describe the service.

Check the **Active** switch if this service is enabled and available for execution.

Post Error is not applicable.

Trace is not applicable.

Debug is not applicable.

Schema Definitions

Note: Request Schema and Response Schema are not applicable to services invoking schema-based objects. They do not appear when the **Business Adapter** is used.

The next two properties define the request and response XML schemas. The schemas are SOAP compatible. The schema XML files are expected to be stored in the Schemas Directory on the Web server running the XAI server.

The **Request Schema** is the XML schema defining the service request. The request sent to the server must adhere to the schema definition.

The **Response Schema** is the XML schema defining the service response. The response generated by the XAI server corresponds to the response schema definition.

The same service may perform several actions on a business object. Use the **Transaction Type** to define the default action performed by a service. The transaction type can be provided when invoking a service, by dynamically specifying a transaction type attribute on the Service element of the XML request. This field may take the following values: **Read, Add, Change, Update, Delete, List** and **Search**.

Note: The difference between **Change** and **Update** is that for **Change**, all field values must be passed in with the request. Field values that are not passed in to the request are set to null. For **Update**, you need only pass the primary key field values and the values of the fields to be updated. All other fields retain their existing values.

Services, which perform a Search, may allow searching based on different criteria. When the Transaction Type value is **Search**, use the **Search Type** to define the default search criteria. The possible values are **Main, Alternate1, Alternate2, Alternate3, Alternate4, Alternate5** and **Alternate6**.

Note: This is a default definition only and it may be overridden at run time when the service is invoked. To override the search type at run time, you should specify the searchType attribute on the Service element of the XML request.

XSL Transformation Definitions

Sometimes, the XML request document does not conform to the request schema, or the response document expected by the service requestor is not the one generated by the adapter. In such cases the request and/or the response documents must be transformed. The XAI server supports transformation through XSL transformation scripts. Transformation scripts may be applied to the request before it is passed to the adapter or applied to the response document before it is sent to the service requestor.

The **Request XSL** is the name of the XSL transformation to be applied to the request document before processing it. The transformation is usually required when the incoming document does not correspond to the XAI service request schema therefore it has to be transformed before it can be processed by the adapter.

The **Response XSL** is the name of the XSL transformation to be applied to the response document when the requester of the service expects the response to have a different XML document structure than the one defined by the response schema for the service.

Click the **WSDL URL** hyperlink to launch a separate window that contains the WSDL definition for the inbound service. Note that the server name and port number for the URL are built using a setting in the common properties file using the XAI HTTP Caller URL setting.

Configuring REST Inbound Web Service Options

This topics in this section describes the configuration needed for using inbound REST web services.

Owner Configuration Lookup

Refer to [Inbound REST Web Service](#) for an overview of REST IWS functionality.

When generating the URL for a REST web service, part of the URL is taken from the owner of the Inbound REST Web Service record. The component to add to the URL is defined in this lookup using the URI Component field. The values are provided by the product.

To view the values, navigate to the [Extendable Lookup](#) portal. Search for and select the **Owner Configuration for REST Services** business object.

Resource Category Lookup

Refer to [Inbound REST Web Service](#) for an overview of REST IWS functionality.

Each Inbound REST Web Service is associated with a Resource Category. The categories are defined as an extendable lookup. The REST URL is built using a component from the IWS record's resource category.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Resource Category** business object. Define values as needed. Typically the category is related to a logical grouping of entities, or maintenance objects, referred to as a 'resource' in REST nomenclature. In some cases, an edge application may have already delivered appropriate resource categories for your use.

Populate the appropriate URI component to include when building the URL for IWS records linked to this resource category.

Maintaining Inbound Web Services

[Inbound Web Services](#) are used to define a specific message that your implementation will receive from an external system and provides configuration needed to process the inbound message.

The product provides support for REST and SOAP services and provides several inbound web services out of the box.

For inbound SOAP web services, by default no annotations are defined for the base inbound web services. You may modify the message options or the annotations for any base IWS record. In addition, you may define additional IWS records for other incoming messages supported by your implementation.

To view an inbound web service, navigate using **Admin > Integration > Inbound Web Service**. You are brought to a query portal with options for searching for inbound web services.

Once an inbound web service has been selected, you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Important! When adding new records, carefully consider the naming convention of the inbound web service code. Refer to [System Data Naming Convention](#) for more information.

The following zones may appear as part of the portal's **Main** tab page

- **Inbound Web Service.** This zone displays the configuration information for the record and its operations.
- **Operations.** This zone lists the operations defined for the selected inbound web service. The zone is only visible for a REST inbound web service. You may navigate to the Inbound Web Service Operation portal to further describe the operation's web service schema.
- **Help Text Fields.** This zone maintains help text information for fields across all operations of the selected inbound web service. The zone is only visible for a REST inbound web service.

Refer to [Inbound SOAP Web Services](#) for specific information about Operations for SOAP records.

Refer to [Inbound REST Web Services](#) for specific information about Operations for REST records.

Note that in addition to standard actions available on this portal, there is also a special **Add to Category** button in the page action area. Click this button to link an inbound web service to one or more [web service categories](#).

Maintaining Inbound Web Service Operations

This portal is used to maintain a REST inbound web service operation. You can access the portal from the **Operations** zone on the Inbound Web Service portal for a REST service.

Refer to [Inbound REST Web Services](#) for specific information about Operations for REST records.

The following zones may appear as part of the portal's **Main** tab page

- **IWS Operation.** This zone provides information about the selected operation.
- **Schema.** This zone describes the request and response schema as defined by the operation's web service schema. The zone is only visible when an operation schema is explicitly defined.
- **Schema Extensions.** This zone manages web service schema extensions that correspond to extensions made to the operation's internal schema. This zone is only visible if the underlying schema was extended using dynamic

data area extension functionality. Each owner that extended the internal schema may provide web service schema information for their extension elements.

- **Options.** This zone lists various options for the operation such as request and response samples. The zone is visible when such options exist for the operation. Note that options are maintained as part of operation record.

The following zones may appear as part of the portal's **References** tab page

- **IWS Operation References.** This zone lists references to the current web service operation. The list includes other inbound web service operation records that reference the current operation via their web service schema. For a GET operation, the list also includes the maintenance object or business object that explicitly references the operation using a **GET Operation** option.

Web Service Schema Nodes and Attributes

A REST inbound web service (IWS) operation invokes a single schema based object, either a Business Object, a Business Service or a Service Script. The object has one schema which by default acts as both the Request and the Response schema. The product provides the ability to define an explicit schema for a web service operation that represents a view of the underlying internal schema for an external facing consumer. Note that the operation schema is a strict view of the internal schema and as such does not introduce structural changes.

While optional, defining an operation schema has the following benefits:

- Declaring the **usage** of an element as to whether it is part of the Request schema, Response schema, both or neither.
- Assigning an **external element name** to an internal element. Useful to avoid cloning of internal services for this purpose only.
- Better management and visibility of **GET operation** references.
- Support HATEOAS style structures outside of the internal schema. This allows for seamless internal processing.
- Providing help text for individual elements.

The following documentation is a complete list of the attributes available to you when constructing an IWS operation schema.

Operation Schema Definition

The following attributes defines the external facing operation schema that establishes the request and response schema for the operation.

Mnemonic	Valid Values	Description	Examples
<code>usage="REQ"</code>		<p>Indicates that the element should be included in the request schema only.</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p>	<pre><customerName usage="REQ" /></pre>
<code>"RESP"</code>		<p>Indicates that the element should be included in the response schema only.</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p>	<pre><customerId usage="RESP" /></pre>
<code>"BOTH"</code>		<p>Indicates that the element should be included in both request and response schema definitions. This is the default value</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p>	<pre><customerName usage="BOTH" /></pre>
<code>"EXCL"</code>		<p>Indicates that the element should not be included in either the request or the response schema definitions.</p> <p>When specified for a group or list element the value applies to the entire container. A specific element in the container may override the container default.</p>	<pre><httpMethod usage="EXCL" /></pre>
<code>mapTo="internal element name"</code>		<p>Maps a web service element to an internal element. By default the internal element name is assumed to be the same as the web service element name. Use this attribute to assign an external facing element name in the operation schema and map it to a corresponding internal element.</p> <p>Note that this is not an XPath expression but rather a reference to a valid element name that corresponds to the structure of the expanded internal schema.</p> <p>The owner of the element must be the same as the owner of the web service schema. If an operation's underlying schema was extended (using dynamic data area extension) then the extending owner may only reference their elements on their web service schema extension for the operation.</p>	<p>Internal schema element:</p> <pre><todoPriority .../></pre> <p>Operation schema element:</p> <pre><priority mapTo="todoPriority"></pre>

Mnemonic Values	Description	Examples
role= "FKGP"	<p>Establishes a group structure that represents a foreign key to an entity.</p> <p>The element itself does not exist in the internal schema. It groups together the foreign key value element(s) along with a corresponding _link element that at run time provides the endpoint URL of that entity's GET operation. Consumers of the web service may use the link to get the data for the entity.</p>	<p>Internal schema element:</p> <pre data-bbox="1162 264 1463 323"><user .../></pre> <p>Operation schema group:</p> <pre data-bbox="1162 401 1463 552"><user role="FKGP"> <user> <_link getOperation="mo:' > </user></pre>

Mnemonic	Valid Values	Description	Examples
	<p>"COLL"</p>	<p>Establishes a group structure that represents a collection of entities that corresponds to an internal service list.</p> <p>The element itself does not exist in the internal schema. It groups together the internal list mapped to a _data element along with a corresponding _link element that at run time provides the endpoint URL for the collection's GET operation. Consumers of the web service may use the link to get a more detailed set of information for each entity in the list.</p> <p>By default all the elements in the referenced list are included in the operation schema. You may explicitly reference and define attributes for specific elements as needed.</p>	<p>Internal schema element:</p> <pre data-bbox="1159 268 1461 520"><alerts type="list"> <alert/> <startDate / > <endDate /> <version /> </_data> </ alerts></pre> <p>Operation schema group:</p> <pre data-bbox="1159 598 1622 829"><alerts role="COLL"> <_link getOperation="... > <_data mapTo="alerts"> <version usage="EXCL > </_data> </alerts></pre>
<p>getOperation="expression"</p> <p>Expression components:</p> <ul style="list-style-type: none"> • mo:'<maintenance object>'; • pk1:<relative xpath to an element in the internal schema>; • pk2:...; • pk3:...; • pk4:...; • pk5:...; <p>Parameters pk2–5 are required to match the maintenance object's prime key definition.</p>		<p>Only valid on _self and _link elements. The attribute is used to reference the default GET operation for an entity as defined by its maintenance object or business object.</p> <p>The application determines the GET operation to use as follows:</p> <ul style="list-style-type: none"> • If the entity's business object references an operation using the GET Operation option then it is used. • If the entity's maintenance object references an operation using the GET Operation option then it is used. • If a GET operation is found that references the maintenance object then it is used. <p>If a GET operation cannot be determined for the entity a standard text indicating that a link is not available is returned instead.</p>	<pre data-bbox="1159 886 1622 955"><_link getOperation="mo:'TO ></pre>
<p>"expression"</p> <p>Expression components:</p> <ul style="list-style-type: none"> • iws:'<inbound web service name>'; • operation:'<operation name>'; • parms:[<external reference as defined on the GET operation record>:<relative xpath of an element name in the internal schema that holds the 		<p>Only valid on _self and _link elements. The attribute is used to reference a specific GET operation along with the information needed to compose its path parameters.</p>	<pre data-bbox="1159 1522 1622 1648"><_self getOperation="iws:'F1 ToDoEntry'; operation:'getTo [ToDoEntryId:ToDoEntryId;]"/ ></pre>

Specialized Elements

The operation schema definition makes use of specialized element names in the style of the Hypermedia as the Engine of Application State (HATEOAS) standard. These elements should only be defined by the operation schema as they are not relevant to nor should be managed by the internal operation service.

The following list describes each element and how it is used.

Element Name	Description	Examples
<code><_self .../></code>	<p>Response payloads may include a "_self" element that contains the endpoint URL of the GET operation related to the entity returned in the response.</p> <p>This is an optional element and only one may exist in an operation schema.</p> <p>Refer to getOperation= schema definition attributes for more information.</p>	<pre><_self getOperation="mo:'TO DO ENTRY'"> </_self></pre>
<code><_link .../></code>	<p>Response payloads may include foreign keys and for those entities, the response includes a "_link" element that contains the endpoint URL of the GET operation for that entity (if it exists).</p> <p>Refer to role= and getOperation= schema definition attribute for more information.</p>	<pre><_link getOperation="mo:'TO DO ENTRY'"> </_link></pre>
<code><_data .../></code>	<p>Provides a standard reference to a list of entities in the internal schema.</p> <p>Refer to role="COLL" schema definition attribute for more information.</p>	<pre><alerts role="COLL"> <_link getOperation="mo:'TO DO ENTRY'"> </_link> <_data mapTo="alerts"> </_data> </alerts></pre>

Documentation Attributes

The following attributes provide additional documentation for individual elements that is included as part of the web service's Open API specification.

MnemonicValid Values	Description	Examples
helpText= “help text field name”	<p>Associates an element with a specific help text record defined for the Inbound Web Service. If the element is included in both request and response schema the same help text is used in both.</p> <p>If this attribute is not specified, and a single Help Text Field record exists for the Field associated with the internal element, that help text record is used. If more than one such Help Text Field record exists the one where the help text name is the same as the Field name is used.</p> <p>Note that an internal element is associated with a Field name via the mdField= attributes, if any, else via the mapField= attribute.</p> <p>No valid for <code>_self</code> and <code>_link</code> elements.</p>	<pre><ToDoEntryId usage="BOTH" helpText="TD_ENTRY"></pre> <p>In this example the inbound web service defines a help text field name “TD_ENTRY” that provides help text for this element. The same help text is included for the element in both request and response schema.</p>
helpTextResponse= text field name”	<p>Associates an element that is included in both request and response schema with a specific help text record to be used in the context of the response schema.</p> <p>Follows same rules as the helpText= attribute.</p>	<pre><ToDoEntryId usage="BOTH" helpText="TD_ENTRY"></pre> <p>In this example the inbound web service defines the following help text records:</p> <ul style="list-style-type: none"> • Help text field name “TD_ENTRY” describes the element sent in the request schema. • Help text field name “TD_ENTRY_RESP” describes the element populated in the response schema.

Deploying Inbound SOAP Web Services

Once an Inbound SOAP Web Service is defined it is not automatically available to the Web Service Clients to access the system. The Deployment Status and the Active flag (set to true) indicate whether a Web Service is available or not. The last step is to deploy the Inbound SOAP Web Services to the Java EE Web Application Server. This deployment phase has a number of steps that are automatically performed when a deployment is initiated:

- The Web Service files are generated and policies are attached.
- The WSDL is generated with appropriate annotations and enumerations.
- The necessary Java stub code to implement the Web Service in the Java EE Web Application Server is generated and compiled.
- The Web Services are built into a valid Web Application Archive (WAR) file.
- Optionally, the newly created Web Services WAR file is deployed to the Java EE Web Application Server. This can also be done manually for clustered deployments, if desired.

There are two methods available for deploying inbound SOAP web services:

- Deployment at the command line using the **ivwsdeploy[.sh]** command as outlined in the Server Administration Guide. This method is recommended for native installations and production implementations.

- Deployment using the Inbound Web Service Deployment portal. This method is only supported in development (non-production) environments.

Inbound Web Service Deployment Portal

To use the online Inbound Web Service Deployment portal, navigate using **Admin > Integration > Inbound Web Service Deployment**.

The following sections describe the base zones that are provided on the portal.

Deploy Inbound SOAP Web Services

The Deploy Inbound SOAP Web Services zone provides information about the last deployment. If the region is a development (non-production) region you may use the **Deploy** button to deploy or re-deploy inbound web services. All inbound web services whose Active switch is Yes will be deployed. All whose active switch is No will be undeployed.

Note: When an Inbound SOAP Web Service is deployed, the value of its service revision field is captured. Certain changes to configuration will require re-deployment to take effect. When any of the following changes occur, the IWS service revision value is incremented. This will cause the deployment status to show **Needs Deployment**.

- Active switch is changed
- An Annotation is added or removed
- An Operation is added or removed.
- The Operation Name, Schema Type / Schema Name, Request or Response Schema, Request or Response XSL for an Operation is changed.

Note: In addition, if the implementation supports XAI services deployed through IWS, the appropriate XAI inbound services will also be deployed or undeployed as required.

Deployment Status

The Deployment Status zone displays a list of inbound SOAP web services in the product, including the deployment status.

The deployment status is determined by comparing the internal Service Revision field on each IWS against the value captured at the time of deployment.

- **Deployed.** Indicates that the IWS has been deployed and no changes have been detected to the configuration.
- **Needs Deployment.** Indicates that the IWS has never been deployed or has been deployed but in the meantime, changes have been detected to the configuration that require redeployment.
- **Undeployed.** Indicates that the IWS is marked as inactive and the IWS is not found to be deployed at this time.
- **Needs Undeployment.** Indicates that the IWS is marked as inactive but the IWS is found to be deployed at this time.

If the IWS has been deployed, the View column will include a **WSDL** link allowing you to launch a separate window to view the WSDL definition.

Note: For cloud installations, the system supports defining the WSDL URI via a substitution value defined for the token URI: `@F1_BASE_IWS_URI@`. The system will use this value per the functionality described in [URI Substitution](#). When no value is defined, the system uses a default URL, which is the appropriate URL for on-premise installations.

Use the broadcast button adjacent to any of the inbound web services listed in the zone to view the details of the IWS record. This causes the **Inbound Web Service** zone to appear. It is the same zone that appears on the [Inbound Web Service](#) maintenance portal.

XAI Inbound Service Deployment Status

The XAI Inbound Service Deployment Status zone is only visible if the feature configuration option **Support XAI Services via IWS** is configured on the **External Messages** feature type or if the system detects that there are XAI inbound services that have been deployed. (The latter condition is checked for the case where an implementation has

XAI inbound services deployed and then chooses to discontinue using this functionality. After changing the feature configuration option to false, one more deployment is required to "undeploy" the XAI services.) The zone displays a list of XAI inbound services in the product that are related to page services. Refer to [Deploying XAI Inbound Service via IWS](#) for more information.

The deployment status is determined by comparing the record's Version field against the value captured at the time of deployment.

- **Deployed.** Indicates that the XAI inbound service has been deployed and no changes have been detected to the configuration.
- **Needs Deployment.** Indicates that the XAI inbound service has not been deployed or has been deployed but in the meantime, changes have been detected to the configuration.
- **Undeployed.** Indicates that the XAI inbound service is marked as inactive or the **Support XAI Services via IWS** is not set to **true** and the XAI inbound service is not found to be deployed at this time.
- **Needs Undeployment.** Indicates that the XAI inbound service is marked as inactive or the **Support XAI Services via IWS** is not set to **true** but the XAI inbound service is found to be deployed at this time.

XAI inbound service does not have the equivalent of a Service Revision field that inbound web service has, which is only incremented when changes are made to the record that impact deployment. For XAI inbound service, the version number on the record is used. This field is incremented when any changes are made, even ones that may not impact deployment. As a result, some XAI Inbound Services may indicate "Needs Deployment" in cases where a redeployment may not be necessary. The recommendation when this occurs is to simply Deploy again to be safe.

If the IWS has been deployed, the View column will include a **WSDL** link allowing you to launch a separate window to view the WSDL definition.

Guaranteed Delivery

There are alternatives for sending messages to the system besides using inbound web services. An external system may be able to send messages to the system in a generic manner where a new web service does not need to be defined for every new type of message. These types of messages may provide a payload (the message) and the service script or business service to invoke. An example of this type of communication is a message sent from a mobile application using RESTful operations.

The external system may have no mechanism for retrying failed messages. For this situation, the product provides an algorithm that may be used to capture incoming messages that should 'guarantee delivery'. A servlet processing this type of message may invoke the [installation algorithm](#) - Guaranteed Delivery, passing the details of the message and an indication if a response should be returned. The algorithm is responsible for storing the message information in a table so that it can be subsequently processed.

Outgoing Messages

"Outgoing messages" is the term used to describe messages that are initiated by our system and sent to an external system. Messages may be sent real time or near real time. The system provides the following mechanisms for communicating messages to external systems.

- **Outbound Messages.** This method allows implementers to use configurable business objects to define the message format and to use scripts to build the message. If sent near real-time the message is posted to the outbound message table waiting for Oracle Service Bus to poll the records, apply the XSL and route the message. If sent real time, the message dispatcher routes the message immediately.
- **Web Service Adapters.** Using a web service adapter, an implementation can consume a WSDL from an external system and create an "adapter" record that references the URL of the external system and creates appropriate request and response data areas to expose the payload information in a format understood by configuration tools. A script may then be written to build the request information and initiate a real-time web service call from within the system.
- **Send Email.** The system supplies a dedicated business service that may be used to send an email real-time from within the application.

All these methods are described in more detail in the following sections.

Outbound Messages

Outbound messages provide functionality for routing XML messages to an external system real-time or in near real time. In addition the functionality supports collecting related messages into a batch to then be sent to an external system as a consolidate XML message.

For each outbound message that your implementation must initiate you define a [business object](#) for the outbound message maintenance object. Using the business object's schema definition, you define the fields that make up the XML source field. These are the fields that make up the basis for the XML message (prior to any XSL transformation).

Each outbound message requires the definition of its schema by creating a business object whose schema describes the information that is provided to the external system. An XSL transformation may then be performed when routing the message to an external system.

For each external system that may receive this message, you configure the appropriate message XSL and routing information.

Because the outbound message type is associated with a business object, your implementation can easily create outbound message records from a script using the [Invoke business object step type](#). Such a script would do the following:

- Determine the appropriate [outbound message type](#) and [external system](#) based on business rules
- Access the data needed to populate the message detail
- Populate the fields in the schema and use the **Invoke business object** script step type for the outbound message type's business object to store the outbound message.
- The resulting outbound message ID is returned to the script and the scriptwriter may choose to design a subsequent step to store that ID as an audit on the record that initiated this message.

The following topics provide more information about functionality supported by outbound messages.

Polling Outbound Messages Using OSB

If the outbound message that needs to be sent to an external system can be sent as an asynchronous message (in 'near real time'), the process initiating the outbound message should create a record in the outbound message staging table. Oracle Service Bus (OSB), is the recommended tool to use to process outbound messages in near real-time.

Outbound messages that should be processed by OSB should be configured with a processing method defined as **SOA** for the external system / outbound message type. No other information is required for defining outbound message types that are processed by OSB.

For the OSB part of the processing, the product provides a custom transport: OUAF Outbound Message that may be used by an implementation to define messages to process and how to process them. This transport processes outbound messages in order of the priority defined on the outbound message type.

This section provides an overview of steps required to develop OSB integrations for outbound messages created by your product.

Before developing OSB integrations, a developer should be familiar with OSB development such as creating proxy services, business services, and message flow/routing. These terms are defined as follows:

Proxy Service: In OSB, a Proxy Service is the entity that processes a given type of message and routes it to a Business Service. A separate proxy service should be defined for each type of outbound message. If a given outbound message type may be routed to different external systems, it is the responsibility of the proxy service to query the external system defined on the outbound message and invoke the appropriate business service (see below). If any transformation is required prior to routing a message to a business service, it is the proxy service's responsibility to perform the transformation.

Business Service: In OSB, a Business Service is an entity that receives a message from OSB and routes it to the appropriate destination. This should not be confused with the Business Service object provided in the product in the configuration tools.

Fastpath: Refer to the technical reference paper *OSB Integration* for more information.

Batch Message Processing

Your implementation may be required to send messages to the same destination as a single XML file with multiple messages include. The following points describe this logic:

- The individual messages that should be grouped together must have a processing method of **batch** on the external system / outbound message type record. The appropriate batch code that is responsible for grouping the messages must also be provided.
- A separate "consolidated message" outbound message type should be configured for the external system with a processing method of **SOA**.
- When outbound message records are created for the individual messages, the batch code and current batch run number are stamped on the record.
- When the batch process runs it is responsible for building the XML file that is a collection of the individual messages. This batch process should include the following steps:
 - Format appropriate header information for the collection of messages
 - Apply the individual message XSL to each message before including the message
 - Insert a new outbound message for the external system with the "consolidated message" outbound message type.
- The consolidated message is ready to be processed by Oracle Service Bus.

Note: No process provided. The system does not supply any sample batch job that does the above logic.

Real Time Messages

The system supports the ability to make web service calls, i.e. sending real time messages, to an external system.

The system supports special functionality for sending an Email message real-time. Refer to [Sending Email](#) for more information.

For other types of real-time messages, the system also uses outbound message type and external system configuration to format and route the message. When defining the configuration for real time messages, an additional step is required to define the mechanism for routing the message using a message sender. The system supports routing messages via HTTP and via JMS. Note that for HTTP routing, the system also supports sending the message using a JSON format.

Just like near real-time messages, initiating a real-time outbound message may also be done from a script. When a real time message is added, the system immediately routes it to the external system. If the external system provided a response message back, the system captures the response on the outbound message. If the outbound message type for the external system is associated with a response XSL it is applied to transform the response. In this case the system captures the raw response as well on the outbound message. Note that the outbound message BO should be configured to capture a response XML in its schema.

Any error (that can be trapped) causes the outbound message to be in a state of **Error**. It is the responsibility of the calling process to check upon the state of the outbound message and take a programmatic action. When the outbound message state is changed back to **Pending** the message will be retried.

The base package provides two business services: Outbound Message Dispatcher (**F1-OutmsgDispatcher**) and Outbound Message Mediator (**F1-OutmsgMediator**) that further facilitate making web service calls. Both business services are similar, allowing the calling script to configure the following behavior (with differences noted):

- Whether or not exceptions encountered while sending the message are trapped. Trapping errors allows the calling script to interrogate any errors encountered and take some other programmatic action.
- Whether or not the sent message is persisted as an actual outbound message record.
 - If a persisted message is desired, the recommendation is to use the Outbound Message Dispatcher. This business service creates the message using standard BO processing, relying on the outbound message logic to route the message and store the record. The message is routed after the BO pre-processing algorithm and after the record is persisted but before the BO post-processing and audit plug-ins are executed. If you need to send

the outbound message ID as part of the message, refer to [Capturing the Outbound Message ID in the Message](#) on page 466 for more information.

- If the message should not be persisted, then the recommendation is to use the Outbound Message Mediator. As mentioned, the Outbound Message Dispatcher creates the outbound message record, relying on the outbound message logic to route the message. If it should not be persisted, it is subsequently deleted. In contrast the Outbound Message Mediator executes the BO pre-processing algorithms and then routes the message explicitly without creating a message record. It is more efficient for scenarios that don't require persistence. Note that the Outbound Message Mediator also supports persistence, but it does so by creating the records without using BO processing. This is not recommended. The Dispatcher is the better option if persistence is desired.

Refer to the descriptions of the two business services for more information.

Designing the System for Outbound Messages

The following sections describe the setup required when using [Outbound Messages](#) to communicate with an external system. The configuration walks you through the steps to configure a single external system and all its messages.

Define the Outbound Message Business Object and Type

The product supplies many outbound message Business Objects along with Outbound Message Types for out of the box functionality.

In addition, implementations may need to define configuration for custom outbound messages. For each outbound message that must be sent to an external system, create a [business object](#) for the outbound message maintenance object. Using the business object's schema definition, your implementation defines the elements that make up the XML Source field (XML_SOURCE). These are the elements that are the basis for the XML message. XSL transformations may be applied to this XML source to produce the XML message.

If your integration is real-time and a response is expected, the Outbound Message business object should also map to the XML Response field (XML_RESPONSE).

- You may decide to capture the response as is and define the element as “raw”. For example

```
<responseDetail mapXML="XML_RESPONSE" type="raw"/>
```

In this scenario, a Response XSL may or may not be needed.

- Alternatively, if the details of the response are needed, you may define specific elements for the response. For this option, depending on how the integration is designed, a Response XSL may be needed to transform the response into the expected XML format.

Once you have your business object and schema, define an [outbound message type](#) for each unique outbound message.

Referencing an XSL

The system supports defining the XSLs as a [managed content](#) record. For backward compatibility, the system supports defining the XSL as a file in the file system. This is a system wide setting, defined using a feature configuration option. The feature type is **External Messages** and the option type is **XSL Location**. Set the value to **F1FL** to support XSL in the file system. The file location is configured using a system property. To support the XSL in managed content, no option is needed as this is the default. You may explicitly define the value of **F1MC** if desired.

Capturing the Outbound Message ID in the Message

If your integration would like to use the system generated Outbound Message ID as a unique identifier with the external system, the following configuration is needed:

- Define an element within the XML Source that should be populated with the system generated outbound message.
- Configure a BO Option on the outbound message's business object using the Option Type **Outbound Message ID XPath** and set the Option Value to the XPath of the element defined to capture the ID.

Note: This functionality is only applicable if the outbound message is persisted.

Support for Dynamic URLs

The product supports the ability to build a dynamic URLs. These are cases where the URL requires information determined at runtime. This is supported with a combination of BO schema definition, URL configuration and appropriate code when creating the outbound message. The following points highlight the steps needed to support this functionality.

- When defining the [Message Sender's](#) URL, use the syntax `${pathParms}` in the location of the URL where runtime information must be inserted. For example: `http://[SERVER_NAME]:1000/rest/services/${pathParms}`
- Include the data area **F1-OM-DynamicConfig** (Outbound message dynamic configuration) in the schema of the business object for the outbound message. This data area includes elements for **pathParms** and **queryParms**.
- In the code that creates the outbound message, populate the **pathParms** and if applicable **queryParms** elements with the appropriate information. The system will build the URL by plugging in the **pathParms** element value followed by a question mark, followed by the **queryParms** element value into the `${pathParms}` location in the URL.

The following is an example of run time values.

```
<dynamicConfiguration>
  <pathParms>job/1234</pathParms>
  <queryParms>firstName=John&lastName=Doe</queryParms>
</dynamicConfiguration>
```

Add SOAP Header Parameters at Runtime

The product supports the ability to add SOAP header parameters to an external message at runtime. The following points highlight the steps needed to support this functionality.

- Include the data area **F1-OM-DynamicConfig** (Outbound message dynamic configuration) in the schema of the business object for the outbound message. This data area includes the element **soapHeaders**.
- In the code that creates the outbound message, populate the **soapHeaders** element with the self contained XML to add to the SOAP header section of the outgoing SOAP request.

Real-Time Message Configuration

Messages are routed to an external system real-time using the outbound message dispatcher or using the real-time send email business service. The system supports routing messages using HTTP and routing messages using JMS. In addition, there is a special type of message sender used for sending emails. The following sections highlights the supported real-time communication and the configuration needed for each.

Email Messages

For sending emails, the following configuration is needed:

- Define a [message sender](#) configured for email. Senders of this type should be configured with the **RTEMAILSNDR** class. The sender context is used to configure the connection information for the connecting to the SMTP server.
- This sender may be defined as the default email sender on the [message option](#) table. Alternatively, the message sender can be provided to the business service as input. Refer to [Sending Email](#) for more information.

Outbound Messages

For other outbound messages that are routed using the real-time outbound message dispatcher, a [message sender](#) must be configured to define how to route the message. The following points highlight more detail related to this configuration.

Determine the communication mechanism prior to configuring the sender.

- When routing the message using JMS, the following configuration must be defined
 - Define an appropriate [JNDI Server](#) that indicates where the JMS resources are located.
 - Define a [JMS Connection](#) to define additional configuration needed for the connection.
 - Define the [JMS Queue](#) or [JMS Topic](#) to define the queue or topic to use.
- When communicating using a JSON format, determine the method to use to convert the XML to JSON. The desired method is driven by how the request should be sent.
 - If choosing the **Base JSON Conversion** method, if XSL transformation needs to be applied prior to the conversion to JSON, then the target XML Request Schema must be defined (using a data area) so that the conversion logic knows the format of the XML it is converting. The XSL is applied to the outbound message's XML Source, resulting in the defined XML Request Schema, which is then converted to JSON. If XSL transformation is not required, then the outbound message's XML Source is converted to JSON.
 - If choosing the **Rootless JSON Conversion** method, the group element mapped to the XML source field is removed by the conversion, resulting in a rootless JSON request document.
 - If the XML source on the outbound message can be converted to JSON using an XSL, then the **XSL Transformation** method may be chosen.
 - You may also choose to convert the XML Source to JSON via the **Standard API Conversion** method (using a Jettison library). With this method, an XSL may optionally be provided. The conversion will be performed on the transformed XML.
 - For the response, if the outbound message BO defines detailed elements for the XML Response field, then the JSON should be converted to this format.
 - If your conversion method is **Base JSON Conversion**, then if the JSON response cannot be converted directly to the XML Response elements on the outbound message BO, then define a Response Schema (data area) that represents the results for the base JSON conversion. In addition, define an XSL that can transform the response from the converted XML to the XML format expected on the BO.
 - If your conversion method is **Rootless JSON Conversion**, the response document is assumed to be rootless. The group element mapped to the XML response field is added by the conversion process, resulting in a well formed XML response document.
 - If the conversion method is **Standard API Conversion** or **XSL Transformation**, the standard API is used to convert JSON to XML. An XSL may be defined to convert the response to the XML Response if needed.
 - If the outbound message BO defines a "raw" element to capture the response, then a response schema and XSL are not necessary. In this case, the system will perform a JSON to XML conversion using the **Standard API Conversion** method (regardless of the conversion method defined) and the result is captured in the XML response.
- For HTTP senders including JSON senders, the system provides the following support for sending messages secured by OAuth authentication:
 - Using Oracle Web Services Manager (OWSM). The system provides a pre-configured set of policies for OAuth (**F1-OAUTH**) using a special extendable lookup. Note that the values of this policy set defines a specific CSF key repository that the implementation should use for capturing its CSF keys. In addition, there is a substitution value defined for the token URI: `@F1_OAUTH2_URI@`. Configure the appropriate URI for this implementation as described in [URI Substitution](#). By default the system does not support additional policy sets to be defined. If your implementation requires a different policy set, contact support.
 - You may provide OAuth related settings as part of the [message sender](#) configuration for a REST API.

Define a [message sender](#) configured for each appropriate routing method. The invocation type should be configured as **Real-time**. For routing via HTTP, use the **RTHTTPSNDR** - HTTP sender class. For routing via HTTP with SOAP format automatically applied, use the **SOAPSNDR** - HTTP SOAP sender class. For routing via HTTP using JSON format, use the **RTJSONSNDR** - JSON sender class. For routing via JMS, use the **RTJMSQSNDR** - JMS queue sender class or **RTJMSTSNDR** - JMS topic sender class and configure the JMS Connection and JMS Queue or JMS Topic. Use the sender context to configure the required values for connecting to the appropriate destination.

Note: Refer to [Support for Dynamic URLs](#) for configuration needed to support dynamic URLs when sending an outbound message. There is specific configuration expected when defining the URL on the Sender in order to support dynamic URLs.

Configure the [external system](#) / outbound message type collection. The processing method defined for the external system / outbound message type must be **Real-time**.

Define the External System and Configure the Messages

Define an [external system](#) and configure the valid outgoing messages and their method of communication (processing method). Refer to [Outbound Messages](#) for more information.

Outbound Message Schema Validation

The outbound messages that are generated by the system should be well formed and valid so that they do not cause any issues in the external system. To ensure this validity you may configure the system to validate messages before they are routed to their destination. Note that the validation is applied just before communication with the sender and therefore after any Request XSL has been applied.

- Define a directory where the valid W3C schemas are located using the Message option **Outbound Message Schema Location**.
- Each [external system](#) message must indicate the appropriate W3C schema to use for validation.

You may turn on or off this validation checking using the Message option **Schema Validation Flag**.

This feature is not supported for cloud implementations.

Configuring the System for Outbound Messages

The following sections describe the setup required when using [Outbound Messages](#) to communicate with an external system.

JNDI Server

If using JMS to communicate outbound messages, define a new JNDI Server. Open **Admin > Integration > JNDI Server**.

Description of Page

Enter a unique **JNDI Server** and **Description**.

Indicate the Provider URL to indicate the location of the JNDI server. A variable may be used in place of all or part of the URL. The variable must be predefined in the substitution variable property file. The value here should enclose the variable name with @. Refer to [Referencing URIs](#) for more information.

Indicate the **Initial Context Factory**, which is a Java class name used by the JNDI server provider to create JNDI context objects.

JMS Connection

To define a JMS Connection, open **Admin > Integration > JMS Connection**.

Description of Page

Enter a unique **JMS Connection** and **Description**.

Indicate the **JNDI Server** to be used. Refer to [JNDI Server](#) for more information.

Use the **JNDI Connection Factory** to indicate the lookup keyword in the JNDI server used to locate the JMS connection.

Where Used

JMS Queue

To define your JMS Queue values, open **Admin > Integration > JMS Queue**.

Description of Page

Enter a unique **JMS Queue** and **Description**.

Enter the **Queue Name** as defined in the JNDI server. This is the JNDI lookup name identifying the queue.

Use the **Target Client Flag** to indicate whether or not the target client is **JMS** or **MQ**.

Select the **JNDI Server** where the queue is defined. Refer to [JNDI Server](#) for more information.

JMS Topic

To define your JMS Topic values, open **Admin > Integration > JMS Topic**.

Description of Page

Enter a unique **JMS Topic** and **Description**.

Select the **JNDI Server** where the topic is defined. Refer to [JNDI Server](#) for more information.

Enter the **Topic Name** as defined in the JNDI server. This is the JNDI lookup name identifying the topic.

Message Sender

The topics in this section describe the maintenance of a message sender

Message Sender - Main

To define a new sender, open **Admin > Integration > Message Sender**.

Description of Page

Enter a unique **Message Sender** and **Description**.

CAUTION: Important! When adding new records, carefully consider the naming convention of the message sender code. Refer to [System Data Naming Convention](#) for more information.

Set **Invocation Type** to **Real-time**.

Indicate the **Message Class** for this sender, which indicates the method used to route the message. The valid sender classes are as follows:

Message Class	Description
RTEMAILSNDR	Email sender.
RTHTTPSNDR	HTTP sender.
RTJMSQSNDR	JMS queue sender.
RTJMSTSNDR	JMS topic sender.
RTJSONSNDR	HTTP JSON sender.
SOAPSNDR	HTTP SOAP sender.

Indicate whether or not this sender is currently **Active**.

For JMS related senders, indicate whether the **MSG Encoding** is **ANSI message encoding** or **UTF-8 message encoding**. (Note that for all other types of senders, the Character Encoding context type is used to configure encoding.)

If the Message Class is one that connects to a JMS Queue or JMS Topic, indicate the appropriate **JMS Connection**

Fastpath: Refer to [JMS Connection](#) for more information.

If the Message Class is one that connects to a JMS queue, indicate the name of the **JMS Queue** to define where the message is to be sent.

Fastpath: Refer to [JMS Queue](#) for more information.

If the Message Class is one that connects to a JMS topic, indicate the name of the **JMS Topic** to define where the message is to be sent.

Fastpath: Refer to [JMS Topic](#) for more information.

Message Sender - Context

The sender may require context information to define additional information needed by the system to successfully send outgoing messages. Open **Admin > Integration > Message Sender** and navigate to the **Context** page.

Description of Page

Define the **Context Type** and **Context Value**, which contain parameters for senders when more information is required. See below for the supported context values for different types of senders.

Email Sender Context

The email sender is used by the business service that [sends email messages real-time](#).

An email sender must point to the Message Class **RTHTTPSNDR**. In addition, the following context records should be defined for senders of this type.

Context Type	Description
SMTP Host name	The SMTP server host name.
SMTP Username	The user ID used to access the SMTP server.
SMTP Password	The password used to access the SMTP server.
Response Time Out	The amount of time the system should wait for a real time response.

HTTP Sender

An HTTP sender is one that sends messages to an HTTP server using the HTTP protocol. HTTP senders should reference a Message Class of **RTHTTPSNDR**, **RTJSONSNDR** or **SOAPSNDR**.

Various parameters are required to establish a session with the target HTTP server. You specify these parameters by defining a collection of context values for the sender. A set of context types related to HTTP variables is provided with the product. The following section describes the context types and where appropriate, indicates valid values.

Before defining the HTTP sender, you need to find out how the HTTP server on the other side expects to receive the request, and in particular, to answer the following questions:

- What is the address of the HTTP server?
- Is the HTTP server using a POST or GET HTTP method?
- If the server is using POST, how are message contents passed? Does it use an HTTP FORM or does it pass the data in the body of an XML message?

Context Type	Description	Values
HTTP URL1 - URL9	<p>Used to construct the URL of the target HTTP server.</p> <p>Since the URL may be long and complex, you can break it into smaller parts, each defined by a separate context record. The full URL is built by concatenating the values in URL1 through URL9.</p> <p>You may use substitution variables when entering values for URL parts. Note that the substitution string @XMLMSG@ may be used for GET calls if an XSL has been applied to convert the message into HTTP GET parameters. It is useful if the HTTP Form is not applicable to the type of message.</p> <p>Refer to Support for Dynamic URLs for configuration needed to support dynamic URLs when sending an outbound message.</p>	
HTTP Method	<p>The HTTP method used to send the message.</p> <p> Note: The SOAP sender message class SOAPSNDP only supports the POST method.</p>	POST or GET
HTTP Transport Method	<p>Specifies the type of the message. You can either send the message or send and wait for a response.</p>	Send or sendReceive

Context Type	Description	Values
HTTP Form Data	<p>Used when the message is in the format of an HTML Form (Content-Type: application/x-www-form-urlencoded).</p> <p>This context specifies the form parameters (data) that should be passed in the HTTP message. Since a form may have multiple parameters, you should add a context record for each form parameter.</p> <p>The value of a form parameter takes the format of $x=y$ where x is the form parameter name and y is its value.</p> <p>If y contains the string @XMLMSG@ (case sensitive) then this string is replaced by the content of the service response XML message. The @XMLMSG@ string can be used in the HTTP Form Data or in the HTTP URL, but not in both.</p> <p>If a context record of this type is defined for a sender, the sender uses the HTML Form message format to send the message even if @XMLMSG@ is not specified in one of the context records.</p> <p>If a context record of this type is not defined for a sender, then the XML is sent with Content-Type: text/plain. When using POST it is put in the HTTP message body.</p> <p>Always required when using the GET method. If you are using the GET method and do not specify a Form Data context record, no message is transferred to the HTTP server.</p> <p>You may use substitution variables when entering values for Form Data.</p>	
HTTP Login User	<p>The HTTP server may require authentication. Add a context record of this type to specify the login user to use.</p>	
HTTP Login Password	<p>The HTTP server may require authentication. Add a context record of this type to specify the login password to use.</p>	

Context Type	Description	Values
HTTP Header	<p>Sometimes the HTTP server on the other side may require the addition of HTTP headers to the message.</p> <p>For each HTTP header that has to be specified you should add a context record with a value having the following format <i>x:y</i> where <i>x</i> is the header name and <i>y</i> is the value for the header</p>	
HTTP Time Out	Indicates the amount of time to wait for a connection to be established with the remote system.	
Character Encoding	Indicates if the message should be encoded. The sender will add to the HTTP's content type header the string <code>; charset=x</code> where <i>x</i> is the value of this context and when sending the message it will encode the data in that encoding.	UTF-8 or UTF-16
Response Time Out	The amount of time the system should wait for the remote system to send a response.	
Sender Security Type	Indicate the desired security type to apply. (Note that additional security types are applicable only to the SOAP Sender. See below for more information.)	BASIC (HTTP Basic), TEXT (Username Token plain text), DIGEST - Username Token Digest, OWSM - OAuth Security via OWSM, OAUTH - OAuth Security.
OWSM Policy Set	Applicable only if the Sender Security Type is OWSM . Defines the policy set to apply.	Enter a valid value for the extendable lookup Set of Policies (F1-SetOfPolicies). The product provides the value F1-OAUTH that may be used here.
OAuth Grant Type	Applicable only if the Sender Security Type is OAUTH . Defines the OAuth specification method for acquiring an access token.	client_credentials
OAuth Access Token URL	Used to construct the URL of the target authorization server. You may use substitution variables to construct the URL.	
OAuth Client ID	The generated identifier for the current application in the external system's authorization server.	
OAuth Client Secret	The secret paired with the OAuth Client ID as provided by the external system's authorization server.	

OAuth Key Ring	Defines the key ring used to store the OAuth Client ID and secret provided by the external system's authorization server. If a key ring is specified, the OAuth Client ID and OAuth Client Secret context entries are not allowed.	
OAuth REST API Scope	The authorization level granted by the end point.	
OAuth Token Request Details in Body	By default, the authorization token request includes the Client ID and Secret information in the message header. This context type may be used to indicate that this information should be sent in the body of the request instead.	Set this to 'Y' to send the Client ID and Secret information as part of the body of the authorization token request.

Real-time HTTP Sender

The following context type is only applicable to senders with the **RTHTTPSNDR** message class.

Context Type	Description
Content Type	Populate a value here to override the Content-Type attribute in the HTTP header, which defaults to text/xml .

SOAP Sender

A SOAP sender is an HTTP sender that automatically adds support for the SOAP format. For this type of sender (message class of **SOAPSNDR**), besides the context values listed above, the following context entries may also be supplied.

Context Type	Description	Values
Message Namespace URI	Used to indicate a specific namespace to be included in messages for this sender. Note that this value is used only when the External Message link to this sender is configured with a Namespace Option of Configured on Sender .	
SOAP Insert Timestamp	Indicate whether a timestamp should be added. Default value is 'N'.	Y or N
SOAP Expiration Delay (in seconds)	Indicate an expiration delay to add to the timestamp. The default value is 60.	

Context Type	Description	Values
Sender Security Type	Additional security types are supported for SOAP senders for specific third party integrations.	CIM - Uses an appropriate namespace and adds security information in the SOAP header specific to Landis+Gyr, MS_V30 - Uses an appropriate namespace and adds security information in the SOAP header specific to MultiSpeak v3.0, MS_V41R - Uses an appropriate namespace and adds security information in the SOAP header specific to MultiSpeak v4.1. ITRON - Uses appropriate SOAP header information security information in the SOAP header specific to Itron.

Note: Refer to [Add SOAP Header Parameters at Runtime](#) for information about dynamically including SOAP Header parameters when sending a message.

JMS Sender

A JMS sender is one that sends messages to a JMS queue or JMS topic. JMS senders should reference a Message Class of **RTJMSQSNDR** or **RTJMSTSNDR**, respectively.

The following parameters are used to connect to the JMS resource.

Context Type	Description	Values
JMS Message Type (Bytes(Y)/Text(N))	Indicates whether the data is sent as a bytes message or as a text message.	Y or N
JMS User Name	Enter the user name to connect to the JMS resource.	
JMS User Password	Enter the password to use to connect to the JMS resource.	
JMS Header	<p>If JMS header values are required for the message, use this context type.</p> <p>For each JMS header that has to be specified, add a context record with a value having the following format <i>x:y</i> where <i>x</i> is the header name and <i>y</i> is the value.</p>	

Application Variables

Some APIs may require application identifying variables to be included in the message payload. These values are typically available at provisioning time and need to be captured in relation to these API configurations.

Note: This type of context is not involved in the process of orchestrating and routing the API call. It needs to be incorporated into the payload by the application logic that composes the message using the "Get Application Variables (FIMsgVars)" service script.

The following parameters may be used to capture application variables.

Context Type	Description	Values
Application ID	Identifies the current environment for this API.	Determined at provisioning time by the API provider.
Tenant ID	Identifies the current tenant for this API.	Determined at provisioning time by the API provider.

Defining Outbound Message Types

Refer to [Outbound Messages](#) for an overview of this functionality.

Use this page to define basic information about an outbound message type. Open this page using **Admin > Integration > Outbound Message Type**. You are brought to a query portal with options for searching for outbound message types.

Note: This page is not available if the **External Message** module is [turned off](#).

Once an outbound message type has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Outbound Message Type** zone provides basic information about an outbound message type. Besides the code and description, the outbound message type captures the outbound message business object and the relative priority of the outbound message. The priority is only applicable if the [outbound message is processed using OSB](#). In addition, if the outbound message type is linked to any web service categories, they are displayed.

CAUTION: Important! When adding new records, carefully consider the naming convention of the outbound message type code. Refer to [System Data Naming Convention](#) for more information.

Note that in addition to standard actions available on this portal, there is also a special **Add to Category** button in the page action area. Click this button to link an outbound message type to one or more [web service categories](#).

The **External System Links** zone is visible if the outbound message type is linked to any external systems.

External Systems

Use this page to define an external system and define the configuration for communication between your system and the external system.

External System - Main

Open this page using **Admin > Integration > External System**.

Note: This page is not available if both the **External Message** and the **Open Market Interchange** modules are [turned off](#).

Description of Page

Enter a unique **External System** and **Description**.

CAUTION: Important! When adding new records, carefully consider the naming convention of the external system code. Refer to [System Data Naming Convention](#) for more information.

Use the field **Our Name In Their System** to specify the identity of your organization (i.e., your external system identifier) in the external system.

Note: The workflow process profile and notification download profile are only applicable to products that support workflow and notification. They are not visible in the product if the **Open Market Interchange** module is [turned off](#).

If this external system sends inbound communications through notification upload staging, the type of workflow process that is created is controlled by the sender's **W/F (Workflow) Process Profile**.

If you send notifications to this external system, select a **Notification DL (download) Profile** that is used to define the configuration of the outgoing messages.

Note: The remaining fields are not visible if the **External Message** module is [turned off](#).

Set **Usage** to **Template External System** for external systems whose outbound message type configuration is inherited by other external systems.

If the outbound message type configuration should be inherited from a template external system, define the **Template External System**. If this field is specified, the outbound message type collection displays the data defined for the template system as display-only.

The **Outbound Message Type accordion** contains an entry for every type of outbound message defined for this external system. For each type of outbound message identify its **Outbound Message Type**.

Define the **Processing Method** for messages of this type. Valid values are **Batch**, **Real-time**, **SOA** and **XAI**.

Define an appropriate **Message Sender** if the processing method is **XAI** or **Real-time**.

Namespace Option is used when your message should include a namespace in the resulting XML. The valid options are **Standard Namespace** and **Configured on Sender**. If the value is Standard Namespace, the system will generate a namespace for the resulting WSDL with the following value: http://ouaf.oracle.com/outbound/AAA_BBB, where AAA is the external system code and BBB is the outbound message type code. If the value is Configured on Sender, then the value of the namespace is taken from the sender context with context type **Message Namespace URI**.

Define an appropriate **Batch Control** if the processing method is **Batch**.

If the message sender is one with a message class of **RTJSONSNDR**, indicate the **JSON Conversion Method**. The valid values are **Base JSON Conversion**, **Standard API Conversion** and **XSL Transformation**. Refer to [Real Time Message Configuration](#) for more information about these methods and the additional configuration that may be applicable.

If the **JSON Conversion Method** is **Base JSON Conversion**, the **Request Schema** is enabled. Populate a data area that defines the schema for the XML format to convert the outbound message's BO schema to prior to performing the JSON conversion. Refer to [Real Time Message Configuration](#) for more information.

The **Message XSL** is the schema used to transform information from the format produced by the system to a format understood by the sender, who receives a message of this type. This is not applicable for Processing Method of **SOA**. Refer to [Referencing an XSL](#) for information about configuring where the XSL is defined.

Enter the file name of the appropriate **W3C Schema** if you want to validate the message built for outbound messages for this external system / outbound message type prior to being routed to their destination. Refer to [Outbound Message Schema Validation](#) for more information. This is not applicable for Processing Method of **SOA**. This feature is not available for cloud implementations.

If the **JSON Conversion Method** is **Base JSON Conversion**, the **Response Schema** is enabled. Populate a data area that defines the schema for the XML format that the JSON message is initially converted to. The XML is then converted to BO XML. Refer to [Real Time Message Configuration](#) for more information.

Response XSL will only be displayed when the processing method is **Real-time**. Refer to [Real Time Messages](#) for more information on how it is used. Refer to [Referencing an XSL](#) for information about configuring where the XSL is defined.

External System - Template Use

If you are viewing an external system whose usage is a **Template External System**, use this page to view the other external systems that reference this one. Open this page using **Admin > Integration > External System** and then navigate to the **Template Use** tab.

Description of Page

The tree shows every external system that references this external system as its template.

Message Option

The Message Option page defines various system settings used by the system when processing external messages.

To define options for your environment, open **Admin > Integration > Message Option**.

Description of Page

The following options are supported.

Option	Description	Option Name
Default Email Sender	This is the default Message Sender used for sending e-mails when no explicit Message Sender is specified.	defaultEmailSender
Default User	The default user is used by the system to access your product when no other user is explicitly specified.	defaultUser
Email Attachment File Location	This is the default location of e-mail attachment files. If not specified, the e-mail service provided with the product assumes a full path is provided with each attachment file.	emailAttachmentFileLocation
Email XSL File Location	This is the default location of e-mail XSL files. If not specified, the e-mail service provided with the product assumes a full path is provided to an XSL file as part of an e-mail request.	emailXSLFileLocation
Messages Language	The default language to use for the messages.	language
Outbound Message Schema Location	Enter the full path of the virtual directory where valid W3C schemas are stored if your implementation wants to validate outbound message schemas . For example: <code>http://localhost/cisxai/schemas</code> .	xaiOuboundSchemaLoc
Schema Validation Flag	Enter Y to turn on schema validation for outbound messages . Enter N to turn this off.	xaiSchemaValidationCheck

Note that the following options are no longer applicable.

Option
To Do Type for Inbound JMS Message Errors
To Do Type for Outbound Message Errors
XSD Compliance

Managing Outbound Messages

Use this page to view information about outbound messages.

Outbound Message - Main

Open this page using **Menu > Integration > Outbound Message**.

Description of Page

Outbound Message ID is the system-assigned unique identifier of the outbound message. These values only appear after the outbound message is added to the database.

The **Processing Method** indicates whether this record will be processed by a **Batch** extract process or **Real-time**. (The value of **XAI** is no longer supported). The value defined on the external system / outbound message type collection populates this value.

When records are created with a processing method of **Batch**, the system sets Extract to **Can Be Extracted**. Change the value to **Not to be extracted** if there is some reason that processing should be held for this record.

For records with a processing method of **Batch**, **Batch Control** indicates the process that will extract this record. This value is populated based on the on the external system / outbound message type's value. **Batch Number** indicates in which batch run this record was extracted or will be extracted.

The **Retry Count** is no longer applicable..

The **Creation Date** indicates the date that this record was created.

The status is no longer applicable.

Outbound Message - Message

Use this page to view the XML source used to build an outbound message. Open this page using **Menu > Integration > Outbound Message** and then navigate to the **Message** tab.

Description of Page

The **XML Source** is displayed.

If a message XSL is defined on the external system / outbound message type record linked to this outbound message, the **Show XML** button is enabled. Click this button to view the XML that is a result of applying the Message XSL to the XML source.

Outbound Message - Response

Use this page to display the XML response. Open this page using **Menu > Integration > Outbound Message** and then navigate to the **Response** tab.

Description of Page

The **XML Response** and optionally the **XML Raw Response** is displayed.

XML Response displays the response data from the system called by the real-time message. If a response XSL is defined on the external system / outbound message type record linked to this outbound message, a transform is performed and the XML Raw Response displays the original, unchanged response.

Web Service Adapters

The base product provides a configuration object called Web Service Adapter that is used to help build configuration objects to allow for functionality in the system to initiate a web service call from within the system. A Web Service Adapter provides the following functionality:

- WSDL (web service description language) import. An implementer can use the WSDL import functionality to read the details of a WSDL into the system
- Internal API generation. The system generates internal data areas that have two main purposes: they provide the API for custom code to define the appropriate input and they provide output data for the web service call using Oracle Utilities Application Framework schema language. In addition, the web service dispatcher uses element mapping defined in the data areas to transform the internal XML into the structure expected by the external system as described in the WSDL.
- Defines the URL needed to perform the web service call at runtime.

Understanding Web Service Adapters

The following topics describe the system functionality in more detail.

Importing a WSDL

Configuring a Web Service Adapter starts by identifying the WSDL (the web service description language document used to define the interface) that will be provided by the external system. The following steps describe the base product functionality provided to allow a user to import a WSDL.

- Navigate to the **Web Service Adapter** page in add mode and select the appropriate base business object.
- Enter a meaningful Web Service Name and appropriate descriptions.
- Provide the URL of the given WSDL.
- Click **Import** to retrieve the details of the WSDL. The system then parses the WSDL details and populates the WSDL Service Name, WSDL Source, WSDL Port, URL and a list of Operations (methods) defined in the WSDL.
- Determine which Operations should be **active** based on the business requirements for invoking this web service. **Active** operations are those that the implementation is planning to invoke from the system. These require appropriate request and response data areas generated for them. The following section provides more information about that.
- Specify the appropriate Security Type to configure the type of security to use when invoking this web service.
- Click Save.

At this point, a web service adapter record is created in pending status. The next step is to generate the request and response data areas for the operations configured as active.

Generating Request and Response Data Areas

Each **active** operation for the web service adapter requires a pair of data areas, request and response, that represent the request and response XML messages for the operation.

The base product provides steps to generate the data areas as follows:

- As described in the Importing a WSDL section above, the operations listed in the WSDL are generated for the web service adapter and the implementer should indicate which operation to activate.
- After saving the **pending** web service adapter, the display lists all the active operations and for each one includes a **Generate** button.
- After clicking **Generate** for an operation, a window appears where the names of the new Request and Response Data Areas may be defined. Click **Save** to generate the data areas.

The generated data areas provide the API for the implementer to use when implementing the web service call in an appropriate algorithm or service in the system. The data areas contain the appropriate mapping from the elements that the implementer works within the code that invokes the web services and the WSDL definitions.

To facilitate generating the request and response data areas, the base product invokes a special business service used to create the appropriate mapping. The business service is defined as a BO option on the Web Service Adapter business object. This allows an implementation to provide a custom business service to further enhance the request and response mapping where appropriate.

Note:

Generated data areas. It is possible to edit and modify the generated data areas after they are created. An implementer can change element names or remove unneeded elements if desired. Manually changing the generated data areas must be done only when absolutely necessary. This is because the system is not able to validate manual changes and issues with the data areas would only be detected at run time.

Activating Web Service Adapters

The business objects provided by the base package for web service adapters include a simple lifecycle of **Pending** and **Active**. Configure the web service adapter and its data areas while in **Pending** status and activate it when it is ready to be implemented in the appropriate system functionality.

Invoking Web Services

To make a call to a web service using a web service adapter, the system has provided a Web Service Dispatcher business service (**F1-InvokeWebService**) to submit a web service call. The calling program is responsible for retrieving all the information to correctly populate the request data required by the web service call before invoking the business service.

Note:

Refer to the detailed description of the business service for more information.

Limitations

The following points highlight limitations associated with the types of web services that the system supports:

- It is possible for one WSDL document to contain definitions for several web services. The system currently supports only one port or service per WSDL document.
- It is possible for a WSDL to support multiple message patterns. The system currently supports only request / response.

Setting Up Web Service Adapters

Use the Web Service Adapter portal to define the configuration needed to communicate with an external system using a web service call. Open this page using **Admin > Integration > Web Service Adapter**. You are brought to a query portal with options for searching for web service adapters.

Once a web service adapter has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Web Service Adapter** zone provides basic information about the web service annotation type.

Please see the zone's help text for information about this zone's fields.

Fastpath: Refer to [Understanding Web Service Adapters](#) for information about common web service adapter functionality.

Sending Email

The framework provides the ability to initiate an email from within the system. The following topics highlight the functionality available.

- Sending email "real time" using a specific business service. The framework provides a business service **F1-EmailService** that supports sending an email. The schema supports elements for all the information required to create an email real time. The SMTP information (host, user name and password) may be provided or may be defined on a message sender, that may be provided as input. In addition, the business service supports using a default message sender defined as a [message option](#). Review the business service schema for information about the input elements.

Note: Retry setting. An option in the system properties file allows your implementation to configure the number of times to retry (if any) if the SMTP server is unavailable. Refer to the server administration guide for more information.

- The business service supports sending attachments. The may either reference attachments from the file system (file name and content ID) or reference attachment records captured in the system's attachment table. Note that attachments in the file system are not supported in a cloud implementation.

Note: Validating attachments. If a Validate Email Attachment algorithm is plugged into the [installation record](#), it is called to validate the attachments supplied, if applicable.

- Using an outbound message to send an email. This option allows for different variations as described in [Outbound Messages](#).
 - Some emails may be created en masse (for example a large group of emails routed to users for a given set of To Do entries). In this case, the records can be created in the staging table for processing using OSB.

- Messages may still be sent real time using one of two business services described in [Real Time Messages](#). This option is an alternative to the dedicated email service described above when aspects of the outbound message functionality are needed, such as the ability to instantiate a record as an audit or to include additional logic via BO plug-ins as part of sending the email.

Web Service Category

The product provides the ability to categorize web services that are defined in the system. The term web services refers to Outbound Message Types, Inbound Web Services, and for those implementations where they are applicable, XAI Inbound Services.

A given web service may be linked to more than one category. The product supplies web service categories and most base delivered web services are configured with appropriate categories. Implementations may define new categories and may link custom web services to base delivered categories or to custom categories. In addition, implementations may link additional categories to base delivered web services. However, implementations may not remove base delivered web services from base delivered categories.

If your implementation uses the [Integration Cloud Service Catalog](#), the integration provides the categories for each web service that is sent to the catalog.

The web service category portal supports adding and removing web services from the category. In addition, the [Outbound Message Type](#) portal and [Inbound Web Service](#) portal each provide a page action button to **Add to Category**.

Defining Web Service Categories

Refer to [Web Service Category](#) for an overview of this functionality.

Use this page to define basic information about a web service category. Open this page using **Admin > Integration > Web Service Category**. You are brought to a query portal with options for searching for web service categories.

Note: This page is not available if the **External Message** module is **turned off**.

Once a web service category has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Web Service Category** zone provides basic information about a web service category.

CAUTION: Important! When adding new records, carefully consider the naming convention of the web service category code. Refer to [System Data Naming Convention](#) for more information.

Once a web service category exists, an **Add Web Services** zone is provided to find and select web services to link to the web service category.

When viewing a category that already has web services linked to it, they are visible in the zone **Included Web Services**. This zone allows a user to remove a customer owned web service from the list.

JMS Message Browser

The JMS Message Browser portal allows you to select a JMS queue and view messages currently in the queue.

In order for a JMS queue to be available on the portal, a [message sender](#) must be defined that is configured for the appropriate JMS queue with the credentials to connect to the queue.

- If your organization sends real-time outgoing messages to a JMS queue, this configuration would exist as per the details in [Real-Time Message Configuration](#).
- If inbound web service messages are routed to the system via a JMS queue, no configuration is needed in the system. However, if you would like to view the messages in the queue in the JMS message browser portal, configuration for the JMS queues as described for outgoing messages is required.

Navigate to the portal using **Main > Integration > JMS Message Browser**.

The JMS Senders zone provides a list of configured message senders eligible for selection.

The JMS Message List zone is visible for the JMS Sender broadcast from the first zone. This zone supports selecting one or more records to delete from the queue. Use the message selector to limit the results to messages that satisfy the message selector. This uses standard JMS API message selector functionality. Refer to the zone embedded help for information about the supported syntax.

The JMS Message Details zone displays a message broadcast from the list zone.

Oracle Integration Cloud Catalog

Oracle Integration Cloud (OIC) is an offering that serves as integration infrastructure for Oracle cloud solutions. The product provides an adapter for OIC to streamline integration between your edge application and OIC.

The product provides a mechanism (referred to as an adapter) for OIC to retrieve the REST catalog and another to retrieve the SOAP catalog from a given product. The expectation is that a given implementation would use either REST or SOAP and not both, but for those implementations that do support both classes of web services, OIC can retrieve both catalogs.

For the SOAP catalog, the adapter retrieves the name, the source system, the WSDL location and namespace for each web service.

For the REST catalog, the adapter retrieves the name, the source system and the OpenAPI Specification for each web service.

It is possible that not every web service supported by an edge product is managed by OIC. In order to only include the appropriate web services in the adapter, configuration is needed to identify which web services to include.

The web service catalog is used to identify the records that should be retrieved by the adapter. Separate catalogs exist for REST and for SOAP

- For SOAP inbound messages, the system supports both the use of [inbound web services](#) and XAI inbound services that are [deployed via IWS](#). Each IWS or XAI inbound service that should be included in the catalog must be flagged in the SOAP catalog. Note that only [deployed](#) services are returned to the catalogue.
- For REST inbound messages, each IWS that should be included in the catalog must be flagged in the REST catalog.
- For outbound message, the system requires the creation of an External System that includes each outbound message type that the external system receives. For outbound messages that are integrated through OIC, the external system itself will represent OIC. Rather than identifying each outbound message type to include in the catalog, only the external system needs to be flagged. The adapter will return web service information for all the outbound message types configured for the external system. If an implementation supports both REST and SOAP, separate external systems should be created to separately group the REST and SOAP outbound messages.

Note: The subordinate catalog functionality is no longer applicable and will be removed in a future release.

Fastpath: Refer to [Maintaining the Web Service Catalog](#) for more information.

Web Service Catalog Configuration

The topics in this section describe the configuration needed in your edge application to integrate with OIC.

Web Service Catalog Master Configuration

The **Service Catalog Configuration** ([master configuration](#)) record defines several system wide settings related to integrating with the service catalog.

It includes configuration for the WSDL base URL for the SOAP catalog. Note that this element supports the functionality described in [Referencing URIs](#). Note that for the REST catalog, the system will use the URL defined in the substitution variable `F1_OPEN_API_BASE_URL`

The subordinate server section is no longer applicable and will be removed in a future release.

For more information about specific fields in the master configuration, refer to the embedded help.

Maintaining the Web Service Catalog

Refer to [Oracle Integration Cloud Catalog](#) for an overview of web service catalog functionality.

To add or remove services that are reported to the OIC catalog, navigate to the portal using **Admin > Integration > Web Service Catalog**.

The Catalog by Class zone provides the list of classes (REST and SOAP). Broadcast the web service class that you want to work with.

The Catalog zone provides a list of services that are currently in the catalog based on the web service class chosen. Users may use this zone to remove services from the catalog.

The Candidate Services zone provides a list of external systems and inbound web services that are not currently linked to the catalog. Users may use this zone to add services to the catalog. The inbound web services will be limited to those with the same web service class as the one broadcast. All external systems are shown regardless of the web service class because there is no web service class configuration on external systems.. The expectation is that implementers will create the external system to include either only REST or only SOAP services and will know which external system to include in which catalog. For the SOAP web service class, if XAI inbound services are applicable, they are also visible.

Note: For inbound SOAP web services and XAI inbound services, they may be selected for the SOAP catalog at any time. However, only [deployed](#) services are returned to the catalog by the OIC adapter.

XAI Documentation Note

The XAI functionality is legacy functionality and not recommended for new implementations. The help topics are no longer provided.

Integrations

This chapter provides high level information about product integrations supported for all products that use Oracle Utilities Application Framework.

Creating Application Links in External Applications

When integrating Oracle Utilities applications with other external applications, you can create links from external applications to specific portals and pages within the Oracle Utilities applications (also known as "deep linking"). These links typically leverage Business Process Assistant (BPA) scripts to help navigate the user to the appropriate target portal or page and to make provided parameter values available for use on the portal or page.

Note: This technique may also be used within the product to launch a new browser tab from within the application when it's important to maintain the current screen. For example, launching the GIS Viewer in Oracle Utilities Work and Asset Management by creating a new browser tab.

To do this, parameters are added to the application URL by appending a question mark (?) to the end and using the syntax "key=value". If you require more than one parameter, use an ampersand (&) to separate each key=value pair. There are several predefined parameter key values recognized by the application. In addition, specific parameters understood by the script may be provided. The following list highlights the predefined parameters.

- **location**=<navigation key> - If the exact page to launch is known, the navigation key value of that page can be part of the URL using 'location='. For example, if an approval process has sent an email to a user to approve an adjustment, the link configured in the email may include the adjustment's navigation key.
- **script**=<BPA script name> - In almost every use case, a script is needed to help navigate to the correct page and display the correct information. Even if a location is known and provided in the URL, if there is context data provided as a parameter, it is the responsibility of a script to move that parameter data from the URL into the page data model, so that the page can access the information and display the correct record. In cases where the target page is dynamic based on information provided by parameters, the script may be used to determine what page to launch.

- **portal=true** - When using the location parameter where the target page is a portal page and passing context data, use this parameter. This allows the system to know that the parameter data must be pushed into portal context.
- **initNav=false** - By default, if a script is provided but the location attribute is not provided, the system navigates to the user's home page prior to executing the script. If the script itself includes a step to navigate to a target page as one of its initial steps, the navigation to the home page is unnecessary and may degrade performance. This optional attribute may be included in the URL to bypass the home page.

Note: The system still requires a page to be launched for technical reasons. A blank portal with no zones is used for this purpose. Users may see this portal (called **Launching Application**) briefly before the navigation initiated by the script. In addition, this is the portal that the user will remain on if there are any errors in the script or if the script does not navigate anywhere.

- **minSidebar=true** - This option minimizes the sidebar area as part of launching the application. (The user will be able to maximize the sidebar themselves if needed). You would use this option to potentially improve the speed at which the application is launched. Whether this is useful will depend on the use case. If the reason for launching the application is to bring the user to a specific record to view details about that record, the sidebar may be providing valuable information about the record. In this case, it may be correct to display the sidebar by default (and not include this parameter in the URL). On the other hand if the use case is that a user is already in the application and clicks a link that opens a new browser tab to show the user specific detail about a chosen record, while keeping the original page open on the first tab, the sidebar may contain the same information already visible on the original tab. In this case, minimizing the sidebar may be beneficial.

Note: For backward compatibility, the system still supports the original parameter **minDashboard=true**, which has analogous functionality.

For example, the following URL illustrates launching the script **CM-StopAutoPay** for a given account, assuming the application URL for launching the system is `http://system-server:1234/cis.jsp`:

- **`http://system-server:1234/cis.jsp?script=CM-StopAutoPay&ACCT_ID=1234512345&location=accountMaint`**

It doesn't matter in which order the parameters are provided. The system processes them in the correct order. For example, the following examples are processed by the system in the same way:

- **`http://system-server:1234/cis.jsp?ACCT_ID=1234512345&script=CM-StopAutoPay&location=accountMaint`**
- **`http://system-server:1234/cis.jsp?ACCT_ID=1234512345&location=accountMaint&script=CM-StopAutoPay`**

These parameters are kept in a common area accessible by any script for the duration of the session. To use these parameters on a script you may reference the corresponding `%PARAM-<name>` [global variables](#). In this example, after the system is launched any script may have access to the above account ID parameter value by means of the `%PARAM-ACCT_ID` global variable. Also note, these parameters are also loaded into temporary storage (to continue the example, there would also be a temporary storage variable called `ACCT_ID` that holds the passed value).

Determining the Application URL

When building the link from within application logic, the service script **F1-EnvURL** may be used to retrieve and build the application URL information.

Navigate to a Given Record's Maintenance Portal

The product provides a script **F1-GotoPrtl** (Navigate to portal for an MO and key values) that may be used for any use case that simply navigates to the maintenance page for a given record and displays that record. This script is only applicable to records that are governed by a business object (and define a navigation option as a BO option). It requires the parameters **mo=** with the maintenance object code of the record and the parameters **pkValue1=** through **pkValue5=** for providing the key values. It looks up the appropriate portal navigation option from the record's BO, populates keys into the 'page data model' and navigates to the portal.

It is also recommended to include the **initNav=false** attribute when building a URL with this script. The example below navigates to the appropriate Migration Data Set portal for the given ID's business object.

- <http://system-server:1234/cis.jsp?script=F1-GotoPrtl&pkValue1=1234512345&mo=F1-MIGRDS&initNav=false>

LDAP Integration

Organizations commonly use a Lightweight Directory Access Protocol (LDAP) security repository as a source of security credentials. The system provides support for importing users and groups from an external LDAP repository into the product to populate Users and User Groups in the system. Once imported, all user and group functions are available. You can resynchronize your LDAP users and groups at any time.

Note: Import only. The system currently supports importing LDAP information. Exporting users and groups from the system to LDAP is not provided.

Note: Additional configuration. When importing new users and / or groups, additional configuration is needed in the base product. For example, after importing a new user group and its users, the user group configuration should be updated to define the valid application services for the user group. After importing a new user, additional configuration may be needed on the user such as valid To Do Roles, valid Home Page, etc.

Fastpath: Refer to [Users and User Groups](#) on page 28 for more information about the application security and what it controls.

This section the functionality provided in the framework application that supports LDAP. Refer to the *LDAP Integration* technical reference paper for more information about typical steps related to the full integration.

LDAP Integration Overview

This topic provides a high level overview of the integration process.

At a high level, the base product provides a process to import user group and / or user definitions from and LDAP repository. This is a one way integration.

- When importing a user, if it is not already found in the system, it will be added; otherwise its attributes will be updated according to the imported information.
- When importing a user group, if it is not already found in the system, it will be added; otherwise its attributes will be updated according to the imported information.
- When importing a user, its user group links will be updated as per the information in the import file. In addition, if there are any user groups linked to the user that are not found in the system, they will be added (however, the other users linked to that group in the LDAP repository will not be added as part of this step).
- When importing a user group, its user links will be updated as per the information in the import file. In addition, if there are any users linked to the user group that are not found system, they will be added (however, the other user groups linked to that user in the LDAP repository will not be added as part of this step).
- The import will not cause any deletions of the User or User Group to occur.

A Batch Process Initiates the Import

A batch process is used to initiate the import of information from the LDAP repository. **F1-LDAP** may be submitted ad hoc or may be set up in a scheduler to periodically re-sync the information from the LDAP repository into the application.

The batch process uses parameters to define how to connect to the LDAP repository. In addition, parameters are used to indicate which user or group is being imported.

Adjusting Data to Import

The system provides several mechanisms for adjusting data that is being added to the system:

- There is an **LDAP Import Preprocess** algorithm plug-in spot on the [installation](#) record. Algorithms plugged in here are called by the batch process prior to the add or update of any records. It may be used to make adjustments to the data before doing updates in the application.

- Specifically for creating or updating Users, the **F1-IDMUser** business object is used to add and create the user. The standard BO Preprocessing algorithm plug-in spot may be used to adjust data prior to creation. Note that the system does not support defining a characteristic to support a template user that can aid in populating configuration for a new user. However, this integration can take advantage of using a default template user as an algorithm parameter. Refer to [Template User](#) on page 29 for more information.
- The LDAP mapping file supports some attributes to perform simple modifications to data.
 - The **transform** attribute supports values to truncate values or to convert data to upper case.
 - The **autoGenerate** attribute is specific to the User ID field. Setting this to true will trigger code that will automatically populate the User ID based on the user's name. Refer to [LDAP Mapping](#) for more information.

Performing Additional Processing After Import

The system provides a plug-in spot on the [installation](#) record called **LDAP Import**. Algorithms plugged into this spot are called after users or user groups have been added or updated. It may be used to perform any extra processing that may need to be executed.

Configuring LDAP Integration

To interface the LDAP based security repository with the authorization component of the Oracle Utilities Application Framework product the following must be performed:

- The location and port number of the LDAP based security repository must be defined to in the JNDI Server.
- The LDAP based security repository must be mapped to the Oracle Utilities Application Framework security model. This mapping is expressed as an XML file containing the LDAP query, rules and defaults used in the transformation.
- The mapping file must be configured on the **F1-LDAP** batch job.

Define the JNDI Server

The first step in the configuration process is to define the location of the LDAP based security repository server so that the interface can connect to the physical attributes of the interface. This is done by creating a [JNDI Server](#).

Note: The LDAP server is strictly not a JNDI source but is treated as a JNDI source for the integration.

Enter a reasonable JNDI Server name and description.

Populate the **Provider URL** using the format **ldap://<hostname>:<portnumber>** where **<hostname>** is the host of the LDAP server and **<portnumber>** is the port used for the interface.

For the **Initial Context Factory**, the interface uses the standard **com.sun.jndi.ldap.LdapCtxFactory** provided with java for the LDAP interface. If your vendor supplies a custom context factory it may be used. Refer to the documentation provided with your LDAP based security repository for further information.

Define Mapping

The critical component of the interface is a file that describes the mapping between the LDAP based security repository and the system's security model. This file contains the mapping, rules and queries used by the LDAP batch program to provide the interface. The LDAP batch job includes the reference to the mapping file as a parameter. Refer to [LDAP Mapping](#) for more information on defining the mapping file.

Configure LDAP Batch Process

At this point, many parameters for the **F1-LDAP batch control** can be updated with system wide configuration.

- JNDI Server, User and Password may all be configured appropriately. Note that it is recommended that the **Security** setting for the Password be set to **Encrypt**.
- The **LDAP Configuration File** should be populated with the name and location of the LDAP Mapping file.
- If the LDAP service has any limitation to the number of objects that may be imported, configure the **LDAP Query Page Size** parameter to enable querying.

Note: Group and User Parameters. The assumption is that the Group or User input parameters are specific to a given import request and as such would not be populated as part of a configuration step.

Note: L2 Cache. The LDAP Import batch process requires the L2 Cache to be disabled since it needs to perform some updates in the outside of the worker threads. Any environment using LDAP Import must set `spl.runtime.batch.L2CacheMode=OFF` in the `threadpoolworker.properties` file. It is recommended to run the LDAP import in its own dedicated threadpoolworker.

LDAP Mapping

An LDAP repository consists of multiple entries. Each entry represents an object in the directory that is identified by a Distinguished Name (DN) and may contain one or more attributes. In a typical LDAP repository there is usually an entry for users and an entry for groups. The connection between users and groups may be implemented in two different ways:

- The users belonging to a group are defined in a special multiple-value attribute on the Group entry.
- The groups to which a user belongs are defined in a special multiple-value attribute on the User entry.

The mapping between LDAP security objects and base security objects is stored in an XML document that can be processed by the LDAP import batch job. As part of setting up your system for LDAP import, you need to define this mapping. The base package provides a sample mapping file called `ldapdef.xml` that can be used as a starting point and changed per your business requirements and your particular LDAP repository.

Once you have defined the mapping XML document, this is configured as a parameter in the **F1-LDAP** batch job.

The XML structure:

- The **LDAPEntry** element maps the LDAP entries to system objects (User or Group). The mapping file must contain one and only one LDAPEntry element for User and one for Group.
- The **LDAPCDXAttrMapping** element within the LDAPEntry element maps attributes in the LDAP entry to attributes in the system object.
- The **LDAPEntryLinks** element describes objects linked to the LDAP entry. When mapping the user entity you need to describe how the groups the user belongs to are retrieved. When mapping the group entity you need to describe how the users contained in the group are retrieved.

The following table describes the attributes to define for each element.

Element	Attribute	Description
LDAPEntry	name	The name of the LDAP entry: - Group - User
	baseDN	The base distinguished name in LDAP for this entry.
	cdxEntity	The name of the base product entity to which the LDAP entry is mapped: - Group - User
	searchFilter	An LDAP search filter that is used to locate LDAP entries. A <code>%searchParm%</code> string in that filter is replaced by the value from the user or group parameter from the F1-LDAP batch job submission.

Element	Attribute	Description
LDAPCDXAttrMapping	Scope	Sets the scope of the search. Valid values are: - onelevel (the value normally used) - subtree
	ldapAttr	The name of the LDAP attribute to be mapped. Note that this may be referenced more than once to allow one LDAP element to map to multiple base product elements. For example, if an email address should be used both for the Login ID and the Email Address.
	cdxName	The name of the base product attribute to be mapped. For User, this is the element within the F1-IDMUser business object. For Group, this is either the 'group' or the 'description'.
	default	The default value that will be assigned to the element referenced in the cdxName attribute when one of the following occurs: - The LDAP attribute contains a null or empty value - The LDAP attribute does not exist or is not specified. Default values are applied only when creating a new entity and are not applied to updated entities.
	autoGenerate	Set this to true in order to turn on auto generation of the user ID. If this is true, the system will define the user id as <first initial of first name>+<last name> all uppercase, to a maximum of 8 digits. If an existing user is found for the generated ID, a number will replace the eight digit (or be appended to the end). The system will increment the number until a unique ID is found.
	transform	Use this attribute to indicate if a transformation of the data should occur. Valid values: uppercase truncate . Note that this attribute should not be used in conjunction with the autoGenerate attribute.
LDAPEntryLink	linkedToLDAPEntity	The name of the linked entity (User or Group). Use User when describing the Group entity. Use Group when describing the User entity.
	linkingLDAPAttr	The multiple-value attribute name on the LDAP entity that contains the linked entity.

Element	Attribute	Description
	linkingSearchFilter	<p>The search filter to be applied to retrieve the list of linked objects, for example:</p> <p>(&objectClass=group)(memberOf=%attr%)</p> <p>The search filter may contain the string % attr % that acts as a substitution string and is replaced at run time by the value of the attribute named "attr" of the imported entity. If the LDAP entry you are describing is a Group and the string is %name %, it is replaced by the value of the "name" attribute of the group you are importing. If the LDAP entry you are describing is a User and the string is %dn%, it is replaced by the "dn" attribute of the User you are importing.</p>
	linkingSearchScope	<p>Sets the scope of the search. Valid values are:</p> <ul style="list-style-type: none"> - onelevel (the value normally used) - subtree

Sample Mapping

The following XML describes a sample mapping. The example makes the following assumptions:

- The base product attribute **displayProfileCode** is defaulted to "NORTHAM" when adding a new user.
- The LDAP Group entry contains the list of users belonging to the group in the **departmentNumber** attribute.
- The groups to which a user belongs are retrieved by applying a search filter.

```

<LDAPEntries>
  <LDAPEntry name=" User" baseDN="ou=people,dc=example,dc=com" cdxEntity="
    user" searchFilter=" (&(objectClass=inetOrgPerson) (uid=%searchParm
    %)) ">
    <LDAPCDXAttrMappings>
      <LDAPCDXAttrMapping ldapAttr="uid" cdxName=" user" />
      <LDAPCDXAttrMapping ldapAttr="cn" cdxName="externalUserId" />
      <LDAPCDXAttrMapping cdxName="language" default=" ENG" />
      <LDAPCDXAttrMapping ldapAttr="givenName" cdxName="firstName"/>
      <LDAPCDXAttrMapping ldapAttr="sn" cdxName=" lastName"/>
      <LDAPCDXAttrMapping cdxName="displayProfileCode" default="NORTHAM" />
      <LDAPCDXAttrMapping cdxName="toDoEntriesAge1" default="30" />
      <LDAPCDXAttrMapping cdxName="toDoEntriesAge2" default="90" />
      <LDAPCDXAttrMapping cdxName="userEnable" default="ENBL"/>
    </LDAPCDXAttrMappings>
    <LDAPEntryLinks>
      <LDAPEntryLink linkedToLDAPEntity="Group" linkingLDAPAttr="departmentNumber" /
    >
    </LDAPEntryLinks>
  </LDAPEntry>
  <LDAPEntry name="Group" baseDN="ou=people,dc=example,dc=com" cdxEntity="
    Group" searchFilter=" (&(objectClass=organizationalUnit) (ou=
    %searchParm%)) ">
    <LDAPCDXAttrMappings>
      <LDAPCDXAttrMapping ldapAttr="name" cdxName="Group" />
      <LDAPCDXAttrMapping ldapAttr="description" cdxName=" Description" default="Unknow
    >
    </LDAPCDXAttrMappings>
    <LDAPEntryLinks>
      <LDAPEntryLink linkedToLDAPEntity="User" linkingSearchFilter="

```

```
(&amp; (objectClass=inetOrgPerson) (departmentNumber=%distinguishedName
%)) "
  linkingSearchScope="onelevel" />
</LDAPEntryLinks>
</LDAPEntry>
</LDAPEntries>
```

Oracle Identity Manager Integration

The *Oracle Identity Manager* product allows a site to centralize their user definitions and password rules to manage and deploy across the enterprise set of products. When an employee joins an organization, changes their name or departs an organization their security presence across an enterprise must be appropriately managed. Oracle Identity Manager allows for users to be provision and managed in a central location.

An integration is provided to allow the ability to create, maintain and remove users in the identity management product and sync those changes to the users defined in the application. The following sections provide additional details about the integration with respect to configuration steps required in an Oracle Utilities Application Framework based product. For more information about the configuration required in the identity management product, refer to the *Identity Management Suite Integration* technical reference paper.

In order to use this functionality, [feature configuration](#) options for the **External Messages** feature type must be configured.

- Set option type **Support SPML Deployment in IWS** to **true**.
- Set option type **Default SPML service security policy** to an appropriate value per your implementation rules.

Template User Functionality

The user object in this product captures configuration used to control access but also preferences. The identify management product allows for extending the configuration to capture user configuration that is specific to this product. However, it does not support providing searches or dropdowns to select valid values. For example, to define the user's Home Page requires the reference to a navigation option. To set up your business process such that the home page is configured when defining the user in the identity management product dictates that the security user types in the correct navigation option reference.

On the other hand, to define a minimal amount of user information in the identity management product may result in a two step process for defining users: first define them in the identity management product with the basic authentication details and setting system defaults for some important fields, then after submitting the new user to be added to this product, navigate to the [user](#) page in this product and fill in all the configuration that is specific to this product.

The product provides support for defining a template that can facilitate the definition of users and reduce some of the challenges listed above. Refer to [Template User](#) on page 29 for information about defining template users along with other details around this functionality.

Once you have template users defined, you should look at extending the configuration in the identity manager product.

- Map the information that is unique to a user and in addition, define a field for the template user. For example, you may choose to only capture the Name (first and last), Email address and User IDs for the user along with its Template User (which is mapped to a user characteristic). Additional fields may be included for capture in the identity management product when defining new users as per an implementation's business needs. For example, if the organization covers multiple time zones, perhaps it is easier to define the user's time zone when defining the user in the identity management product.
- When the new user is uploaded to the system, the algorithm used by the system to create the user looks for the existence of a template user sent as a characteristic of type **F1-TMUSR**.
- Once the new user is created, its configuration can now be adjusted, if applicable.

Note: There is configuration needed in Oracle Identity Management to capture the template user and any other information that the implementation has chosen to define in the identity management product when

provisioning a new user. Refer to the *Identity Management Suite Integration* technical reference paper for more information.

Provision Users with SCIM Open Standard

The product provides a REST web service **F1-SCIMUser** (SCIM User Provisioning) that supports adding, changing or viewing details of a user where the API follows the SCIM standard.

The following points highlight some of the mapping between the SCIM API and the application's user record.

- The user record in the application supports only first name and last name. The SCIM standard supports additional detail such as middle name, suffix and prefix. These elements are ignored when adding or updating a user.
- The SCIM standard supports a collection of email addresses. The application only supports one email address. As such, only the first email address is used when adding or updating a user.
- The integration relies on the use of a Template User so that the user is created with appropriate application configuration associated with each user. The system copies application settings from the template user to the new user being provisioned. If the external system is able to support referencing a template user such that it can be provided with the payload, the integration expects the user type element in the API to reference the template user. If it's not possible to provide a template user ID in the user type element, you should define a default template user using an algorithm parameter. Refer to [Template User](#) on page 29 for more information.

Refer to the web service definition for more information about the supported integration.

Template User Functionality

The user object in this product captures configuration used to control access but also preferences. The identify management product allows for extending the configuration to capture user configuration that is specific to this product. However, it does not support providing searches or dropdowns to select valid values. For example, to define the user's Home Page requires the reference to a navigation option. To set up your business process such that the home page is configured when defining the user in the identity management product dictates that the security user types in the correct navigation option reference.

On the other hand, to define a minimal amount of user information in the identity management product may result in a two step process for defining users: first define them in the identity management product with the basic authentication details and setting system defaults for some important fields, then after submitting the new user to be added to this product, navigate to the [user](#) page in this product and fill in all the configuration that is specific to this product.

The product provides support for defining a template that can facilitate the definition of users and reduce some of the challenges listed above. Refer to [Template User](#) on page 29 for information about defining template users along with other details around this functionality.

Once you have template users defined, you should look at extending the configuration in the identity manager product.

- Map the information that is unique to a user and in addition, define a field for the template user. For example, you may choose to only capture the Name (first and last), Email address and User IDs for the user along with its Template User (which is mapped to a user characteristic). Additional fields may be included for capture in the identity management product when defining new users as per an implementation's business needs. For example, if the organization covers multiple time zones, perhaps it is easier to define the user's time zone when defining the user in the identity management product.
- When the new user is uploaded to the system, the algorithm used by the system to create the user looks for the existence of a template user sent as a characteristic of type **F1-TMUSR**.
- Once the new user is created, its configuration can now be adjusted, if applicable.

Note: There is configuration needed in Oracle Identity Management to capture the template user and any other information that the implementation has chosen to define in the identity management product when provisioning a new user. Refer to the *Identity Management Suite Integration* technical reference paper for more information.

User Redirection

The product allows an implementation to support the ability for a customer to authorize a customer service representative (CSR) to view the customer's account information in a customer facing portal (Digital Self Service), to see exactly what the end customer is seeing/experiencing.

When the request for the CSR to view the customer information is received, the following steps occur:

- The security server for the customer facing portal is contacted to obtain a temporary grant code.
- The redirection response returns the grant code and the URL of the target customer facing portal.
- The browser redirects to the user to this URL with the grant code, which is further authenticated and automatically exchanged for an authorization token, allowing the CSR to log in.

Standard security measures with private/public key encryption using JSON Web Tokens (JWT) ensures that only the implementation's enterprise application is allowed to communicate with the implementation's customer facing portal server. The system also provides a plug-in spot to allow for additional information, such as the customer's name and email address, to be included in the call to the security server.

This feature works in conjunction with functionality provided by the enterprise customer application. Refer to the documentation for that product for information about how this feature is supported.

Note: The product has been designed to potentially support other types of redirection besides the mentioned use case by adding another entry in the Redirection Target lookup (F1_REDIRECTION_TARGET_FLG). However, the internally provided services work specifically for the Digital Self Service use case. There is no guarantee that they would work for a different redirection use case. Please contact product support if your implementation would like to implement a different redirection scenario.

Redirection Security Context Plug-in

The product supports a plug-in spot to allow for the system to populate additional keys and values to add to the JWT (JSON Web Token) when calling the external security service.

In addition, the product provides an Extendable Lookup BO **Redirection Security Context (F1-RedirectionSecurityContext)** to define the key mnemonic values. For an enterprise product or implementation to populate additional keys, use the extendable lookup to define the key mnemonics. Then provide an algorithm that uses the available information about the customer and populates the security context keys and values by determining the related data in the system.

Master Configuration

The master configuration **Redirection Targets Configuration (F1-RedirectionTargetsConfig)** defines the information needed to contact the security server to obtain a grant code. It also defines the redirection URL.

Build an Anchor Hyperlink

The service script **Return a Hyperlink to the Redirect Servlet for a given Target (F1TargetLink)** is provided to allow for a link to be placed on a UI map or in a zone to initiate the redirection request. Refer to the service script detailed description in the metadata for more information.

Batch Scheduler Integration

The Oracle Database includes an enterprise wide scheduler to simplify the scheduling of background processes. The scheduler is implemented by the *DBMS_SCHEDULER* package. The product provides an integration with the Oracle Scheduler to facilitate scheduling background processes shipped with the product.

At a high level, the integration with the Oracle DBMS Scheduler supports the following entities:

- **DBMS Program.** A program should be defined for each Batch Control that needs to be scheduled by the DBMS scheduler. A program would typically invoke a batch job, but it could be configured to set certain options instead.
- **DBMS Chain.** A Chain defines a series of steps with dependency rules between them. A step references a program, with the program performing the actual work for that step. A rule is attached to each step to identify

its dependent steps and the condition for when that step should be executed. For example, in a chain consisting of STEP_A and STEP_B, where STEP_B can only start if STEP_A was successful, the rule for STEP_B to start would specify a condition of "STEP_A SUCCEEDED".

- **DBMS Schedule.** A predefined frequency for jobs that need to be run periodically, for example, nightly jobs.
- **DBMS Job.** Defines a plan to perform a specific program or a chain periodically on a specific schedule or ad-hoc.

The product provides a set of business services to maintain these entities as well as submit jobs, manage submissions and report on past submissions. Refer to business services that start with the prefix "F1-DBMS" for more information.

Note: For details on the integration, refer to the *Server Administration Guide* which contains the API. In addition, refer to the technical reference paper *Oracle Scheduler Integration* that provides guidelines for using this integration.

Data Synchronization

Your implementation may need to communicate certain data to external systems. This may be part of a data warehousing requirement or an integration effort. The synchronization process has two main parts. First, the change to the data must be detected and captured. Once that is accomplished, the next step is to manage the communication of that change to the external systems involved. The changes must be captured in chronological order so as to avoid systems going out of sync.

Understanding Data Synchronization

The product supports various options for managing an ongoing synchronization of an entity to an external system. While each integration involves unique business rules, in many cases the process is quite similar and involves the following overall steps:

- When an entity is added, changed or deleted logic determines whether the change is eligible for synchronization and if so a sync request record is initiated to manage the synchronization process. The base product uses the **Audit** plug-in spot on the maintenance object to allow for such logic to be performed when a change is detected to a record for that MO. The framework calls the algorithm defined on this plug-in spot in the event a change to the MO has been detected. Refer to the description of the plug-in spot on [Maintenance Object - Algorithms](#) for more information about when this plug-in is called.
- The processing of the sync request is deferred to batch so that the communication with the external system does not impact the updating transaction. It also ensures that the data being shared with the external system is fully committed to the database.
- When processed, sync request logic manages the following aspects of the process:
 - Determines whether the synchronization is still needed and if not discards the request.
 - Prepares the outbound message with the entity's synchronization details and sends it to the external system.
 - Manages errors and retry attempts as needed.

The following sections describe the various data synchronization options supported by the product.

Accumulative Data Synchronization

The product supports a data synchronization method by which several changes made to an entity may be accumulated and sent together as a single message to the external system.

The following points describe the functionality at a high level:

- When an entity is added, changed or deleted, a snapshot of the entity's data from before the change is captured on one or more sync requests, one for each external system the data needs to be interfaced to. The before-update snapshot is used as a base line for detecting all changes made since then at the time of sending the message to the external system.
- Sync requests are processed by the next monitor batch process.
- The processing of the sync request typically involves business rules that compare the before-update snapshot with the current content of the entity to detect all change made. If changes were made, logic may decide to proceed with the sending the synchronization message otherwise the request is discarded. These rules are also responsible for handling any errors encountered while communicating with the external system and manage retry attempts as needed.

This functionality is supported by logic supplied in the base business object Sync Request (**F1-SyncRequest**). Note that each edge application delivers an appropriate child business object for this BO for each specific synch scenario supported in that product. Some of the functionality below is accomplished using configuration on the parent BO delivered by the framework while other functionality may be delivered by the child BO. In addition, there may be more complex use cases supported by your specific product integration. Refer to your specific application's library of Sync Request business object along with the documentation related to your specific product integration for more information.

The following sections describe key aspects of this data synchronization approach.

Capturing the Change

The base product provides a change data capture (MO Audit) algorithm **F1-GCHG-CDCP** that may be used by maintenance objects that need to be synchronized by this method. This algorithm creates a Sync Request record for the changed record, capturing the MO code and the primary key, if it doesn't find an existing sync request for the same record (and the same business object) in the initial state. The sync request business object used is the one defined in the **Sync Request BO** option on the MO for the record that was changed. If more than one such option exists then multiple sync requests are created.

Your specific product may also introduce additional Audit algorithms to cater for more sophisticated examples.

When creating the sync request record, typically the Sync Request BO will have a pre-processing plug-in that captures a snapshot of the record's data prior to its change. This will be used in subsequent steps to verify that the external system needs to be notified of the change.

Confirming that a Sync is Needed

Once a sync request is captured, there are several steps performed prior to any information being sent to the external system.

Note: This section only highlights key steps. Please refer to the business object configuration, its lifecycle and algorithms for a thorough picture of the full functionality..

- When a Sync Request record is created, its initial state (**Pending**) is configured to be processed by a batch monitor. That way, records are added to the sync request table throughout the day but all are processed together. The MO audit algorithm ensures that a new synch request is not created if a Pending record already exists for a given MO / PK combination (for the same business object). However, it is possible that a record for that MO / PK exists in a subsequent "non-final" (such as **Awaiting Acknowledgement**). This state includes a monitor algorithm to check for that condition and to skip transitioning if another record exists. This is done to ensure that the existing record is fully processed before this new record is processed.
- The next state of the lifecycle is **Determine if Sync Needed**. This step uses an algorithm to take a snapshot (called the 'final snapshot') of the data and compare it against the initial snapshot taken when the record was created. Based on the logic of the algorithm, it may decide to proceed (transition to **Send Request** or to discontinue (transition to **Discarded**).

Communicating to the External System

Once it is confirmed that the sync should occur, a message must be sent to the external system. The following points highlight the basic functionality.

- An algorithm linked to the **Send Request** state. The expectation is that this algorithm creates an outbound message that routes the information to the external system appropriately. The algorithm must determine the external system and outbound message type to use. Business objects for Sync Request support BO options to define the external system and outbound message type to use for this algorithm.
- Once the outbound message is triggered, the record transitions to the **Awaiting Acknowledgement** status. This state is used to hold the sync request from further state transitions until an acknowledgement is received from the external system. Note that this step relies on implementation of a response mechanism from the external system. It is recommended to implement a response as this helps control the chronological flow of information. The product supplies the business service **F1-UpdateSyncRequest** that transitions the sync request to either the next default state (in this case the **Synchronized** state) if a positive acknowledgement is received; or the state associated with

the Rejection transition condition (in this case the **Error** state) if a negative acknowledgement is received. In addition, this state may be configured with a monitor algorithm that detects that a timeout limit has been reached.

- For records that enter the **Error** state, it is recommended to configure an algorithm that creates a To Do entry to alert someone of the problem. Refer to the integration documentation for more information. The state is already preconfigured with an algorithm to complete To Dos when exiting the state.
- The final state **Synchronized** is used to mark the successful synchronizations. However, for more complicated use cases, this state may be used to trigger some additional action. Refer to the documentation for your specific product integration for more information.

Generic Data Synchronization

The product supports a generic data synchronization method by which each change to an eligible entity triggers a synchronization flow that communicates details about the entity to one or more external systems.

The following points describe the functionality at a high level:

- The integration of a specific entity (maintenance object) and an external system is enabled and configured using a **Data Synchronization Control** (F1-DataSyncControl) extendable lookup record.
- Rules supporting the integration reside in a **synchronization script** referenced on the control record.
- When an entity is added, changed or deleted, a sync request may be initiated for each integration according to business rules defined by the corresponding synchronization script.
- Sync requests are processed by the next monitor batch process.
- When the sync request is processed, data is synchronized to the external system according to business rules defined by the corresponding synchronization script.

This functionality is supported by logic supplied in the base business object Generic Data Sync Request (**F1-GenericDataSync**). This business object does not need to be extended to support specific integration rules as these rules reside in the synchronization script associated with each integration's data synchronization control record.

The following sections describe key aspects of this data synchronization approach.

Data Synchronization Control

The **Data Synchronization Control** (F1-DataSyncControl) extendable lookup defines the configuration needed to support an ongoing data synchronization of an entity to an external system. The configuration defines the entity's maintenance object, the external system it is synchronized with and references a synchronization script that manages the specific synchronization rules for this integration. An integration is considered enabled when its corresponding control record is in active status.

The data synchronization script is called in the following modes:

- When the entity is added, changed or deleted, the script is called in **Check** mode to determine whether a sync request should be created for the changed entity and a specific external system.
- When the sync request is processed, the script is called in **Process** mode to prepare and send the outbound message to the external system. Alternatively the script may request to discard the request or indicate that it should be processed later. The latter may be used when there is a need to wait until certain conditions are met before sending the message to the external system.

Note that the configuration for a maintenance object and a specific external system may be overridden by another configuration defined with a higher sequence number.

Confirming that a Sync is Needed

The base product provides a change data capture (MO Audit) algorithm **F1ONGDATASYN** that may be used by maintenance objects that need to be synchronized by this method. The algorithm consults the synchronization script associated with each active integration control record configured for the entity as to whether the external system needs to be notified for this change. Once confirmed, the algorithm creates a Sync Request record for the changed record, capturing its MO code and the primary key, along with the corresponding external system.

Note that the decision as to whether to create a sync request or not is controlled by the integration specific synchronization script while the creation of the sync request is the responsibility of the audit algorithm. As such, the same sync request BO is used for all integrations, with no provision for capturing integration specific details.

It is recommended to design the synchronization script to only approve the creation of a synchronization request when it is needed. This prevents unnecessary creation of sync requests that would otherwise be discarded when eventually processed.

Managing the Synchronization Process

Once a sync request is captured, there are several steps performed prior to any information being sent to the external system.

Note: This section only highlights key steps. Please refer to the business object configuration, its lifecycle and algorithms for a thorough picture of the full functionality..

- When a Sync Request record is created, its initial state (**Pending**) is configured to be processed by a batch monitor. That way, the changes that triggered the request are fully committed before being communicated to an external system.
- When the sync request record is processed, a monitor algorithm calls the synchronization script associated with the corresponding integration's control record to manage the synchronization process. The synchronization script may indicate either of the following:
 - The request is not yet ready to be processed, i.e. it should remain in its current status and get processed again by the next batch run.
 - The request should be canceled. This indication results in the transition of the record to the **Canceled** status.
 - The request was successfully processed. The synchronization script has prepared the outbound message and routed the information to the external system appropriately. This indication results in the transition of the record to the **Sent** status.
- If an error occurs while processing the request, a To Do Entry is raised to capture the error details and the record is set to the **Error** status. Retry processing of the sync request continues with each batch process until the request is either sent or canceled.

Communicating to the External System

Typically the communication with an external system is finalized when the message is successfully sent and successfully processed by the external system. Depending on the specific integration, the message may not be processed right away by the external system but rather queued and processed later. In this situation, the sync request may need to be further acknowledged as successfully processed (set to the **Acknowledged** status) upon an explicit response mechanism from the external system. The product supplies the web service **F1-UpdateAndTransitionSyncRequest** that may be used to process such acknowledgements.

Maintaining Sync Requests

The system provides a Sync Request portal that is used to view the in progress or completed sync request records.

The menu location of the portal depends on your specific edge product. It may be in a Data Synchronization menu or perhaps in the Batch menu. You are brought to a query portal with options for searching. The options may differ based on your specific product.

Once a sync request has been selected, you are brought to the maintenance portal to view and maintain the selected record.

An **Actions** zone may appear to display specific actions. Alternatively, the actions may be displayed directly in the display area of the **Sync Request** zone.

The **Sync Request** zone provides basic information about the sync request record.

Depending on your specific product additional zones may appear.

Operational Analytics

The framework provides several building blocks and tools that the edge applications may use to implement analytic reports directly from the operational application using Oracle Utilities Analytics Visualization product (referred to in this section as the analytics visualization product). The following sections provide more information about this functionality.

Understanding Operational Analytics

The following sections describe the type of configuration supported in your product to integrate with the analytics visualization product. Refer to the Oracle Utilities Analytics Visualization documentation for more information.

Direct Data Access

The analytics visualization product's canvases report directly off of the operational system (with the exception of batch run analytics) thus eliminating the need of an ETL process. Selected tables and views have been designated as dimensions and facts for the purpose of generating the Start Schemas used by these canvases.

Batch Run Analytics

There is a high volume of batch run data in the operational system that changes frequently and is recorded in a complex set of relationships. The product provides snapshot tables to capture only the batch run and thread data required for analytics. Using these tables for batch subject area views both improves performance and supports extracting the data for upload to other environments.

The snapshot tables are populated in increments. The **Batch Run Analytics Snapshot Update** and the **Batch Thread Analytics Snapshot Update** processes are run on an ongoing basis; each snapshot update selects only the batch runs and threads not yet included in the snapshot. Parameters are supplied to restrict the selected data based on a range of days from the current date, to support the initial uptake of data. It is recommended that batch run data is updated before the batch thread data, as only threads with corresponding records in the batch run snapshot will be added. Refer to batch controls **FIBRANSN** and **FIBTANSN** for more information.

The **Batch Run Analytics Data Export** and **Batch Thread Analytics Data Export** processes are provided to extract the batch data in increments for upload to other environments. These processes assume that a **Data Export Control** exists for each of the snapshot maintenance objects, to capture the date of the previous extract as a reference point for selecting the next set of records. Refer to batch controls **FIBRANEX** and **FIBTANEX** for more information.

Calendar and Time Dimensions

Analytic reports rely on calendar and time dimensions to support various hierarchical grouping by date and time.

The Calendar dimension provides a level-based definition of the standard calendar and fiscal calendar in a flattened representation that is commonly used in data warehouses. This is necessary to enabling customers to group by calendar week, months, quarter and fiscal calendar period, quarter and fiscal year etc. Note that fiscal information about a specific date is optional and sourced from your edge application specific accounting calendar

In the same way, the Time dimension provides a level-based definition of each minute in a day, supporting reports that group by hours, AM/PM etc.

Note: Calendar dimension records are generated by a batch process; one record for each date in a specified period of time. You need to run the **Generate Calendar Dimension** batch process on an ongoing basis to cover the standard and accounting calendar days needed to support your business. Refer to **F1-BICDD** batch control for more information.

Note: Time dimension records are also generated by a batch process; one record for each minute in a day. You need to run the **Generate Time Dimension** batch process once to generate all the records. Refer to **F1-BITMD** batch control for more information.

Bucket Configuration

The analytics visualization product provides support for defining a set of ranges, each representing a bucket for which extracted measures can be grouped and classified under the relevant bucket. The framework product provides support for viewing and defining the buckets. Refer to [Bucket Configuration](#) for more information.

Analytics Attribute Mapping

The product supports mapping of characteristics to user defined fields associated with dimensions in the analytics visualization product. Each characteristic table that is associated with a dimension table is provided with pre-generated user defined fields identified by unique column sequence numbers in the analytics visualization product. The mapping of characteristics to dimension user defined fields is maintained directly on the dimension portal. You may also review these mappings using the [Analytics Attribute Mapping](#) portal.

Logical Dimension

The Element Name of a foreign key field to a dimension represents a distinct logical version of the dimension. This allows for different logical dimensions to be based on the same dimension table. For example, a "Location" dimension may be referenced as a "Main Location" on one fact and also as an "Alternate Location" on the same or other fact. While both elements refer to the same dimension as foreign keys, each represent a distinct logical dimension via their element names. In the same way, while each date field is implicitly considered as a foreign key to the Calendar dimension, each distinct element name establishes a unique logical dimension. For example, a "Start Date" element name and an "End Date" element name are distinct logical dimensions of the underlying Calendar dimension.

Some logical dimensions may represent an aggregated or summarized form of another logical dimension. They are also known as "shrunken" dimensions. For example, the "Calendar Month Dimension" view is an aggregated dimension of the Calendar dimension. Establishing a link between a summarized dimension and its detailed dimension allows the analytics visualization tool to drill from one fact to another for performance reasons when they are indirectly linked via the same logical dimension but at different aggregation levels. For example, "Fact A" represents daily records and "Fact B" aggregates the same measures at a monthly level. Associating the "month" field in "Fact B", which is a foreign key to the "Calendar Month Dimension" view, with the logical dimension name of the "date" field in "Fact A" allows analytic queries to use "Fact B" for queries at the monthly level or above which perform better than performing them on the more granular "Fact A".

Analytics Configuration

Depending on which product or products you have installed, there may be some configuration needed for the analytics visualization product. Refer to [Defining Analytics Options](#) for more information.

Calendar and Time Dimensions

This portal is used to view generated calendar and time dimension records.

Refer to [Understanding Operational Analytics](#) for an overview of operational analytic functionality.

Navigate using **Admin > Analytics > Calendar and Time Dimensions**.

The following zones may appear as part of the portal's **Main** tab page:

- **Calendar Dimension.** This zone lists most recent calendar dimension records. You may filter the list to review records generated up to a specific date.
- **Calendar Date.** This zone provides information about a selected calendar date.
- **Time Dimension.** This zone lists all time dimension records.

Maintaining Bucket Configurations

Several key performance indicators in the analytics product look at measurement values (for example: the age of an asset or the age of debt) classified into a number of pre-defined groups also known as buckets. The overall metric can then be reported by the different buckets and allow various analyses.

For example, the age of an asset can be classified into the following buckets:

- Less than 6 Months
- 6-12 Months
- One Year and Older

The age of debt, also known as arrears can be classified onto the following buckets:

- 0-30 Days
- 30-60 Days
- 60-90 Days
- 90+ Days

The definition of the buckets is extracted to the Business Intelligence data warehouse, to be used as dimensions.

Bucket Definition Considerations

Each type of bucket is defined using a bucket configuration Business Object. The bucket definition considerations and/or rules will vary based on the bucket configuration business object used. The business objects available are driven by your specific product. For a list of available bucket configurations business objects, navigate to the business object page and view the business objects for the Bucket Configuration maintenance object.

Setting Up Bucket Configurations

To maintain the bucket ranges for the bucket configuration(s) applicable to your product, open **Admin > Analytics Configuration > Bucket Configuration**.

You are taken to the query portal where you can search for an existing bucket configuration. Once a record is selected, you are brought to the maintenance portal to view and maintain the selected record.

Note: Your specific product may also include an Analytics Configuration portal that displays the list of existing and potential bucket configuration records, allowing you to drill into this page to view the record in detail.

The **Bucket Configuration** zone provides basic information about the bucket configuration.

For more information about the elements supported refer to the zone's help or to the relevant analytics integration documentation for your product.

Defining Analytics Options

Refer to [Understanding Operational Analytics](#) for an overview of the operational analytics functionality.

Your specific product may require some system wide configuration to be defined when using operational analytics.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Analytics Options** business object.

Use the embedded help to review information about the options to define.

Defining Analytics Tables

This portal is used to search for Analytics Table definitions. An Analytics Table record exists for each table or view in the operational system that represent dimension and fact tables in the Operational Analytics product.

Refer to [Understanding Operational Analytics](#) for more information.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Table**. You are brought to a query portal with options for searching for a specific record. Once a record has been selected you are brought to its maintenance portal to view and maintain the selected record.

Defining Analytics Dimensions

This portal is used to maintain metadata for Analytics Dimension tables. A dimension record exists for each table in the operational system that represents a dimension table in the Operational Analytics product.

Refer to [Understanding Operational Analytics](#) for more information.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Table**. You are brought to a query portal with options for searching for a specific record. Once a dimension record has been selected you are brought to this portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page

- **Analytics Table.** This zone provides information about the selected dimension record.
- **Fields.** This zone lists all the fields that define the dimension table. Fields may be selected from the dimension's underlying operation table using the **Excluded Fields** zone or added as computed fields.
- **Dimensions.** This zone lists dimension tables that this dimension references via foreign key constraints.
- **Referenced By.** This zone lists dimension and fact tables that reference this dimension via foreign key constraints.
- **Characteristic Mapping.** This zone manages characteristic mapping extensions for the dimension. Refer to [analytics attribute mapping](#) for more information.
- **Excluded Fields.** This zone lists fields from the dimension's operational table that are not included in the dimension table.

Note: The ability to introduce custom analytics dimensions is currently not supported.

Defining Analytics Facts

This portal is used to maintain metadata for Analytics Fact tables. A fact record exists for each table or view in the operational system that represents a dimension table in the Operational Analytics product.

Refer to [Understanding Operational Analytics](#) for more information.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Table**. You are brought to a query portal with options for searching for a specific record. Once a fact record has been selected you are brought to this portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page

- **Analytics Table.** This zone provides information about the selected fact record.
- **Fields.** This zone lists all the fields that define the fact table. Fields may be selected from the fact's underlying operation table or view using the **Excluded Fields** zone or added as computed fields.
- **Dimensions.** This zone lists dimension tables that this fact references via foreign key constraints.
- **Excluded Fields.** This zone lists fields from the fact's operational table or view that are not included in the fact table.

Note: The ability to introduce custom analytics facts is currently not supported.

Defining Analytics Attribute Mapping

This portal maps extensions to user defined fields provided for tables associated with an analytics dimension table that capture well defined extension data. A common example of this type of data are characteristics.

These mappings may be directly maintained on the operational [Analytics Dimension](#) portal. Refer to [Understanding Operational Analytics](#) for more information.

If your system is integrated with the Oracle Utilities Analytics product refer to [Understanding Analytics Integration](#) for more information about ETL based characteristic mapping.

You can access the portal from the **Admin Menu > Analytics Configuration > Analytics Attribute Mapping**. You are brought to a query portal with options for searching for a specific mapping record. Once a record has been selected you are brought to the this portal to review the information for the selected record.

The **Analytics Attribute Mapping** zone on the portal's **Main** tab page provides information about the mapping record.

Note: For characteristic mapping, only **Adhoc** and **Pre-defined** characteristic types are supported.

Note: For the product provides support for identifier mapping for operational analytics in this release but only the metadata definition is supported. The support for these types of attributes in the operational analytics product is in a future release.

Analytics Integration

The framework provides several building blocks and tools that the edge applications may use to implement integration with the Oracle Utilities Analytics product (referred to in this section as the analytics product). The following sections provide more information about this functionality.

Understanding Analytics Integration

The following sections describe the type of configuration supported in your product to integrate with the analytics product. Refer to the Oracle Utilities Analytics documentation for more information.

Master Configuration

Edge applications that include an integration to the analytics product typically include a master configuration record that captures information needed for the extract, load and transformation step, such as extract parameters. These records are provided by the specific edge products and may be viewed and maintained on the [master configuration](#) portal.

Note that your specific edge application may deliver an **Analytics Configuration** portal that displays the information from the master configuration record along with other analytics related configuration.

Bucket Configuration

The analytics product provides support for defining a set of ranges, each representing a bucket for which extracted measures can be grouped and classified under the relevant bucket. The framework product provides support for viewing and defining the buckets. Refer to [Bucket Configuration](#) for more information.

ETL Based Characteristic Mapping

The product provides objects to allow mapping configuration of characteristics in the product to user defined fields on dimensions in the analytics product. The mapping is used by the extract process to populate target user defined columns with corresponding characteristic data.

This type of mapping relies on configuration in the Allowed Target Dimensions [extendable lookup](#). The extendable lookup is used to define each Target Table in the analytics product that has one or more user defined fields that may be populated with characteristic values. It also defines the valid characteristic entities that may act as the source for the characteristic data.

Note: The framework does not provide any values in this lookup, but edge products that support mapping provide values in this lookup. Please refer to your specific product's integration chapter and refer to the Oracle Utilities Analytics documentation for more information.

Refer to [Defining Analytics Attribute Mapping](#) for more information.

Change Data Capture Using Sync Request

Depending on the specific edge application and version you are using, there may be components of the integration that use Sync Request for the change data capture step. If that functionality applies to your implementation, the following points highlight how to get more information:

- Refer to the administration guide for Oracle Utilities Analytics to confirm if your product integration is using Sync Request for any change data capture functionality.
- Review the Sync Request Business Objects provided by your product for analytics integration.
- Refer to [Data Synchronization](#) for a high level understanding of the process.

Business Flags

It is possible that information detected in one product may be useful or even critical to share with another product. The framework provides functionality for receiving information from an external system that acts as a type of flag or alert that may need investigation. This allows any system to store detected business flags in a common way and share that information with one or more other systems.

Understanding Business Flags

The following is an example of a use case for business flags. Imagine that DataRaker highlights potential theft of service at a certain location. That product may initiate a business flag alert to various products owned by the implementation with a recognized "standard name" for the business flag, such as "TAMPER".

- If Oracle Utilities Meter Data Management receives this business flag, it may initiate a service investigation monitor.
- If Oracle Utilities Mobile Workforce Management receives this business flag, it may initiate a service investigation activity.
- If Oracle Utilities Customer Care and Billing receives this business flag, it may initiate a hold on billing for that location.

Note that the framework product supplies basic functionality to support logic that is common to all edge applications that implement business flag functionality. However it is the individual edge applications that supply more specific functionality (business objects and algorithms) for specific use cases, if applicable.

The following sections highlight functionality supported for business flags in the framework. Refer to the edge application product documentation for more details for supported use cases.

Standard Name

To ensure that Business Flags are universally understood across all edge applications and to simplify integration each Business Flag will have a Standard Name. This is a name that is used by all the products when sending information to each other. That way, if DataRaker product sends Oracle Utilities Meter Data Management a "TAMPER" business flag, it should result in the same functionality as when Utilities Customer Care and Billing sends a "TAMPER" business flag.

Standard Names are defined using an extendable lookup. In addition to common extendable lookup fields, the standard name also references a category and a class. The lookup also supports defining one or more external names, for cases where information is communicated from an external system that does not send the expected Standard Name.

The framework delivers the class values but does not deliver any standard names or category values. Refer to your specific edge application products to verify if any standard names or categories are delivered. Your implementation may configure appropriate standard names and categories based on your business rules.

Business Flag Type Defines Behavior for a Standard Name

Although the definition of the business flag standard names should be universally understood by the various integrated products that support them, each individual product defines what should occur when a business flag with a given standard name is created. This is configured using a business flag type. Only one active business flag type may exist for a given standard name. Business flags that are received from an external system will define the standard name, but will not have knowledge of the specific business flag types defined. The business flag type is determined based on the standard name.

The business flag type defines the business object to use when creating the resulting business flag record. The business object defines the lifecycle of a resulting business flag record.

Business Flag Type Algorithms

The business flag type includes support for algorithms. This allows for an implementation to define a common business object that may be used for different business flag types (if a common lifecycle is followed) but allow for different functionality to kick in depending on the business flag type.

The product supplies a plug-in spot for **Additional Processing** that may be invoked by a business flag that enters the Additional Processing state. Refer to your product's library of business objects to determine if there is an Additional Processing state that supports calling algorithms on the business flag type.

Objects Linked to a Business Flag

There are two types of links between an object in the system and a given business flag.

Affected Entity

Each business flag is associated with a single record in the system that is considered the “affected entity” or the entity that the business flag is associated with. The affected entity is defined by the specific business objects designed for the use cases supported by your edge product. For example, many utility base products may configure service point as the affected entity for its business flag use cases. Each business flag created is linked to a specific service point. Linking a specific entity to each business flag allows for algorithms to trigger functionality for that entity such as an investigation order. In addition, algorithms may be implemented in other business process areas that look for the existence of a business flag and act accordingly.

Related Objects

The business flag supports linking one or more related objects to a business flag to make it easier to trigger functionality or for impacted business processes to look for business flags. For example, when creating a business flag for a given service point, it may be useful to link all the accounts that are currently linked to the service point. Then, if an account oriented process should check for a business flag, it can look directly for a business flag linked to the account in its related object.

Impacted Business Process

The product supplies support for associating one or more impacted business processes to a business flag type. This configuration is used when functionality for that business process is impacted in some way based on the existence of a business flag of a given type. For example, maybe some process is put on hold when a certain type of business flag exists.

Note that configuring a business process on business flag type is not enough to trigger any impact on that business process when a business flag exists. There must also be some logic implemented in the business process functionality itself that knows to look for a business flag for a given record that is configured to impact the business process.

The definition of the business process is at the discretion of the edge application that supplies functionality to support this. For example, the business process could be defined as something broad such as “billing” or could be something more granular such as “billing estimation”. The system supplies an extendable lookup to use for configuring the supported business processes. Refer to the values of the business process extendable lookup in your edge application or to the edge application specific Business Flag documentation for more information about supported business processes.

Dates

A business flag supports two dates: a Business Flag Date/Time and a Business Flag **End** Date/Time

- The business flag date / time is required for all business flags. For some types of business flags only one date is needed.
- For business flags that have a start and end period, the business flag date/time acts as the start date and the other field is the end date.

For a business flag that has a date range, it may be important for functionality implemented for [impacted business processes](#). How the process treats the date will depend on its functionality.

- For some processes, the business flag is essentially expired after the end date has passed. This applies to impacted processes that are only looking at the current status of data in the system. For example, collection processing could be held if there is a business flag currently in effect (where the current date is within the date range). It would never look at historical business flags.
- For some processes where historical data may be relevant, a business flag effective during that same historical period may impact the process. For example if a business flag denotes an outage event for a given time period, perhaps estimated consumption should never be calculated for that time period.

Note that because business flags have a status, the design for the lifecycle of the business objects for the above effective dated use cases must carefully consider the states. For business flags that are considered expired after the end date passes, the BO lifecycle may be designed to transition to a final state after that date such that the record is no longer included in active processing. For business flags that continue to impact processing for a historic period, the BO lifecycle may be designed to remain in a non-final state such that it is clear that the record is still applicable.

Creating Business Flags

Business flags may be created in a system for one of the following reasons:

- A message is received from an external system that initiates the creation of a business flag. In this case, logic in the external system has detected some situation that this product is being alerted about.
- Business logic in this product detects a situation that should be investigated or should act as a flag. In this scenario, there may not be any integration needed depending on the business rules.
- Business logic in this product detects a situation that another integrated product should be alerted about. In this scenario, the business flag record is used to send out information to the integrated product.
- A user manually creates a business flag based on knowledge of the affected entity. For example, a customer service representative may create a business flag as a result of contact with the customer.

Creating a Business Flag from a Web Service

The system supplies both a REST and SOAP inbound web service that may be used for an external system to initiate (or update) a business flag. The REST service is **F1-BusinessInsights**. The SOAP service is **F1-BusinessFlagSync**. In both cases, the web service invokes a "driver" service script whose ultimate responsibility is to determine the appropriate Business Flag Type based on the standard name or external standard name, and therefore the appropriate business object for the new business flag. Because different products may have different logic related to creating a business flag, the service script calls another service script linked to the maintenance object using the Business Flag Sync MO option.

The "driver" service script includes a "contextData" group, which in turn references the data area **F1-BusinessFlagContext**. This data area is to allow for an external system to provide additional information for a given business flag use case. For any integration that requires additional information to be passed in from the external system, a separate data area should be used to define the additional elements; and that data area should refer to **F1-BusinessFlagContext** as its extended data area.

The framework does not supply a Business Flag Sync service script, however individual edge applications supply a service script based on the use cases it supports out of the box.

Note: For products that are continuing to use XAI for external messages, the product also includes an XAI inbound service for the same Business Flag Sync Driver service script. Note that the product recommendation is to discontinue use of XAI and use [inbound web services](#) instead.

Error Handling

If there is a problem in trying to create a business flag based on incoming information, the Business Flag Sync Driver service script creates a special business flag record using the Business Flag Error Business Object. This is also configured on the maintenance object as an option. The framework product supplies the business object Business Flag Error (**F1-BusinessFlagError**) for this functionality. Refer to the business object description and configuration for more information.

Confidence

There may be use cases where a condition is suspected, but not confirmed. The originating system should be able to assign a "confidence" level to the business flag.

For example, Oracle Utilities Analytics Insights or other machine learning platforms will aggregate and analyze large amounts of data to identify potential insights that need investigation. These platforms can initiate a business flag with a **Suspected** confidence.

An application receiving this business flag may adjust the confidence to either **Confirmed** or **Rejected**.

- Setting the confidence to **Confirmed** is the equivalent of a true positive.
- Setting the confidence to **Rejected** is the equivalent of a false positive.

Note that the application that receives a business flag is responsible for acting on the value based on business rules. Any updates to the confidence can be communicated to the other products that received the same business flag, if desired.

Additionally, creating a business flag in the application with a confidence of **Missed** provides a way to denote a missed insight. This is the equivalent of a false negative.

Because a utility implementation may have multiple applications installed that support business flags, the following guidelines are suggested for designing where the confidence flag should be updated.

- If Oracle Utilities Service Order Management is implemented, it has the responsibility of updating the confidence flag and communicating the update to other products.
- Otherwise, the assumption is that Oracle Utilities Customer Care and Billing owns field work orchestration and that it will have the responsibility for updating the confidence flag and communicating the update to other products.

No product logic is provided to enforce the above suggestions, however, the business objects supplied by the different edge applications will support the recommended implementation.

Business Flag Updates from External System

When the product that is responsible for updating the Confidence flag makes a change, it should initiate an outbound message to alert other products. On the receiving side, the same inbound web service and Business Flag Sync service script is responsible for the update. Refer to [Creating Business Flags](#) for more information.

Setting Up Business Flag Configuration

The following topics highlight the general configuration steps required to use business flag functionality. Your specific product may supply additional functionality to support specific use cases for business flags. Refer to your specific product's documentation and the library of business objects supplied for Business Flag in your product for more information.

Standard Name Category Characteristic Type

Define one or more categories for grouping your standard names into logical business groupings.

Navigate to the [Characteristic Type](#) page. Search for and select the Business Flag Category characteristic type (**F1–BUSFC**).

Define desired category values and descriptions to be used for the standard names.

Standard Name Lookup

Navigate to the [Extendable Lookup](#) portal. Search for and select the **External Insights Standard Name** business object.

Define values that are recognized in the external systems that your implementation is receiving business flag details from.

Define a **Category** for the standard name that is appropriate for your product. Note that the category does not have to be in sync with standard name definitions in external products.

Select a **Class** for the standard name that is appropriate for its usage.

Refer to the embedded help for more information about configuring this object.

Business Process Lookup

If your specific product supports configuring business processes that may be impacted by the existence of a business flag, they are defined as an extendable lookup.

Navigate to the [Extendable Lookup](#) portal. Search for and select the **Business Process** business object.

Integration Configuration

The following points highlight configuration required to support receiving business flag information from an external source:

- Define a record for each [External System](#) that the product may be receiving business flag records from. This should be a value known by the external system and provided when new business flags are sent to this product.

When this product should initiate business flag information to be sent to an external system, configure one or more [Outbound Message Type](#) records. For each one, update the External System to configure how each outbound message type is communicated to the external system.

Defining Business Flag Types

Refer to [About Business Flags](#) for an overview of business flag functionality.

To maintain the business flag types applicable to your product, open **Admin > Integration > Business Flag Type**.

This is a standard [All-in-One portal](#).

The information captured on the business flag type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Maintaining Business Flags

This section describes the functionality supported for viewing and maintaining business flags.

Refer to [About Business Flags](#) for an overview of business flag functionality.

Navigate using **Main > Integration > Business Flags**. You are brought to a query portal with options for searching for business flags.

Once a business flag record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Business Flag** zone provides basic information about a business flag. Refer to the embedded help for more information.

Market Transaction Management

This section describes various entities and aspects involved in the configuration and maintenance of market transactions. The framework product supplies basic functionality to support the objects related to market transaction management. However more specific functionality (business objects and algorithms) for specific use cases are supplied by the edge applications.

Understanding Market Transaction Management

Several objects are provided to support market transaction management.

- **Market Message Type.** This object is used to define the different types of market messages, both inbound and outbound and to define the appropriate market message Business Object to use when creating objects of this type.
- **Inbound Market Message.** This object captures the instance of a market message received from an external source.
- **Outbound Market Message.** This object captures the instance of a market message that will initiate a message to an external source.
- **Market Process Type.** This object is used to define configuration related to processes that may be initiated to support steps that should be execute to support an inbound or an outbound market message. It defines the market process Business Object to use when creating market processes of this type. It may also define one or more market process event business objects to initiate events that are generated to support steps within the market process.
- **Market Process.** This object captures the instance of a market process that may be created to carry out business logic related to a specific inbound or an outbound market message.
- **Market Process Event.** This object is used to orchestrate individual events that may occur to support steps in a given market process.
- **Market Configuration.** This object may be used to capture configuration needed to support market transactions. Each type of configuration should use a Business Object to define what information needs to be captured.

Each type of configuration may define up to five key fields that may be used to uniquely identify an individual configuration instance.

Configuring Market Transaction Management

The following sections describe market transaction management configuration options.

Defining Market Configurations

Each market configuration is used to define one or more options for a given type of configuration (based on a delivered business object).

The product defines a generic set of portals, described here, that may be used to define any type of market configuration. However, it may be that your implementation includes more specific configuration portals for certain types of market configurations.

Open this page using **Admin > Market Transaction Management > Market Configuration**.

You are brought to the **Market Configuration Query** where you need to search for the market configuration (i.e., its business object).

Once you have found the appropriate market configuration, select the value and you are brought to a standard [All-in-One](#) portal that lists the existing values for the market configuration. The standard actions for an All-in-One portal are available here.

Defining Market Message Types

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Admin > Market Transaction Management > Market Message Type**.

This is a standard [All-in-One](#) portal.

The information captured on the market message type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Defining Market Process Types

This page is used to define market process types which control behavior of the resulting market processes and the valid market process events that could be triggered as a market process progresses through its lifecycle.

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Admin > Market Transaction Management > Market Process Type**.

This is a standard [All-in-One](#) portal.

The information captured on the market process type depends on the business objects supported by your product. Refer to the embedded help text for more information.

Maintaining Market Transactions

The following sections describe various pages available to view and work on market transactions.

Maintaining Market Processes

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Main > Market Transaction Management > Market Process**. You are brought to a query portal with options for searching for market processes.

Once a market process record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Market Process** zone provides basic information about a market process. Refer to the embedded help for more information.

Related Objects

The related object tab includes several zones that display various objects that may be related to the market process.

Related Market Messages and Processes

This zone displays any entries in the related object collection that are outbound market messages, inbound market messages or market processes.

Related Processes

This zone displays market processes that are linked to this market process using the explicit related process table. The market processes linked here are marked either as a parent, a child or a sibling market process.

Other Related Objects

This zone displays market process events linked to this market process. In addition, the zone displays any miscellaneous objects that are linked to the market process in the related objects collection, besides outbound market messages, inbound market messages and market processes.

Maintaining Market Process Events

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

You can view this page when drilling into a market process event from the [Market Process](#) related objects tab.

Once a market process record has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The **Market Process Event** zone provides basic information about a market process. Refer to the embedded help for more information.

Related Objects

The related object tab includes a zone that displays all entries in the market process event's related object collection.

Maintaining Market Messages

Refer to [Understanding Market Transaction Management](#) for an overview of market messaging functionality.

Open this page using **Main > Market Transaction Management > Market Message**. You are brought to a query portal with options for searching for market messages. Both inbound market messages and outbound market messages may be queried here.

Once a market message record has been selected, you are brought to the appropriate maintenance portal (inbound market message or outbound market message) to view and maintain the selected record. The inbound market message portal and the outbound market message portal have similar portal tabs and zones.

The **Market Message** zone provides basic information about the market message. Refer to the embedded help for more information.

Related Objects

The related object tab includes several zones that display various objects that may be related to the market process.

Related Market Messages and Processes

This zone displays any entries in the related object collection that are outbound market messages, inbound market messages or market processes.

Other Related Objects

This zone displays any miscellaneous objects that are linked to the inbound / outbound market message in the related objects collection, besides outbound market messages, inbound market messages and market processes.

Content Migration Assistant (CMA)

This chapter describes the Content Migration Assistant (CMA), a facility to enable the export of data from one environment to another.

CAUTION: This chapter is intended for users responsible for creating environments for testing.

Understanding CMA

The Content Migration Assistant (CMA) provides implementers with a flexible, extensible facility for migrating data from one environment to another (e.g., from a development environment to a production environment). Data is exported from the source system to a file. The file can then be checked in to a version control system for reuse, or can be immediately imported into the target system and applied.

Note: As used in this chapter, *source* systems are those on which export-related activities are conducted and *target* systems are those on which migration updates are to occur.

The following points highlight some common use cases for using this tool:

- Seeding a newly created environment with configuration data. For example, if you are creating test environments, you can import configuration data from a development environment. In this case, you will probably set up a "copy all configuration" type of migration. Another use case is if you want to troubleshoot an issue in production, you may want to copy all production configuration to a test environment.
- Updating an existing test environment with new configuration or updates to configuration from a development environment. In this case your set of objects will be more targeted and you are doing more of an incremental migration.
- Promoting tested configuration to your production environment.
- Migrating selected master and transaction entities from one environment to another for testing purposes.

Here are key aspects of the import process that apply to all cases:

- When records exist in both the target and the source, the CMA tool will fully **replace** the object with the version from the source. Special consideration should therefore be given to records whose **primary key is system generated** to ensure the correct entity is being replaced.
- While typically the source version of an object is applied directly onto the target environment, CMA does provide a way to [Adjust Imported Data](#).
- The import process **does not handle deletion** of records in the target environment. When importing records from a source environment to a target environment, the import process for the migrated records is able to identify objects to add and objects to change. There is no mechanism for indicating that records in the target environment should be deleted. The absence of those records in the import is not enough because the migration may be only importing a subset to add or update. If data on the target system must be deleted, users must delete the records in the target accordingly. Note that CMA does orchestrate the deletion of child rows of an object as a result of a comparison. This is only applicable to child records that are owned by the implementation.

Note: You may review and delete previously imported configuration entities using the [Configuration Deletion](#) on page 548 portal.

Configuration steps are mainly used to define the data to migrate at the source system but also involve tasks to be performed at the target environment. Note that the products provide base delivered configuration that may be used as is or used as a template for building more specific configuration for a given implementation. At a high level, configuration tasks involve the following entities:

- System wide settings are defined in the **Migration Assistant Configuration** master configuration record.
- Each type of record that may be copied requires a **Migration Plan**. The migration plan is used to identify the maintenance object (MO) for the record (using a business object) and allows for instructions to specify related records that may be included in the migration.
- A **Migration Request** is used to define the data to include in a given migration export.

Refer to [CMA Configuration](#) for more information.

Once you have a migration request defined to include desired data to export, the next steps are to export from the current environment and import to the target.

- The **Export** process includes all the steps needed to select records to be exported from the source environment and create the export file. For more information, refer to [Exporting a Migration](#).
- The file created by the export, which is a BINARY file, needs to be transferred from the export directory to the import directory. The transfer needs to be done in such a way as to preserve the file structure. Refer to [Additional Migration Considerations](#) for more information.
- The **Import** processes include all the steps needed to read an imported file, compare the data in the file to the data in the target, review the proposed changes and apply the updates. For more information, refer to [Importing and Applying a Migration](#).

The topics in this section provide a general understanding of the Content Migration Assistant (CMA) tool.

Types of Migrations

The Content Migration Assistant is used for two general types of migrations: wholesale and targeted. The following topics provide some additional information about these concepts.

Wholesale Migrations

Wholesale migrations are used when migrating all the configuration and/or administrative data from one environment to another. For example, a wholesale migration might be used when migrating administrative data from a development or test environment to a production environment.

A wholesale migration may be comprised of one or more migration requests that in total include all the administrative data to move. Migration plans used in wholesale migrations may be designed to omit subordinate instructions related to explicit foreign keys that are identified through constraints as they are not needed, assuming that the data they are referring to will also be included in the migration.

With the ability to group migration requests, the expectation is that implementations follow these guidelines:

- Multiple migration requests using the Criteria-based or Entity List migration request classes are used to group information logically together to allow for more reuse.
- A Group migration request is used for the export. This allows for one data set to export and one data set on the import side, simplifying the process. Note that depending on the amount of data, this may be a large import set to process. An implementation may find it easier to create multiple migration requests that break down the process into several steps.

You should consider that the framework product provides base migration requests and your specific edge product may provide base migration requests as well that may or may not include framework migration plans. Using the product provided migration requests is beneficial with respect to maintenance. As features are added to the product (including new administrative maintenance objects), any impact on CMA should be included in the product owned migration requests. If your implementation introduces new custom administrative maintenance objects that should be included in CMA, then custom migration plans and a custom migration request should be added. Your implementation can build a Group migration request that includes the base migration request and your custom migration requests to have a consolidated export.

Note: Refer to [Framework Provided Migration Objects](#) for information about migration requests provided in the framework product. Refer to your specific product's documentation for information about addition base provided migration requests.

Targeted Migrations

A targeted migration refers to migrating a specific subset of data from one environment to another. Migration plans used in targeted migrations are designed to be self-sufficient and include all necessary subordinate instructions needed to ensure that the exported entity can be imported without encountering referential integrity errors. With this type of migrations, any relationship explicitly excluded from the migration plan assumes the related entity already exists in the target environment. Examples of targeted migrations include:

- Migration of a new portal, its zones, and its application service.
- Migration of all outbound message types.
- Migration of selected accounts and their related master and transactional entities to a lower environment for testing purposes.

Migrating Configuration Data

A main use of CMA is to migrate configuration data, where the source environment is considered a kind of system of record and the target environment is getting updates based on changes to the source environment. Alternatively, you may be seeding a new environment. The expectation is that the target record is updated to look like the source record.

Configuration data may include a mixture of records that have an owner flag and ones that do not. The comparison step of the import process will generate appropriate insert or update SQL statements for the following data found in the export:

- Configuration data in a maintenance object with no owner flag. This is purely implementation data.
- Configuration data in a maintenance object with owner flag, where the owner is **Customer Modification**. For example, implementer-specific business objects.
- Configuration data in a maintenance object with owner flag, where the main record is owned by the product but where a child record exists with an owner of **Customer Modification**. For example, implementer-specific algorithms added to a base owned business object.
- Customizable fields in a record that is owned by the product. For example, the priority of a based owned To Do type.

Migrating Business Data

CMA may be used to perform a targeted migration of selected master entities and their related transactional data from one environment to another. For example, migrating a subset of accounts and their related data for testing purposes.

The following points highlight key differences between business data and configuration data that call for special considerations when designing your business data migrations:

- Migration of business data typically involves a much higher number of records in a data set compared with a configuration-only data set. While there is no explicit limit to the size of a data set, some reasonable limit has to be assumed.
- Having large sets of entities depend on relatively few entities in the same data set significantly slows the import process. This situation occurs when mixing configuration data, master data and high volume transaction data in a single migration. We therefore recommend designing separate migrations for these data classes. Refer to the **Reduce Dependency Between Migration Objects** section below for more information.
- All business entities have a system generated key. Refer to [Data with System Generated Primary Keys](#) on page 516 for more information.

The following sections expand on topics and concepts related to business data migration.

Reduce Dependency Between Migration Objects

CMA leverages the application's referential integrity and business rules to ensure entities remain compliant and valid when imported into another environment. These rules are there to prevent an entity from being imported when any of the entities it references do not exist in the target environment. When both the referencing entity and the entity it references are part of the same data set they establish a **dependency** that dictates the sequence in which these entities should be processed in order to be successfully imported. Note that the tool supports even the more complex and rare situations wherein the dependency between entities is cyclical, i.e. entity A (directly or indirectly) refers to entity B while entity B (directly or indirectly) refers back to entity A, for which sequential processing is not enough to guarantee a successful import.

The tool uses foreign key relationships between entities in the same data set to identify sets of dependent entities and group them into separate migration transaction records. Note that these foreign keys are defined in the application's [data model](#) repository and not at the database level for greater flexibility. The larger the migration transaction the more complex the process is to successfully import all its objects. So while the tool is designed to support all types of dependencies (sequential and cyclical), handling very large sets of dependent objects may incur a significant performance cost.

While configuration entities tend to be highly inter-dependent, the total number of entities that comprise the entire set of configuration objects is relatively small. Therefore, the impact on performance such dependencies have when importing a configuration-only data set is negligible. On the other hand, configuration entities tend to be referenced on many master and transaction entities as they control many aspects of the latter's business rules. As such, mixing configuration and business data in the same data set is likely to form extremely large sets of business entities that dependent on a small number of configuration entities. It is therefore strongly recommended to import or set up configuration data in the target environment prior to importing business data into it.

In a similar way, some transactional data tends to be of a much higher volume compared to the master data entities they reference. Here too, it is strongly recommend to migrate master data entities prior to their high volume related transactional data. For example, many interval measurement records (transaction data) reference the same measuring component (master data). Migrating a large volume of measurement data along with their measurement component

would result in a very large migration transaction that may take long to import. Importing the measurement components prior to migrating their interval measurements will eliminate unnecessary dependencies within the measurements only data set and significantly improve the performance of the overall process.

Reasonable Data Volume

The overall volume of all business entities to migrate in a single data set should be reasonably sized. For example, importing several hundreds of accounts and their related master and transactional data is considered a reasonable size. Migrating too much data may reach physical and performance limitations of the tool.

You may use any supported migration request methods for describing the entities to export. If you opt for an Entity List migration request, consider using the [Collect Entity](#) zone to build the list of entities as you browse them on their respective portals.

Single Source of Data

CMA uses an entity's prime key to determine if it is new to the target environment and therefore should be added or refers to an existing record and therefore needs to be replaced with the new version. All business entities have system generated keys, which are environment specific. It is therefore possible to have different entities in separate environments having the same prime key. When migrating entities whose keys are system generated, it is strongly recommended to migrate data to a target environment from a single source environment and avoid creating such entities in the target environment using the application. This practice ensures that prime keys for an imported entity are always in sync with their source environment. Refer to [Data with System Generated Primary Keys](#) on page 516 for more information and considerations.

No Deletion

CMA does not handle deletion of entities of any kind, whether they are configuration or business entities. If a test needs to be repeated using an initial snapshot of the data, you should restore your target environment to a backup taken before test data was imported and import the latest version of the test data. If there is no need to delete previously imported entities, you may keep reloading test data from a single source environment as needed.

Bulk Import Mode

By default, the import process creates a migration object for each imported entity. This allows for granular reporting and error handling at the entity level. When importing a high volume data set of business entities, this granular management has a performance toll. In this situation, you may want to use the **Bulk Import** option on the migration data set import request. In this mode, a single migration object record is created for multiple entities of the same maintenance object. In the same way, a single migration transaction record is created for multiple logical transaction groups. Using this option reduces the migration object management effort throughout the process and thus results in better performance.

Note that each entity is still individually compared and validated, as in regular import processing, but if one entity is invalid the entire migration object is not applied hence impacting all entities grouped together with it. Bulk import mode is useful when importing a large set of data from a validated data source such that almost no errors are anticipated.

This option is only supported for master and transaction maintenance objects, i.e. it is not applicable to configuration migrations.

Insert Only Mode

By default, the comparison step of the import process needs to determine whether the imported entity is new and therefore should be added, represents a change to an existing entity and should be updated or the entity is unchanged. When importing a high volume data set of business entities that are all new to the current environment, this check is time consuming and can be avoided. In this situation, you may use the **Insert Only** option on the migration data set import request to indicate that all imported entities are assumed to be new additions to the current environment. By doing so, the import process avoids unnecessary steps to determine whether the entity should be added or updated and thus contributes to a faster import process.

This option is only supported for master and transaction maintenance objects, i.e. it is not applicable to configuration migrations.

Separate Batch Processes for Managing Business Migration Objects

By default, the same import related batch processes manage configuration and business data migrations. Typically, business data migrations involve high volume of records compared to much lighter configuration data sets. Processing them together by the same batch process may slow down the performance of configuration migrations, preventing them from completing faster and more frequently. The issue mainly affects test-like environments where mixed data class migrations are more common: configuration data is imported from a lower environment and large test data is imported from a higher environment. You may adjust the base product's configuration in such environments to benefit from separating the import processes for configuration and business data.

Note that the ability to separate import processes applies to migration objects only because of their volume. Migration data set and transaction records are of low volume and as such remain managed by the same batch processes.

Designated batch processes are provided for importing migration objects containing business data but they are not used by default:

- F1-MGOPB - Migration Object Monitor (Business)
- F1-MGOAB - Migration Object Monitor (Business) - Apply

Follow these steps to use these separate designated batch processes for business data:

- Update the **Migration Object Business Data** (F1-MigrObjectBus) business object to reference the business data related batch controls on the following statuses:
 - **Pending, Error Applying, Needs Review** - Migration Object Monitor (Business) - F1-MGOPB
 - **Approved** - Migration Object Monitor (Business) - Apply - F1-MGOAB
- If your organization uses event driven job submissions for CMA batch processes then refer to [Running Batch Jobs](#) for additional configuration steps.

Data with System Generated Primary Keys

For records with system generated keys, there is an issue if the target environment already has a record with the same key but doesn't represent the same record. The tool shouldn't be just updating that target record with the view of the source in case this will break foreign key relationships that exist in the target.

The tool provides support for administrative data with system-generated primary keys. The logic relies on the maintenance object to use a method that looks at other attributes of the record (considered a "logical key") to detect whether the record being migrated already exists in the target region or not. The examples in this section are based on the Attachment maintenance object. Common attachments are considered administrative data. The attachment MO uses the file name and the creation date as the "logical key".

Imagine a common attachment for the "standard rate codes" file exists in a source region with the key 123456789. The table below highlights possible situations at the target region and actions supported in CMA.

Scenario	Target Situation	Action	Comments
1	No matching record	Record can be added with key 123456789.	
2	Record exists with key 123456789 and logic confirms that it is also the "standard rate codes" attachment.	Record can be updated.	
3	Record exists with key 123456789, but logic detects that it is not the "standard rate codes" attachment.	Record is not updated. An error is issued.	The system cannot update this record because it's not the right attachment record.

Scenario	Target Situation	Action	Comments
4	The system detects that another attachment record exists for the "standard rate codes" attachment with a different ID.	Record is not updated. An error is issued.	Assumption is that the record was created directly in the target or was copied from a different source.

The use cases described in scenarios 3 and 4 above would require key mapping to keep track of the id from the source to the id in the target so that any other records from the source that reference this key as a foreign key would be updated as part of the migration. This functionality is not supported.

Scenarios 1 and 2 above are supported for maintenance objects that use the method to detect the logical key.

Note: If a maintenance object with a system generated key does not supply a method to detect the logical key, CMA will update an existing record with the same ID. For maintenance objects in the framework that provide this method, refer to [Framework Provided Migration Configuration](#). For your specific edge application, refer to the CMA addendum for information about support for data with system generated keys.

The product recommends that an implementation establishes a migration strategy such that records with system generated keys are always created in the same region and always follow a standard migration path for promoting the data from this source region to other regions. Following this strategy, you would minimize or eliminate the possibility that a record for the same logical key is created in multiple places such that different IDs would be generated as described by scenario 4 above.

MOs with a Mixture of Administration and Non-Administration Data

There are some MOs that contain a mixture of master or transaction data and administrative data. The Attachment is an example of this. The product supports common attachments and owned attachments. Owned attachments are records that are specific to its owner. The owner could be master or transaction data and its attachments are therefore considered master or transaction data. Owned attachments are not candidates for migration using CMA. Common attachments on the other hand are considered administrative data and may be candidates for migration using CMA. For these use cases, an implementation may follow the suggested strategy of only creating the administrative data in one region so that IDs for common attachments are not reused. However, it is reasonable and expected that owned attachments are being created in the target region and may receive a system generated key that matches the key of a common attachment from the source region.

To try to minimize this issue, the system includes special logic to be used by any MO that may contain administrative data mixed in with master or transaction data. This special logic generates the key of an administrative record with a zero (0) in the middle of the key and ensures that the keys for master and transaction data do not include a zero in this spot. For maintenance objects in the framework that use this method, refer to [Framework Provided Migration Configuration](#). For your specific edge application, refer to the CMA addendum for information about additional maintenance objects that may be in this category.

Importing Data that References a User

Although the tool supports copying users from one environment to another, the assumption is that it will be more common for implementations to define their valid users for each environment separately. In fact, the default CMA configuration for copying security configuration assumes that users are not being copied.

There may be times were a record is being copied from one environment to another where a user is referenced on the record but that user is not valid in the target environment. For example, if a batch control is configured as Timed with a user referenced, if this batch control is copied to another environment, what should happen if that user is not found? You may not want that user defined in the target environment. To handle this, the product provides support for a Default User that you can define in the [migration assistant configuration](#). If this default user is configured then any time the CMA import process recognizes that a record references a User and the user does not exist in the target environment, it updates the record to instead refer to the default user.

Note: Please note that if you are trying to copy entities that includes valid users, you should ensure that all the users are copied to the target environment first. Otherwise, the entity will be updated to refer to the default user, which may not be your intention.

Note: If you copy records that reference a User within an XML field or CLOB, the CMA input tool is not able to detect that. A pre-compare algorithm is recommended if this use case exists in your implementation.

Additional Considerations

The following sections describe some additional considerations for CMA.

File Transfer Considerations

When moving the export file between systems, use the binary transfer option of whatever tool you use to move the file so that line-end characters are not converted from Linux-style to Windows-style or vice versa.

It is recommended to avoid using 'txt' for the export file's extension (defined in the [master configuration](#)). That file extension by default implies a non-binary file and tools that perform file transfer may treat this as a non-binary file unless explicitly stated. The recommendation is to define 'cma' as the extension. This is not a recognized file extension and most file transfer tools will transfer the file as is.

Note that if the file gets converted, there are two likely outcomes - either a numeric conversion error, or a buffer under-run error may be received when attempting to import the file.

Multi-Language Environment Considerations

If your implementation uses a language other than English, it means that migrated administration objects may have multiple language rows (because English is always enabled). There are some important points with respect to multiple languages and CMA:

- As described in [User Language](#), there are steps to follow when supporting an additional language. The steps outlined in that topic highlight that for system data, translation of the strings may be provided via a language pack provided by the product or may be the responsibility of your implementation. In either case, this effort is non-trivial and will have its own established plan. The expectation is that the translation of the system data is applied for each region at your implementation site. CMA should not be used to create a new language in a target region.
- For administrative / control data that your implementation develops as part of your project, the expectation is that descriptions for your supported language are entered in the region that is considered the source region used to promote changes to regions in the "chain". For example, control data is entered in a development region and promoted to a test with the supported language enabled in both regions.
- What if you export data from a region with more languages enabled than your target? This scenario is perhaps a case where the source region is a type of test or playpen region where the additional language is enabled for other purposes. In this case, if the language code doesn't exist at all in the target region, the import will produce an error given that the code is invalid. If the language code exists but is not enabled, this will cause the extra language rows to be inserted in the target region, but will not cause any issues. They are simply ignored.
- What if you export data from a region with fewer languages enabled than your target? In this situation, the import process will only create language rows for the languages that were copied from the source. It will not automatically create language rows in the target as part of the import. For this situation, the recommendation is to run the **New Language** batch program (**F1-LANG**) that creates any missing language entries.

Versions and CMA

This topic addresses two separate version related topics with respect to using CMA between two environments.

- Different versions of the application
- Different CMA file format versions

Different Versions of the Product

CMA was developed with the main requirement of copying data between two environments that are on the same version of the product. For example, copying configuration data from a development environment to a test environment on the same product version.

In general, there isn't anything about how CMA functions that would limit your ability to copy data between two different versions of the product. However, it's possible that your product has enhanced the functionality of a specific

object to add or remove columns or change the type of data captured in those columns or has changed the validation around how data should be captured.

Our products follow strict standards for upgrading clients to ensure backward compatibility. Upgrade scripts in the blueprint process know what was changed from one release to another and update the data accordingly where applicable. When using CMA to move data from one version of the product to another, you are bypassing these upgrade scripts. It means your data is not being adjusted as expected. It's not recommended unless you are certain that the data of an object from one version is compatible in the other version. The following points highlight this in more detail.

- For objects whose structure and rules have not changed between the two versions, there should be no issues.
- For objects that have changed between the two versions, there are scenarios that may cause additional steps.
 - If the target environment is a later version and includes a new optional column on an object that was not present in the source, the import should go through without any issues.
 - If the target environment is a later version and includes a new required column on an object that was not present in the source, a 'pre-compare' algorithm could be used to populate the new required value. Your implementation can provide this algorithm to populate the data according to your business rules.
 - If the target environment is an earlier version than the source, we cannot guarantee that there won't be specific issues encountered with specific objects.

File Format Version

If your implementation has decided that you are going to use CMA across product versions, given all the cautions described in the previous section, this section provides information on the rare case where CMA has a change in who it writes the export file.

When creating the export file, the format of the file is specific and the CMA import step knows how to read the file. It is rare, but there are times when the product makes an enhancement to CMA that requires a change in the structure of the export file at which point the 'version' of the CMA file is incremented.

The CMA file format version has no impact to migrations that are exported and then imported into the same version of Oracle Utilities Application Framework. However, if your implementation has different environments on different versions of the product where the CMA file format is also different, then the system has functionality to cater for these differences.

- If you are exporting data from a lower file format version to a higher file format version, there is nothing special that you need to do. The export step captures the file format version and the import step reads this information and processes the file accordingly.
- If you are exporting data from a higher file format version and the product currently supports exporting to a lower file format version, at export time you are prompted for the earlier file format version. You may indicate the you want the earlier file format version when creating the migration data export.

Note: The product supports exporting to an earlier file format version for a reasonable amount of time, but not in perpetuity. If you don't see any option in the user interface to export to an earlier file format, it means that it is not supported in that release.

CMA Configuration

The following sections describe tasks required for CMA configuration.

Master Configuration - Migration Assistant

The **Migration Assistant Configuration** [master configuration](#) record defines system wide configuration used in both the source environment and the target environment.

As described in [Importing Data that References a User](#), if you have records being imported that may reference a user does not exist (and shouldn't exist) in the target environment, define a Default User here.

In both the source environment and the target environment, the system needs to know the location of the export directory and the import directory along with the expected file suffix. For these fields, implementations may also rely on the system defaults. If no Migration Assistant Configuration record is found, the system assumes that there is an entry defined in the system's substitution variable list for **F1_CMA_FILES**. Further it defaults the values as follows:

- Export directory is the value for this variable plus "**\export**".
- Import directory is the value of this variable plus "**\import**".
- File suffix is set to **cma**

Refer to [Referencing URIs](#) for more information about the substitution variable list.

For additional information about specific fields in the master configuration, refer to the embedded help.

Note: This record can be updated at any time to change details. The new configuration takes effect on all subsequent exports and imports.

Migration Plans

A migration plan defines one or more types of objects that are eligible for migration. It is essentially a set of instructions describing how the data to be exported is structured, allowing objects to be migrated together as a logical unit to ensure consistency and completeness.

The migration plan is always related to a given maintenance object, defined using its primary instruction. Multiple migration plans may exist for a given maintenance object if there are different requirements for migrating records in that MO under different circumstances. For each migration plan, you decide if additional data should be included as part of an object using subordinate instructions. For example, when copying a single algorithm type, should the system only copy that algorithm type record, or should it also copy all its algorithms and its related script (if applicable)? Refer to [Types of Migrations](#) on page 512 for more information.

The following topics describe defining a migration plan as well as other topics for a migration plan.

Defining a Migration Plan

To view or define a migration plan, navigate using **Admin > Implementation Tools > Migration Plan**.

Use the **Migration Plan Query** portal to search for an existing migration plan. Once a migration plan is selected, you are brought to the maintenance portal to view and maintain the selected record.

CAUTION: Important! If you introduce a new migration plan, carefully consider its naming convention. Refer to [System Data Naming Convention](#) for more information.

The following points provide information about defining **Instructions** for a migration plan.

The **Instruction Sequence** uniquely identifies the instruction. The recommendation is to use increments of 10 to allow insertion of other instructions in the future.

Select **Primary** for the first **Instruction Type**. All migration plans must contain one and only one primary instruction. All subsequent instructions require a **Subordinate** instruction type. In this case, the **Parent Instruction Sequence** must be entered. This number, used to maintain the defined relationships in the exported data, must match an instruction sequence number at a higher level in the hierarchy.

The instruction **Description** provides a business description of the instruction.

Select a **Business Object (BO)** to define the type of object from which data will be derived.

Note: Though BOs are specified in each instruction, it's important to understand that each BO is used only for filtering purposes. The migrated data set comprises the complete contents of the *maintenance object* that the business object structure is defined against. For a more detailed explanation of this, see [Understanding the BO Filtering Process](#).

Note: Refer to [Identifying Tables to Exclude From Migrations](#) for information about defining child tables to always exclude from a migration.

Traversal Criteria is used to define the relationship between each of the objects in a migration plan. The system provides three options to define how the child object is connected to the parent object so the system knows how

to traverse from one object to another. **Traversal Criteria Type** options are **Constraint**, **SQL** and **XPath**. The following points explain each option:

- **Constraint** allows you to select a table constraint that represents a given record's relationship to another record in the system via a foreign key constraint defined in the meta-data. If **Constraint** is selected, the following additional fields are enabled:
 - **Constraint ID** is a unique identifier for the constraint. The search will show the valid table constraints for the MO of the instruction's BO and the MO of the parent instruction's BO.
 - **Constraint Owner** is used to define the owner of the constraint. This is populated automatically when selecting a constraint from the search.
- **SQL** lets you specify SQL join criteria between the parent instruction's object and the child object in the **SQL Traversal Criteria**. The syntax of the the traversal criteria is a WHERE clause (without including the word WHERE). When referring to a field on the parent instruction's object, use the syntax #PARENT.TABLE_NAME.FIELD_NAME. When referring to a field on the current instruction's object, use the syntax #THIS.TABLE_NAME.FIELD_NAME. For example, the following statement is used on a migration plan for Business Object, where the parent instruction is the BO and the subordinate instruction is used to reference the UI Map that is referred to as a BO option with the option type "F1DU":#PARENT.F1_BUS_OBJ_OPT.BUS_OBJ_OPT_FLG = 'F1DU' AND @trim(#THIS.F1_MAP.MAP_CD) = @trim(#PARENT.F1_BUS_OBJ_OPT.BUS_OBJ_OPT_VAL).
- The **XPath** option lets you apply syntax in an XPath expression referencing elements in the instructions' referenced business objects. This is entered in the **XPath Traversal Criteria**. For example, the display map collection statement in the SQL example noted above would be written as follows in XPath: #this/mapCd = #parent/businessObjectOption/businessObjectOptionValue AND #parent/businessObjectOption/businessObjectOptionType = 'F1DU'. This technique allows foreign key references that are mapped inside an XML column to be referenced.

Note: The #parent expressions may access elements that are stored in an XML column and described using mapXML and mdField. However, the #this expressions must refer to fields available in the business object using the mapField reference.

Defining **Next Migration Plan** provides the ability to indicate that in addition to copying the object defined in the instruction, any additional instructions included in that referenced migration plan will also be included in an export.

The **Algorithms** grid contains algorithms associated with each instruction. You must define the following for each algorithm:

- Specify the **System Event** with which the algorithm is associated (see the table that follows for a description of all possible events).
- Specify the **Sequence** and **Algorithm** for each system event. You can set the **Sequence** to 10 unless you have a **System Event** that has multiple **Algorithms**. In this case, you need to tell the system the Sequence in which they should execute.

System Event	Optional / Required	Description
Pre-Compare	Optional	Algorithms of this type may be used to adjust the data after it is moved to the target system. These may only be defined on the primary instruction. Refer to Adjusting Imported Data for more information.
Import	Optional	Algorithms of this type are no longer supported.

Understanding the BO Filtering Process

Migration plan instructions require the definition of a business object to provide CMA with information about the record related to the instruction.

If the business object is the physical business object for the maintenance object, then CMA assumes that the instruction applies to all records that satisfy the traversal criteria. CMA recognizes the physical BO by comparing the BO to the value defined in the maintenance object option. If the business object defined is not the physical BO, then CMA will limit the records in the instruction to those that explicitly reference this BO or reference a child of this BO as its [identifying BO](#) value. (In other words, this BO must be in the parentage hierarchy of the records to be included in the instruction.)

Note: Unlike Bundling, CMA does not use the BO schema to drive what data is copied for a given record. The BO is only used as a filtering mechanism for selecting records. Refer to [Identifying Tables to Exclude from Migration](#) for information about how to ensure a child table is not included in a migration.

For example, if you define a migration plan for Master Configuration and use the physical business object for the instruction (**F1-MstCfgPhysicalBO**) then all master configuration records are considered for the instruction. If instead the business object you define is Migration Assistant Configuration (**F1-MigrationAssistantConfig**) then only the record related to this business object is included in the instruction.

Migration Plans for Objects with XML-Embedded Links

When migrating objects where foreign key references are captured in the object's XML based field, subordinate instructions are needed to define the foreign key references in order for CMA to understand the relationships. This is in contrast to direct foreign keys where CMA can determine the relationships using constraints. The instructions provide two purposes. Defining instructions ensures that the related objects are included in the migration, if appropriate. If you know that the related objects are included because of other criteria, the instructions allow CMA to group related objects into transactions. This helps in the apply process at import time to ensure that related objects are grouped together. However, the apply process includes iterative steps to try to overcome dependencies like this so defining the instructions is not critical for this purpose.

The following are options for creating migration plans with XML-embedded links:

- One option is to use the specific logical (business) BO in the primary instruction to define the object you are copying. With this option, the subordinate instructions may use XPath criteria to define the related foreign key. When this approach is used, a separate Migration Plan must be created for each logical BO. (Refer to [Understanding the BO Filtering Process](#) for more information.) This option would only be used in isolated cases.
- Another option is to create a migration plan that uses the Physical BO as the primary instruction, and then include a subordinate instruction for the real logical BO, using SQL Traversal to join the object to itself by its primary key. Note that with this technique, the records that reference the logical BO will still only be included in the export file once. At this point further subordinate instructions may use XPath notation to define the foreign key data. Using the physical BO as the primary instruction ensures that all records in the MO are considered. The subordinate instructions with the logical BO and XPath notations will only apply to the records that are applicable to that BO. This option is useful for MOs that have a small number of logical business objects with disparate foreign keys.
- Another option is to use the physical BO in the primary instruction and use raw SQLs in the subordinate instruction's traversal criteria to identify the foreign keys using substring commands. A separate Subordinate Instruction is needed for each SQL corresponding to each element occurrence. Using this technique has the same advantages of the previous in that all records for the MO are included in the migration. However, this technique may be useful for maintenance objects with a larger number of business objects expected where each has one or more foreign keys. It's especially useful if many business objects reference the same foreign key. Then only one instruction is required for that foreign key. Note that a single migration plan may use this technique and the XPath technique for different elements.

A migration request may have multiple migration plans for the same maintenance object. That allows for some flexibility and long term maintainability in that the above techniques may be used in multiple migration plans. Consider the following example:

- A product provides base business objects with foreign keys defined in the XML field and provides the appropriate migration plan with instructions. An implementation extends this business object or perhaps creates their own business object for the same maintenance object and includes different additional foreign keys in the XML. Rather than duplicating the base migration plan and adding additional instructions for the additional foreign keys, the implementation can create a second migration plan for the MO with the additional foreign keys defined. A migration request should be defined to include both migration plans. In this case if the implementation has only

one custom BO, they can choose to use the custom BO as the primary instruction as described above in the first option.

Defining a Migration Request

Migration Requests are used to define the data to be included in a migration. To view or define a migration request, navigate using **Admin > Implementation Tools > Migration Request**.

Use the **Migration Request Query** portal to search for an existing migration request. Once a migration plan is selected, you are brought to the maintenance portal to view and maintain the selected record.

There are three types or classes of migration request. The system provides a base business object for each along with a migration request class, which matches the business object. The subsequent sections provide more information about each class of migration request.

Note that all migration requests support defining a Category, which allows implementers to categorize the migration request.

In addition, all classes of migration request include the following zones:

- **Migration Request** This zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.
- **Referencing Migration Requests** This zone is only visible if the displayed migration request is included in a Group migration request. It lists each group migration request that includes it.

Other zones may appear for specific classes of migration requests. See the following sections for more information.

Criteria-based

This type of migration request defines a set of entities to be logically included together as part of a migration. For each migration instruction, selection criteria is defined to indicate which records for each MO should be included. Selection may be defined using SQL, an algorithm, an entity tag or explicit primary key values.

- For selection using SQL Statement, refer to the embedded help for examples.
- For selection using Algorithm, the algorithms that are eligible to be plugged in here are those valid for the **Migration Request - Select** system event.
- For selection using Entity Tag, reference a tag name. The entities linked to the tag at export time would be included in the export file.
- For selection using Specific Keys, the primary key (1 through 5) must be explicitly specified. Multiple rows are allowed.

Entity List

This type of migration request allows the user to choose explicit MO / prime keys. The MOs that are eligible are those that are configured with a **Default Migration Plan** option. Although the user is managing MO / PKs, the migration instructions are still defined with a migration plan. The system maps the migration instructions in a similar way to a **Criteria-based** migration requests that use a Specific Key selection type. Note however that it will create a separate migration instruction for each MO / PK combination. It does not try to group all PKs for the same MO / migration under one migration instruction.

For this type of migration request, a user adds a migration request record with its description and other main information. Then, a special zone **Add Entities** is provided to find and select records based on a selected maintenance object and add to the migration request. The user is prompted to provide a reference and comments, if desired. If the category selected is one that requires a reference, then this will be validated. Alternatively, you may also use the [Collect Entity](#) zone to add specific entities as you review them on their respective maintenance portals.

When maintaining a migration request with existing entities, they are visible in the zone **Migration Request Entities**. This zone allows a user to remove the entity from the list.

Group

This type of migration request points to other migration requests. This allows you to define separate migration requests that represent logical groupings of migration plan instructions for ease of maintenance, but to combine all the separate migration requests into a single "grouped" migration request for streamlined export / import purposes.

The CMA export process will build an extract that includes the union of all the objects that qualify for the export and group them together based on their relationships.

Identifying Tables to Exclude From Migrations

Some maintenance objects that are eligible to be migrated may include child tables that should not be included in the migration. For example, if an object includes log tables, the entries in the log should reflect the actions on the object in that system, and will be different between the source system and the target system. If you have a custom Maintenance Object that includes tables you don't wish to migrate (such as a log table), use the **Non-Migrated Table** option on the MO to specify this table. All child records for this table will also be ignored during migration.

Another use case to consider is a child "many-to-many" table that connects two administrative objects and exists in the maintenance object of both tables. The child table may be in both MOs for convenience sake, but it may be that one MO is considered more of a "driver" object and the other more of a subordinate. If you are doing a migration where you want to copy a subset of objects, you may want to only copy the driver object and its children and their data but not their children. For example, a To Do Type includes a collection of valid To Do Roles and in turn the To Do Role refers to its To Do Types. If an implementation wants to copy a single To Do and include all its related information, including its To Do Roles, it does not want the migration of each To Do Role to in turn copy all its To Do Types (and their data).

Note: The MO option must be set in both the Source and Target systems for a given MO.

Configuring Custom Objects for Migration

During the implementation and extension of the product, new custom administrative maintenance objects may be introduced. If your implementation would like to migrate records in those maintenance objects using the Content Migration Assistant, additional steps must be performed, which are highlighted in the following sections.

Physical Business Object

As described in [Understanding the BO Filtering Process](#), the migration plan requires a business object for its instruction. The business object is used to identify the records eligible for inclusion in the migration. Assuming your custom tables use one or more "logical" business objects for their processing, your implementation must decide if these business objects are appropriate for use by the migration plans, or if a physical BO is warranted. If so, [create an appropriate physical BO](#).

Review MO Option Configuration

The following points highlight maintenance object (MO) configuration that should be reviewed or updated to support CMA:

- If a physical BO was created (above), link it to the MO as an option using the appropriate option type.
- Be sure that your MO defines an appropriate [FK Reference](#) and includes an Option on the MO that identifies the FK Reference. This is used by various portals and zones for CMA when showing detail about records being imported into the target region. Also be sure that this FK reference defines an Information program.
- As described in [Identifying Tables to Exclude From Migrations](#), an MO option is used to identify child tables for an MO that should never be included in a migration. If your custom maintenance object includes a standard Log table, than the recommendation is to list that table as an excluded table. Depending on the specific design of the maintenance object, there may be other child tables to define.

Characteristic Type Configuration

The CMA import process will attempt to create a log record for any administrative object that includes a log table. If your implementation has introduced any custom administrative tables that you plan to include in a migration request and it includes a log table, you must, to ensure that the log creation is successful, add your log table as a valid characteristic entity to the characteristic type **F1-MGO** (Migration Object).

Navigate to [Characteristic Type](#) and select the characteristic type **F1-MGO**. Navigate to the **Characteristic Entity** tab and add a row to include the characteristic entity for your custom maintenance object's log table.

Standard CMA Configuration

Create one or more migration plans for the new object, depending on the type of data in the maintenance object and the types of migrations you envision:

- If you have implemented only one "logical" business object used to define the data in the MO, then a single migration plan that references the this BO (or the maybe the MO's physical BO) is appropriate.
- If you have implemented more than one "logical" business object, would the data for multiple business objects get copied together? Then perhaps a single migration plan that references the MO's physical BO is appropriate.
- Are there additional foreign keys defined using mapXML in the business object(s) for the MO? If so, then it is recommended to include sub-instructions to define the links. At this point, if multiple "logical" BOs exist, your implementation may choose to define all the additional elements in the same migration plan or choose to define separate migration plans for each logical BO.
- Your implementation may decide to define more than one migration plan for the same type of record based on the types of migrations you plan to include. For example, you may decide to include a migration plan that copies only the records in this maintenance object. You may decide to define another migration plan that copies the records in this MO along with related records in another MO (for a special type of migration). Having said that, be sure to design the migration plan with reuse in mind to minimize maintenance efforts.

In order to support **Entity List** migration request, a default migration plan must be defined as an option on the maintenance object. This should be a single migration plan that supports all types of business objects for the MO.

If your implementation has a template migration request to use for migrations, include the new migration plan(s) as appropriate.

CAUTION: Important! New migration plans and migration requests should follow naming conventions. Refer to [System Data Naming Convention](#) for more information.

The CMA Execution Process

The following diagram illustrates a high-level view of the Content Migration Assistant execution process. The subprocesses illustrated here are described in more detail in the following sections.

Exporting a Migration

The migration export process begins in the source environment by defining a **Migration Data Set Export**, which specifies a defined **Migration Request** and provides a file name and description for the export file. After the data set is defined and saved, the **Migration Data Set Export Monitor** batch job can be submitted generate the export file. The lifecycle of the Migration Data Set Export business object includes algorithms that select the appropriate records according to the migration request, determine dependencies between records to build groupings of related objects and create the export file.

The following topics provide more detail about this process.

Migration Data Set Export

To migrate data from one region to another, define a **Migration Data Set Export**. This establishes the export file name and identifies the migration request.

To view an existing migration data set export, navigate using **Admin > Implementation Tools > Migration Data Set Export**. Use the query criteria to locate the desired data set.

Note that you can also initiate the creation of an export data set from the [Migration Request](#) portal using the **Export** button.

The export requires the name of an existing **Migration Request**.

Enter a unique **File Name** for the export. Do not use spaces in the name, and do not enter the file extension or a path. The output location and file extension of the intended export file, which should appear in the **Export Directory** and **File Suffix** labels, are defined as described in the topic [Migration Assistant Configuration](#).

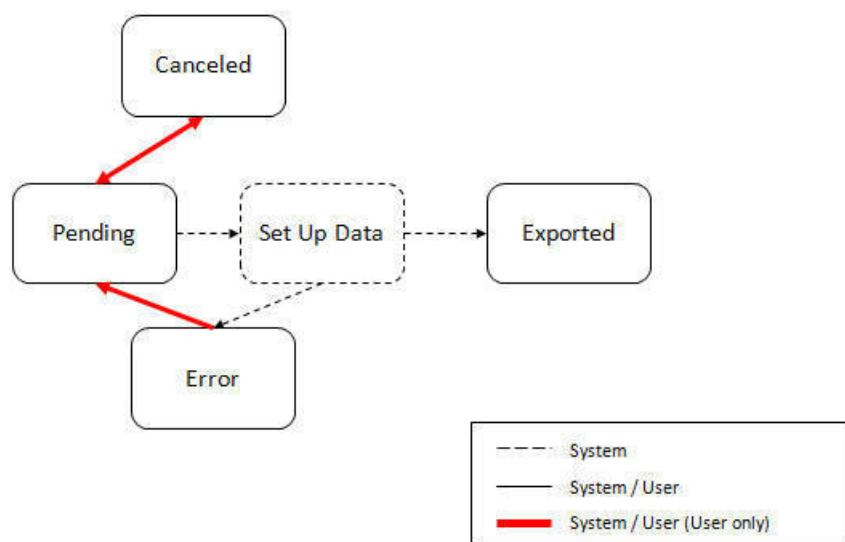

Enter an **Export Description** to provide information about the purpose of the export. Note that this field is not language enabled.

The **Source Environment Reference** is for information purposes. It should be populated with text that provides a meaningful description of the source environment. The default value is the URL of the source environment.

The **Migration File Version** is only visible if the product currently supports creating a file in an earlier [file format version](#). If this element is visible and you are planning to import the file in a target environment that uses an older migration file format version, indicate the lower file format version that you wish the export to use.

Export Lifecycle

The following diagram describes the lifecycle of a Migration Data Set Export (data set).

The following points describe the lifecycle.

- The data set is created in **Pending** status.
- A user may choose to temporarily **Cancel** a pending data set to prevent it from being processed. The user can later return it to the Pending state when desired.
- The record remains in Pending until its monitor batch job is submitted. The **Migration Data Set Export Monitor (F1-MGDPR)** selects pending records and transitions them to **Set up data**. Refer to [Running Batch Jobs](#) for more information.
- Set up data is a transitory state that includes the algorithm that does the work of determining the objects to include in the export and group related objects together into a transaction. If everything is successful, the export file is written to the appropriate file location and the record transitions to **Exported**. If an error is detected, the process stops and the record transitions to **Error**.
- If a record is in error and it is possible to correct the error, the record may be transitioned back to Pending to try again.

When the process is marked as **Exported**, the export file can be imported into the target system.

Note: The export process creates a file, providing the benefits of having a standalone file. It can be stored in a version control system for audit purposes or provided to others for import purposes.

CAUTION: Under no circumstances should exported data files be edited manually. Doing so could cause data corruption when the file content is applied to the target environment.

Note: The export functionality is supported using the business object **Migration Data Set Export** (F1-MigrDataSetExport). The expectation is that implementations will use the delivered base business object and its logic and will have no reason to implement a custom business object for the CMA export process.

Importing and Applying a Migration

The import process is broken down into four general steps: Import, Compare, Approve, Apply. The following points provide an overview of the steps.

- **Import.** The first step covers importing the file and creating appropriate Migration Import records in the target environment to facilitate the subsequent steps.
- **Compare.** The compare step reviews each object that is in the import file and compares the object in the import against the equivalent record in the target environment. The comparison step results in noting which objects are unchanged, which are new (and the appropriate SQL to insert them) and which objects are changed (and the appropriate SQL to update them). Based on user configuration at import time, the objects that qualify for the import may be in a state that requires review or may be pre-approved.
- **Approve.** Once the comparison is complete, the user should review the results. There may be records marked for review. All of these records must be approved or rejected before the import can proceed. Users may choose to suppress individual SQL statements for a given object that is approved. When the user is satisfied with the results of the comparison and has completed the review, the import is marked to proceed to the Apply step. Optionally, a migration import may be configured to automatically apply.
- **Apply.** This is the final step and is the step where the records in the target environment are added or updated. Because of potential high volumes of data and because of possible dependencies between records, this step supports two levels of attempting to apply the records. There is an apply step at the object level and an apply step at the transaction level. This will be described in more detail below.

Import Step

The import process starts with verifying the import directory configured as described in the following topic [Master Configuration - Migration Assistant](#) and ensuring that the exported file is located in that directory. Then, in the target environment, a **Migration Data Set Import** record should be created. The user indicates the file name.

In addition, the user decides what the default status should be for resulting objects.

- The **Default Status for Add** sets the default status for objects that are determined to be *new* during the import comparison process. The default is to automatically set new objects to **Approved** status. Other options are to set any new objects to **Rejected** or **Needs Review** status.
- The **Default Status for Change** sets the default status for objects that are determined to be *changed* during the import comparison process. As with new objects, the default for changed objects is **Approved**, with **Rejected** or **Needs Review** options available.

The user may also configure the **Automatically Apply** flag to **Yes**. This allows for use cases where the migration is repetitive and has been tested and the user feels that there is no need for manual approval. Note that when configuring this setting, neither of the Default Status values may be set to **Needs Review** and at least one must be set to **Approved**.

The file to import contains a list of all the objects included in the export. Any objects that the export step determined to be related have been grouped into “transactions”. Once the Migration Data Set Import is created, the next step is for the system to read in the file and create Migration Transactions and Migration Objects.

By default, the import step creates a Migration Object for each entity in the file. When importing a high volume data set of business entities, the user may request to import entities in bulk mode for performance reasons. In this mode, a single Migration Object record may contain multiple entities from the file. If at least one of the entities included in the migration object record is new and the remaining ones are either new or unchanged then the **Default Status for Add**

setting applies to it. If at least one included entity is determined to be changed then the **Default Status for Change** applies to the record. Refer to [bulk import mode](#) for more information.

The following is a portion of the Migration Data Set Import lifecycle as it pertains to the import step.

The following points describe the lifecycle.

- The data set is created in **Pending** status.
- The record remains in Pending until its monitor batch job is submitted. The **Migration Data Set Import Monitor** (F1-MGDIM) selects pending records and transitions them to **Ready to Compare**. Refer to [Import Process Summary](#) and [Running Batch Jobs](#) for more information.

The Ready to Compare state has an algorithm that is responsible for reading the related import file and creating the migration transactions and migration objects. The data set remains in this state until the comparison step is complete.

Note: A user may choose to **Cancel** a data set. Refer to [Cancelling a Data Set](#) for more information.

The following diagram highlights the relationships of the resulting migration import records.

The migration transaction and migration object each have their own lifecycle that will help manage the subsequent compare and apply steps. At the end of the import step, the status values of the three types of records are as follows:

- Migration Data Set Import is in the **Ready to Compare** state.
- Migration Transaction is in the **Pending** state.
- Migration Object is in the **Pending** state.

Note: The import functionality is supported using business objects supplied by the base product. The expectation is that implementations will use the delivered base business objects and their logic and will have no reason to implement a custom business objects for the CMA import process. The base business objects are **Migration Data Set Import** (F1-MigrObjectImport), **Migration Transaction** (F1-MigrTransactionImport) and **Migration Object** (F1-MigrObjectImport).

Compare Step

The import step results in the creation of one or more migration objects. Typically, one migration record is created for each record selected in the export based on the export's migration request and its configuration. Related objects are grouped together in migration transactions.

When importing a high volume data set of business entities, the user may request to import entities in bulk mode for performance reasons. In this mode, a single Migration Object record may contain multiple entities from the file. Refer to [bulk import mode](#) for more information.

The next step in the import process is the Comparison step. In this step, the data captured by the import file for each object is compared to the view of that object in the target environment.

To cater for a possible large volume of objects, the comparison is done via a batch monitor. To aide in performance of the process, the monitor is performed on the migration objects so that it can be run multi-threaded. Once the objects are finished with the comparison, the migration transactions and the migration data set should be updated with an appropriate overall status before continuing to the next step. As a result, the comparison actually requires three steps: Migration Object Comparison, Migration Transaction Status Update and Migration Data Set Export Status Update. The steps are explained in detail in the following sections.

Note: Refer to [Running Batch Jobs](#) for more information about streamlining the various steps in the process.

Migration Object Compare

This is the main step of the comparison. The **Migration Object Monitor** (F1-MGOPR) selects pending migration object records and transitions them to **Comparing**. This is a transitory state that includes the algorithm that does the work of comparing. There are various possible outcomes that could occur based on the logic in the algorithm. The following diagram illustrates a portion of the migration object lifecycle that pertains to comparison.

Note: When using [separate batch processes for business data](#) the **Migration Object Monitor (Business)** process (F1-MGOPB) works in the same way to compare business migration objects.

The following points describe the lifecycle.

- When **Pending** records are selected by the monitor batch job, it transitions to **Comparing**. If the migration object refers to one or more pre-compare algorithms, they are executed to [adjust the data prior to comparison](#). Then algorithm will determine the appropriate next state by comparing the source data to the target data.

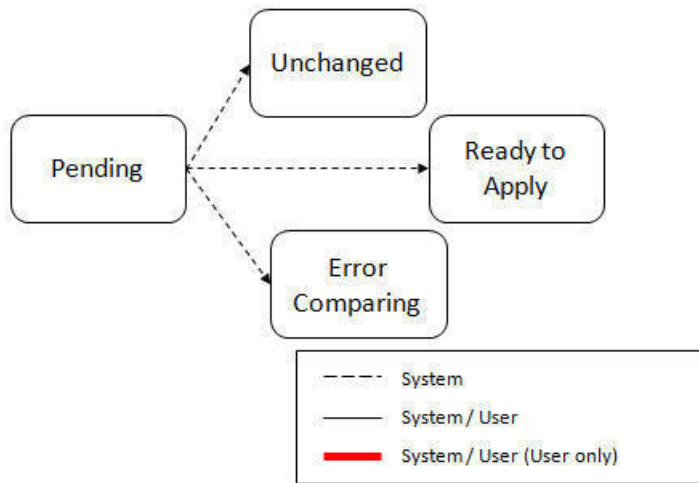

- Entity related notes:
 - If the record in the migration object is found in the target environment and the data is exactly the same, the record transitions to **Unchanged** (with the object action value also set to **Unchanged**).
 - If the record in the migration object is found in the target environment and the data is different, the algorithm sets the object action value to **Change** and generates the appropriate SQL to be used later in the Apply step to update the record. It then transitions to **Approved**, **Needs Review** or **Rejected** based on the Default Status For Change setting captured on the Data Set.
 - If the record in the migration object is not found in the target environment, the algorithm sets the object action value to **Add** and generates the appropriate SQL to be used later in the Apply step to insert the record. It then transitions to **Approved**, **Needs Review** or **Rejected** based on the Default Status For Add setting captured on the Data Set.
 - When the import is performed in **bulk mode** each included entity is compared separately but the overall status of the record is set as follows:
 - If all included entities are unchanged then the migration object record transitions to **Unchanged** (with the object action value also set to **Unchanged**).
 - If all included entities are either unchanged or changed then the object action value is set to **Change**, corresponding SQLs are generated for the changed entities only and the migration object transitions based on the Default Status For Change setting captured on the Data Set.
 - If all included entities are either unchanged or new then the object action value is set to **Add**, corresponding SQLs are generated for the new entities only and the migration object transitions based on the Default Status For Add setting captured on the Data Set.
 - If some of the included entities are new and some changed then the object action value is set to **Mixed Actions**, corresponding SQLs are generated for the each entity and the migration object transitions based on the Default Status For Change setting captured on the Data Set.
 - If there is any issue with attempting to parse the object data from the import, the record transitions to **Error Comparing**.
 - If there is any reason that the imported object is not valid for import, the record transitions to **Cannot Apply**. The log will be updated with the error that caused the record to transition to this state. An example is that perhaps the record was exported in a different version of the product and has additional elements that are not recognized in this version.

Note: Refer to [Cancelling a Data Set](#) for information about cancelling a data set and its impact on its related objects.

Migration Transaction Status Update

After the import step, the migration transaction remains in the Pending state until all its objects have completed the comparison step. At that point, the status of the transactions should be updated based on the results of their objects. The **Migration Transaction Monitor** (F1-MGTPR) selects pending migration transaction records and runs its monitor algorithms. There are various possible outcomes that could occur based on the logic in the algorithms. The following diagram illustrates a portion of the migration transaction lifecycle that pertains to comparison.

The following points describe the lifecycle possible next states after Pending.

- If any related migration object is in the Error Comparing state, the transaction transitions to **Error Comparing**.
- If all related migration objects are in the Unchanged state, the transaction transitions to **Unchanged**.
- Otherwise, the transaction transitions to **Ready to Apply**. This means that at least one object is in an “apply-able” state.

The transaction remains in the **Ready to Apply** state until a user has approved the data set to move to the Apply step and the transaction’s related objects have attempted to apply themselves. This is described in more detail below.

Note: Refer to [Cancelling a Data Set](#) for information about cancelling a data set and its impact on its related objects.

Migration Data Set Import Status Update

Once all the objects and all transactions have been updated via the previous two steps, the migration data set export must be updated based on the results of their transactions. The **Migration Data Set Import Monitor** (F1-MGDIM) selects Ready to Compare data sets and runs its monitor algorithms. Note that this is the same monitor process that is used to select Pending data sets. There are various possible outcomes that could occur based on the logic in the algorithms. The following diagram illustrates the portion of the migration transaction lifecycle that pertains to comparison.

The following points describe the lifecycle possible next states after Ready to Compare.

- If any related migration transactions is in the Error Comparing state, the data set transitions to **Error**.
- If all related migration transactions are in the Unchanged state, the data set transitions to **Unchanged**.

- Otherwise, the transaction transitions to **Awaiting Approval**. This means that there are no errors and at least one object is in an “apply-able” state.

The data set remains in the **Awaiting Approval** state until a user decides that the data set and all its records are ready to progress to the Apply step.

Note: A user can choose to cancel a data set at any time while it is in progress. Refer to [Cancelling a Data Set](#) for more information.

Approval Step

Once the comparison is complete and the data set transitions to the Awaiting Approval state, a user needs to progress the data set to **Apply Objects** to trigger the Apply step. The following points describe steps a user may take during the approval step.

- If the data set configuration for the Default State for Add and Change was set to **Approved**, then any migration object that is determined to be eligible for the Apply step will be in the Approved state. In this situation, a user may want to review the data set and its transactions and objects to see verify that the results make sense. At that time, the user is able to move an object to Needs Review or Rejected as appropriate.
- If the data set configuration for the Default State for Add and Change was set to **Needs Review** for either option, then each migration object in the Needs Review state must be reviewed and the user must either Reject or Approve each object before moving to the Apply step.
- If the data set configuration for the Default State for Add and Change was set to **Rejected** for either option, the assumption is that the rejected records don’t need to be reviewed. But if a user finds a rejected record that shouldn’t be rejected, it may be transitioned to Approved (or Needs Review) as appropriate.

A user has the option to mark one or more SQLs within a migration object to be suppressed. In this case, if the migration object is approved, then only the SQLs that are not marked as Suppressed will be applied. This option is useful when importing a record that has many child records. It may be that the user wants to only include a subset of the child records. This may be done by suppressing the child records that should not be included.

Once the user is comfortable with the data set's results and no more objects are in the Needs Review state, the user should transition the record to **Apply Objects**. This will initiate the Apply step.

Alternatively, if the Automatically Apply flag was set to **Yes** when creating the import record, the import data set will progress from **Awaiting Approval** to **Apply Objects**. Refer to [Import Process Summary](#) for more information.

Note: Refer to [Maintaining Import Data](#) for details about the pages provided to help the user review a data set and its transactions and objects to help in the approval step.

Note: A user can choose to cancel a data set at any time while it is in progress.

Apply Step

The apply step is the step where records in the target environment are added or updated. Like the comparison step, the apply step is actually multiple steps to optimally handle high volume and dependencies between records as smoothly as possible.

Note: Refer to [Running Batch Jobs](#) for more information about streamlining the various steps in the process.

Before explaining the apply steps in detail, the following points highlight the type of data that may be included in a given data set.

1. Records that have no foreign keys and therefore no dependencies on other records. Examples: Message, Display Profile.
2. Records that have foreign keys that may already be in the target. Examples: Algorithms for existing algorithm types, To Do Roles for existing To Do Types.
3. Records that have foreign keys that are new records but also part of the migration. CMA detected the relationship at export time and grouped the objects in the same transaction. Example: Script-based Algorithm Type where the script is also in the migration.

4. Records that have foreign keys that are new records but also part of the migration. CMA did not detect the relationship. This may occur if the referenced foreign key is in a XML or parameter column and the migration plan did not include an instruction to explicitly define the relationship. Example, a Zone that references a visibility script.
5. Records that have circular references where both records are new and are part of the migration. CMA detected the relationship at export time and grouped the objects in the same transaction. Example: plug-in Script for a BO plug-in spot. The script references the BO and the BO references an algorithm for the script's algorithm type. Another example is when the same record is maintained by multiple maintenance objects and therefore exists in multiple migration objects.

To handle high volume data, the first step in the apply process is to perform the apply logic at the migration object level via a multi-threaded batch job. This should result in all records in categories 1 and 2 above being applied successfully.

For records in categories 3 and 4 above, if a record with a foreign key is added or updated before its related record, the validation will fail. However, if the related record is added first and then the record referring to it is added, validation will pass. The tool handles these dependencies as follows:

- Dependency between master and transaction entities is typically hierarchical and in most cases straight-forward. The tool leverages that knowledge to orchestrate the processing of objects in an optimal way that follows their dependency order as much as possible. Note that relationship between entities could be complex and this approach does not eliminate all processing order related errors but rather significantly reduce them.
- Dependency between configuration entities is more complex and inter-twined and therefore migration objects are not ordered, i.e. the multi-threaded batch process may not process records in the desired order.
- To overcome the potential issue of processing order related errors, the Apply step has special functionality, described in detail below.

For records in category 5 above, the circular reference will mean that the apply process at the object level will not successfully add or update these records. The apply process at the transaction level will cover these records. This is described in detail below.

Apply Objects

Once the Data Set is in the state of **Apply Objects**, the **Migration Object Monitor - Apply** process (F1-MGOAP) runs to attempt to apply the objects.

Note:

When using [separate batch processes for business data](#) the **Migration Object Monitor (Business)- Apply** process (F1-MGOAB) works in the same way to apply business migration objects.

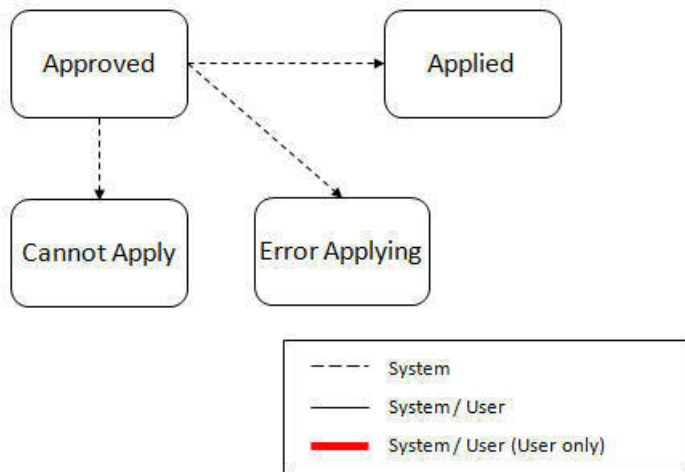

The background process in conjunction with the Apply algorithm have special functionality to ensure records in categories 3 and 4 (above) successfully apply during this step:

- The **Migration Object Monitor - Apply** process is a special one that continually re-selects records in the **Approved** state until there are no more eligible records to process.
- When an error is received in the Apply Object algorithm, the algorithm increments an "iteration count" on the migration object record. If the iteration count does not exceed a maximum count (noted in the algorithm), the object remains in the **Approved** state and is eligible to be picked up for processing again. If the iteration count exceeds the maximum defined in the algorithm, the record transitions to the **Error Applying** state.

Note: When submitting this Apply batch job, be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker. Doing this will cause the 'excess' threads to wait for the supported number of threads to finish.

The following diagram is the portion of the migration object lifecycle that pertains to the Apply step.

At the completion of the Apply monitor process, typically the objects will be in the **Applied** state or the **Error Applying** state. The records in the Error Applying state are in that state for one of two reasons.

- They are in category 5 described above where the records have a circular reference with another record. For this scenario, the Apply Transactions step described below should successfully apply the records.
- There is some other error that is unrelated to the records in the current migration. In this case, manual intervention may be required. Refer to the [Resolving Errors](#) section below for more information.

As shown in the diagram, the Apply Objects algorithm may also detect a reason that the object cannot be applied. This may occur if the object in the target environment has been updated since the comparison step, making the SQL captured at that point no longer applicable. If this occurs, after the current migration is fully applied, the original file may be imported again, and new comparisons can be generated and applied.

Apply Transactions

Ideally, after the Apply Objects step, all the objects are **Applied** or are in **Error Applying** due to the "circular reference" situation. The typical next step is to turn over responsibility to the transactions. The migration transactions can then attempt to apply their objects in bulk.

In order to ensure that multiple background processes are not trying to select migration objects to run the Apply step, the Transactions are only eligible to attempt to "apply my objects" if the Data Set is in the **Apply Transactions** state.

A monitor algorithm (executed by the data set monitor batch process) on the Apply Objects state checks to see if all migration objects are no longer **Approved** or the count of records in **Error Applying** does not exceed a configured limit. If so, it automatically transitions the record to the **Apply Transactions** state.

If the number of objects in **Error Applying** exceeds a configured limit, the monitor algorithm does not automatically transition the record. In that case, a user must determine if the large number of errors can be resolved or manually transition to **Apply Transactions** (despite the large number of errors). The [Resolving Errors](#) section below describes alternative steps that the user may take if there are errors.

Once the Data Set is in the state of **Apply Transactions**, the **Migration Transaction Monitor - Apply** process (F1-MGTAP) runs. It attempts to apply the transaction's objects. If no migration objects are in error, the migration

transaction simply transitions to **Applied**. If any of the migration objects are in **Error Applying**, the background process and the Apply algorithm have special functionality to try to overcome dependencies in migrated objects:

- The Apply algorithm selects all migration objects in error and performs all their SQL, then validates all the records. If there are objects in the transaction with circular references, they should pass validation at this point.
- Because there may still be some dependencies across transactions, similar error handling described in the Apply Objects step occurs here. When an error is received in the Apply Transaction's Object algorithm for any of the objects in the transaction, the algorithm increments an "iteration count" on the migration transaction record. If the iteration count does not exceed a maximum count (noted in the algorithm), the transaction remains in the **Ready to Apply** state and is eligible to be picked up for processing again. If the iteration count exceeds the maximum, the record transitions to the **Error Applying** state. Note that if any objects in the transaction are in error, none of the objects are applied. They all remain in error.
- The **Migration Transaction Monitor - Apply** process is a special one that continually re-selects records in the **Ready to Apply** state until there are no more eligible records to process.

Note: When submitting this Apply batch job, be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker. Doing this will cause the 'excess' threads to wait for the supported number of threads to finish, erasing the benefit of the iteration processing.

The following diagram is the portion of the migration transaction lifecycle that pertains to the Apply step illustrating the points above.

If at the end of the transaction level Apply process there are transactions in error (and therefore there are still objects in error), a user must review the errors and determine how to fix them. Refer to the [Resolving Errors](#) section below for more information.

Resolving Errors

As mentioned in the previous sections, errors may be received after the Apply Objects process runs. If the number of records in error is below a certain limit (and the data set monitor batch job is submitted to execute the monitor algorithms) the system will automatically transition the data set to the **Apply Transactions**. If the monitor batch job is not run or if the number of objects in error exceeds a certain limit, a user must make the decision after viewing the errors in the Objects in Error zone on the [Migration Data Set Import](#) portal.

- If the errors appear to be dependency related, the user can decide to let the "transactions apply their objects" and transition the data set to **Apply Transactions**, described above.
- If the errors appear to be related to an outside issue that can be manually resolved, the user may choose to fix the issue and redo the Apply Objects step.
- The user may also decide to reject one or more objects to remove them from the migration.

After the Apply Transactions step, if there are still errors, a user must review the records and determine how to proceed. Errors are visible in the **Transactions in Error** zone on the [Migration Data Set Import](#) portal.

- The user may decide to reject one or more objects to remove them from the migration.
- The user may manually resolve an issue external to the migration and then decide to do one of the following:

- Redo the **Apply Objects** step. This is recommended if there are a large number of Objects still in error and not a large number of dependencies expected. The benefits of running the Apply Objects multi-threaded will ensure that the process runs efficiently.
- Redo the **Apply Transactions** step.

Because the objects and transactions are in Error Applying, in order to "retry" the Apply step after manually fixing an error, the system needs to move the records back to the state that allows them to be picked up by the appropriate Apply process. For migration objects, records need to be moved back to **Approved**. For migration transactions, records need to be moved back to **Ready to Apply**. The following points describe the Retry logic for migration objects.

- If a user decides to **Retry Objects** (using an action button on the Migration Data Set Import page), the data set transitions to the **Retry Objects** state. At this point the Migration Object monitor must be run.
- The monitor on the **Error Applying** state for the objects detects that the data set is in the state of **Retry Objects** and that triggers the transition back to **Approved**.
- The next step is to transition the data set from **Retry Objects** to **Apply Objects**. This may be done manually or by running the Migration Data Set Import monitor process.
- Now the objects are eligible to be picked up by the object level Apply process.

Analogous logic exists for the migration transactions.

- If a user decides to **Retry Transactions** (using an action button on the Migration Data Set Import page), the data set transitions to the **Retry Transactions** state. At this point the Migration Transaction monitor must be run.
- The monitor on the **Error Applying** state for the transactions detects that the data set is in the state of **Retry Transactions** and that triggers the transition back to **Ready to Apply**.
- The next step is to transition the data set from **Retry Transactions** to **Apply Transactions**. This may be done manually or by running the Migration Data Set Import monitor process.
- Now the transactions are eligible to be picked up by the transaction level Apply process.

The retry logic may also occur when transitioning between the Apply Objects and Apply Transactions depending on whether or not there are errors. The following scenario highlights this point.

- After the **Apply Objects** step there are objects in **Error Applying**. The data set transitions to **Apply Transactions** and the Apply step is done at the transaction level.
- After the **Apply Transactions** step there are transactions in **Error Applying**.
- User chooses to try to apply objects again (by clicking **Retry Objects**). The steps outlined above for retrying objects are followed at this point.
- After the apply objects, user may choose to retry objects again (after fixing errors if applicable).
- At some point the user will transition to **Apply Transactions** again. If there are transactions in **Error Applying**, the system will automatically transition the data set to **Retry Transactions** and the steps outlined above for retry transactions are followed.

Finalize Apply Step

Once all the migration objects for a migration transaction are in a final state (**Applied**, **Rejected** or **Cannot Apply**), the migration transaction transitions to the **Applied** state. Once all the migration transactions are in the **Applied** state, the Migration Data Set record transitions to the **Completed** and the import is complete.

Note: To review the full lifecycle for each record, refer to the Business Object - Summary tab in the application metadata for the base business objects **Migration Data Set Import** (F1-MigrObjectImport), **Migration Transaction** (F1-MigrTransactionImport) and **Migration Object** (F1-MigrObjectImport).

Adjusting Data Prior to Comparing

There are reasons that the data you are importing requires some adjustment before applying it in the target environment. In such cases, an algorithm plugged into the [migration plan](#) primary instruction may be used to adjust the data when importing. This algorithm is executed by the comparison algorithm before any comparison is performed. Algorithms of this system event receive the view of the source record (being imported) and the view of the existing record in the target region, if it exists. The data is provided using the physical BO of the migration plan's

maintenance object. The algorithm may make changes and pass a new view of the record that should be used for the comparison. This system event supports multiple algorithms that are executed in sequence. Each algorithm receives the original record's data, the target record's data (if applicable) and the 'new' view of the data (as populated by previous algorithms, if any). The final 'new' view of the data is used for the object comparison. The system includes the algorithms linked to the primary instruction of the migration plan from the source environment. If the system finds any additional pre-compare algorithms linked to the migration plan's primary instruction in the target system, those algorithms are also executed.

Fastpath: Refer to [Base Business Objects](#) for more information about physical BOs.

Some examples of records that may require import algorithms.

- Batch Control references its next batch sequence number along with snapshot information like the last run date / time. This information is only relevant with respect to its environment. The instruction for a batch control can include an algorithm to not overwrite the batch sequence number when copying a batch control.
- Some products include administrative objects that reference a master data object. Master data objects are not copied as part of CMA. An import algorithm may be used to adjust the referenced master data foreign key when importing, for example to reset it (or not overwrite when updating). If the algorithm knows how to find the appropriate master data record to link, that may also be included.
- If you are importing data that from a source environment on a lower version, if the object you are importing has been enhanced in the latest release with a new required field, you may need to provide an algorithm to populate data in that field.

Note that it is possible to use the algorithm to "reset" the source data as a way of indicating that the record should not be imported. For these situations, the migration object comparison step will transition the record to **Unchanged** and will use an object action value of **Canceled**. (Note that object action is a simple lookup value. The record is not transitioned to the **Canceled** BO state as to reserve that status for user initiated cancellations of the object or one of its parent records). This technique not expected to be used often because ideally using appropriate selection criteria at export time should ensure that the only records exported are those that should be imported.

Note: Legacy 'Import' system event. The system originally provided an Import system event / plug-in spot. The purpose of algorithms for this plug-in spot were similar in that they were meant to adjust imported data prior to adding or updating. The algorithms were executed in the Apply step. The logic does not allow for easily interacting with the record using a BO. This makes it difficult to use a plug-in script as the plug-in type. In addition, it is difficult to update elements in an XML column. The support for the plug-in spot will be removed in a future release. Algorithms to adjust the data should be using the pre-compare system event.

Import Process Summary

The following table summarizes the steps required to complete the import process from start to finish. Note that this section **only a summary** and assumes that you are familiar with the details described in the previous sections. It highlights what steps are manual and what steps are performed by a batch monitor process. For each step, the table highlights the Next Action sequence that would occur. For the Apply steps, there are two parts where multiple next actions are possible based on whether there are errors and the user's decision on how to resolve the error. Refer to [Resolving Errors](#) for more information. The possible next actions have the same sequence with a letter following the sequence highlighting the action to take based on the results of the previous step.

Note: When running the Apply batch jobs, be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker.

Also note that a sequence and action marked in bold is considered the "normal path".

When using [separate batch processes for business data](#) any reference to a migration object monitor batch process applies also to the business data related batch controls.

Step	Seq	Action	Manual / Batch	Portal - Action	Batch Control	Record Impacted - Resulting Status	Next Action Sequence
Import	10	Create Import record	Manual	Migration Data Set Import - Add		Migration Data Set Import - Pending	11
	11	Import file	Batch		F1- MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Ready to Compare Migration Transaction - Pending Migration Object - Pending	20
Compare	20	Migration Object Compare	Batch		F1- MGOPR - Migration Object Monitor [When using separate business data processes submit also F1- MGOPB (Migration Object Monitor (Business))]	Migration Object - Approved, Needs Review, Rejected, Unchanged or Error Comparing	21
	21	Migration Transaction status update	Batch		F1- MGTPR - Migration Monitor	Migration Transaction - Ready to Apply, Unchanged or Error Comparing	22

Step	Seq	Action	Manual / Batch	Portal - Action	Batch Control	Record Impacted - Resulting Status	Next Action Sequence
	22	Migration Data Set Import status update	Batch		F1- MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Awaiting Approval, Apply Objects (if configured for Automatic Apply), Unchanged or Error	30
Approval	30	Review comparison results, approve / reject as needed (This step is skipped if the data set is configured for Automatic Apply)	Manual	Migration Data Set Import, drill in to the Transactions / Objects as necessary.		Migration Object - Approved or Rejected (no records should be in Needs Review) Migration Data Set Import - Apply Objects	40
Apply	40	Apply Objects	Batch		F1- MGOAP - Migration Object Monitor - Apply [When using separate business data processes submit also F1- MGOAB (Migration Object Monitor (Business) - Apply)]	Migration Object - Applied or Error Applying	41 Appropriate next action is based on error review, if applicable.

Step	Seq	Action	Manual / Batch	Portal - Action	Batch Control	Record Impacted - Resulting Status	Next Action Sequence
	41a	Migration Data Set Import status update - auto transition to Apply Transactions. Only applicable if the number of migration objects in Error Applying is below a threshold	Batch		F1- MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Apply Transactions	42
	41b	Migration Data Set Import status update - manual transition to Apply Transactions. Occurs if user reviews errors and determines that they may be resolved in the Apply Transaction step. System detects that all the transactions are in the Ready to Apply state and proceeds to the Apply Transactions state. System detects that there are transactions in the Error Applying state and transitions instead to the Retry Transactions state.	Manual	Migration Data Set Import - click Apply Transactions			
						Migration Data Set Import - Apply Transactions	42
						Migration Data Set Import - Retry Transactions	45

Step	Seq	Action	Manual / Batch	Portal - Action	Batch Control	Record Impacted - Resulting Status	Next Action Sequence
	41c	Migration Data Set Import status update - manual transition to Retry Objects. Occurs if user reviews errors and decides to fix an external error and wants to try the batch level Apply again at the object level.	Manual	Migration Data Set Import - click Retry Objects		Migration Data Set Import - Retry Objects	44
	42	Apply Transactions	Batch		F1- MGTAP - Migration Transaction Monitor - Apply	Migration Transaction - Applied Applying Migration Object - Applied or Error Applying	43 Appropriate next action is based on error review, if applicable.
	43a	Migration Data Set Import status update - auto transition to Completed Applicable if all transactions are Applied	Batch		F1- MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Completed.	N/A
	43b	Migration Data Set Import status update - manual transition to Retry Objects. Occurs if user reviews errors and decides to fix an external error and wants to try the batch level Apply again at the Object level.	Manual	Migration Data Set Import - click Retry Objects		Migration Data Set Import - Retry Objects	44

Step	Seq	Action	Manual / Batch	Portal - Action	Batch Control	Record Impacted - Resulting Status	Next Action Sequence
	43c	Migration Data Set Import status update - manual transition to Retry Transactions. Occurs if user reviews errors and decides to fix an external error and wants to try the batch level Apply again at the Transaction level.	Manual	Migration Data Set Import - click Retry Transactions		Migration Data Set Import - Retry Transactions	45
	44	Migration Objects status update from Error Applying back to Approved. Occurs if user chose to Retry Objects.	Batch		F1- MGOPR - Migration Object Monitor [When using separate business data processes submit also F1- MGOPB (Migration Object Monitor (Business))]	Migration Object - Approved	
		Migration Data Set Import status update from Retry Objects to Apply Objects	Batch		F1- MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Apply Objects	40

Step	Seq	Action	Manual / Batch	Portal - Action	Batch Control	Record Impacted - Resulting Status	Next Action Sequence
	45	Migration Transactions status update from Error Applying back to Ready to Apply. Occurs if user chose to Retry Transactions or if the user transitions to Apply Transactions and the system detects that there are Transactions in the Error Applying state.	Batch		F1-MGTPR - Migration Transaction Monitor	Migration Transaction - Ready to Apply	42
		Migration Data Set Import status update from Retry Objects to Apply Objects	Batch		F1-MGDIM - Migration Data Set Import Monitor	Migration Data Set Import - Apply Transactions	42

The following table summarizes the batch monitor jobs that are used in the import process. You can see that there are special monitor processes for the Apply step for both the Object and Transaction. However, for all other states that have monitor logic, the standard monitor process for that MO is used.

Batch Control	Description	Comments
F1-MGDIM	Migration Data Set Import Monitor	Processes data set records in the following states: <ul style="list-style-type: none"> • Pending • Ready to Compare • Apply Objects • Retry Objects • Apply Transactions • Retry Transactions
F1-MGTPR	Migration Transaction Monitor (Deferred)	Processes transaction records in the following states: <ul style="list-style-type: none"> • Pending • Error Applying

Batch Control	Description	Comments
F1-MGTAP	Migration Transaction Monitor - Apply	Processes transaction records in the Ready to Apply state where the data set is in the Apply Transactions or Canceled state.  Note: Be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker.
F1-MGOPR	Migration Object Monitor	Processes object records in the following states: <ul style="list-style-type: none"> • Pending • Needs Review (check for Data Set cancellation) • Error Applying
F1-MGOPB	Migration Object Monitor (Business) Applicable only when separate business data processing is enabled.	Similar to F1-MGOPR (Migration Object Monitor) but restricted to business data migration objects.
F1-MGOAP	Migration Object Monitor - Apply	Processes object records in the Approved state where the data set is in the Apply Objects or Canceled state.  Note: Be sure to set the number of threads to a number that does not exceed the number of threads supported by the thread pool worker.
F1-MGOAB	Migration Object Monitor (Business) - Apply Applicable only when separate business data processing is enabled.	Similar to F1-MGOAP (Migration Object Monitor - Apply) but restricted to business data migration objects.

Refer to [Running Batch Jobs](#) for more information about managing the batch jobs, including ways to automate the above steps.

Canceling a Data Set

A user may choose to **Cancel** a data set to prevent it from being processed at any point during the process.

If related migration transactions or migration objects have already been created, they will not be canceled as part of the data set getting canceled (due to possible high volumes of related records). They will be canceled the next time an appropriate monitor batch process runs. The child records checks to see if the data set has been canceled prior to any state transition.

Additional Note Regarding Imports

The following points describe miscellaneous comments related to Migration Import.

- CMA relies on the fact that database referential integrity constraints are not in place, and that the SQL statements can be run in any order within the transaction. Any archiving solution that requires referential integrity constraints

(such as Information Lifecycle Management) would not be possible on this data. Given that CMA migrations comprise administrative data and not transactional data, this should be a reasonable exception.

- The validation that is performed is only via the **Page Validate** service. BO validation algorithms are not executed. Page validation does not include validation of the business object against the schema (for example, for required fields, field sizes, etc.).
- If multiple migration requests are exported at the same time, on the import side, you should consider importing, reviewing, and applying an entire file/data set before moving on to the next one. The reason is that if objects are included in more than one file, two sets of "inserts" will be generated, but only the first will succeed. The second will cause the object to transition to "Cannot Apply". If instead you wait until the first file is completed before importing the second, the second data set will not generate any SQL for the object, since it has already been inserted. It's a matter of efficiency: If you first import all files and then try to apply all, you'll have to identify the duplicated object as an error and then mark the object as rejected before applying the transaction. This may also be avoided by using a Group migration request to include all objects in one file rather than multiple files.
- The system provides an algorithm to purge "unchanged" migration objects for a given migration data set. This may be plugged in as a BO exit algorithm on the **Ready to Compare** state for the Migration Data Set Import business object (**F1-MigrDataSetImport**).

The following points describe miscellaneous comments related to importing a business data set in [bulk mode](#).

- The number of entities included in each migration object is captured on the migration object record.
- The comparison step only generates SQLs for new or changed entities. SQLs are not generated for unchanged entities.
- Searching for migration objects based on their included entities is only supported for entities that were determined as new or changed. In other words, this type of search by included entities is only possible after the comparison step is performed.

Caching Considerations

There are two important caching considerations when using CMA to migrate administrative data.

- The "apply" batch processes update data. As described in [Batch Cache](#), if any batch job is updating data marked as "cached for batch" it must be run in a special thread pool. Contact your system administrator and ask for the name of a thread pool that has turned off caching. This thread pool name must be entered in the batch controls used for CMA processing in the **Thread Pool Name** parameter.
- After a successful migration, the target region now has new administrative data which needs to be part of various caches. It is recommended to flush the server cache (which will trigger a 'global' flush of the cache). If the thread pool workers in the target region are configured to refresh their caches when a global flush is requested, then this is the only step required. If not, then the **F1-FLUSH** batch job should also be submitted to refresh the caches used in batch processing.

Fastpath: Refer to [Caching Overview](#) for more information.

Fastpath: Refer to [Running Batch Jobs](#) for more information about running CMA batch jobs.

Maintaining Import Data

This section describes the portals provided to add, view and maintain migration import data.

Migration Data Set Import

Use the Migration Data Set Import portal to view and maintain migration data set import records. Refer to [Importing and Applying a Migration](#) for an overview of the import process.

Navigate using **Admin > Implementation Tools > Migration Data Set Import**. You are brought to a query portal with options for searching for import data sets. In addition, the query provides an option to specifically search for data sets that have either objects in error or transactions in error. Once a data set has been selected, you are brought to the maintenance portal to view and maintain the selected record.

The following zones are visible on the **Main** tab:

- **Migration Data Set Import.** This zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.
- **Entity Summary.** This zone provides a summary count of all migration objects included in the current data set across the various statuses.

The following zones are visible on the **Transactions** tab:

- **Migration Data Set Transactions in Error.** This zone is only visible if there are transactions for this data set in a non-final state that have errors. It indicates the error for each transaction. A user may use this zone to review errors after the monitor batch job to apply transactions completes. The errors received when attempting to apply objects at the transaction level may differ from those received when attempting to apply objects at the object level. A transaction log is created for each object error received and these exceptions are shown in this zone.

Note: Refer to [Apply Step](#) for more information about resolving errors.

- **Migration Data Set Transactions.** This zone is visible once the [Import Step](#) has occurred and lists all the transactions that are related to the data set. To see more information about a specific migration transaction, click the hypertext for its ID. This brings you to the [Migration Transaction](#) portal.

The following zones are visible on the **Objects** tab:

- **Migration Data Set Objects in Error.** This zone is only visible if there are objects for this data set in a non-final status that have errors. It indicates the error for each object. A user may use this zone to review errors after the monitor batch job to apply objects completes. Using the error information shown, the user can choose to drill into the record to transition it to **Error Applying** or choose to manually fix the cause of the errors and click **Retry Objects**. The user may also choose to select one or more records to **Reject**.

Note: Refer to [Apply Step](#) for more information about resolving errors.

- **Migration Data Set Impacted Object Summary.** This zone is visible once the [Import Step](#) has occurred and lists the objects that are related to the data set. To see more information about a specific migration object, click the hypertext for its ID. This brings you to the [Migration Object](#) portal. A user may choose to update the status of one or more records by checking the records and clicking **Approve**, **Reject** or **Needs Review** accordingly.

Migration Transaction Portal

This page appears after drilling into a specific migration transaction from the migration data set portal or from the migration object portal.

Refer to [Importing and Applying a Migration](#) for an overview of the import process.

The following zones are visible on the main tab:

- **Migration Transaction.** This zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.
- **Migration Transaction Objects.** This zone lists the objects that are related to the data set. To see more information about a specific migration object, click the hypertext for its ID. This brings you to the [Migration Object](#) portal. A user may choose to update the status of one or more records by checking the records and clicking **Approve**, **Reject** or **Needs Review** accordingly.
- **Entity Summary.** This zone provides a summary count of all migration objects included in the current transaction across the various statuses.

Migration Object Portal

This page appears after drilling into a specific migration object from the migration data set portal or from the migration transaction portal.

Refer to [Importing and Applying a Migration](#) for an overview of the import process.

The **Migration Object** zone contains display-only information about the selected record. Please see the zone's help text for information about this zone's fields.

The **Migration Object - List of SQL Statements** zone lists the SQL statements that have been generated as a result of the comparison step. A check mark in the Suppressed checkbox indicates that the SQL for that row will not be applied during the apply step.

The **Migration Object - Algorithms** zone displays any pre-compare algorithms that are associated with the migration plan for this migration object.

Configuration Deletion

Use the Configuration Deletion portal to review and delete configuration entities that were previously imported and are no longer needed. Refer to [Importing and Applying a Migration](#) for an overview of the import process.

Navigate using **Admin > Implementation Tools > Configuration Deletion**. You are brought to a portal where you can define a set of import data sets as representing a complete imported configuration and delete entities that were previously imported but not included in the reference set.

The following zones are visible on the **Main** tab:

- **Configuration Summary.** This zone summarizes the number of imported entities by maintenance object that are included in a selected set of import data assets that represent a complete imported configuration. Selecting a maintenance object lists potential entities for deletion.
- **Entities to Delete.** This zone lists potential entities for deletion, i.e. entities of the selected maintenance object that were previously imported but not included in the reference data set. You may select and delete entities from this list.

Running Batch Jobs

There are several batch jobs that are part of the CMA process, especially the import step (which are highlighted in [Import Process Summary](#)). And in some cases, a single batch jobs may process multiple states in the same business object lifecycle. Implementations must decide the best way to manage the batch job submission depending on how they plan to work.

- **Batch scheduler.** If an implementation wishes to put these batch jobs in the batch scheduler, a given job may need to be included several times to manage progressing the records to completion.
- **Timed Batches.** The batch controls can be configured as timed batches so that they run every N minutes based on the setting. This allows for the batch jobs to run periodically and process whatever is ready. A user doesn't have to manually submit a batch request. Navigate to the [Batch Control](#) page and select the appropriate batch controls. For each one, change the Batch Control Type to **Timed**. Fill in the additional information that appears for timed batches.
- **Event Driven.** The system provides BO enter plug-in algorithms and batch control post processing plug-in algorithms that automatically submit the appropriate next batch job for that step in the process. This allows for as much automation as possible for the steps that don't require user input. Note that configuration is required because the BOs / batch controls are not configured for this scenario by default. The following table highlights the BO and status where an algorithm may be plugged in and the name of the algorithm to use.

Business Object	Status	Algorithm
Migration Data Set Export	Pending	F1-MGDPR-SJ (Submit Migration Data Set Export Monitor).
Migration Data Set Import	Pending	F1-MGDIM-SJ (Submit Migration Data Set Import Monitor).
	Ready To Compare, Retry Objects	F1-MGOPR-SJ (Submit Migration Object Monitor). When using separate batch processes for business data add also this algorithm: F1-MGOPRB-SJ (Submit Migration Object Monitor for Business Data).

Business Object	Status	Algorithm
	Apply Objects	F1-MGOAP-SJ (Submit Migration Object Apply Monitor). When using separate batch processes for business data add also this algorithm: F1-MGOAPB-SJ (Submit Migration Object Apply Monitor for Business Data).
	Apply Transactions	F1-MGTAP-SJ (Submit Migration Transaction Apply Monitor).
	Retry Transactions	F1-MGTPR-SJ (Submit Migration Transaction Monitor).

The following table highlights the batch controls where an algorithm may be plugged in and the name of the algorithm to use.

Batch Control	Algorithm
F1-MGTPR (Migration Transaction Monitor)	F1-MGDIM-NJ (Submit Migration Data Set Import Monitor).
F1-MGTAP (Migration Transaction Monitor - Apply)	F1-MGDIM-NJ (Submit Migration Data Set Import Monitor).
F1-MGOAP (Migration Object Monitor - Apply) When using separate batch processes for business data update also this batch control:	F1-MGDIM-NJ (Submit Migration Data Set Import Monitor).
F1-MGOAB (Migration Object Monitor (Business) - Apply)	
F1-MGOPR (Migration Object Monitor) When using separate batch processes for business data update also this batch control:	F1-MGTPR-NJ (Submit Migration Transaction Monitor).
F1-MGOPB (Migration Object Monitor (Business))	

- **Manual submission.** The user managing the CMA import process submits the appropriate batch jobs on demand when a particular step is ready. Navigate to [Batch Job Submission](#), select the appropriate batch control and fill in the parameters as needed.

Note that for the CMA batch processes used to migrate administrative data, there are multiple important caching considerations. Refer to [Caching Considerations](#) for more information.

CAUTION: Be sure that the Thread Count set when submitting the batch job does not exceed the number supported by the thread pool. Otherwise the extra threads will wait until the supported number of threads are finished, possibly resulting in a large number of errors in the Apply steps.

Refer to the parameter descriptions in the batch control metadata for more information about filling in the parameters.

For additional details on submission controls, refer to the topic [Batch Job Submission Portal](#) in the Batch Jobs section.

CMA Reference

This section provides additional reference information.

Framework-Provided Migration Configuration

This topic describes special information relating to migration objects provided for use by CMA in the product. Additional objects may be provided by your specific product. Any special information for objects is provided separately in each product's documentation.

The following points highlight some information about Framework-provided migration requests. Navigate to the migration request page in the application to view the details of all provided objects.

- Several base migration requests are supplied to logically group system and administrative tables. For example, there is a migration request for Framework System Configuration **F1-SystemConfig** where most system configuration objects are included. There is another one provided for CMA related configuration objects.
- The system supplies a group migration request **F1-FrameworkConfig** (Framework Configuration), which includes several other migration requests. The expectation is that this migration request includes all the typical objects that are included in a wholesale migration. Your specific product may include this migration request into its own group migration request to support a wholesale migration of all the framework and product administrative tables. An implementation may choose to build a custom group migration request. In this case, review the various migration requests provided by base to see if any may be included as components for the custom migration request. Then any new migration plans added to the base migration request in future releases are automatically included in future migrations.
- There are several different security related migration requests that include different combinations of migration plans to support multiple possible business requirements related to security migration. Note that the security migration request included in the above mentioned group migration request is the one that does not include users. If your implementation wants to copy users to a target environment, refer to [Importing Data that References a User](#) for some considerations.

Note: Refer to your specific product's CMA documentation for its recommendation on which migration requests to use for a full migration of framework and product administrative tables.

The following points highlight some information about the Framework-provided migration plans. Navigate to the migration plan page in the application to view the details of all provided objects.

- Fields and characteristic types are not migrated with an object (like a business object or a data area) unless specifically indicated.
- The **Application Service** used by an object is migrated only if it is CM-owned.
- The **Batch Control** object optionally references a User (for 'timed' batches). Refer to [Importing Data that References a User](#) for some considerations about copying the user. Also note that when running a batch job, snapshot information is captured on the batch control. Updates like this increment the version number. If a batch control record is part of the migration and the comparison step has detected a change to the batch control, the Apply step will error out for this batch control if a batch job is submitted between the compare and apply step.

Note: CMA batch controls that are part of the import step are executing and as such, the system does not include these records in a migration. If your implementation changes default parameters for any of the batch controls, the recommendation is to manually make those changes to the target region.

- The base migration plans for MO and BO include instructions to copy option types that use foreign key references to refer to other objects. Note that the data stored in the options are not validated, so defining these instructions is not required when doing wholesale migrations. However, including subordinate instructions for foreign key references is useful for targeted migrations to ensure that the related data is included in the migration. If you add additional MO or BO option types that use foreign keys and you want to support targeted migrations, you must create custom migration plans and requests for MO and BO, respectively to include these referenced objects in the migration plan. Note that you do not need to duplicate the instructions in the base migration plans. You may define the additional migration plans to only have the additional custom option types. When submitting a migration request for MO or BO you must include both the base migration plans and the custom migration plans in the request.
- For scripts, schema-based objects and zones, the migration plans provided by the product migrate, through constraints, some of the typical associated data with them. However, data specified through alternate formats (such as through **Edit Data** steps in scripts, referenced in schemas for schema-based objects, or data from mnemonics in zone parameters, etc.) are not identified and combined in the same transaction. The iterative processing functionality of the import step should resolve any timing issues that may result in validation errors for these types of objects.
- There are two migration plans for **Scripts**. The migration plan **F1-ScriptOnly** migrates just the script and its **Application Service** (provided the Application Service is CM-owned). The migration plan **F1-Script** includes most related objects, but does not migrate any objects referenced in the edit data area steps. It does not move the

Function maintenance object. It may be included in any appropriate custom targeted migration request where scripts and related data should be migrated.

- If your implementation includes a **Feature Configuration** setting for the **F1_DBCONINFO** entry that will be included in a migration request, be sure that the import user on the target region has the appropriate security rights to this entry (**Administrator** access mode for the Feature Configuration application service (**CILTWSDP**)).
- The common attachments in the Attachment maintenance object may be considered administrative data to include in a migration. Because this MO has a system generated key, as described in [Administrative Data with System Generated Primary Keys](#), it uses a logical key of the file name and the creation date to determine if the record exists in the target environment. In addition, this MO contains administrative data (common attachments) and non-administrative data (owned attachments). To try to minimize the possibility of key "collision", new common attachments receive a generated key that includes a zero in the middle whereas owned attachments receive a generated key that does not have a zero in the middle.
- The Menu maintenance object has a user defined key, however, its menu lines and menu items have system generated keys. To avoid the possibility of overriding a menu line or menu item incorrectly, the menu MO will check the menu line's menu name in the source and target to be sure they match and will check the menu item's menu line in the source and target to be sure they match otherwise an error will be issued in the comparison step.
- For the system messages, the product provides three different migration plans.
 - Message Category and its Messages (F1-MessageCategory). This migration plan is included in the **F1-SystemConfig** migration request.
 - Message Category (F1-MessageCategoryOnly). This migration plan is provided to support a targeted migration where an implementation has created a custom message category and wants to move it but doesn't want to move all its messages.
 - Message (F1-Message). This migration plan is provided to support a targeted migration where only specific messages within a message category should be migrated.
- For lookup values, the product provides two different migration plans.
 - Lookup Field and its Values (F1-Lookup). This migration plan is included in the **F1-SystemConfig** migration request.
 - Lookup Value (F1-LookupValue). This migration plan is provided to support a targeted migration where only specific lookup values within a lookup field should be migrated.
- There are some system data objects where no information in a base delivered record may be modified by an implementation. For these records, the base delivered migration requests include selection criteria to only select CM-owned records (because the base records will always exist in the target region assuming both regions have the same release). An example is Algorithm Type. The **F1-SystemConfig** migration request only includes CM-owned algorithm types. However, many system data objects support custom changes to one or more fields, for example the Zone object allows an implementation to override the zone text or certain parameters. Other system data objects support custom additions to a collection. For example, the Maintenance Object allows an implementation to add algorithms or options. For the migration plans related to these system data objects, all records are included in the base delivered migration requests to allow for any customized configuration to be migrated. It means that during the Import / Compare step many base delivered objects that are not customized will be marked **Unchanged**.
- Many of the integration related maintenance objects that include references to environment-specific data, such as Message Senders. This data should be migrated with extreme care. When appropriate, consider taking advantage of URI substitution. Refer to [Referencing URIs](#) for more information.

Facts

Fact is an optional configuration tool for simple workflow-type business messages or tasks. The base package does not provide a dedicated Fact user interface because fact is generic by design. Implementations configure their own user interface to visualize the desired custom business process. The topics in this section describe the generic Fact entity and how it can be customized.

Fact Is A Generic Entity

The Fact maintenance object is a generic entity that can be configured to represent custom entities and support automated workflows for a variety of applications. Each fact references a business object to describe the type of entity it is. A status column on the fact may be used to capture its current state in the processing lifecycle controlled by its business object.

The maintenance object also supports a standard characteristic collection as well as a CLOB element to capture additional information.

Fact's Business Object Controls Everything

A fact's business object controls its contents, lifecycle and various other business rules:

- Its schema defines where each piece of information resides on the physical Fact maintenance object.
- It may define a lifecycle for all fact instances of this type to follow. Each fact must exist in a valid state as per its business object's lifecycle definition.
- It may define validation and other business rules to control the behavior of facts of this type.

Fastpath: For more information about business objects, refer to [The Big Picture of Business Objects](#).

Fact Supports A Log

The Fact maintenance object supports a log. Any significant event related to a Fact may be recorded on its log. The system automatically records a log record when the fact is created and when it transitions into a new state. In addition, any custom process or manual user activity can add log entries.

Fastpath:

Refer to [State Transitions Are Audited](#) for more information on logging.

Conversion

This section describes the overall conversion process and the tools provided to support it.

Understanding The Conversion Process

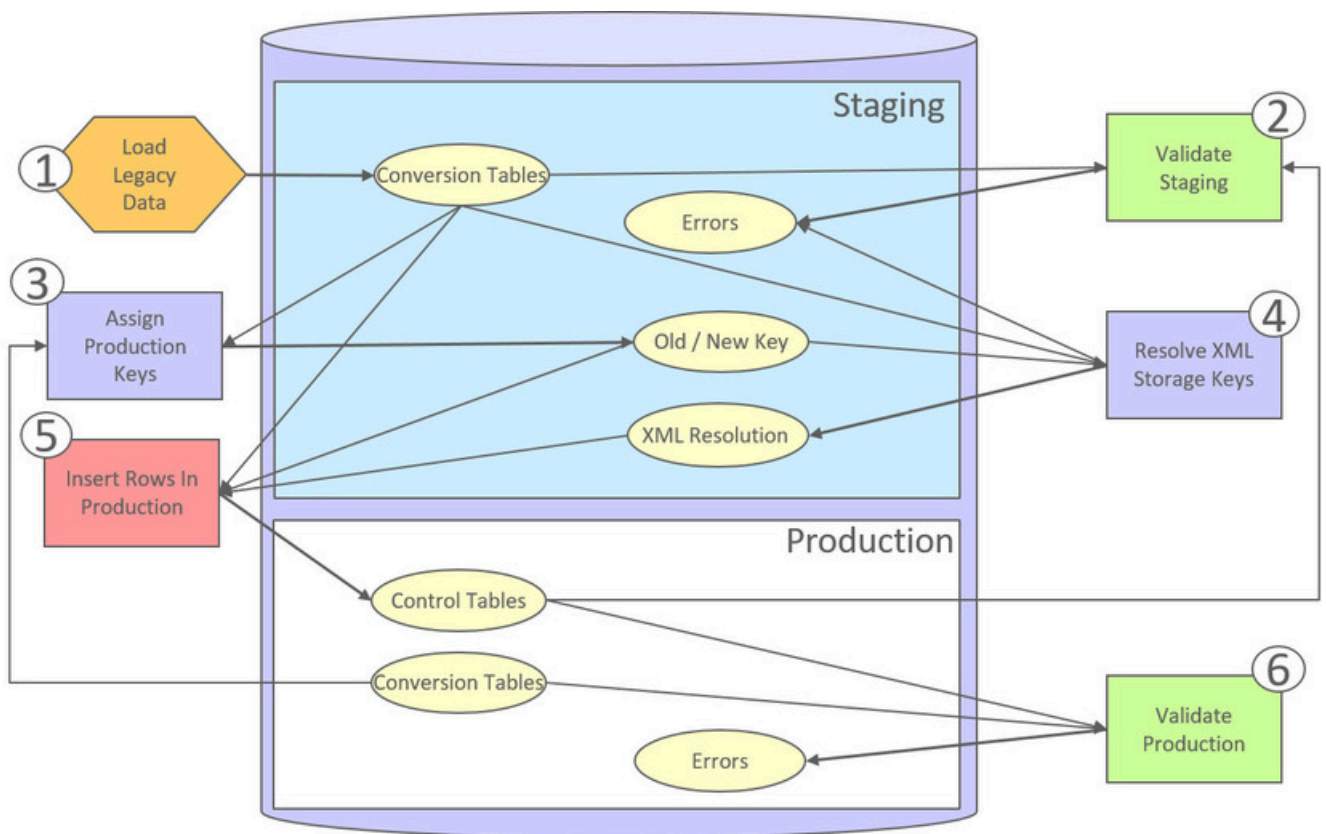

When you're ready to convert data from your legacy system, you will have analyzed your processing requirements according to your business and organizational needs and set up the control tables accordingly. After the control tables are set up, you are ready to load data into the system from your legacy system.

There are two table owners in the system database. We refer to the first owner as **staging** and the second owner as **production**. The staging owner is linked to the tables into which you insert your pre-validated data. The production owner is linked to the tables used by your production system.

Note: It's important to notice that **control tables exist only in production**. In staging, they exist as views to the production schema. Refer to [Multiple Owners In A Single Database](#) for more information about table ownership.

The conversion effort involves several steps as illustrated in the following diagram:

The following points briefly outline each of the above tasks:

- **Load Legacy Data.** During this step, your legacy data is loaded into the system. Notice that you are not migrating this data directly into production. Rather, your rows are loaded into tables that are identical to the production tables; they just have a different owner. Mapping legacy data into the system is probably the most challenging part of the conversion process because the system is a normalized database (and most legacy applications are not).
- **Validate Staging.** During this step, the system validates the data you loaded into the staging tables. Note that validation rules validate your staging data using the control tables that have been set up in production.
- **Assign Production Keys.** During this step, the system allocates random, clustered keys to the rows in the staging database.
- **XML Resolution.** During this step, the system resolves legacy keys that may be mapped to an XML storage field with new values that were assigned in the key assignment step.
- **Insert Rows Into Production.** During this step, the system populates your production tables with rows from the staging. When the rows are inserted, their prime keys and foreign keys are reassigned using the data populated in the key assignment and XML resolution steps.
- **Validate Production.** During this step, you rerun the object validation processes, but this time against production. We recommend performing this step to confirm that the insertion programs have executed successfully.

Note: Additional steps may be needed to support specific data conversion requirements. Refer to your product's documentation for additional conversion related information.

This section further discusses concepts and guidelines related to the conversion process.

Conversion Entities

Conversion is enabled for selected master and transaction maintenance objects. In the same way, only a subset of a maintenance object's tables are enabled for conversion.

The following is provided for each maintenance object that supports conversion:

- An [entity validation](#) batch control. This batch process validates data in staging and can also be run to validate data in production.

- A [key assignment](#) batch control for each **table** that is eligible for conversion and has a system-generated key.
- An [XML resolution](#) batch control if the maintenance object has at least one table that includes an XML storage field.
- An [insertion to production](#) batch control for every **table** of the maintenance object that is eligible for conversion.

You may review the conversion configuration provided for an entity and more using the [Conversion Entity Dashboard](#) portal.

Conversion Steps

The following sections provide more details about the steps in the conversion process.

Note: Additional steps may be needed to support specific data conversion requirements. Refer to your product's documentation for additional conversion related information.

Load Legacy Data Into Staging Tables

This section provides some high level discussion about mapping and loading legacy data to the system's staging tables.

Mass Load Utility

Unless in a Cloud installation, you can use any method you prefer to load data from your legacy application. However, we recommend that you investigate your database's mass load utility (as opposed to using insert statements) as the mechanism to load the staging tables. In addition, we strongly recommend that you disable the indexes on these tables before populating these tables and then enable the indexes after populating these tables.

Note: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

Populating Keys

Some tables in the staging database have keys that are system-assigned random numbers. Special consideration should be given when populating these keys. Refer to [A Note About Keys](#) for more information on how to properly populate these tables. Those tables that don't have system-assigned random numbers have keys that are a concatenation of the parent's prime-key plus one or more additional fields.

Populating Characteristic Tables

There are many maintenance objects that include a characteristic table used to capture miscellaneous information about the object. Most of these tables include an indexed column used when searching by characteristic value called Search Characteristic Value. During conversion and depending on the type of characteristic, this column must be populated as follows:

- **Predefined.** Populate search characteristic value with the contents of the characteristic value column converted to upper case.
- **Ad hoc.** Populate search characteristic value with the first 50 bytes of the ad hoc characteristic value column converted to upper case.
- **Foreign key.** Populate search characteristic value by concatenating the values of each foreign key characteristic value column to a maximum of 50 bytes.

Validate Information In The Staging Tables

During the first validation step, the system validates the data you loaded into the staging tables. This section provides some high level discussion about the validation process.

A Batch Process Per Maintenance Object

Each of the maintenance objects that are eligible for conversion must be validated using its respective entity validation conversion batch process. These are classic background processes that can also be run against production data.

These processes are multi-threaded and have no dependency on other processes.

Validation Mode

By default, each entity is fully validated for schema as well as entity validation rules, at the maintenance object and business object level. The batch process performs the same business rules that are used to validate data added by users in your production system. You may restrict the batch process to perform schema validation only or entity validation rules only using a batch parameter. This may be useful in identifying common data issues in preliminary runs.

Random Sample Mode

By default all records are selected for validation. The "Process Every Nth" batch parameter allows you execute this process in a random-sample mode to highlight pervasive errors. In this mode, you are actually telling the batch process to validate every N records.

We strongly recommend validating each entity in the following steps:

- Execute the validation batch process in random-sample mode.
- Review and correct the errors. Note, you can use the base package's transactions to correct an error if the error isn't so egregious that it prevents the object from being displayed on the browser.
- After all pervasive errors have been corrected; re-execute each object's validation batch process in all-instances mode to highlight elusive, one-off errors.

Reported Errors

Errors encountered during validation are logged onto the conversion Validation Error (CI_VAL_ERR) table. Note that at the start of this job, all rows in the conversion error table for the process maintenance object are deleted.

You can view errors highlighted by the validation process using the [Conversion Entity Dashboard](#) portal.

Recommendations To Speed Up Validation

The following points describe ways to accelerate the execution of the validation process:

- Ensure that statistics are recalculated after data has been inserted into the staging tables.
- Execute the process multi threaded.
- Execute shorter running validation processes (e.g., less records) first so that the error data can be analyzed while other processes are busy running.
- Remember that validation can be run in random-sample mode. We recommend running these batch processes using a large sample value for this parameter until the pervasive problems have been rectified.

Note: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

Another use for these programs

In addition to validating your objects after conversion or an upgrade, the validation programs have another use. Say for example, you want to experiment with changing the validation of a business entity and you want to determine the impact of this new validation on your existing records. You could change the validation and then run that entity's validation batch process- it will produce errors for each record that fails the new validation.

Allocate Production Keys

During the key assignment step, the system assigns a new key for each legacy key for a table that its prime-key requires a system-generated random key. The conversion process allocates new prime keys to take advantage of the system's parallel processing and data-clustering techniques in the production system (these techniques are dependent on randomly assigned, clustered keys).

The topics in this section provides some high level discussion about the key assignment process and describe the background processes used to assign production keys to the staging data.

The Old Key / New Key Table

It's important to understand that the system does not overwrite the prime-keys on the rows in the staging database, as this is a very expensive IO transaction. Rather, a series of tables exist that hold each row's old key and the new key that will be assigned to it when the row is [transferred into the production database](#). We refer to these tables as the "old key / new key" tables.

The convention "<1st letter of owner flag>K_<table_name>" is used to denote the old key / new key table name. For example, the old key / new key table for CI_ACCT is called CK_ACCT.

The insertion batch process that transfers the rows into the production database use the new key for the main record of the key along with any other record where this key is a foreign key. In the same way, the XML resolution process resolves conversion foreign keys residing in XML storage fields and replaces them with their corresponding new keys from these table.

A Batch Process Per Table

A key assignment batch process is provided for each table that has a system-generated key and belongs to a maintenance objects that is eligible for conversion. The batch process is responsible for populating the corresponding old key / new key table (i.e., you don't have to populate these tables). These processes are single threaded. Refer to a table's corresponding key assignment batch process for more information.

Key Assignment Dependencies

Most tables with system-generated keys do not inherit part of their key from another table's key. Their corresponding key assignment batch process have no dependencies and can therefore be executed in any order you please.

Some tables inherit part of their key from another table's key. Key assignment batch processes for such tables must be executed in key inheritance order. In other words, the key assignment process for a table should be run after the process that generates keys for the entity it depend on. The [Conversion Entity Dashboard](#) portal displays key inheritance dependency information if any exist for a conversion entity.

Note:

You may run multiple key assignment batch process in parallel as long as they are independent with respect to key inheritance.

Iterative Conversions

Rather than perform a "big bang" conversion (one where all records of an entity are populated at once), some implementations have the opportunity to go live on subsets of their entity base. If this describes your implementation, please be aware that the system takes into account the existing prime keys in the production database before it allocates a new key value. This means when you convert the next subset of customers, you can be assured of getting clean and unique keys.

Key assignment logic creates the initial values of keys by a manipulation of the sequential row number, starting from 1. After any conversion run, a subsequent conversion run will start with that row number again at 1, and the possibility of duplicate keys being assigned will be higher. The key assignment batch process allows you to specify a starting value for that row number. The purpose of this parameter is to increase the value of row number by the given value, and minimize the chance of duplicate key assignment. This parameter is only used if you are performing conversions where data already exists in the tables in the production database.

Run Type

Key assignment is performed in two steps:

- **Initial Key Generation.** The system allocates new keys to the rows in the staging tables (i.e., it populates the respective old key / new key table).
- **Duplicate Key Resolution.** The system reassigns keys that are duplicates compared to production.

By default, both steps are performed at the same run but you have the option to run them separately by indicating which step to run via a batch parameter. The proper use of this parameter will greatly speed up the key assignment step as described under **Recommendations To Speed Up Key Generation** section.

Recommendations To Speed Up Key Generation

The following points describe ways to accelerate the execution of the key generation programs.

- For a non-Cloud installation:
 - Make the size of your rollback segments large. The exact size is dependent on the number of rows involved in your conversion. Our research has shown that processing 7 million rows generates roughly 3GB of rollback information.
 - Setup the rollback segment(s) to about 10GB with auto extend to a maximum size of 20GB to determine the high water mark
 - A next extent value on the order of 100M should be used.
 - Make sure to turn off all small rollback segments (otherwise Oracle will use them rather than the large rollback segments described above).
 - After the key assignment programs execute, you can reclaim the space by:
 - Keep a low value for the "minimum extent" parameter for the rollback.
 - Shrink the rollback segments and the underlying data files at the end of the large batch jobs.
- Compute statistics on the old key / new key tables after every 50% increase in table size. Key generation is performed in tiers or steps because of the inheritance dependency between some tables and their keys. Although key generation for the inheritance dependency tier currently being processed is performed by means of set-based SQL, computation of statistics between tiers will allow the database to compute the optimum access path to the keys being inherited from the previous tier's generation run.
- Optimal use of the **Run Type** batch parameter.
 - Before any key assignments, alter both the "old key" F1_CX_ID index and the "new key" CI_ID index on the old key / new key tables to be unusable.
 - Run all key assignment batch processes in tiers, submitting each job to only perform the **Initial Key Generation** step.
 - Rebuild the indexes on the old key / new key tables. Rebuilding the indexes using both the PARALLEL and NOLOGGING parameters will speed the index creation process. Statistics should be computed for these indexes.
 - Run all key assignment batch processes in the current tier that were previously run in initial key generation mode, to perform the **Duplicate Key Resolution** step. This will reassign all duplicate keys.

Note: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

XML Resolution

Most system-generated foreign keys are stored in physical fields and characteristic tables and as such their legacy value is replaced with its corresponding new key as part of the insertion to production process. Rarely, maintenance objects may store system-generated foreign keys in an XML storage field, i.e. a field defined with the data type of CLOB or XML. This step is only applicable to such maintenance objects.

During this step, the system resolves convertible system-generated foreign keys that may reside in XML storage fields you may have loaded into the staging tables. This section provides some high level discussion about the XML resolution process.

The XML Resolution Table

It's important to understand that the system does not overwrite the prime-keys on the XML storage fields in the staging database, as this is a very expensive IO transaction. Rather, a corresponding XML resolution table exists for each table that defines an XML resolution field to capture each row's resolved XML storage content, i.e. the content with all the old keys replaced with the new assigned keys.

The convention "<1st letter of owner flag>R_<table_name>" is used to denote the XML resolution table name.

The [insertion](#) batch process that transfers the rows into the production database replaces each XML storage field with its resolved value from the corresponding XML resolution table.

A Batch Process Per Maintenance Object

Each of the maintenance objects that are eligible for conversion and support XML storage fields is provided with an XML resolution batch process. These batch processes must be run to resolve foreign keys that may reside in these XML storage fields.

These processes are multi-threaded and must be executed after the key assignment step has completed and before inserting data to production.

XML Resolution Eligibility

Not all maintenance objects that support XML storage fields actually store convertible system-generated foreign keys in their XML storage field. If none of the business objects associated with the maintenance object involve mapping of such foreign keys to an XML storage field then XML resolution is not needed for any row in the maintenance object. The XML resolution batch process detects such situation and completes right away without storing any rows in any of the maintenance object's XML resolution tables.

Note: If the XML resolution batch process detects that the maintenance object is eligible, the maintenance object must reference a physical BO. If a product delivered business object supports system-generated foreign keys in an XML storage field, the product should be supplying a physical BO. If your implementation has system-generated foreign keys in an XML storage field in a custom business object for a maintenance object where the product has not supplied a physical BO, you must [create a physical BO](#) and link it to the maintenance object.

Only Resolved Values Are Captured

XML storage fields typically store large amounts of data. To avoid capturing the same XML content redundantly, the system only stores values in the resolved XML storage fields if the resolved value is different than the original value, i.e. at least one key was resolved.

If for a given record the resolved XML content is the same as the original content then the following rules apply:

- If this is the primary table of the maintenance object a record is inserted into its corresponding XML resolution table for that record with no value in the XML storage field.
- If this is a child table of the maintenance object then no record is inserted into the corresponding XML resolution table for that record.

Reported Errors

Errors encountered during XML resolution are logged onto the conversion Validation Error (CI_VAL_ERR) table. Note that at the start of this job, all rows in the conversion error table for the process maintenance object are deleted.

You can view errors highlighted by the XML resolution process using the "Validation Error Summary" page.

Insert Production Data

The topics in this section describe the background processes used to populate the production database with the information in the staging database.

A Batch Process Per Table

An insert to production batch process is provided for each table of a maintenance objects that is eligible for conversion.

The batch process is responsible for transferring to production all the rows from the staging table while replacing all references to old keys with their corresponding new keys as follows:

- Keys residing in prime keys, foreign key fields and characteristics are resolved using the corresponding [old key / new key](#) tables.
- Keys residing in generic foreign key reference tables where each row represents a reference to an entity's maintenance object and prime key values are also resolved using the corresponding [old key / new key](#) tables. Note that all entities referenced this way must either be convertible or view of production. A reference to an entity that is explicitly marked as not convertible is not supported as it cannot be resolved.
- Keys residing in XML storage fields are resolved using the corresponding [XML resolution](#) tables.

Note: Foreign keys residing in any other form of storage are not resolved. For example, any references stored in raw elements, log records, or any other field that is not used as an XML storage field.

All insertion batch processes are independent and may run concurrently. Also note, all insertion batch processes can be run in many parallel threads as described in the next section (in order to speed execution).

Recommendations To Speed Up Insertion

The following points describe ways to accelerate the execution of the insertion batch processes:

- Before running the first insertion batch process:
 - Rebuild the index on the prime key on the old key / new key table.
 - Re-analyze the statistics on the old key / new key table.
 - Alter all indexes on the production tables being inserted into to be unusable.
- After the insertion programs have populated production data, rebuild the indexes and compute statistics for these tables.

Note: In a Cloud installation, refer to the “Data Conversion Support for Cloud Implementations” for more information about the various tools provided to support database related conversion tasks.

Validate Production

During this step, you rerun the [object validation batch processes](#), but this time in production. We recommend rerunning these batch processes to confirm that the insertion batch processes have executed successfully. We recommend running these batches in random sample mode (e.g., validate every 1000th object) rather than conducting a full validation in order to save time. However, if you have time, you should run these processes in full validation mode (to validate every object).

A Note About Keys

The prime keys of the tables in the staging database are either system-assigned random numbers or they aren't. Those tables that don't have system-assigned random numbers have keys that are a concatenation of the parent's prime-key plus one or more additional fields. Every table whose prime key is a system-assigned random number has a related table that manages its keys; we refer to these secondary tables as "key tables".

The following points provide more information about the key tables:

- Key tables are used by programs that allocate new keys. For example, before a new key is allocated, the key assignment program checks the corresponding key table to see if it exists.
- Key tables only have two columns:
 - The key of the object.
 - An environment ID. The environment ID identifies the database in which the object resides.
- Key tables are named the same as their primary table with a suffix of "_K". For example: The key table for CI_ACCT is CI_ACCT_K.
- The key table for a table whose prime key is a system-assigned is defined on its table definition record.
- When you populate rows in tables with system-assigned keys, you must also populate a row in the related key table. For example, if you insert a row into CI_ACCT, you must also insert a row into CI_ACCT_K. The environment ID of these rows must be the same as the environment ID on this database's [installation record](#).
- When you populate rows in tables that reference this record as a foreign key, you must use the appropriate key to ensure the proper data relationships. For example, if you insert a row in CI_SA for the above account, the ACCT_ID column must contain the temporary account key.

- When you insert rows into your staging database, the keys do not have to be random, system-assigned numbers. They just have to be unique. A later process, [Allocate Production Keys](#), will allocate random, system-assigned keys prior to production being populated.

Multiple Owners In A Single Database

The conversion process relies on the following table owner configuration in the system database:

- The production owner is linked to the tables used by your production system. These tables have an owner ID of CISADM.
- The staging owner is linked to the tables into which you insert your pre-validated data. These tables have an owner ID of CISSTG.

The staging owner schema is almost identical to the production schema, with the following exceptions:

- Control tables are not actual tables in staging but rather views to the corresponding tables in production.
- Conversion specific tables designed solely to support the conversion process exist only in the staging schema. For example, tables that manage key assignment and XML resolution.

This section provides some high level concepts related to these table owners.

Validation Always Uses Production Control Data

When the validation batch processes run against your staging data, they validate the staging data against the production control tables (and insert errors into the staging error table). This means that the SQL statements that access / update entities needs to use the staging owner whereas the SQL statements that access control tables need to use the production owner. But notice that when these same validation batch processes run against production, the SQL statements will never access the staging owner. Rather, they all point at the production owner.

This is accomplished as follows:

- A separate application server must exist for each owner. Each application server points at a specific database user ID.

Note: In a Cloud installation, the application server may only point to a specific database user ID at any point in time. Refer to the “Data Conversion Support for Cloud Implementations” for more information about switching owners.

- The database user ID associated with the staging owner uses CISSTG as the owner for the master and transaction tables, but it uses CISADM as the owner of the production control tables.
- The database user ID associated with the production owner uses CISADM as the owner for all tables.

You may wonder why we went to this trouble. There are several reasons:

- We wanted to reuse the validation logic that exists in the programs that validate your production data. In order to achieve this, these programs must sometimes point at the staging owner, and other times they must point at the production owner (and this must be transparent to the programs otherwise two sets of SQL would be necessary).
- We wanted to let you use the application to look at and correct staging data. This can be accomplished by creating an application server that points at your staging database with the ownership characteristics described above.
- We wanted the validation programs to be able to validate your production data (in addition to your staging data). Why would you want to validate production data if only clean data can be added to production? Consider the following scenarios:
 - After an upgrade, you might want to validate your production data to ensure your pre-existing user-exit logic still works.
 - You may want to conduct an experiment of the ramifications of changing your validation logic. To do this, you could make a temporary change to user exit logic (in production) and then run the validation jobs on a random sample basis.
 - You forget to run a validation program before populating production and you want to see the damage. If you follow the instructions in this document, this should never happen. However, accidents happen. And if they do, at least there's a way to determine the ramifications.

Only Validation Can Work In Both Owners

While the redirection of owner ID's is a useful technique for the validation batch processes, it cannot be used by the key assignment and production insert batch processes? Why, because these processes have to access the same tables but with different owners at the same time. They also need to reference conversion specific tables that do not exist in production. For example, the batch process that inserts rows into a table in production must select rows from the staging version of that table, resolve keys from the conversion old key / new key mapping tables and insert the resolved records into the production version of that same table

This is accomplished as follows:

- In staging, a view to production exists for each eligible to conversion table. These views have hard-coded the database owner to point to production. For example, there is a view called CX_PER that points at person table in production.
- The key assignment and insertion programs use these views whenever then need to access production data.

Conversion Entity Dashboard

This portal provides an overview of a maintenance object's conversion configuration along with information related to its current status and progress within the overall conversion process.

Refer to [Understanding Conversion](#) for more information.

You can access the portal from the **Admin Menu > Implementation Tools > Conversion Entity Query**. You are brought to a query portal with options for searching for a specific maintenance object that is eligible for conversion. Once a maintenance object has been selected you are brought to the conversion entity dashboard portal to review the information for the selected record.

The following zones may appear as part of the portal's **Main** tab page.

- **Tables.** This zone provides information about tables that belong to the maintenance object and are marked as eligible for conversion.
- **Batch Controls.** This zone lists the conversion batch controls defined for the maintenance object in the order they should be executed within the conversion process along with current execution details if any.
- **Error Summary.** This zone provides a summary of all conversion errors related to the maintenance object.
- **Duplicate Keys.** This zone lists duplicate legacy keys that need to be resolved by the key assignment conversion process.

The **Errors** tab page provides a query zone that allows you to review conversion errors related to the maintenance object by various criteria.

Data Export

This section describes concepts and tools related to the various types of data export methods supported by the product.

Understanding Data Export

The application supports the following classes of export methods for a maintenance object:

- **Generalized.** This method may be used for maintenance objects that are low to medium in volume and update activity. Most maintenance objects are eligible for this method.
- **Specialized.** This method should be used for maintenance objects that are high in volume or very frequently updated.

Note: It is your organization's responsibility for designing the process by which these files are imported to one or more target environments.

This section discusses concepts and guidelines related to data export features.

Generalized Data Export

The generalized data export method provides a file-based export of data in JSON format. Exporting the data of a maintenance object using this method involves an initial export of the entity's entire data followed by an ongoing export of changes as they are made over time. These processes are illustrated in the following diagram:

The overall process involves the following steps:

- Enable entities for export in the [Generalized Export Dashboard](#) portal. You may enable many entities at once. This step also allows you to enable ongoing export of these entities.
- Submit the Generalized Initial Export Initiator (**F1-GEXPI**) batch process to export the current content of all enabled entities. This step submits a separate batch process for each entity you have enabled for export.

Note: A full database export can be used instead. The export file can be imported in the target environment to establish the initial baseline. Cloud customers may contact cloud operations to request such export for on-premise use. This schema export is limited for reporting purposes and is intended for initial extract only.

- Schedule the Generalized Ongoing Export (**F1-GEEEXO**) batch process to run periodically.

The following sections further discuss concepts and guidelines related to the generalized data export method.

Eligibility

While most entities are eligible for generalized data export, not all of them are. Here are a few of the common reasons for that:

- The entity manages extremely high volume of data. Tracking changes to such entity would double the volume of managed data and impact overall performance.
- The entity is updated very frequently. Tracking these events may impact overall performance.
- The entity is used by the product's infrastructure and operational processes. These entities are maintained differently and cannot be subject to the generalized data export methods.

By default a maintenance object is eligible for the generalized data export method unless explicitly marked otherwise by the **Data Export Class** option. The option may be used to mark an entity as either not allowed for any type of export or allowed for a [specialized](#) export only. The lack of such explicit option means the maintenance object is eligible for the generalized export.

CAUTION: If an entity is explicitly marked as not eligible for generalized data export there is a good reason for that and its configuration should not be changed.

One Method Fits All

The generalized data export method is designed to accommodate many eligible maintenance objects in a generic way that must also take performance considerations into account. For this reason this method does not support entity specific filtering options nor custom rules of any kind.

The following rules apply to all entities that may be exported using this method:

- Entire data is exported.
 - All fields on all tables that belong to the maintenance object are exported except for “key” and “log” tables if any.
 - Maintenance object log tables typically do not contain useful business information and as such are omitted from export for performance and data volume reasons. However, there are entities for which log records provide analytical value. When applicable, use the **Export Log Tables** option to explicitly include log tables for a specific maintenance object.
- Same data structure and format is used for all entities. Refer to the **Record Format** section for more information.
- Data is exported to files only. Refer to the **Export To Files Only** section for more information.
- All changes are captured. It is not possible to exclude some changes from being tracked for ongoing export based on custom business rules.
- When data changes, a full snapshot of the data related to that entity is exported to avoid heavy data merging on the target side.
- When the entity is deleted, only the primary key of the entity is exported along with an indication that it is deleted.

Note: Export is not supported for entities that rely on the logical time zone functionality. This type of definition is not commonly used and includes maintenance objects that at least one of their fields is defined as stored in **Logical Standard Time**.

Export To Files Only

The immediate destination of both initial and ongoing export processes are files in a customer specified location. In a Cloud installation files are created in a customer owned Object Storage.

Based on your business requirements you may further consume these files by downstream applications such as data lakes etc.

Enabling Data Export

To enable data export for an eligible maintenance object a **Data Export Control** record needs to be created. The record keeps an indication of whether the initial export for the maintenance object has been completed or not and whether changes made to the entity should be tracked and exported on an ongoing basis. A designated portal allows you to enable the generalized data export for many maintenance objects at once as well as monitor their current export status at a glance. Refer to [Generalized Export Dashboard](#) portal for more information.

CAUTION: Enabling and disabling entities for export should only be made via the Generalized Export Dashboard or the Data Export Control portals to ensure the configuration is valid and complete.

CAUTION: When applicable, ongoing data export should be enabled before submitting the initial export batch process for the entity. This ensures that changes made during the initial export are properly tracked.

Ongoing export options are cached in various online and batch caches. In order for these options to take effect and track entity changes made by any online or batch process, the various caches must be properly flushed when these options are changed. Using the designated portals to enable entities for export triggers a 'global' flush of the caches. If the batch thread pool workers are configured to refresh their caches when a global flush is requested, then this is the only step required. If not, then the **F1-FLUSH** batch job should also be submitted to refresh the caches used in batch processing. Refer to [Caching Overview](#) for more information.

Initial Data Export

Each maintenance object that is eligible for the generalized data export method is associated with an initial data export batch control that is referenced on the maintenance object using the **Export Batch Control** option. The same

common batch program is used by all these batch controls to export the entire data of an entity to files. The process is multi-threaded and produces one file per thread by default. An optional batch parameter allows for multiple smaller files to be generated per thread by setting a limit on the number of records written to each file. Refer to the **File Size** section for more information.

Instead of manually submitting the generalized initial export batch process for each maintenance object you have enabled for export, submit the **F1-GEXPI** Generalized Initial Export Initiator batch process to automatically submit them all at once.

The initial export process for each maintenance object updates the corresponding data export control record for the maintenance object to indicate that the process has started and updates it again upon completion. This allows you to view the overall status of the initial export across all enabled entities on the [Generalized Export Dashboard](#) portal.

Note that the initiator batch process only submits batch processes for enabled maintenance objects that according to their data export control record their initial export has not started yet. If you need to export one or more entities again, reset the initial export status indication on their data export control records and submit the initiator batch process again.

The initial export file name is constructed as follows:

```
INIT_EXPORT[_file_prefix(optional)]_[maintenance object]_[batch run]_[thread]_[thread count]
[_file sequence].json.gz
```

The "file sequence" part of the file name is used only when more than one file is created per thread. The sequence suffix is populated starting from the second file as follows 2.

Refer to any of the individual generalized initial export batch controls and the initiator batch control for more information.

Restricting Initial Export By Date

By default, the Initial Data Export batch process exports the entire data for an entity. In some situations, typically around high volume historical data, there may be a need to restrict the export to more recent data, for example the last few months of data.

The initial export batch process supports an optional batch parameter **Restrict By Date** that can be used to limit the scope of data to export. The parameter references a date field and a requested time frame in terms of number of days prior to business date. Refer to the **F1-GEIXP** Generalized Initial Export Template batch control for more information.

CAUTION: Excluding records from export should be carefully considered as this may result in data discrepancies when the excluded data is referenced on other exported entities.

Note: The option is only applicable to specific entities that have a qualifying reference date and the time frame for export may vary for each customer. Therefore, the new parameter is not added to any base product Initial Export batch control aside of the template batch control for documentation purposes. You may clone the base product batch control for a specific entity and add the parameter as per your business needs.

Ongoing Data Export

Data changes are tracked by the Capture Change for Ongoing Export (**F1-MO-REGCHN**) Maintenance Object Audit algorithm. The algorithm records the prime key of a changed entity in a designated **Data Export Update** table that serves as a queue of changed entities to export. The queue is later on consumed by the ongoing data export batch process.

Note: The Maintenance Object Audit plug-in spot is capable of tracking changes made to the entity by any layer of the application. Making changes using direct SQL would bypass this mechanism and therefore should be avoided.

The audit rule is added to a maintenance object when the ongoing data export option on its corresponding data export control record is enabled. In the same way the audit rule is removed from the maintenance object when the ongoing export option is disabled.

Note: The ongoing export option has to be enabled on the data export control record for the entity before it is initially exported. This ensures changes made while the initial export process is in progress are not missed.

Unlike the initial export batch process that requires a batch control to be defined for each eligible maintenance object, a single batch process is used to export ongoing changes made to all entities.

The following describes the ongoing export batch process at a high level:

- All changes queued in the Data Export Update table are exported to a designated ongoing export file. Refer to the **Managing a Large Backlog** section for more information.
- A full snapshot of the data related to the changed entity is exported to avoid heavy data merging on the target side.
- Once exported, records are deleted from the Data Export Update table.

The process is multi-threaded and a separate file is produced for each thread by default. An optional batch parameter allows for multiple smaller files to be generated per thread by setting a limit on the number of records written to each file. Refer to the **File Size** section for more information.

Note: It is important to schedule the ongoing export batch process to run frequently enough to avoid accumulating a high volume of records in the Data Export Update table. The smaller the table is kept the faster it is for the change data capture mechanism to add records to it.

The ongoing export file name is constructed as follows:

```
INC_EXPORT_[batch run]_[thread]_[thread count]_[timestamp]
[_file sequence].json.gz
```

The "file sequence" part of the file name is used only when more than one file is created per thread. The sequence suffix is populated starting from the second file as follows `_2`.

Refer to Generalized Ongoing Export (**F1-GEEXO**) batch control for more information.

File Size

The initial export batch process produces a single file per thread by default. For some high volume entities this may result in files that are too large to manage. To produce multiple and smaller files for a specific entity, limit the number of records written to each file by setting the corresponding parameter on the initial export batch control defined for the entity. The same parameter may be provided when submitting the Initial Export Initiator batch process, in which case the initiator value is used only when a corresponding value has not been defined on the entity's specific batch control record.

In the same way, the ongoing export batch process produces a single file per thread by default. To produce multiple and smaller files, limit the number of records written to each file by setting the corresponding parameter on the batch control.

To avoid the creation of too many files by a single batch run, the system sets a maximum limit of around 500 files per run. When the requested number of records per file is determined to cause the number of generated files to exceed the system limit, the actual value used is adjusted to meet the system limit.

Managing a Large Backlog

When a large backlog of changes accumulates in the ongoing export queue for some reason, the next batch takes longer to export which delays the downstream import step. A better option is for the backlog to be cleared in smaller "chunks", allowing the downstream process to import them as they are made available.

You may limit the number of records the batch process exports using the **Thread Processing Limit** batch parameter. When specified, the number of records exported by each thread is capped by the specified limit, leaving the remaining records to be consumed by subsequent batch runs. Instead of waiting for the next scheduled batch run, a new batch process may be automatically submitted, if explicitly requested to do so using the **Automatic Backlog Clearance** batch parameter.

It is important to ensure that the backlog clears gradually and that the queue resumes its normal size in a timely manner. The processing limit must therefore be set with an appropriate value that would promote proper clearance of

the queue. To do so, at least 20% of the queue, and no less than 100,000 records, must be consumed by each batch run across all threads. If the specified limit does not meet the minimum clearance requirement then the processing limit is adjusted accordingly.

Record Format

Data is fetched and exported directly from the database in bulk read operations for performance reasons. For that reason, the structure used does not reflect the logical data model of the entity but rather its physical list of tables. Data for a given instance is organized by tables followed by rows in each table and for each row its list of fields in JSON format.

The following describes the format and structure used:

```
{
  "OBJ": "<mo name>",
  "TIMESTAMP": "<export time in ISO format for example 2019-07-25T11:06:04.740615Z>",
  "PK1": "<mo pk1 value>",
  "PK2": "<mo pk2 value if any>", ← PK2-5 should only be included when applicable
  "PK3": "<mo pk3 value if any>",
  "PK4": "<mo pk4 value if any>",
  "PK5": "<mo pk5 value if any>",
  "DELETED": true, ← should only be included when the entity is deleted
  "DATA":
  {
    "<MO table name 1>":
    [
      {<name value pairs of all fields in row 1 in that table>},
      {<name value pairs of all fields in row 2 in that table>},...
      {<name value pairs of all fields in row n in that table>},...
    ],
    "<MO table name 2>":
    [
      {<name value pairs of all fields in row 1 in that table>},
      {<name value pairs of all fields in row 2 in that table>},...
      {<name value pairs of all fields in row n in that table>}
    ],...
    "<MO table name n>":
    [
      {<name value pairs of all fields in row 1 in that table>},
      {<name value pairs of all fields in row 2 in that table>},...
      {<name value pairs of all fields in row n in that table>}
    ]
  }
}
```

Notes about field values and formats:

- All fields for a row are included even when the field is empty or null.
- All string values are trimmed of excess trailing spaces but if a field is empty it exported as an empty string "" and not null.
- An empty array is used for a table node when no records exists for the entity in the table.
- Date/time information is converted to UTC time zone and exported in ISO format for example 2019-07-25T11:06:04.740615Z.
- Deletes have an explicit indicator in the header.

Order of Consuming Files

It is important to apply all the initial export files for a maintenance object before applying ongoing change files to ensure data consistency.

The following is a recommended procedure for consuming generalized data export files:

- Apply all initial data export files before ongoing export files.

- Apply initial files for a maintenance object in run number order.
- Apply ongoing export files in run number order.
- If a new initial export is available the file consumption procedure should be changed temporarily as follows:
 - Stop consumption of ongoing export files.
 - Apply the new initial export files.
 - Resume consumption of ongoing export files.

Recover from a Lost Ongoing Export File

The ongoing export batch process keeps a backup of all entity keys, that were exported on a specific batch run, in a designated backup table. In rare situations where an ongoing export file is deleted or becomes corrupted before it gets processed, the backup table may be used to identify the missing changes and export them again.

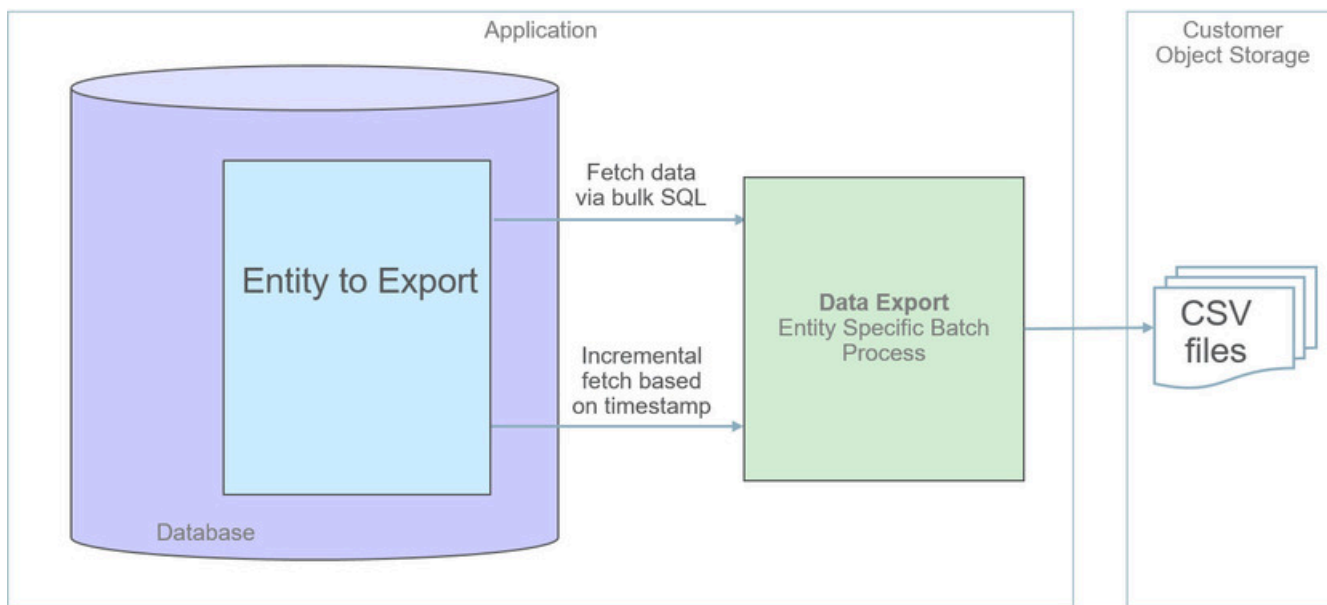

Use the Restore Generalized Export Keys (**F1-GERST**) batch process to recover from this situation. The process identifies the entities that were exported during a specified batch run and adds them back to the ongoing changes queue from the backup table. The entities would then be exported again when the next ongoing export runs. This method does not restore the exact content of the original file that was lost as it cannot be reproduced. Instead, the process ensures that the entities that were included in the lost file would be exported again.

Note: Backup records follow a weekly retention policy for performance reasons. They are meant to support near future situations of file recovery and are not an historical change data capture log.

Specialized Data Export

Several performance considerations are called for when exporting the data of a high volume entity or an entity that is updated in extremely high frequency. The generalized method does not fit such entities and a specific batch process is designed for each, aiming to achieve an optimal export method for the entity. The initial run of the process exports the entity's existing data while subsequent runs of the same process exports data incrementally, i.e. it exports records that were added or updated since the previous run based a timestamp field. The overall process is illustrated in the following diagram:

The following sections further discuss concepts and guidelines related to the specialized data export method.

A Specific Process For Each Entity

A maintenance object that is designed to be exported using the specialized method is explicitly marked as such by the **Data Export Class** option and its specific batch process is defined using the **Export Batch Control** option.

All specialized batch processes are designed to export the data in a CSV format as it produces smaller files in size compared to more verbose formats. Refer to each batch process for more information about specific export considerations and parameters.

Enabling Data Export

To enable data export for a maintenance object a specialized type of [Data Export Control](#) record needs to be created. The record serves as an indication that such entity should be exported and keeps track of the date and time through which data has been exported so far, allowing subsequent export run to only export incremental changes.

Incremental Data Export

The specialized export method tracks changes incrementally from prior export run and does not use a change data capture mechanism. It therefore relies on a timestamp field on the primary table of the maintenance object to indicate when data was added or changed. Only entities that were added or changed since the previous export run are exported with each subsequent run. The date and time through which data has been exported is recorded for each maintenance object on its corresponding Data Export Control record.

Order of Consuming Files

Specialized data export files should be consumed in run number order to ensure a consistent and chronological uptake of data.

Defining Data Export Control

This portal is used to maintain Data Export Control records. These records capture your organization's export settings and current export state for a selected maintenance object. For a generalized export it keeps an indication as to whether the initial export for the maintenance object has been completed or not and whether changes made to the maintenance object should be tracked and exported on an ongoing basis. For a specialized data export it keeps the date/time through which data was exported.

Refer to [Understanding Data Export](#) for more information.

You can access the portal from the **Admin Menu > Implementation Tools > Data Export Control**. You are brought to a query portal with options for searching for a specific record. Once a data export control record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The **Data Export Control** zone provides information about the selected record.

Generalized Export Dashboard

The number of maintenance objects that are eligible for generalized export is large. This portal allows you to easily select and enable export for many eligible entities at once as well as review the current export state of those already enabled at a glance.

Refer to [Generalized Data Export](#) for more information about the generalized data export method.

You can access the portal from the **Admin Menu > Implementation Tools > Generalized Export Dashboard**.

The following zones may appear as part of the portal's **Main** tab page.

- **Export Entities.** This zone lists entities for which generalized data export control settings have already been set.
- **Eligible Entities.** This zone lists entities that are eligible for the generalized data export method and for which such settings have not yet been set.

Meter Solution Products Functional Overview

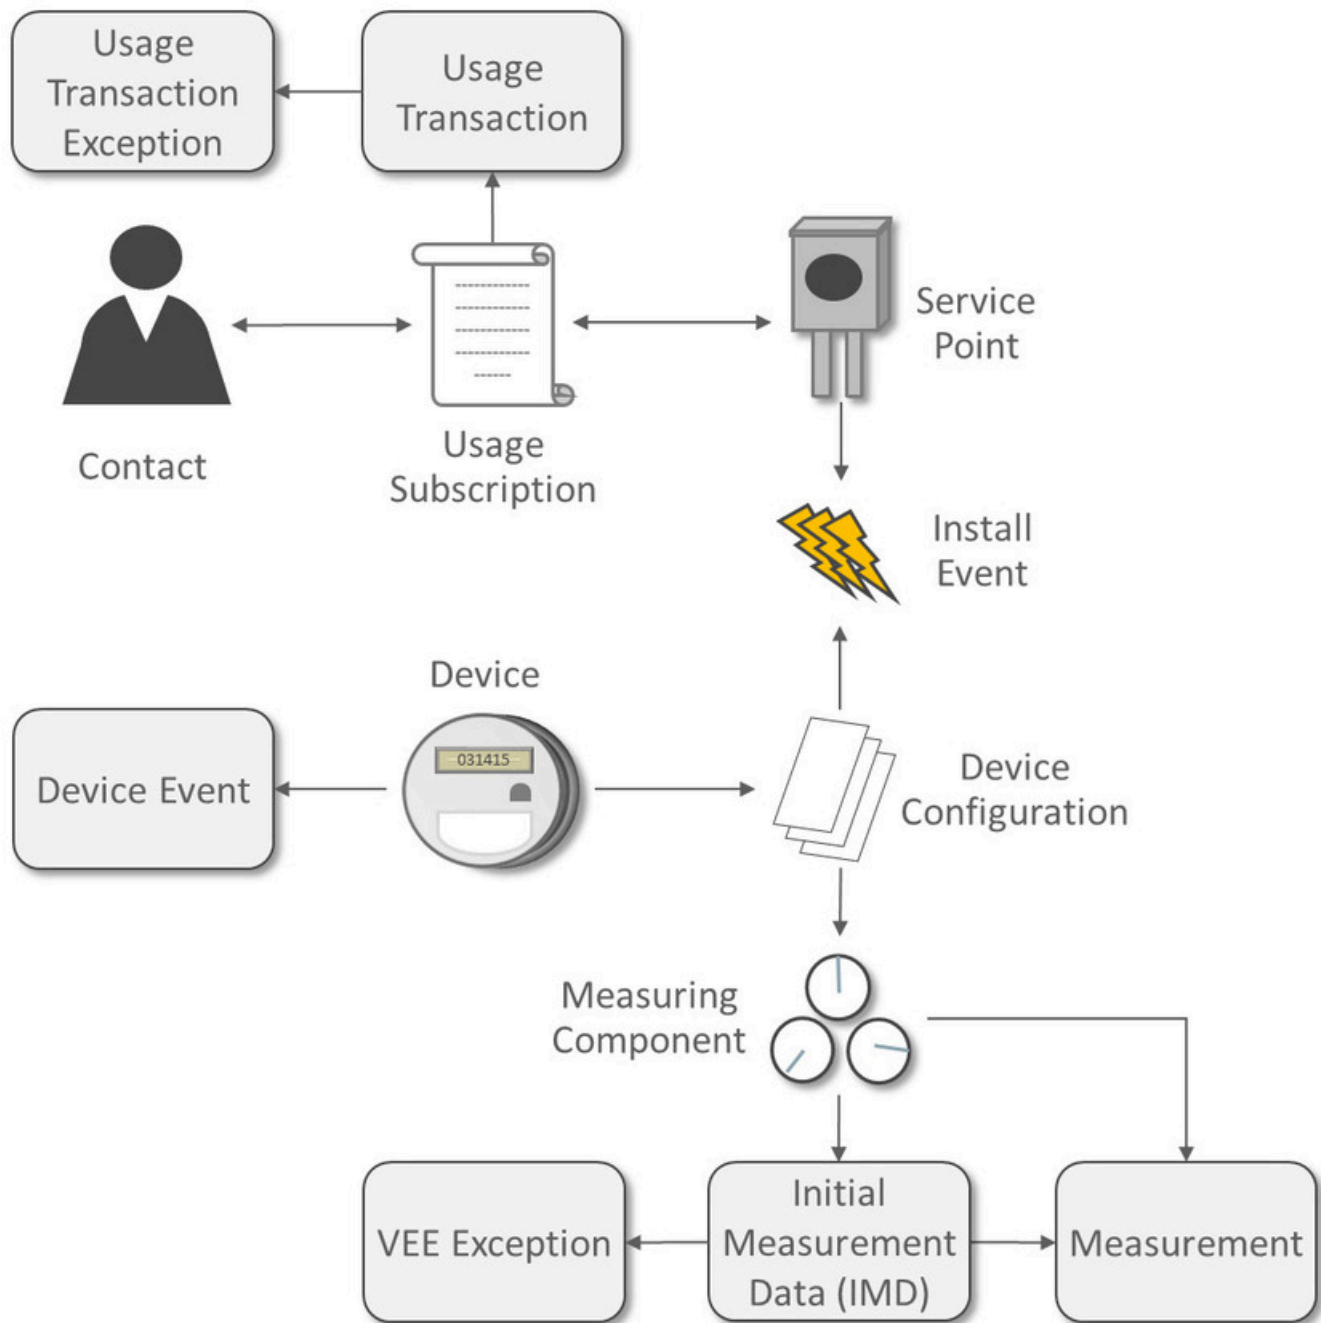

Introduction

Oracle Utilities meter solution products provide functionality for handling large volumes of meter and device data that enable increased accuracy, flexibility, and scalability. The following outlines the most crucial business processes that are enabled within the system:

- Defining meters, meter configurations, service points, and meter installations.
- Loading meter readings and interval data from a head-end system or other source.
- Automatic validation, editing, and estimating measurement data.
- Robust editing capabilities for readings and interval data
- Calculating and publishing bill determinants, and other data, from measurement data to be used in external, downstream systems; such as, billing or pricing.

Oracle Utilities meter solution products store a lot of important data; including, meters, service points, customer contacts, and everything in between.

Measurement, VEE, and Usage Calculation for Billing

A **Device** represents a physical meter, communication module, or some other device in the field. A **Service Point** is the point where service is delivered to a customer and a device can be installed. The **Install Event** is a record of a specific device that is installed at a Service Point. A **Contact** is the customer that is associated with the Usage Subscription.

In order to properly track the way that a device is configured, the **Device Configuration** keeps a record of which types of data should be measured for the device. A **Measuring Component** represents a single channel of data for a device; for example, a device may have multiple measuring components: one that represents kWh interval data, another that represents kWh scalar readings, and a third that registers Voltage interval data.

Energy data received from meters is initially stored as **Initial Measurement Data (IMD)**. Once the **VEE** process is executed, if the data passes then **Measurements** are created. If the data fails, however, then **VEE Exceptions** are created.

A **Usage Subscription** tracks a set of usage calculations that should be performed for a single or multiple Points. In order to perform calculation of usage (often referred to as bill determinants), a **Usage Transaction** is created through a request from the billing system. If any issues are encountered in the usage calculation process, or from a usage transaction validation, then **Usage Transaction Exceptions** are created.

Service Orders and Remote Commands

An **Activity** in Oracle Utilities Meter Data Management is a very flexible object that is used for various processes. Two of the key processes handled by Activities are:

- Remote Commands involve communicating with a Head End system to perform actions or retrieve data from a meter; for example, remote connects, remote disconnects, and on-demand reading.
- Service Orders are methods where work can be performed at a Service Point; for example, enabling service, disabling service, and meter exchanges.

Oracle Utilities meter solutions products include the following functional areas:

- **Device Management** is used by analysts and administrators to manage and define the devices used to record and capture meter data.
- **Device Installation** is used by analysts and administrators to manage device installation; including, defining markets and service providers, service points, contacts, and installation events.
- **Measurement Data** is a normalized way of storing data from a meter that involves some form of measurement (such as, kWh and CCF). Both interval data and scalar readings are held in this common storage location.

- **Validation, Editing, and Estimation (VEE)** is used by administrators to define validation, editing, and estimation rules to be applied to measurement data. VEE Exceptions may result from validation or estimation failures and should be worked by analysts through the To Do process.
- **360 Degree Search and View** is used by analysts and administrators to search and view data for devices, measuring components, service points, usage subscriptions, and contacts.
- **Consumption Sync** provides an automatic method to keep interval data and scalar readings in sync with one another.
- **Usage Calculation** is used by administrators to manage the calculation of usage data and to provide the results of those calculations (commonly referred to as bill determinants) to external systems and parties. Usage calculation groups and rules define calculation rules to be applied to measurement data. Usage Transaction Exceptions may result from usage calculation and should be worked by analysts through the To Do process.
- **Device Events** provide a view of specific events that have occurred on a meter. These are often unexpected and can indicate an issue with the meter.
- **Communication** helps track the instances when communication occurs with external systems. This is heavily used to track remote commands against Head End systems.
- **Aggregations** are used by analysts and administrators to search, view, and maintain aggregated measurements that represent a summarization of other measurements from a set of devices and/or measuring components.
- **Master Data Sync** defines the methods that data is automatically synchronized to Oracle Utilities Meter Data Management from external sources; such as, a CIS and/or Asset Management system.
- **Outage Storm Mode** is a way for Oracle Utilities Meter Data Management to detect widespread outages and suppress estimation for those meters until normal data communication resumes.
- **Dashboards** provide high level metrics for Oracle Utilities Meter Data Management operators to monitor operational trends as well as overall system health.
- **Service Issue Monitor** can be setup by administrators to monitor various conditions within Oracle Utilities Meter Data Management and automatically create a Service Investigative Order, if those conditions are met.
- **Service Order Management** provides a centralized program for managing the complex interactions required for Service Order processing. This area is especially valuable for managing service order processing that involves remote communication with a Head End for connects, disconnects, and on-demand readings.
- **Market Settlement** provides the core functionality for calculating and settling energy changes.
- **Information Lifecycle Management** is an automated method that administrators can configure to prepare data for archiving or purging after a defined period of time for the record type.

Architectural Overview

Oracle Utilities meter solution products are used to maintain information about meters and the service points at which they are installed. The applications provide means of recording measurements and events associated with meters in the field as well as the ability to compute usage for the recorded measurements.

Oracle Utilities meter solution products comprise the following functional areas:

- **Device Management:** the maintenance of physical meters in the field
- **Device Installation:** the maintenance of service points and the installation of meters in the field. This includes the means of registering outside systems to Oracle Utilities Meter Data Management for provider/consumer-specific processing of meter events and activities
- **Device Communication:** the maintenance of communications between Oracle Utilities Meter Data Management and head-end systems, including import of usage and events.
- **Validation, Editing, and Estimation:** the maintenance of measurement data and the engine used to validate and modify that data as it comes in
- **Usage Management:** the engine that calculates billable usage recorded on devices, applying factors and dividing the usage into configurable time of use periods
- **Aggregation:** summarization of measurement data for reporting and analysis purposes
- **Data Synchronization:** synchronizing data between Oracle Utilities Meter Data Management and other Oracle Utilities applications (including Oracle Utilities Operational Device Management and Oracle Utilities Customer Care and Billing).

- Oracle Utilities DataConnect: extraction of consumption and master data for use in external systems.
- Settlement: calculation and reconciliation of energy charges within a market

Oracle Utilities Meter solution products are built upon the Oracle Utilities Service and Measurement Data Foundation, a framework that provides shared functionality used by Oracle Utilities Meter Data Management, the Oracle Utilities Smart Grid Gateway adapters, and other Oracle Utilities products. Oracle Utilities Meter Data Management and the Oracle Utilities Service and Measurement Data Foundation are built atop the Oracle Utilities Application Framework.

Naming Conventions

Oracle Utilities Meter solution products use naming conventions to identify and distinguish entities that belong to different Oracle applications. These conventions can help you locate entities and understand their context.

Each base product uses a 2-character prefix for all its entities. For Oracle Utilities Meter solution products, these prefixes are as follows:

Product Name	Prefix
Oracle Utilities Application Framework	F1
Oracle Utilities Service and Measurement Data Foundation	D1
Oracle Utilities Meter Data Management	D2
Oracle Utilities Smart Grid Gateway for Landys+Gyr	D3
Oracle Utilities Smart Grid Gateway for Echelon	D4
Oracle Utilities Smart Grid Gateway for MV-90	D5
Oracle Utilities Smart Grid Gateway for Sensus RNI	D6
Oracle Utilities Smart Grid Gateway for Silver Springs Networks	D7
Oracle Utilities Smart Grid Gateway for Itron OpenWay	D8
Oracle Utilities Smart Grid Gateway for Adapter Development Kit	DG
Oracle Utilities Customer Self Service	WX
Oracle Utilities Meter Data Management Demo Data*	DM

*Note: this is not actually a product but rather a set of data that demonstrates Oracle Meter Data Management functionality.

Oracle recommends that you follow these naming conventions and develop your own set of conventions for the entities you create. If you create new entities, DO NOT use these prefixes; use the prefix "CM" (or some other unique prefix) to identify entities that have been customized.

High Level Functional Areas

A high level overview of the functional areas for Oracle Utilities Meter solution products has been defined in the [Functional Overview](#) section of the *Oracle Utilities Meter Solution Business User Guide*. This may be worthwhile to review to become better oriented to the areas of the Administrative User Guide before reading on.

Meter Data Management Configuration Setup Sequence

This section provides the suggested order for the setup of Meter Data Management and Smart Grid Gateway administrative data.

	Entity	Description
1	Feature Configuration	These are options that can be set to impact system processing. Typically these have wide ranging impact across several modules (e.g., multi-time zone support)
1	Country	Your organization's country.
1	Currency	Your organization's native currency.
1	Display Profile	Controls how dates, times, and numbers displayed.
1	Language	The language to use for this implementation.
1	Time Zone	Your organization's base time zone.
1	Work Calendar	The work calendar for your organization, which identifies your public holidays.
2	Installation Options	Control various global aspects of the system.
2	To Do Role	Used to associate users with To Do entries.
2	To Do Type	Used to define types of To Do Entries.
3	User	Defines a user's user groups, data access roles, portal preferences, default values, and To Do roles.
3	User Group	A group of users who have the same degree of security access.
3	Service Type	Defines specific types of service for which usage can be recorded and captured (electric, gas, steam, etc.).

4	Division	Delineates between different operating companies within a large conglomerate of utilities.
4	Unit of Measure	Quantities measured and recorded by the system (CCF, KWH, KW, etc.).
4	Service Quantity Identifier	Used to further distinguish between measured quantities that have identical UOM/TOU combinations.
4	Time of Use	Modifiers for a given unit of measure that indicate a period of time during which a quantity has been used (On-Peak, Off-Peak, etc.).
4	Factor	Centrally stored sets of values for use in validation rules, bill determinants calculations, and other processes.
4	Market	Defines jurisdictions or regulatory environments in which a Service Point participates.
4	Measurement Cycle	Defines the schedule for manual meter reading of devices at Service Points in that cycle
4	Measurement Cycle Schedule	Define the dates on which devices are scheduled to be read for a given measurement cycle.
4	Outbound Message	Defines messages sent to external systems.
4	Processing Timetable Type	Defines types of schedules that can be referenced by different processes and objects.
5	External System	Defines External Systems with which Oracle Utilities Meter Data Management should be able to communicate.
6	Head End Systems External Applications Market Participants	External entities that serve various roles relative to the application (head-end systems, billing systems, market participants, outage management systems, etc.).
6	Contact Type	Defines properties of a class of entities (businesses, persons).
7	Activity Type	Defines properties common to a specific type of activity.

7	Communication Type	Define properties common to a specific type of communication.
7	Service Task Type	Defines specific types of tasks performed by external users (self-service meter reads, self-service outage notifications, etc.)
7	Dynamic Option Type	Defines information common to dynamic options of a specific type.
7	Manufacturer	Individual companies that makes devices. Manufacturers also reference models.
7	Exception Type	Defines properties common to VEE Exceptions of a specific type.
8	VEE Group	Collections of VEE Rules that are applied to initial measurement data.
9	VEE Rule	Standard and custom VEE Rules that perform checking and/or manipulation of initial measurement data.
10	VEE Eligibility Criteria	Dictates whether a VEE Rule can execute based on a set of defined criteria.
11	Measuring Component Type	Defines the most important properties of a measuring component.
11	Measuring Component Comparison Type	Defines details by which measuring component data can be compared to determine the days that most closely resemble a specific day being evaluated.
12	Device Configuration Type	Defines properties of Device Configurations of a given type.
13	Device Type	Defines information about a class of devices.
14	Service Point Type	Defines specific types of points at which service is delivered.
14	Service Point Quantity Type	Defines types of quantities that can be stored for a service point.
14	Usage Subscription Quantity Type	Defines types of quantities that can be stored for a usage subscription.

15	TOU Group	Used to limit the set of Time Of Uses that are usable in a TOU schedule.
16	TOU Map Template	Schedules used for TOU map data generation.
17	TOU Map Type	Define important properties of TOU maps of a given type.
18	Usage Transaction Exception Type	Defines properties common to Usage Transaction Exceptions of a specific type.
18	Usage Calculation Group	Collections of usage calculation rules that are applied to measurement data to calculate bill determinants for Usage Subscriptions.
19	Usage Calculation Rule	Defines rules that perform calculations on measurement data to generate bill determinants and other values used by external systems.
20	Usage Calculation Rule Eligibility Criteria	Dictates whether a usage calculation rule can execute based on a set of defined criteria.
21	Usage Subscription Type	Defines collections of properties common to a set of Usage Subscriptions.
22	Data Source	Defines the source of data for dynamic aggregation, such as measurement data from usage subscriptions linked to a service point, badged or unbadged items, or measuring component sets
22	Dynamic Aggregation Measuring Component Type	Define the most important properties of a measuring component used with dynamic aggregation.
22	Measuring Component Set	Define the dimensions and criteria by which dynamic aggregation will be performed.
22	Aggregation Group	Define the ordering of a series of related aggregations based on a set of configured measuring component Sets.
23	Settlement Subscription Type	Defines collections of properties defining a class of settlement subscriptions.

23	Settlement Unit	Defines the “lowest common denominator set” of dynamic aggregation dimensions.
23	Settlement Calculation Group	Defines collections of settlement calculation rules that are used to perform settlement calculations, including calculating service point quantities, totaling consumption and usage for settlement units, application of losses, and allocation of unaccounted for energy (UFE).
23	Settlement Calculation Rule	Defines rules that perform settlement calculations, including calculating service point quantities, totaling consumption and usage for settlement units, application of losses, and allocation of unaccounted for energy (UFE).
23	Settlement Item Type	Defines specific types of end-customer settlement accounts.
23	Market Contract Type	Defines specific types of market contracts used in settlement processing.
23	Market Product Set	Defines the highest level grouping for a set of market products that will be processed together.
23	Market Product Type	Define types of products used in settlement processing.
24	Processing Methods	Control various behaviors for external applications, head end systems, and market participants within the system such as which message is sent, how an external value is translated, among others.
24	Master Configuration	Configuration that applies to series of modules that acts as a central point of configuration rather than embedding repetitive configuration throughout a set of algorithms.
24	Information Lifecycle Management	Information Lifecycle Management (ILM) is designed to address data management issues, with a combination of processes and policies so that the appropriate solution can be applied to each phase of the data's lifecycle.

24	Analytics	Defines the extract parameters, the bucket configurations and configuration snapshots used for extracting data for Oracle Utilities Analytics
----	---------------------------	---

Operational Device Management Table Setup Sequence

This section provides the suggested order for the setup of Operational Device Management administrative data.

Sequence	Entity	Description
1	Configuration Type	Defines the information required for various asset configurations with other assets, components, firmware, and other data.
1	Service History Questions	Used to guide workers through corrective and preventive inspection processes as part of an asset's service history.
1	Service History Type	Defines the main attributes for service history of a certain type. Types might include maintenance, inspection, service, test, measurement, and so on.
2	Asset Location Type	Defines the details of asset or component locations of a certain type. Valid types of asset locations can include service points, other locations for installed assets, or any other location as defined by your organization.
2	Out of Service Location Type	Defines attributes of types of locations where assets that are out of service are stored and maintained. Examples of out of service locations include warehouses, storerooms, and repair shops.
2	Organization	Used for categorization and reporting for locations.
2	Configuration	Documents and manages valid setups for assets and components. This includes a specification for each asset or component in the configuration as well as the valid value for each parameter, such as the firmware version of each asset.

3	Out of Service Location	Defines physical locations where assets are stored or repaired such as a storeroom, warehouse, or service facility. When assets are changed to statuses such as “In Repair” or “Pending Disposition” the asset location is typically moved to an out of service location.
3	Configuration Reports	Provides a summary of currently installed configurations.
4	Asset Type	<p>Defines the attributes for assets and components of a certain type, including information such as the valid location types and service history types for the assets and whether or not such assets can have attached components.</p> <p>When setting up Asset Types, asset type codes should match corresponding device type codes in Meter Data Management (see Meter Data Management Table Setup Sequence).</p>
5	Asset Activity Type	<p>Defines the attributes for asset activities of a certain type, including scheduling information , exception handling, attachments, and related completion event types.</p> <p> Note: Asset activity types are automatically created when Service Order Management Field Task Types are created (values for the Field Task Type extendable lookup).</p>
5	Asset Completion Event Type	Define various processes or events to be executed when completing an asset activity such as asset replication, service history creation, attachment creation, and activity creation.
5	Asset Inbound Communication Type	Defines the information required for the system to receive messages from external systems.

Understanding Online / Batch Loaders

Online / Batch Loaders enable the quick loading of data into the system. Data can be loaded for any business object as it uses the business object's schema to load data into the application.

Note: We recommend that this process not be used to load data for objects maintained through merged maintenance, such as Service Type, Unit of Measure, Service Quantity Identifier, Time of Use, Service Point Type, or Service Point as this process may not properly populate data for all maintenance objects supported by merged maintenance.

Two types of loaders are supported:

- **Online Loaders** easily upload smaller amounts of data. Use this type of upload process when uploading small numbers of records or data for business objects without complex lifecycles and business object rules such as Organizations. The data is loaded through the user interface to create the target objects.
- **Batch Loaders** should be used for larger volumes of data and for complex business objects such as Assets. Batch loaders load data from files on the server or attachments. Batch loaders use a two-step process that first creates the inbound sync request and uploads the file to a staging table and secondly, uploads the sync request from the staging table to either create the target objects or create another dedicated inbound sync request that handles the complexity of a particular object.

Processing uses the creation of a request type to facilitate the upload process:

- For online request types, the actual data is stored within and processed by the request.
- For batch request types, two options for batch load are supported; from a file located on the server or from an attachment in the application. Either the file name (file on server) or the attachment id (attachments) is stored on the request, the data is loaded into the generic inbound sync requests, and the request acts as a header record for all the generic inbound sync requests.

A csv file is the format used for loading data (see **Creating CSV Files**, below). The loader has very strict requirements as to the format of the file. Please see the embedded help in the **Data** section on the Online Loader Request business object for details and additional tips.

Creating CSV Files

While data can be manually entered into the system, the most efficient method for uploading the data is to use one of the CSV data templates already available for all appropriate business objects.

The first step is to create a .csv file (comma delimited) from the business object of the portal being loaded.

The following is an example using Organization (W1-Organization):

1. Navigate to **Admin**, select **Location**, select **Organization**, and then select **Search**.
2. Search for and select a record.
3. Expand the **Record Information** section and click the "Organization" **Business Object** link to navigate to the **Business Object** portal.
4. Click the **View Schema** link on the **Main** tab and then copy the elements from the business object to a CSV file to create your data.

1	Sequence	Primary Key	Field 01	Field 02	Field 03
2	1	Organization	Organization Type	Disposition	description
3	2	nodeId	nodeType	nodeDisposition	description
4	3		Group	W1AC	Group 1
5	4		Group	W1AC	Group 2

Notes:

- Columns in the top row match the elements in the list of the request business object (header).
- The row with the lowest sequence number (1) is the description of xpaths to help users read the file and is ignored by the processing.

- The business object processing treats the row with the second lowest sequence number (2) not as data, but as the xpath to move data to the target business object, in this case, W1-Organization.
 - Note that the configuration of some business object mean that this cell may start with a “+” sign. Also note that the file always treats this cell as a formula and adds an “=” sign to the front of the data string, as indicated by “#NAME?” (For example: =+nodeId/nodeType). You must reformat the cell to “Text” and remove the “=” sign.
- Rows with sequence number three (3) and up are treated as data.
- For objects where the primary key is a system generated ID (such as the case with Organization), the Primary Key column cells blank.

Note: When adding records that reference look up values use the lookup field value, not the description. For instance, the Disposition field references the NODE_DPOS_FLG lookup, for which the "Active" field value is "W1AC". For fields that reference other objects, use the code, not the description.

Other Formatting Issues

The following information addresses known formatting issues in working with the CSV data template:

- Dates need to be formatted as yyyy-mm-dd (2020-10-27).
- Date and Time should be formatted as yyyy-mm-dd-hh.mm.ss.
- Columns based on lookup values that have leading zeroes will need to match the values in the CSV file.
- A link needs to be created when you want to include the “parent”, which has a system generated ID, in the same file with the “child”. For example, if you want to populate the Parent Organization’s ID in the same file, you would need to insert a link (for example, @3, which is the @ symbol plus the Sequence #) in the row where the system generated ID would reside.
- If multiple rows contain the same Primary Key, only the last row is loaded. All values for the Primary Key need to be on the same row.

Initiating Requests

There are two steps involved in loading data using this process: creating the request type and the request.

Creating Request Types

1. Navigate to **Admin**, select **General**, select **Request Type**, and then select **Add**. The **Select Business Object** screen opens.
2. Select the request type business object that corresponds to your request type (“Online Loader Request Type” or “Batch Loader Request Type”) from the **Request Type Business Object** drop-down list and click **OK**. The **Online Request Type** or **Batch Request Type** screen opens (based on the business object selected).
3. Enter a code and meaningful description for the request type in the **Request Type** and **Description** fields. For example, "Online Loader Request Type" or "Batch Loader Request Type".
4. Enter a **Detailed Description** (optional).
5. For request types based on the Batch Loader Request Type business object, specify whether or not the contents from the attachment record will be deleted once the upload is finished (Yes or No) in the **Deleted Attachment Upon Finish** drop-down list.
6. Click **Save**.

Creating Requests

Online Requests

1. Navigate to **Menu**, select **Tools**, select **Request**, and then select **Add**. The **Select Type** screen opens.
2. Select your online loader request type and then click **OK**. The **Online Loader Request** screen opens.
3. Select the business object for your loader in the **Business Object** field.
4. Select your CSV file to upload or enter the data directly into the **Data** section and then click **Save**. Note: If examples of online requests are already available in your system, search for the appropriate request, click **Edit**, and either use the existing data if it applies, or click **CSV File To Upload** to upload your already formatted and

populated CSV file. You can also click **Download To CSV File** and manually populate the data into the file and then click **CSV File To Upload** to upload the file. Your request will open in the **Request** zone in the "Created" state.

5. Click **Load Data** in the **Record Actions** section to submit the request. If successful, the status of the request will be "Loaded". Check the **Request Log** for requests that do not transition to a "Loaded" status. You will need to click **Back to Created** to reset the request back to the "Created" status and click **Edit** to fix the issue before resubmitting the request.

Batch Requests

1. Navigate to **Menu**, select **Tools**, select **Request**, and then select **Add**. The **Select Type** screen opens.
2. Select your batch loader request type and then click **OK**. The **Batch Loader Request** screen opens.
3. Select an external system from the **External System** drop-down list.
4. Select the business object for your loader in the **Business Object** field.
5. Enter a commit frequency in the **Commit Frequency** field.
6. Enter the **File Name** or search for and select the **Attachment** that should be in the request and click **Save**.
 - For **Batch File Upload** — The Filename is specified in the request. Comma delimited files should be uploaded to or available on the server. Run the W1-GBUPL batch job to create the sync request. Parameter File Name and File Path should match the file name and path of the file. Once the job has ended and the request is loaded, run the F1-SYSRQ batch job to process the created sync request.
 - For **Batch Attachment Upload** — The Attachment ID is specified in the request. Comma delimited file is uploaded as an attachment. Run the W1-GAUPL batch job to create the sync request. Parameter Request ID should match the created request. Once the job has ended and the request is loaded, run the F1-SYSRQ batch job to process the created sync request.
 - Use the following parameters when running the F1-SYSRQ batch job:
 - Maintenance Object: F1-SYNCREQIN
 - Restrict by Batch Code: True
 - Restrict by Business Object: W1-GenericDataLoaderSync
 - Restrict by Status Code: PENDING

Additional Resources

How to Get Support

Oracle is deeply committed to technical support services for its products. The Oracle Support online portal provides a reliable, easy-to-use method for obtaining technical support for Oracle Utilities Meter Data Management. To register as a new user for Oracle Support, go to <https://support.oracle.com> and follow the steps shown on the screen.

Oracle policies for standard technical support services are available at <http://www.oracle.com/us/support/policies/index.html>.

Knowledge Base Articles

Once you have access to Oracle Support, finding Knowledge Base articles is an easy process.

1. Log in to <https://support.oracle.com>.
2. Select the **Knowledge** tab at the top of the Oracle Support portal.
3. Under the Knowledge Base section, type "**Oracle Utilities Meter Data Management**" as the product.
4. Enter key search topics into the **Enter search terms** box.
5. Click **Search**.

The search results will display all knowledge articles stored on Oracle Support related to Oracle Utilities Meter Data Management for your key topics.

Important Articles

While there is a vast library of important Knowledge Base articles on Oracle Support, the list below highlights a few of the key knowledge articles that should be helpful if you're looking for additional detailed information about Oracle Utilities Meter Data Management:

Article Name	Knowledge Base Article Number
Information Center: Meter Data Management and Smart Grid Gateway Version 2	1907636.2
Related Measuring Component Consumption Sync Technical Reference Paper	1672461.1

Support Hot Topic Emails

Oracle Support provides a way to receive daily or weekly updates on new information posted for Oracle Utilities Meter Data Management.

1. Log in to <https://support.oracle.com>.
2. Select the **Settings** tab at the top of the Oracle Support portal. (Note: this tab may be hidden for you and may require clicking a dropdown on the right side of the tabs)
3. Once on the Settings screen, choose the **Hot Topics E-mail** from the set of options on the left.
4. Under Delivery Options, choose **Send With Selected Options**.
5. Choose your delivery frequency: either Daily or Weekly.
6. Add content which interests you: there are a number of options available. To subscribe to updates for Oracle Utilities Meter Data Management, hit the **Add...** button under Selected Products. Enter "Oracle Utilities Meter Data Management" for the Product then choose the types of information for which you'd like to receive an email.
7. Make sure you click **Apply** at the bottom once you've made all of your selections.

Embedded Help

Oracle Utilities Meter Data Management, like all Oracle Utilities Application Framework applications, provides extensive internal documentation. For example, detailed descriptions of system objects are included in the objects' maintenance portals. The lifecycle of each business object is described on the Lifecycle tab and depicted in flow diagrams on the Summary tab. This information is extremely useful for implementers and system administrators.

Embedded help is provided for all non-obvious fields in most portals and zones. If a field has associated help text, a question mark icon appears next to the field when the zone is displayed.

Leveraging Demonstration Data

One of the best ways to understand Oracle Utilities Meter Data Management is through a thorough review of the demonstration data (also referred to as "demo data") provided by Oracle. The demo data for Oracle Utilities Meter Data Management provides the following:

- An overall view of how to implement the product for common needs
- Examples of the productized solutions to solve key utility scenarios
- Some examples of adding "customer modifications" on top of Oracle Utilities Meter Data Management

This demo data can be downloaded along with the Oracle Utilities Meter Data Management. It's recommended that this be installed into an isolated environment for reference purposes separate from other development or testing environments.

Once installed, the demo data scenarios can be found in two places within Oracle Utilities Meter Data Management:

- A zone named **Demo Scenarios** is shown in the Sidebar. This provides a quick method to link to the 360 Degree View for the specific demo meter.
- An extendable lookup named **Demo Scenarios Catalog** describes each of the scenarios in detail. This matches the scenarios displayed in the Demo Scenarios zone.

NOTE: Oracle recommends that you do not clone the demonstration environment as a basis for a new production environment. The demonstration environment typically includes transactional data that will be irrelevant to your production environment and can cause unexpected issues if it is not purged correctly. The recommended process is to start a new production environment from a new installation and migrate "clean" system data (such as business objects and algorithms) and administrative data (such as sample activity types or other administrative entities) from the demonstration and/or test or development environments as applicable. Instructions for using these tools are contained in the [Bundling](#) and [Content Migration Assistant](#) sections in the Oracle Utilities Application Framework *Administrative User Guide*.

Customer User Groups

A number of Customer User Groups have been established (one in the United States and others internationally) that are specific to sharing best practices and learnings about Oracle Utilities Meter Data Management and Oracle Utilities Smart Grid Gateway (SGG). If you're interested in participating in a Customer User Group, contact the appropriate Product Manager.

Oracle Forums

Oracle Forums is a way for you to suggest ideas for Oracle Energy and Water solutions. Oracle Forums provides an easy way to submit feature ideas directly to product owners in Oracle Energy and Water. Once an idea is submitted, other users can comment on and vote for your idea to show their support.

Submitting an idea is simple. When you go to [Oracle Forums](#), click **Sign In** to enter your Oracle account information or create a new account. Once you have signed in, select **New Post**. Select a solution category, title, and description for your idea. Click **Add Post** and product owners will be notified of your suggestion.

Best Practices

Performance Recommendations

This section includes best practices and recommendations regarding performance.

Partitioning and Data Removal

- **Implement Partitioning:** Partitioning is essential to manage the large amounts of data coming into Meter Data Management. Customers will have significant performance problems without partitioning. Partitioning is required for good performance and to organize the data so old data can easily be dropped from the database. Customers need historic partitions (for conversion and replacement reads) and future partitions.
 - Cloud Implementations: Customers should run 'Add Partition' jobs, **K1-ILMAD** and **F1-ILMSV** (for sub-partitions, if needed) on a regular basis to ensure that new partitions are created regularly.
 - On-Premise Implementations: Please refer to the *Oracle Utilities Meter Data Management Database Administration Guide* for partitioning guidelines for on-premises implementations.

- **Implement Compression:** Compression is essential to reduce the size of the database. For standard hardware we recommend Advanced Compression. For engineered systems that use Oracle Exadata, we highly recommend HCC (Hybrid Columnar Compression) this reduces the overall database by approximately 50%.
 - Cloud Implementations: Customers should use the “ILM Automation – Non-Measurement Compression” (F1-ILMNC) batch process to change the compression level from Advanced to Hybrid Columnar for non-Measurement data at least two months old, which can result in significant disk space savings. Use the following parameters when running this batch process: Owner, MO (optional), DOP (Degree of Parallelism), Estimated Time Limit (How long job can run until it will not compress another partition). In larger databases this can run for several days a month.
 - On-Premise Implementations: Please refer to the *Oracle Utilities Meter Data Management Database Administration Guide* for compression guidelines for on-premises implementations.
- **Setup Information Lifecycle Management (ILM):** – The Information Lifecycle Management processes mark items eligible to be removed and update partitions to segregate the data that can be removed. Customers need to define the “ILM Configuration” default retention periods (via the ILM Master Configuration). The retention period should be defined for all ILM objects. ILM Crawlers are provided for low volume transactions. High Volume transactions are marked as eligible for archiving automatically.
 -  **Note:** Completed IMDs (Initial Measurement Data records) can be removed shortly after being imported. Removing IMDs after 3 months will reduce the compressed database by approximately 50%. There will be database storage savings by archiving other ILM objects as well, such as Activities and To Do Entries.

Different types of implementations call for different approaches to using ILM.

- Cloud Implementations: Run the ILM Crawlers Batch Job (batch controls by object) and once the data is aged request Cloud Operations to move the partitions to Object Storage.
- On-Premise Implementations: Please refer to the *Oracle Utilities Meter Data Management Database Administration Guide* and [Information Lifecycle Management](#) for ILM guidelines for on-premises implementations.

Device Channels to Process

Oracle does not recommend customer process all channels of data that Meter Data Management can derive.

- Oracle does not recommend utilities hard-code devices with time of use periods (e.g.: on-peak, off-peak). Hard-coded time of use periods will likely require reprogramming in the future when those periods change. Meter Data Management can easily calculate time of use values from interval data.
- Oracle does not recommend customers hard-code demand channels (such as channel used to measure kW), since these must be reset every bill cycle. Demand can be derived from kWh interval data.
- Likewise, Oracle does not recommend customers hard-code channels for Power Factor since that can be derived from kWh and kAVRh interval data.

Data Conversion

- Only convert essential data. Only convert objects that are essential to running the business.
- Pay careful attention to measurement data. Measurement data is very, very large and may take weeks to convert. Consider this: if it takes one hour to load measurements every day, how long will it take to load 5 years of measurements? Although conversion jobs are faster than regular data loading, measurement conversion still takes time. Here are a few measurement best practices:
 - Projects are encouraged to only convert the minimum amount of measurement data required.
 - If historical measurements are required, try to limit the amount of data converted. The best practice is to convert 13 months of consumption to support VEE.
 - Only convert channels absolutely required, usually billing channels, and don't convert other interval data if not needed.
 - Measurement data values should be converted directly into the Measurement table and not use the IMD and VEE processes.

- **Do not convert Initial Measurement (IMDs).** Completed IMDs are not needed for any Meter Data Management processes.
- Remember that billing quantities will likely also be stored in the customer information system, so confirm that the measurement data is required before conversion.

Initial Measurement Loading Recommendations

- Initial measurement data (IMD) processing is impacted by a number of factors, including the size of the IMDs being processed, and other concurrent processing (such as other batch processes).

The size of an IMD is determined by two primary factors, the interval size and the duration of the IMD.

- The interval size determines how many measurement values are contained in the IMD. For example, an IMD containing 1 days' worth of measurement of hourly intervals contains 24 interval values, while an IMD containing 1 days' worth of measurement of 15-minute intervals contains 96 interval values, and an IMD containing 1 days' worth of measurement of 5-minute intervals contains 288 interval values. All three contain 1 days' worth of measurements but will require different amounts of compute processing.
- The second factor impacting the size of an IMD is its duration. However, as noted above the interval size of the IMD plays a significant role in determining the overall size of the IMD. As a general rule, the smaller the interval size, the shorter the duration should be.

We recommend that you limit the number of measurements in a single IMD. In general we recommend a maximum of 1 days' worth of measurements in a single IMD, but this should be adjusted based on the interval size (again, the smaller the interval size, the shorter the duration should be). We recommend trying different combinations of durations and the number of IMDs (such as 3 IMDs per day each containing 8 hours of intervals, 4 IMDs per day each containing 6 hours of intervals, and so so) to find a volume that works best in your environment.

One other factor to consider is the impact on database storage. In general, the number of IMDs has a greater impact on database storage than the number of intervals within each IMD – sending more IMDs per day results in a larger impact on database storage. For example, sending the same number of intervals in a day in a single IMD has a smaller database storage impact than sending the same number of intervals spread across multiple IMDs.

Mitigating concurrent processing involves optimizing the scheduling of IMD and other processing to best suit the needs of your implementation. The initial measurement data and event loading processes should be scheduled to avoid overlap with other intense processes. For instance, do not produce bill determinants when loading meter readings.

If you are processing “fabricated” IMDs to migrate data, keep in mind that the system has not been tested or benchmarked for this purpose. For example, including 30 days' worth of measurements in a single IMD is not typical, and has not been performance tested.

Typically, projects use tools such as SQL Loader to migrate large volumes of historical data directly into the Measurement table rather than use IMDs.

- When processing files of varying sizes, the `chunkSize` parameter can be used to facilitate improved processing throughput by distributing work across multiple batch threads. See [Common Parameters](#) for more information about the `chunkSize` parameter.
- When processing payloads using middleware implementations, keep the number of devices to 2,000 per file for optimum usage and event processing through Oracle Service Bus. A lower number of devices, per file, will take more time for processing. A higher number of devices, per file, leads to high growth in garbage collection leading to waits and results in lower throughput. Please note, the optimum number of transactions per file may vary by head-end system.
- The system includes a number of Initial Measurement Data (IMD) monitor batch processes that can be used to minimize performance issues when adding large numbers of historical or backlog readings. These use the IMD as the processing work unit instead of the Device Configuration. This prevents situations in which an error on an IMD rolls back processing for all of the IMDS for a given device configuration. These include:
 - D1-IMDV2 (IMD Monitor - Physical Devices V2): used to process initial measurements related to physical devices

- D1-IMDD2 (IMD Monitor - Deferred IMDs V2): used to process previously held or deferred IMDs
- D1-IMDM2 (IMD Monitor - Unattached MCs V2): used to process IMDs for standalone measuring components without a Device Configuration such as weather or price data

Refer to the Detailed Descriptions of these batch processes for additional information about each.

- Initial measurement payloads should have very selective criterion to get to the exact measuring component (MC). In an ideal case, it should be the MC identifier along with device serial number. If this is not provided, then the UOM/TOU/SQI configured on the MC type is used to retrieve the exact business object (BO) from the Service Provider which might have the same values for multiple channels.
- Populating the raw data section of the IMD record will reduce overall throughput. Avoid retaining “raw” data in Smart Grid Gateway payload processing whenever possible.
- Payload processing (in which usage and event data are loaded into the system) should be run separately from measurement processing (in which VEE is performed and final measurements are created). Do not run these processes simultaneously.
- Load initial measurements and perform VEE processing every 4 to 6 hours to optimize performance.
- The duration of individual initial measurements (IMDs) within a payload should be no shorter than the time elapsed between when payloads are collected and delivered (with a minimum of 4 to 6 hours per initial measurement). For example if your system is collecting and delivering measurements three times a day, the duration of individual initial measurements should be approximately eight hours.
- Avoid loading large numbers of initial measurements for a single device configuration in a single payload.
- We recommend configuring a monitor process on the Pending status of the Initial Load initial measurement business objects so that the VEE and measurement creation processes can be deferred to batch processing.
 - Deferring processing has the following additional benefits:
 1. It can ensure chronological processing for scalar reads which provides more efficient processing. Processing scalar reads out of order can result in additional work as reconciliation initial measurements will be created and processed to true up the consumption calculations.
 2. It can ensure measuring components are processed in order based on their relationships. For example, if a scalar channel is configured as the check channel for an interval channel, the scalar channel will be processed first so that its data is available for sum checks and any interval gap filling required.
 - Configuring deferred processing involves adding the “IMD Monitor – Physical Devices” Batch Control as the Monitor Process on the Pending status to the following business objects:
 - D1-InitialLoadIMDInterval
 - D1-InitialLoadIMDScalar
 - When initial measurement processing is deferred it will be necessary to schedule the “IMD Monitor – Physical Devices” Batch Control to run more frequently. It should be scheduled such that it runs with a higher thread count immediately after the Itron Scheduled Reads cycle has completed and with fewer threads throughout the rest of day to pick up any other initial measurements that might be received (such as those received via On Demand Read commands).

VEE Recommendations

- The High-Low VEE Rule is very “heavy” in terms of performance. This rule has an intensive hit on performance of the Initial Measurement loading process. Customers are encouraged to use the Usage High-Low rule, which has a less significant performance impact. If the VEE rule version is being used, the historic pre window should be set as low as possible based on business needs.
- Each VEE Rule included in VEE processing can have an impact on overall performance. The table below summarizes the relative costs in terms of performance for several commonly used VEE Rules. Using this table when designing your VEE groups and rules can help identify potential performance challenges.
- For example, using "Minimal Impact" rules will likely have little to no significant impact on performance, while using several "Moderate Impact" rules could result in performance challenges, and using the High Low Check rule is very likely to introduce noticeable impacts to VEE processing performance.

Relative Cost	VEE Rules
---------------	-----------

Minimal Impact (0% - 5%)	Interval Interpolation Interval Replacement Rule Interval Size Validation Interval Spike Check Negative Consumption Check Scalar Replacement Rule UOM Check
Moderate Impact (5% - 20%)	Final Measurement Validation Interval Adjustment From Scalar Interval Averaging Multiplier Check Scalar Calculation From Interval Scalar Proration Sum Check
Significant Impact (20%)	High/Low Check

- Consumption sync processes should only be run on devices where the difference in consumption is outside the defined tolerance as dictated by the sum check tolerance. In a production environment, running consumption sync for two percent of devices or less is advisable.
- For cloud implementations, custom rules must be written using Groovy or Oracle Utilities Application Framework scripting.
- Run performance testing on all configuration changes performed that impact portions of Oracle Utilities Meter Data Management with high transactional processing.
- Any VEE Rules, whether provided as part of base product or custom developed, should be configured to query no more than 30 cumulative days of historical data (i.e. High/Low) to help optimize the data loading process
- A good way to troubleshoot a VEE Rule is to use the Trace section of the IMD Log. When an IMD is in Pending status, the **Trace On** button can be used to trace all VEE Rules fired during IMD processing. Once processing is complete, view the Log tab of the IMD and review the results in the **IMD Trace Log** section. For any custom developed VEE Rules, the average run time should be no longer than the average run time of other base product VEE Rules. Also, the impact of different configuration can be checked through this method as well.
- Load initial measurements and perform VEE processing every 4 to 6 hours to optimize performance.

Measurement Processing Recommendations

- Payload processing (in which usage and event data are loaded into the system) should be run separately from measurement processing (in which VEE is performed and final measurements are created). Do not run these processes simultaneously.
- When performing Periodic Estimation for the first time, avoid running estimation for large numbers of devices for a long periods of time. The Smart Meter State Monitor Process (D1-SMMTR) used to initiate periodic estimation is designed to perform estimations for a small number of devices per run, not the entire meter population in the system.

Aggregation Recommendations

- When defining the **Aggregation Horizon** for aggregation processing, the horizon should ideally be around 7 days or less (barring specific requirements that call for an longer horizon, such as in the case of some final settlement calculations).

For each day in the horizon the system aggregates each day that many times. For example, setting the Aggregation Horizon to 30 means that each day is aggregated 30 times. The benefit of aggregating a day multiple times is that each day the quality of the data could improve if initial measurements arrive late. However there is a cost associated with a large horizon because the system is aggregating a much larger set of measurement data to catch a statistically smaller amount of changes the further into the past a day is.

- A short **Aggregation Horizon** is recommended in particular when configuring Measurement Quality and Timeliness aggregations used with Oracle Utilities Analytics Visualization. Refer to [Configuring Timeliness and Quality Aggregation for Use with Oracle Utilities Analytics Visualization](#) on page 1186 for more information.

The **Aggregation Horizon** is defined on Master Measurement Aggregator Type (D2-MasterMsrmtAggregatorType).

Usage Transaction Recommendations

- Usage transactions should NOT be used as an extraction tool to perform the mass export of measurement data.
- Saving derived interval data and sending the data to an external system via the "Save Interval Vector" and "Extract Interval Data" options on the "Vector and Service Quantity Math" and "Get Interval Data" usage calculation rules can have a noticeable impact on usage transaction processing. Usage transaction processing can be improved by up to 45% if extraction of interval data is eliminated. Use of these options should be limited to situations in which they are absolutely required.
- Use the Usage High Low rule instead of the VEE High Low rule where possible.
- For Outbound Messages, the schema extraction for usage transactions should be converted into a RAW string operation to allow for more efficient Pre-Processing logic.

User Interface Recommendations

- For better performance, user interface zones should be initially collapsed when not required for 90% or more of business processes. The initial state of zones (collapsed or not) can be controlled via the "Portal Preferences" tab on the **User** portal.
- The number of records returned to the user interface for a zone should be limited to 50 rows when building custom zones against large transactional tables.
- UI Map schemas should be specific to the displayed data. This will make sure that application will not visit all the elements that are not required for display.
- A good way to troubleshoot a screen in the user interface is to go to the **Preferences** in the top right hand corner of the application and choose the **Portal Preferences** tab. Choose the appropriate portal and set all zones to "Initially Collapsed". Next, navigate back to the screen that has performance issues, expand the zones one by one, and measure the execution time of each zone. This should be an accurate step-by-step representation of the full screen execution. This testing is especially important for **custom** user interfaces.
- For optimal user interface performance, Oracle Utilities Meter Data Management users should ensure their computer set to **high performance mode** so all CPU resources are used. Also, check if allocating additional memory through your browser's default settings helps improve performance.

Exception Handling Recommendations

- Don't create To Do entries unless they are absolutely required
- Use the VEE Exception Handler (D1-VEERuleExceptionHandler) and Usage Exception Handler (D2-UsageRuleExceptionHandler) rules to limit the number of To Do entries created by VEE and usage rule processing.
- Do not create To Do entries for exceptions for which Service Investigative Orders are being created.

- Purge To Do data on a regular basis (see [Partitioning and Data Removal](#))

SQL Recommendations

- Avoid making unbounded SQLs statements with no boundary condition on date columns.
- Reduce CLOB searches and use physical columns wherever possible.
- Implement caching to pre-fetch data instead of issuing multiple SQLs.

Custom Rules and Processes

- When creating custom rules and processes, don't use plug-in scripts for high volume transactions. Use Groovy or Java (on-premises implementations only).

Cloud Services

- Java is not allowed in cloud service environments, so implementations are encouraged to use Groovy when creating custom VEE and or usage calculation rules. Training regarding using Groovy with Oracle Utilities Application Framework applications can be found in the [Oracle Utilities Learning Subscription](#) available from Oracle University.

Testing Recommendations

- "Day in the Life" performance testing with production-level data volumes should be performed on a Test Environment before going live.

Java Recommendations — On-Premises Implementation Only

1. For areas where the transactional volume is high (such as Initial Measurement), use Hibernate SQL for non-CLOB fields whenever possible as opposed to reading entire Business Object. If a CLOB field must be retrieved, then either Entity or Lite BO should be used. Reading the full Business Object should be used as the last resort for high volume areas. This process should be considered for updating data as well when it provides the same functionality as updating the Business Object. These methods should only be considered if BO level validations, pre-processing, and post-processing aren't required.
2. For a simple SQL select statement needed in Java (not many joins and no complex logic), using Hibernate SQL provides a benefit over using a Business Service and a Zone since the entities are cached for Hibernate SQL.
3. "Lite" Business Objects are provided as a way to access the main fields for a BO without pulling back all of the information. Retrieving less information will speed up the process for reading the BO.

Data Access and Retrieval Recommendations

This section includes best practices and recommendations regarding access and retrieval of data.

Measurement Retrieval

For performance reasons, measurements are written/updated directly in the database through the use of direct SQL (JDBC). Because of this, the Hibernate cache will not always be aware of changes that are made for measurements and become stale for data updated in the current session. This means that when retrieving measurements during the same session in which they were inserted into the database using the Java classes provided with the application and Hibernate can return incorrect results. We recommend using direct SQL (JDBC) to retrieve measurement data directly in these situations.

In summary:

- Pre-existing measurements that have not been altered in the current session can be retrieved using Java classes.
- Measurements that have been inserted or updated by the IMD within the current session should be retrieved using direct SQL (JDBC).

Referencing Master Data by Identifiers

Understanding Referencing Master Data by Identifiers

There are many places within admin configuration where direct references to master data can be made. Since master data relies on system generated keys this configuration often breaks once migrated to a new environment since the master data referenced does not exist in the target environment. To alleviate this issue, in each of these instances, a user defined identifier can be used instead of the system generated keys.

This has an added benefit for installations that support multiple time zones by enabling the identification of the master data to not only search by the user defined identifier but also the time zone of the instance data. This is advantageous because it allows one set of admin configuration to satisfy master data in multiple time zones since things like TOU Maps and profile measuring components will be identified at run time using the identifier and time zone.

The following types of data can be referenced by an identifier on admin configuration:

- **Device:** can be referenced by a device identifier type. An example of this can be seen on the Specification Lookup (D1-SpecificationLookup) extendable lookup.
- **Measuring Component:** can be referenced by a measuring component identifier. When multiple time zone support is enabled the measuring component's time zone will also be evaluated. There are two major patterns for this:
 - *Profile Factors:* The profile factor itself will reference the measuring component by identifier and then the admin configuration will point to the profile factor. An example of this is the profile factor list on interval measuring component types.
 - *Direct Measuring Component references:* An example of this is the Final Values Overlay Profile (D1-FinalValuesOverlayProfile) extendable lookup.
- **TOU Map:** can be referenced by the TOU map template code. The appropriate TOU map is then found by searching for the appropriate TOU map that references a TOU map type for the supplied TOU map template. When multiple time zone support is enabled the TOU map time zone will also be evaluated. An example of this is the default TOU map that can be configured in the display profile of a measuring component type.

During execution the identifier supplied will be used to find the appropriate master data entry. The following validation will occur:

When multiple time zone support is off: the search must find one and exactly one master data entry for the identifier type and value.

When multiple time zone support is on: the search must find one and exactly one master data entry for the identifier type, identifier value, and time zone. Note: some installations may want to use master data across time zones, this can still be achieved by supplying one and only one master data entry for the identifier type and value:

When the search fails to find the master data for the identifier type, identifier value, and time zone and there is only one entry for the identifier type and value that master data will be used (thus allowing one master data entry to be used across time zones)

When the search fails to find the master data for the identifier type, identifier value, and time zone and there are multiple entries for the identifier type and value an error will be encountered.

Smart Grid Gateway Native Implementations

When implementing Oracle Utilities Meter Data Management, Oracle Utilities Smart Grid Gateway, and Oracle Utilities Customer to Meter, Native implementations are recommended for both on-premises and Platform-as-a-Service (PaaS) implementations. See [Smart Grid Gateway Adapter Native Implementations](#) on page 938 for more information.

Recommendations for Creating an On-Premises Production Environment

Oracle recommends that you do not clone the demonstration environment as a basis for a new production environment. The demonstration environment typically includes transactional data that will be irrelevant to your production environment and can cause unexpected issues if it is not purged correctly. The recommended process is to start a new production environment from a new installation and migrate "clean" system data (such as business objects and algorithms) and administrative data (such as sample activity types or other administrative entities) from the demonstration and/or test or development environments as applicable.

Your implementation can use bundling and/or the Content Migration Assistant to move system and administrative data. Instructions for using these tools are contained in the [Bundling](#) and [Content Migration Assistant](#) sections in the Oracle Utilities Application Framework *Administrative User Guide*.

Contact [Oracle customer support](#) if further assistance is required.

System-Wide Options

Installation Options - Framework

Configuring Installation Options - Framework

Installation options define the individual applications installed on your system and identify algorithms used to implement core system functions. These options also define global parameters such as the administrative menu style (alphabetical or functional), the country, language, currency code, as well as the base time zone to use for this implementation.

Installation options are stored in the installation record for your system. Use the Installation Options - Framework portal to configure these options. This portal is part of the OUAF and is described in detail in the Framework documentation.

Base Time Zone

The time zone setting of the Installation Options - Framework determines the time zone for all date/times stored within the system. Each date/time, based on the configuration of that field, is stored in either standard or legal time within this base time zone.

Refer to the [Glossary of Terms](#) in the *Oracle Utilities Meter Solution Business User Guide* for definitions Standard Time and Legal Time

Note: The installation record does not dictate the server time zone, but rather must match it.

Installation Algorithms

Installation algorithms implement global system functions and can be customized for each implementation. The base package supports the following installation options for Meter Data Management-related system events:

- **Geocoding Service:** Responsible for geocoding an address (converting an address to a geocode latitude/longitude pair).
- **Global Context:** Sets global contexts (displayed in the Global Context Sidebar zone) based on the value of existing global contexts. For example, if the Service Point is specified, this algorithm sets the Device by finding the most recently installed Device on the service point. It then sets the Measuring Component by finding the most effective Device Configuration and retrieving any measuring component linked to it. It then sets the Usage Subscription by finding the most recent active usage subscription linked to the service point. The contact is set by finding the main contact for the usage subscription.

Additional detail on how global context is populated can be found in the detailed description of the D1-GBCTX-DF Algorithm Type.

- To Do Pre-creation:
 - In Meter Data Management, the D1-TDPCRE (To Do Precreation) algorithm associates a To Do entry via characteristics to the related the related Device, Measuring Component, Service Point, Contact, Usage Subscription, Activity Type and Activity based on the drill keys of the To Do entry.
 - In Customer to Meter, the following algorithms are used to associate a To Do Entry via characteristics with related objects:
 - C1-TDCR-CHAR (Link Account/Premise/Person/SA/SP to To Do)
 - C1-TDCR-DFRL (Default To Do Role via Account/Premise)
 - D1-TDPCRE (To Do Precreation)
 - X1-TDPCRE (Customer to Meter To Do Pre-Creation)

Note:

Additional detail on how the To Dos are associated to related data can be found in the detailed descriptions of these algorithms type.

See [Installation Options](#) in the Oracle Utilities Application Framework *Administrative User Guide* for related information on the installation portal.

Feature Configurations

Configuring Feature Configurations

Some of the features in Oracle Utilities Application Framework based applications are configured by populating options on a "feature configuration". For example, if your implementation uses Oracle Utilities Customer Care and Billing's batch scheduler, you must populate a variety of options on the batch scheduler's feature configuration.

Note: Refer to [Defining Feature Configurations](#) in the Oracle Utilities Application Framework *Administrative User Guide* for additional information.

Oracle Utilities Meter Data Management uses the following types of feature configurations (please note that more information can be found on each of these options by viewing their detailed description in the Feature Configuration portal):

Measurement Data Options

Measurement Data Options are used to define behavior related to periodic estimation of initial measurement data, including:

- **No of Hours in Past to Retrieve Last Usable Measurement:** This option is leveraged by scalar periodic estimation to restrict how far into the past it will search for existing measurements when the last contiguous measurement is being initialized on the measuring component. This is to ensure that the first time scalar period estimation is executed on a large number of measuring components that have not been initialized for periodic estimation the system does not execute a large number of unbounded queries into the past which would result in poor performance.

Business Intelligence Configuration

Business intelligence configuration is used to define external data source indicators used when Oracle Utilities Meter Data Management is integrated with Oracle Utilities Business Intelligence. External data source indicators allow business intelligence extracts to properly link the external identifiers to the source external system. The Value of the Data Source Indicator option should match the Environment ID on the Installation Option of the external system.

General System Configuration

This feature configuration is owned by Oracle Utilities Application Framework but there are several important option types that have been created specific to Oracle Utilities Meter Data Management:

- **Multi Time Zone Support:** By default the system assumes an installation operates within a single time zone. In order to enable multiple time zone functionality this option must be defined and set to "DIYS".
- **CCB Link URL:** this option is used to provide the destination URL for hyperlinking into Oracle Utilities Customer Care and Billing.
- **Trace On Flag:** can be set to automatically trace any initial measurement being processed. Note: if the initial measurement has had trace explicitly turned off then no tracing will occur. This is useful for tracing initial measurements created through automated processes where you are unable to set the trace flag directly.
- **System Override Date :** this option type is provided by OUAF but it is highly useful in testing prior to production. When set it will override the system date/time for all users. The format must be entered as: YYYY-MM-DD. For example January 1st 2010 would be 2010-01-01.

Note:

Refer to [Configuring Multi-Time Zone Support](#) for additional information on setting up multi-time zone support.

Time Zones

Configuring Time Zones

To support businesses spanning across multiple time zones, the system stores all date and time information in a single common time zone known as the base time zone or the server time zone. Furthermore, date and time information is stored in either standard time (i.e. independent of any Daylight Savings Time adjustments, if applicable, in that time zone) or legal time (i.e. shifted according to Daylight Savings Time).

The system also allows data to be entered and displayed in a different time zone in legal time (i.e. adjusted for Daylight Savings Time, managing the conversion back and forth between the data entry time zone and the storage time zone).

Entities associated with a physical location such as measurements (initial and final), measuring components, device configurations, devices, installation events, service points, and usage subscriptions are entered and displayed in the specific time zone where they occur, the entity time zone. The rest of the application uses the base time zone to display date and time information.

When configuring time zones the following fields are of high importance:

- **Time Zone Name:** identifies the Olson time zone and as such defines the appropriate offset from Greenwich Mean Time as well as the schedule for shifting into and out of Daylight Savings Time.
- **Default Time Zone Label:** will be appended to date times that do not fall within Daylight Savings Time
- **Shifted Time Zone Label:** will be appended to date times that do fall within Daylight Savings Time

Note: The server time zone must be correctly specified on the installation options record for the system to work properly.

For additional information see [Defining Time Zones](#) in the *Oracle Utilities Application Framework Administrative User Guide*.

Configuring Multi-time Zone Support

As a default the system assumes operations are in a single time zone. This has a few high level impacts:

- All master data must have a time zone that is equal to the base time zone. As such all master data will have the same time zone and that time zone will be the base time zone

- Certain logical complexities are avoided during high volume processing given the knowledge that all master data time zones are equal to the base time zone.

If your implementation resides within multiple time zones then the Multi Time Zone Support feature configuration must be enabled. Doing so will allow master data to be defined with any time zone configured in the system. It will also enable logic to convert time zones between the master data time zones and the base time zones.

You can access the feature configuration portal from the **Admin > General > Feature Configuration**.

From the list of results returned select the feature name for the feature type General System Configuration. For the option type Multi Time Zone Support supply "D1YS" as the value to turn multiple time zones on.

Refer to [Multiple Time Zone Support](#) for information about how functional processing is impacted by multiple time zone support.

Defining General Options

Units of Measure

Understanding Units of Measure

Units of Measure (UOM) identify quantities measured and recorded, such as KWH, KW, cubic feet, degrees Celsius, etc. UOMs are based on a specific service type.

Important Unit of Measure System Events

Unit of Measure supports the following business object algorithm system events:

- **Axis Conversion:** this event receives a list of measurements along with a source UOM and interval size and a target UOM and interval size. It should then perform the necessary actions to convert the source UOM and interval size into the target UOM and interval size. Refer to the algorithm Axis Conversion algorithm (D1-AXIS-CONV) as an example.

Configuring Units of Measure

This portal is used to display and maintain a Unit of Measure.

Refer to [Understanding Units of Measure](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Unit Of Measure**.

The following zones may appear as part of the portal's **Main** tab page...

- **Unit of Measure List:** This zone lists all units of measure. Broadcast a record to display the details of the selected record.
- **Unit of Measure:** This zone provides information about the selected unit of measure.

Service Quantity Identifiers

Understanding Service Quantity Identifiers

Service Quantity Identifiers (SQI) are used to further distinguish between measured quantities that have identical UOM/TOU combinations, including situations in which the distinguishing identifier of a UOM is not accurately described as a TOU. Some examples include: Generated, Consumed, etc.

SQIs can also be used as a stand-alone representation of a service quantity that is not measured (one that is not properly described as a UOM) within a usage service quantity collection (such as a billing determinant).

Configuring Service Quantity Identifiers

This portal is used to display and maintain a Service Quantity Identifier.

Refer to [Understanding Service Quantity Identifiers](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Service Quantity Identifier**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Quantity Identifier List:** This zone lists all Service Quantity Identifiers. Broadcast a record to display the details of the selected record.
- **Service Quantity Identifier:** This zone provides information about the selected Service Quantity Identifier.

Time of Use

Understanding Time of Use

Time of Use (TOU) periods are modifiers for a given unit of measure that indicate a period of time during which a quantity has been used, such as On-Peak (meaning during a time when the greatest quantity of some consumable is being used), Off-Peak (meaning during a time when the least amount of some consumable is being used), etc.

Configuring Time of Use

This portal is used to display and maintain a Time of Use.

Refer to [Understanding Time of Use](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Time Of Use**.

The following zones may appear as part of the portal's **Main** tab page:

- **Time Of Use List:** This zone lists all Time Of Use records. Broadcast a record to display the details of the selected record.
- **Time Of Use:** This zone provides information about the selected Time Of Use.

Service Types

Understanding Service Types

Service Types define specific types of service for which usage can be recorded and captured, such as electric, gas, steam, etc.

Configuring Service Types

This portal is used to display and maintain a Service Type.

Refer to [Understanding Service Types](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Service Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Type List:** This zone lists all Service Type records. Broadcast a record to display the details of the selected record.
- **Service Type:** This zone provides information about the selected Service Type.

Divisions

Understanding Divisions

Divisions are used to delineate between different operating companies within a large conglomerate of utilities.

Divisions can have one or more characteristics defined.

Divisions can be defined on several other objects and entities in the system, including:

- Service Point
- Service Order Activities (Request Orchestration activities)
- Service Order Field Activities
- Usage Subscription/Usage Subscription Type
- Usage Calculation Group
- Settlement Calculation Group
- Aggregation Group
- Data Source
- Market Product Type
- Market Product Set

Divisions can be associated with individual users on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

Configuring Divisions

You use the **Divisions** portal to display and maintain divisions.

Refer to [Understanding Divisions](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Division**.

The following zones may appear as part of the portal's **Main** tab page:

- **Division List:** This zone lists all division records. Broadcast a record to display the details of the selected record.
- **Division:** This zone provides information about the selected division.
- **Characteristics:** This zone displays a list of characteristics defined for the selected division.

Factors

Understanding Factors

Factor are a centrally stored set of values for use in validation rules, bill determinants calculations, and other processes.

A factor can have different values depending upon some definable attribute of a system object, such as customer size associated with a service point. Examples of factors can include minimum and maximum thresholds, loss factors, etc. Classes of factors are defined that can have numeric values (as in the above examples), or values pointing to profile measuring components, or VEE groups.

A factor's values are effective-dated values - either a number, a profile measuring component, a temperature profile measuring component, a VEE group, or some custom-defined value - assigned to a factor and associated to the value of some attribute of a system object. For example, consider a service point that can be classified as residential, commercial, or industrial. The tolerance percentage by which a customer's consumption can exceed last month's consumption can be based on the service point category.

For this example, factor values for a single factor called "tolerance percentage" could be:

- Residential - 20%
- Commercial - 10%
- Industrial - 5%.

Configuring Factors

This portal is used to display and maintain Factors and Factor Values.

Refer to [Understanding Factors](#) for more information.

Prerequisites: You must define factor characteristic source algorithms, factor characteristic types, and factor characteristic values before you can create a factor. Refer to the Oracle Utilities Application Framework online help for more information about algorithms, characteristic types, and characteristic values.

You can access the portal by selecting **Admin**, then **General**, then **Factor**.

The following zones may appear as part of the portal's **Main** tab page:

- **Factor List:** This zone lists all factor records. Broadcast a record to display the details of the selected record.
- **Factor:** This zone provides information about the selected factor.
- **Factor Char Value and Factor Value List:** This zone lists the characteristic values associated to the factor characteristic. For each characteristic value it will display the related factor values. From this zone you can click the **Factor Value** link to see the factor value in more detail on the **Factor Value** portal.

Markets

Understanding Markets

Markets define the jurisdictions or regulatory environments in which a service point participates.

Markets also define market relationships for valid service providers and their roles within a market (distributor, etc.). While each service point specifies only one market, a utility may serve more than one market, and different service points throughout the utility's service territory can be linked to different markets.

For each service provider defined for a market, you can also specify a fallback service provider.

Service Providers in Deregulated Markets

Some utilities operate in deregulated markets. In implementations in deregulated markets, the system can send information to and receive information from a variety of market entities. These entities are defined as service providers.

For example, a service point's distribution company and/or energy supply company may subscribe to its consumption, or a service point's meter service provider may send requests to ping the meter that's installed at the service point to verify connectivity between the meter and its head-end system.

Different Relationship Types in Different Markets

Each market can define different relationship types between its service providers. A single instance of Oracle Utilities Meter Data Management or Oracle Utilities Smart Grid Gateway may have service points in different markets where each market has different relationship types and service providers. For example:

- In a regulated market the distribution company is the de facto energy supplier and meter service provider.
- Another market might have two relationship types and a single service provider for each relationship:
 1. There is a single energy supply company for the entire market
 2. There is a single meter service provider for the entire market

Yet a another market might have two relationship types (energy supply and meter service). In this market, there might be multiple service providers for each relationship type. Each service point can choose any of the relationship type's service providers. If a service point does not declare a specific service provider for a given relationship type, the relationship type's "fallback" service provider is assumed.

Configuring Markets

This portal is used to display and maintain a Market.

Refer to [Understanding Markets](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement Market**, then **Market**.

The following zones may appear as part of the portal's **Main** tab page:

- **Market List:** This zone lists all Market records. Broadcast a record to display the details of the selected record.
- **Market:** This zone provides information about the selected market.

Market Participants

Understanding Market Participants

Market Participants are participants in a deregulated environment. Relationships between market participants are defined in a particular market record. Refer to [Understanding Markets](#) for more information.

Each market participant can be associated to an [external system](#) which is used to define the messages that can be sent to that market participant and how each message is sent.

Configuring Market Participants

This portal is used to display and maintain market participants.

Refer to [Understanding Market Participants](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement Market**, then **Market Participant**.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Participants List:** This zone lists all market participant records. Broadcast a record to display the details of the selected record.
- **Market Participant:** This zone provides information about the selected market participant.
- **Market Participant Characteristics:** This zone lists characteristics defined for the market participant.
- **Market Contracts:** This zone lists market contracts where the market participant is either the Buyer or Seller.
- **Processing Method List:** This zone provides the list of processing methods defined for the market participant.
- **Translation Method List:** This zone provides the list of translation methods defined for the market participant.
- **Inbound BOs Send By Service Provider:** This zone lists inbound business objects that are sent by this market participant. The identification is driven by the business object having a Business Object Option of type "Sent By Service Provider" that references the current market participant.

Understanding Processing Methods

Head end systems, external applications, and market participants can have one or more associated processing methods that define the format or means by which it receives or sends data from or to the application, such as bill determinants, interval data, or meter events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and usage transactions. Processing methods can also be used to define the information an external system wishes to subscribe to receive from our application.

At the lowest level processing methods are used to identify an outbound message type, business object, batch control, or message category and number.

Each processing method is comprised of a business object that defines what is being mapped as well as how it should be mapped.

Important Processing Method System Events

The actual logic to determine the appropriate output for a given head end system, external application, or market participant and processing role for a processing method is executed by the following system event:

- **Determine Processing Method(s):** is a business object algorithm system event that takes in a head end system, external application, or market participant, a processing role, and a list of relevant input data aka related object (e.g. a measuring component, device, etc). For the head end system or external application and the input data it will analyze the selection criteria to determine the appropriate output.

How Processing Methods Work

Processing methods perform two basic tasks:

- They define the criteria for selecting the appropriate output. This can be as simple as providing a single object in return without qualification or in more involved situations it could support determining the appropriate return object based on characteristics of the data being processed. This is accomplished through the data structure defined on the processing method business object.
- They evaluate the criteria for selecting the appropriate output given a specific head end system, external application, or market participant. This is accomplished through the Determine Processing Method system event on the processing method business object.

Each processing method business object can be associated to one or more processing roles. This is done by adding the Applicable Processing Role business object option. It is these processing roles that actually create the association between a head end system, external application, or market participant, the processing method, and the functional event that is being executed. For example, when initial measurement data is processed through the IMD Seeder the processing role Initial Measurement Creation is used to identify the processing method "How to Create MC Related Information" which maps a particular measuring component type to the appropriate initial measurement business object to be used for processing.

When system logic requires the results of a processing method the service Determine Service Providers and Methods is used. This service is available to call via Java or from within scripting through the business service of the same name. It can be called in one of two ways:

With a head end system, external application, or market participant: identifies the appropriate output for a single head end system, external application, or market participant being processed for the input processing role and related objects

Without a head end system, external application, or market participant: used to identify subscribing systems. This will provide a list of any head end system, external application, or market participant that has the input processing role and an appropriate output given the related objects.

Processing Methods Available

There are the following processing methods provided by the base package:

Name	Details	Business Object
How to Create OB COMM/Send OB Message	Identifies Message Number/Category, Business Object, Outbound Message Type and allows for an override by a device type.	D1-HowToCreateActivityOBComm
How to Create MC Related Information	Identifies a business object and allows for an override by measuring component type.	D1-HowToCreateMCInformation
How to Process Device Event Related Info	Identifies a business object, outbound message type, and batch control by device event category allowing for an override by device event type.	D1-HowToProcDvcEvtsInformation

How to Process Device Related Information	Identifies a business object and allows for an override by device type.	D1-HowToProcessDeviceInfo
How to Send Activity Related Information	Identifies a batch control and business object by activity type and allows for an override by device type.	D1-HowToSendActInformation
How to Send Activity Related OVB Messages	Identifies an outbound message type, message category, and message number and allows for override by activity type.	D1-HowToSendActivityResponse
How To Create US Related Information	Identifies a business object and allows for override by usage subscription type.	D2-HowToCreateUSInformation
How To Send US Related Information	Identifies a batch control, business object, and outbound message type and allows for override by usage subscription type.	D2-HowToSendUSInformation
How to Process Service Point Related Info	Identifies a business object and allows for override by service point type.	D1-HowToProcSPRelatedInfo
How to Send Field Activity Related Info	Identifies a outbound message type and allows for an override by field task type.	D1-HowToSendFARelatedInfo
How to Send Field Activity Remark Info	Identifies an outbound message type for an activity remark type.	D1-HowToSendActivityRemarkInfo
How to Translate External Value	Identifies a business object and allows for override by identifier.	D1-HowToTranslateExternalValue
How to Request Customer Notification	Identifies a list of outbound message types.	D1-HowToRequestCustomerNotific
How to Process Business Flag Related Info	Identifies an outbound message type and allows for an override by business flag type.	D1-HowToProcessBusinessFlagInf

Processing Timetable Types

Understanding Processing Timetable Types

Processing timetable types define types of schedules that can be referenced by different processes and objects in Oracle Utilities applications such as Oracle Utilities Meter Data Management and Oracle Utilities Market Settlements Management. For example, if a process requires requesting data from an external system on a daily basis, a daily processing timetable type could be used to define the details of this schedule.

Processing timetable types are used by standalone data request measuring components to control the schedule by which requests for data are processed (for example, in a settlement process in which zonal load is requested on a daily basis). They are also used in the attribute data snapshot creation process.

The base package includes two processing timetable type business objects used with specific scheduling patterns:

- **Daily Processing Timetable:** Used for daily schedules
- **Defined Dates Processing Schedule:** Used for schedules that should execute on specific dates.

Parameters used to define processing timetable types include:

- **Execution Frequency Class:** Designates the type of processing timetable, Daily or Defined Dates (based on the business object)
- **Scheduling Information:** Details about how the schedule is executed, including:
 - **Period Cut-Off Time:** The time of day that represents the end of a period. In many instances this will be 12:00 AM. However, for something like a "Gas Day" this might be set to 09:00 AM.
 - **Earliest Execution Time:** Used to prevent records from being processed until after this time each day. This time relates to the processing time.
 - **Lag / Lead:** A flag that indicates whether periods in the past (Lag) or future (Lead) should be processed (applies to Daily schedules only)
 - **Lag Days / Lead Days:** The number of days in the past (Lag) or future (Lead) that should be processed (applies to Daily schedules only)
 - **Restrict Processing by Work Calendar:** Used to restrict processing to only the work days configured in the Work Calendar and will exclude any holidays added to the calendar (applies to Daily schedules only)
- **Workflow Information:** Details about how the processing timetable aligns with process workflows, including warning time and target due time
- **Processing Dates:** A list of specific dates on which the process should be executed (used with Defined Dates Processing Schedule only)

Configuring Processing Timetable Types

Refer to [Understanding Processing Timetable Types](#) for more information.

You can access the portal by selecting **Admin**, then **General**, then **Processing Timetable Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Processing Timetable Type List:** This zone lists all processing timetable type records. Broadcast a record to display the details of the selected record.
- **Processing Timetable Type:** This zone displays details for the selected processing timetable type.

Defining Asset Options

Note: The asset management functionality described in this section is available only to cloud implementations using Oracle Utilities Customer Cloud Service or Oracle Utilities Meter Solution Cloud Service.

Asset Activity Types

Understanding Asset Activity Types

Activity types define the main attributes broad range of activities, such as maintenance, repairs, inspections, field work etc. The base package includes an asset activity type business object (W1-SOMActivityType) that should be used when created asset activity types.

Activity types are defined by:

- **Activity Business Object:** The business object used for asset activities of this type

- **Activity Schedule Information:** Default scheduling information for asset activities of this type, including Activation Lead Days, Work Lead Days, and Activity Disposition.
- **Attachments:** One or more attachments associated with asset activities of this type, such as procedures or checklists.
- **Exception Handling:** Details regarding exception handling for asset activities of this type, including default To Do Type, To Do Role, and retry options.
- **Completion Event Types:** One or more completion event types associated with asset activities of this type. See [Understanding Completion Event Types](#) for more information.
- **Object To Create:** The service history type to be created by asset activities of this type. Service history records are created by Create Activity Type's Service History completion events.

Refer to [Defining Asset Activity Types](#) for more information about setting up asset types.

Note: Asset activity types are created by the system when [field task types](#) are created in Service Order Management.

Defining Asset Activity Types

You use the **Activity Type** portal to display and maintain asset activity types.

Refer to [Understanding Asset Activity Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Activity Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type:** This zone displays basic information about the activity type.
- **Attachments:** This zone attachments associated with the activity type.

Asset Completion Event Types

Understanding Asset Completion Event Types

Asset completion event types are used to define various processes or events to be executed when completing an asset activity such as asset replication, service history creation, attachment creation, and activity creation.

Asset completion event types are referenced on activity types to indicate which completion events should be included as part of the lifecycle of activities of that type. For example, this affects when service history is created for an activity, and the disposition of the assets on an activity as the activity is processed. Asset completion events can be configured as optional or required for activities of different types.

Asset completion event types are defined by:

- **Completion Event Business Object:** The business object used for asset completion events of this type
- **Identifiers:** One or more identifiers that can be used to characterize asset completion events of this type
- **Inbound Communication:** Information used to create asset completion events of this type using information defined within an inbound communication business object, or within its raw message
- **UI Payload Create Data Mover:** XPath statements executed when creating asset completion events of this type online. These statements are used to populate elements within the payload from the completion event business object.

Refer to [Defining Completion Event Types](#) for more information about setting up completion event types.

Defining Asset Completion Event Types

You use the **Completion Event Type** portal to display and maintain asset completion event types.

Refer to [Understanding Asset Completion Event Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Completion Event Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Completion Event Type** : This zone provides information about the selected completion event type, including as inbound communications and attachments.
- **Unlink Activity Types**: This zone enables the removal of an activity type from the completion event type. To remove an activity type select the activity type(s) to remove and click **Remove**. The selected activity types will no longer appear in the **Unlink Activity Types** zone.
- **Link Activity Types**: This zone enables adding an activity type to the completion event type. To link an activity type:
 1. Enter search criteria in the **Activity Type Description** field and click **Search**. The zone will display a list of activity types matching your search criteria.
 2. Select the activity type(s) to add and click **Link**. The selected activity types will now appear in the **Unlink Activity Types** zone.

Asset Inbound Communication Types

Understanding Asset Inbound Communication Types

Asset inbound communication types define the information required for the system to receive messages from external systems. These typically hold value mappings of the inbound communication elements to an xpath element in the completion message.

Asset inbound communication types are defined by:

- **Inbound Communication Business Object**: The business object used for asset inbound communications of this type
- **Exception Handling**: Details regarding exception handling for asset inbound communications of this type, including default To Do Type, To Do Role, and retry options.
- **Message Validation**: Source elements within the inbound communication business object or raw message used for validation of asset inbound communications of this type
- **Communication Data Mapping**: Information used to populate communication business object elements from information within the communication's raw message
- **Attachment Suppression**: Substitution text used in place of large data attachments in the completion event list on the inbound communication. Used when messages received from an external system contain attachment data that are very large.

Refer to [Defining Asset Inbound Communication Types](#) for more information about setting up asset inbound communication types.

Defining Asset Inbound Communication Types

You use the **Communication Type** portal to display and maintain asset inbound communication types.

Refer to [Understanding Asset Inbound Communication Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Inbound Communication Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Communication Type List**: This zone lists all asset inbound communication type records. Broadcast a record to display the details of the selected record.

- **Communication Type:** This zone provides information about the selected communication type, such as attachment suppression, communication data mapping, message validation and exception handling.

Asset Types

Understanding Asset Types

Asset types define the attributes for assets and components of a certain type including information such as the valid location types and service history types for the assets and whether or not such assets can have attached components.

Asset types are defined by:

- **Component Relationship:** A flag that indicates if components can be installed on assets or components of this type
- **Asset Business Object:** The business object used for assets or components based on this asset type
- **Valid Location Types:** A list of location types where assets or components of this type can be located
- **Valid Attached To Asset Types:** A list of valid asset types where components of this type can be attached (applicable to components only)
- **Valid Service History Types:** A list of valid service history types that can apply for assets or components of this type

Refer to [Defining Asset Types](#) for more information about setting up asset types.

Asset Classes

Assets are defined by classes, each of which is based on a specific business object, and determines the type of asset: an asset or a component.

The table below lists the asset classes and the business object for each.

Asset Class	Business Object
Asset	W1-AssetType (Operational Device Asset Type)
Component	W1-ComponentType (Operational Device Component Type)

Defining Asset Types

You use the **Asset Type** portal to display and maintain asset types.

Refer to [Understanding Asset Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Asset Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Asset Type :** This zone provides information about the asset type.
- **Asset Type Statistics:** This zone displays statistics for the asset type.

Service History Questions

Understanding Service History Questions

Service History Questions are used to guide workers through corrective and preventive inspection processes as part of an asset's service history.

Service history questions are associated to a service history type which is then associated to an asset type.

During a corrective or inspection process, workers can be guided through a series of questions assessing the condition of the asset. The answers can be “weighted”, which when calculated, gives an overall score as to the condition of the asset. The calculation is generally a sum (answer points * question weight), but can vary depending on the service history type. The total inspection points are then normalized to an overall grade or score. The condition rating and confidence rating are also calculated and the asset is updated with the appropriate values.

A service history question’s answers can be defined as check boxes, multiple choice, or free-form text.

Refer to [Defining Service History Questions](#) for more information about defining service history questions.

Defining Service History Questions

You use the **Service History Question** portal to display and maintain Service History questions.

Refer to [Understanding Service History Questions](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Service History Question**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Question:** This zone provides information about the question.
- **Service History List:** This zone displays a list of service history types that reference the question.

Service History Types

Understanding Service History Types

Service history types define the main attributes for service history of a certain type. Types might include maintenance, inspection, service, test, measurement, and so on.

Service history types are defined by the following:

- **Service History Business Object:** The business object used to create service history records of this type.
- **Category:** The category to which service history records of this type belong. The base package includes the following categories:
 - Downtime
 - Failure
 - Inspection
 - Maintenance
 - Repair
- **Subclass:** The specific subclass of the service history type, based on the **Service History Business Object**. Oracle Utilities Customer To Meter supports two subclasses of service history types:
 - Operational Device Service History
 - Questionnaire Service History

Each service history type subclass includes other specific configuration information, outlined below.

Operational Device Service History Types

Operational Device Service history types are also defined by the following:

- **Service Schedules:** One or more template work orders and time intervals that should be used to schedule work order generation for service history records of this type

Questionnaire Service History Types

Questionnaire Service history types are also defined by the following:

- **Follow-up Actions:** One or more actions intended as “follow-up” actions for service histories of the service history type, such as work orders or work order activities, users can configure those follow-up actions on the service history type. Note that if a regulatory compliance requirement is associated with a follow-up action, a compliance type must be specified. For example, a Service History Type of “Grade 2 Gas Leak”, might include a follow-up action of “Recheck” which could be configured with a “30 day” Compliance Type and a follow-up action of “Repair” which could be configured with a “1 year” Compliance Type.
- **Stop Processing Service History Type:** One or more service history types that should stop the processing of **Follow-up Actions**. For example, certain problem that needs follow up actions was reported. Then another service history, which indicates the problem has been fixed or its severity has changed, is recorded. Businesses might want to stop/cancel the follow up actions based on the original problem/severity.
- **Questions:** A list of one or more questions used to guide inspection of an asset. Questions are defined in the **Questions** portal.

Defining Service History Types

You use the **Service History Type** portal to display and maintain service history types.

Refer to [Understanding Service History Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Service History Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Service History Type:** This zone provides information about the service history type.
- **Questionnaire Tree:** This zone displays the service history types’ questionnaire, based on the questions defined for the service history type. Applicable for Questionnaire service history types only.
- **Unlink Asset Types:** This zone lists the asset types currently linked to the service history type. To unlink one or more asset types, check the corresponding checkboxes and click **Remove**.
- **Link Asset Types:** This zone is used to search for and link asset types to the service history type. To link new asset types,
 1. Enter search criteria in the **Asset Type Description** field.
 2. Click **Search**.
 3. Select the asset types to link by checking the corresponding checkboxes.
 4. Click **Link**.

Configuration Types

Understanding Configuration Types

Configuration types define the information required for various asset configurations with other assets, components, firmware, and other data.

Configurations are referenced on specifications which are then referenced on assets and components to indicate the best way that these entities can work with the other entities that they are connected to in the field.

Configuration types are defined by the following:

- **Configuration Class:** The class for configurations of this type
- **Configuration Category:** The category of configurations of this type
- **Configuration Business Object:** The business object used for configurations of this type

Configuration Classes

In general configuration classes define the types of connections that are being configured. Each configuration class is based on a specific business object, which is the business object used for configurations of each class and type.

The table below lists the configuration classes and the business object for each.

Configuration Class	Business Object
Single Asset	W1-SingleAssetConfig (Single Asset Configuration)
Asset/Component	W1-AssetCompConfig (Asset/Component Configuration)
Asset to Asset	W1-AssetToAssetCompConfig (Asset to Asset/Component Configuration)
Asset/Component to Asset	W1-AssetCompToAssetConfig (Asset/Component to Asset Configuration)
Asset to Asset/Component	W1-AssetToAssetConfig (Asset to Asset Configuration)
Asset/Component to Asset/ Component	W1-AssetCompToAssetCompConfig (Asset/Component to Asset/Component Config)

Defining Configuration Types

You use the **Configuration Type** portal to display and maintain configuration types.

Refer to [Understanding Configuration Types](#) for more information.

You can access the portal by selecting **Admin**, then **Asset Management**, then **Configuration Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration Type List:** This zone lists all configuration type records. Broadcast a record to display the details of the selected record.
- **Configuration Type :** This zone provides information about the selected configuration type.

Configurations

Understanding Configurations

Configurations document and manage valid setups for assets and components. This includes a specification for each asset or component in the configuration as well as the valid value for each parameter, such as the firmware version of each asset.

Configurations are defined by the following:

- **Configuration Type:** The [configuration type](#) upon which the configuration is based
- **Status:** The current status of the configuration
- **Configuration Detail:** Specific information related to the configuration such as the assets and components involved, the firmware, characteristics, identifiers and other important information

Defining Configurations

You use the **Configuration** portal to display and maintain configurations.

Refer to [Understanding Configurations](#) for more information.

You can access the portal by selecting **Admin**, then **Configuration Report**, then **Configuration**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration:** This zone provides information about the selected configuration.
- **Configuration Attachments:** This zone lists any attachments defined for the configuration.

Configuration Reports

Understanding Configuration Reports

Configuration reports provide a summary of any currently installed configurations.

These reports show whether the configuration in an installation is valid or invalid, the identifiers and values being used, and display all of the assets/components and other elements that make up the installed configuration.

Configuration reports are defined by the following:

- **Reporting Mode:** The mode in which the report is run (One Time or Recurring)
- **Status:** The current status of the report (Pending or Submitted)
- **Report Criteria:** Specific information used to establish the filter criteria when generating the report, such as the assets and components involved, the firmware, characteristics, identifiers and other important information.
- **Report Result:** Specific information for each configuration, including the number of configurations, the assets and components involved, and the specifications and firmware versions of each. If the configuration is invalid, the **Configuration** column is blank in the report results. Users can navigate to specific valid configurations to review and edit the setup as needed. In addition, users can generate a work order to correct, reconfigure, or otherwise maintain any of the configurations by clicking **Generate Activity**.

Base Package Configuration Reports

The base package includes a number of configuration reports, each based on one of the support configuration classes (see [Understanding Configuration Types](#)).

The table below lists the configuration reports and the business object for each.

Configuration Report	Business Object
Single Asset Configuration Report	W1-SingleAssetCfgRpt
Asset/Component Configuration Report	W1-AssetCompCfgRpt
Asset to Asset Configuration Report	W1-AssetToAssetCfgRpt
Asset/Component to Asset Configuration Report	W1-AssetCompToAssetCfgRpt
Asset to Asset/Component Configuration Report	W1-AssetToAssetCompCfgRpt
Asset/Component to Asset/Component Configuration Report	W1-AssetCompToAssetCompCfgRpt

Defining Configuration Reports

You use the **Configuration Report** portal to display and maintain configuration reports.

Refer to [Understanding Configuration Reports](#) for more information.

You can access the portal by selecting **Admin**, then **Configuration Report**, then **Configuration Report**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Configuration Report:** This zone provides information about the selected configuration report.

Defining Location Options

Note: The asset location functionality described in this section is available only to cloud implementations using Oracle Utilities Meter Solution Cloud Service.

Asset Location Types

Understanding Asset Location Types

Asset location types define the details of locations of a certain type where assets or components can be installed. Valid types of asset locations can include service points, other locations for installed assets, or any other location as defined by your organization.

Asset location types are defined by the following:

- **Class:** The general class for asset locations of this type, such as commercial or residential, a shop or warehouse, etc.
- **Location Business Object:** The business object used for asset locations of this type
- **Number of Assets Allowed:** A flag that indicates whether or not asset locations of this type can accommodate a single or multiple assets
- **Service Type:** The type of service (electric, water, etc.) that asset locations of this type support
- **Allow Related Work Locations:** A flag that indicates whether asset locations of this type should be allowed to be connected to a work location
- **Valid Parent Location/Organization Types:** One or more valid parent locations and parent organizations that can be referenced on asset locations of this type. Used primarily for reporting.
- **Valid Communicate-To Location Types:** One or more asset location types to which asset locations of this type can communicate. The **Tree View** tab of any asset or location will display other related assets with a visual indication of their relationship.

Note: Asset location types are used to define locations where assets and components are installed. Locations where assets that are out of service are stored and maintained are defined via [Out of Service locations](#) and [Out of Service location types](#).

Defining Asset Location Types

You use the **Asset Location Type** portal is used to display and maintain asset location types.

Refer to [Understanding Asset Location Types](#) for more information.

You can access the portal by selecting **Admin**, **Location**, then **Asset Location Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Asset Location Type List:** This zone lists all asset location type records. Broadcast a record to display the details of the selected record.
- **Asset Location Type:** This zone provides information about the selected asset location type.

Organization Types

Understanding Organization Types

Organization types define the main attributes for organizations of a certain type.

Organization types are defined by the following:

- **Class:** The general class organization. Parent organizations have a class of “Parent”.
- **Organization Business Object:** The business object used for organizations of this type
- **Valid Parent Organization Types:** One or more valid parent organizations that can be referenced on organizations of this type. Used primarily for reporting.

Defining Organization Types

You use the **Organization Type** portal is used to display and maintain organization types.

Refer to [Understanding Organization Types](#) for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Organization Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Organization Type List:** This zone lists all organization type records. Broadcast a record to display the details of the selected record.
- **Organization Type:** This zone provides information about the selected organization type.

Organizations

Understanding Organizations

Organizations are used for categorization and reporting for locations.

For example, your reporting may include a hierarchy that groups locations by a structure of parent and child organizations.

Organizations are defined by the following:

- **Organization Type:** The organization's type. [Understanding Organization Types](#) for more information.
- **Organization Disposition:** The current status of the organization (Active or Inactive)
- **Parent Organization:** The parent organization, if applicable.
- **Main Contact:** A contact for the organization

Defining Organizations

You use the **Organization** portal to display and maintain organizations.

Refer to [Understanding Organizations](#) for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Organization**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Organization:** This zone provides information about the organization.
- **Child Locations / Organizations:** This zone lists any child locations and/or organizations for the current organization.

Out of Service Location Types

Understanding Out of Service Location Types

Out of service location types define attributes of types of locations where assets that are out of service are stored and maintained. Examples of out of service locations include warehouses, storerooms, and repair shops.

Out of service location types are defined by the following:

- **Class:** The general class (storeroom, meter shop, etc.) of out of service locations of this type
- **Location Business Object:** The business object used for out of service locations of this type
- **Valid Parent Location/Organization Types:** One or more valid parent locations and parent organizations that can be referenced on out of service locations of this type. Used primarily for reporting.

Defining Out of Service Location Types

You use the **Out of Service Type** portal is used to display and maintain out of service location types.

Refer to [Understanding Out of Service Location Types](#) for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Out of Service Location Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Out of Service Location Type List:** This zone lists all out of service location type records. Broadcast a record to display the details of the selected record.
- **Out of Service Location Type:** This zone provides information about the selected out of service location type.

Out of Service Locations

Understanding Out of Service Locations

Out of service locations are physical locations where assets are stored or repaired such as a storeroom, warehouse, or service facility. When assets are changed to statuses such as “In Repair” or “Pending Disposition” the asset location is typically moved to an out of service location.

Out of service locations are defined by the following

- **Location Type:** The out of service location’s type. See [Understanding Out of Service Location Types](#) for more information.
- **Location Disposition:** The current status of the out of service location (Active or Inactive)
- **Parent Location/Organization:** The out of service locations’ parent location or organization (if applicable)
- **External ID:** An ID used to identify the out of service location in external systems
- **Address Information:** The physical address of the out of service location
- **Contacts:** The primary contact for the out of service location. See [About Contacts](#) and [Maintaining Contacts](#) for more information about creating and maintaining contacts used with out of service locations.
- **Field Information:** Additional information about the physical location, such as GPS coordinates

Defining Out of Service Locations

You use the **Out of Service Location** portal to display and maintain out of service locations.

Refer to [Understanding Out of Service Locations](#) for more information.

You can access the portal by selecting **Admin**, then **Location**, then **Out of Service Location**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Out of Service Location:** This zone provides information about the out of service location.
- **Current Activities:** This zone provides a summary of the activities that are currently associated to the location.
- **Asset Summary:** This zone provided statistics about the number of assets, by asset type, that are currently associated with the location.
- **Owned Attachments:** This zone lists attachments owned by the location.
- **Referenced Attachments:** This zone lists attachments related to the location.

Note: See [About Contacts](#) and [Maintaining Contacts](#) for more information about creating and maintaining contacts used with out of service locations.

Defining Device Options

Command Sets

Understanding Command Sets

Command sets are used to define a group of commands that are not eligible for a particular device. For instance, if Commission or Decommission commands should be considered ineligible for a particular device model, a command set that references the Device Commission and Device Decommission business objects could be created and associated with that device model.

Command sets are specified for individual device models via the Manufacturer portal.

Individual devices of a particular model can be configured to override ineligibility if needed.

Configuring Command Sets

This portal is used to display and maintain a Command Set.

Refer to [Understanding Command Sets](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Command Set**.

The following zones may appear as part of the portal's **Main** tab page:

- **Command Set List:** This zone lists all Command Set records. Broadcast a record to display the details of the selected record.
- **Command Set:** This zone provides information about the selected Command Set.

Manufacturers

Understanding Manufacturers

Manufacturers are the companies that makes devices.

A device's manufacturer is defined as an attribute of the device itself.

Each manufacturer can have zero or more models defined. Models for a single manufacturer can have diverse service types.

- Models can specify an **Exclude Command Set** that references commands that are not eligible for that model. Refer to [Understanding Command Sets](#) for more information.
- The **Device Command Set Override** field indicates if a command set defined by in **Exclude Command Set** field may be can be overridden and specified at the device.

Configuring Manufacturers

This portal is used to display and maintain a Manufacturers.

Refer to [Understanding Manufacturers](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Manufacturer**.

The following zones may appear as part of the portal's **Main** tab page:

- **Manufacturer List:** This zone lists all Manufacturer records. Broadcast a record to display the details of the selected record. **Manufacturer:** This zone provides information about the selected Manufacturer.

Head End Systems

Understanding Head End Systems

Head end systems are systems that collect measurement data and meter events for eventual submission to the application. Many devices can communicate to the application through a single head-end system, but a utility may have numerous head-end systems through which they communicate with devices.

Head end systems utilize processing methods that specify the type of initial measurement data and device events to create for devices (and their related measuring components) based on measuring component type. Head end systems also utilize processing methods that specify how smart meter commands are processed.

Refer to [Understanding Processing Methods](#) for more information about processing methods.

Head End Systems Impact Data Import and Export

Head end systems are configured to identify how a particular external system communicates data with Oracle Utilities Meter Data Management. This includes:

- The identifier type used to locate devices and measuring components. These are used both on import and export of data.
- The date/time format used in various data imports (i.e. whether or not the date/time format includes time zone information).

Please refer to the embedded help for more information about these fields.

Each head end system can be associated to an [external system](#) which is used to define the messages that can be sent to that service provider and how each message is sent.

Understanding SGG Adapter Configuration

This section describes how to use a head end system's SGG Adapter Configuration portal.

You can use the SGG Adapter Configuration portal to view configuration information and access configuration components for an SGG adapter head end system.

Note: This portal displays configuration information for head-end systems that reference an SGG Adapter Configuration Sheet extendable lookup..

To use the configuration information portal for an SGG adapter head end system:

Select **Admin > Device > Head End System**.

In the Head End system List zone, click the Broadcast icon for the head-end system you wish to view.

Click the SGG Adapter Configuration tab to view the configuration information.

The SGG Adapter Configuration portal contains the following zones:

- **SGG Adapter Configuration Tracker:** This zone displays the configuration details of the adapter, as defined by the SGG Adapter Configuration Sheet extendable lookup referenced on the head end system. The configuration details include:

The components required for usage and event processing and command processing. To view more details about the components, you can click the component name to go to the business object for the component. For example, you can click the business object "SSN - Connect or Disconnect" to go to the business object portal for the SSN - Connect or Disconnect business object.

Status messages describing the configuration status of components. The following table lists the status messages that may be displayed and the possible actions you can take:

If the status message is...	You can...
Set up this processing method	Click the processing role to set up the processing method.
This processing method has been configured	Click the processing role to view the configured processing method.
Update your processing method with a communication BO	Click the status message to set up the processing method.
Update your external system / outbound message type with an Message sender	Click the status message to go to the external system.
Update your processing method with an outbound message type	Click the status message to set up the processing method.
Add a value to get started	Click the status message to go to the extendable lookup.
Values Existing: (number)	Click the status message to go to the extendable lookup.
Add a communication type	Click the status message to go to the communication type portal.
Add a device event type	Click the status message to go to the device event type business object for the communication type. This message appears only for Echelon type adapters.
Master Configuration has been added	Click the status message to view the Master Configuration portal.
Add Master Configuration for this adapter	Click the status message to view the Master Configuration portal.

Upload Statistics Aggregators: This zone lists the IMD Upload Statistics Aggregator measuring components associated with the head-end system.

Configuring Head End Systems

This portal is used to display and maintain Head End Systems.

Refer to [Understanding Head-End Systems](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Head End System**.

The following zones may appear as part of the portal's **Main** tab page:

- **Head End System List:** This zone lists all Head End System records. Broadcast a record to display the details of the selected record.
- **Head End System:** This zone provides information about the selected Head End System.
- **Processing Method List:** This zone provides the list of processing methods defined for the Head End System.
- **Translation Methods List:** This zone provides the list of translation methods defined for the Head End System.
- **Inbound BOs Sent By Service Provider:** This zone lists inbound Business Objects that are sent by this Head End System. The identification is driven by the Business Object having a Business Object Option of type "Sent By Service Provider" that references the current Head End System.

Measuring Component Types

Understanding Measuring Component Types

Measuring component types define the most important properties of a measuring component.

Measuring component types define what a measuring component measures (KWH, temperature, etc.), how regularly it measures it, and whether it should be connected to a physical device, or if it's used as a scratchpad measuring component or an aggregator measuring component. Measuring component types also specify how the measuring component's final measurements should be stored, how the measuring component's user-defined values should be calculated, and specific rules governing validation, editing, and estimation (VEE) for measuring components of the type. In addition, measuring component types define display properties and valid attribute values for measuring components belonging to the type.

The following configurable items are available for most measuring component types:

- **Value Identifiers:** These store the values of UOM, TOU, and SQI that identify the measured amounts for measuring components of this type. Value identifiers specify the quantities stored on the measurement records for measuring components of this type. Please refer to the Measuring Component Type Value Identifiers topic later in this section for more information.
- **Valid VEE Groups:** These define the VEE groups considered valid for measuring components of this type. Each group supplied here will be available to be selected on measuring components of this type and act as an override to the Fallback VEE Groups.
- **Fallback VEE Groups:** These define default VEE groups for a specific VEE Group Role that can be used with all measuring components of this type. This alleviates the need to specify the same VEE groups on multiple measuring components of the same type. Changes made to these groups will automatically apply to all measuring components of this type unless they have specified their own VEE groups for that particular VEE Group Role. Each VEE group is designated a VEE group role that indicates when and how the VEE group is used (for initial load, manual override, estimation, etc.).
- **Eligible Profile Factors (interval only):** These define the profile factors that are considered to be eligible for interval measuring components of this type. One profile factor can be identified as the default. The default profile factor will be automatically selected in system processing when a profile factor is required.
- **Valid Profile Factors for Conversion from Scalar to Interval (scalar only):** These define the profile factors that are considered to be eligible for scalar measuring components of this type when converting scalar measurements to interval measurements. These profile factors are used to produce a curve of interval data from a scalar value. Without one of these factors defined scalar to interval conversion will use a flat line method (i.e. evenly divide the scalar value across the intervals). One profile factor can be identified as the default. The default profile factor will be automatically selected in system processing when a conversion profile factor is required.
- **Valid Scratchpad Measuring Component Types:** These define the scratchpad measuring component types considered valid for measuring components of this type.
- **Related Statistics Measuring Component Types:** These define the measuring component types that will be used to store statistical information about the historical usage of measuring components of this type. Please refer to [Configuring Measuring Component Statistics](#) for more information on how this list is used.
- **Display Properties:** Defines how measurement data for measuring components of this type is displayed, including:

- *Display Configuration*: Details related to how measurements are displayed, including the 360 chart rendering method, number of hours of data to display, the maximum days to search for measurements, the default TOU map used, the TOU by Day Profile factor used, and default measurement condition.
- *Event Bar Profiles*: The event bar profiles used when displaying measurement data for measuring components of this type. Event bar profiles are defined as values for the 360 View Event Bar Profile extendable lookup.
- *Final Values Overlay Profiles*: The final values overlay profiles used when displaying measurement data for measuring components of this type. Final values overlay profiles are defined as values for the Final Values Overlay Profile extendable lookup.
- *Measurement Conditions Not Shown on Chart*: The measurement conditions that should be omitted from rendering onto 360 Degree charts. Measurements whose conditions match these values will be rendered as gaps. For example, many 360 Degree charts use the condition "No Read - System" to represent the lack of a measurement, by adding this condition to this list a gap will be rendered instead of a line with a 0 quantity measurement and a condition of "No Read - System".

When creating a measuring component type the following options are available:

Name	Details	Business Object
Interval Channel Type - Physical	Provides the configuration for a physical interval channel (including interval size). This is recommended for measuring components that measure consumptive usage in interval sizes up to 1 hour.	D1-IntervalChannelTypePhysical
Interval Channel Type - Scratchpad	Provides the configuration for a scratchpad interval measuring component.	D1-IntervalChannelTypeScratchp
Interval Channel Type - Physical Subtractive	Provides the configuration for a physical subtractive interval channel. In addition to standard interval configuration (including interval size) it also provides additional subtractive specific configuration (e.g. rollover validation, estimate reevaluation, etc). This is recommended for measuring components that measure subtractive usage in interval sizes up to 1 hour.	D1-IntrvlChanTypPhysSubtractiv
Register Type	Provides the configuration for a physical register that is manually read (e.g. rollover validation). These can be either consumptive or subtractive but are expected to be read infrequently (e.g. once a month).	D1-RegisterTypePhysical

Auto-Read Register Type	Provides the configuration for a physical register that is automatically read. In addition to the standard register configuration (e.g. rollover validation) it also provides details around the schedule of expected readings (e.g. first daily measurement time and expected hours between measurements). These can either be consumptive or subtractive but are expected to be read frequently (e.g. at least once per day).	D1-AutoReadRegisterType
	Note: these measuring component types can also be used to model interval data that is received with a large interval size (24 hours and larger).	
Aggregator Type	Provides the configuration for an aggregation measurement.	D2-AggregatorType

Note: For “interval” data with an interval size greater than one hour, use the D1-AutoRegisterReadType measuring component type business object and the D1-RegisterAutoRead measuring component business object. This business object is well suited to daily and sub-daily readings. Using an interval data business object can result in measurement date problems during daylight saving time.

Refer to [Configuring an Out-of-the-box Aggregation](#) for more information about aggregation configuration

Measuring Component Type Value Identifiers

Measuring components are configured to measure specific types of quantities this is defined by the list of value identifiers on the measuring component type. Up to eleven value identifiers can be specified. The primary measured quantity should be identified using the Value Identifier Type of Measurement. An additional ten derived values can be computed based on the primary measurement, these are identified with the Value Identifier Type of Value 01 through Value 10. Each value identifier is constructed of:

- **Unit of Measure:** The unit of measure for the quantity being recorded. Examples include kilo-watt hours (kWh), kilo-watts (kW), therms, cubic feet (CCF), temperature (Fahrenheit or Celsius), etc. Refer to [Understanding Units of Measure](#) for more information.
- **Time of Use:** Modifiers for a given unit of measure that indicate a period of time during which a quantity has been used, such as On-Peak (meaning during a time when the greatest quantity of some consumable is being used), Off-Peak (meaning during a time when the least amount of some consumable is being used), etc. Refer to [Understanding Time of Use](#) for more information.
- **Service Quantity Identifiers:** Used to further distinguish between measured quantities that have identical UOM/TOU combinations, including situations in which the distinguishing identifier of a UOM is not accurately described as a TOU. Generally, SQI is only used when multiple measuring components measure the same thing, but in different ways. A meter that measures both generation KWH and consumption KWH could use SQIs to differentiate between the two. Refer to [Understanding Service Quantity Identifiers](#) for more information.
- **Value Derivation Algorithm:** Unlike UOM, TOU, and SQI this is not used in the identification of what is measured but rather is used to calculate a derived value based on the primary measurement. An algorithm from the list should be selected that contains the appropriate logic for calculating the derived value. This is applicable for those value identifiers with a Value Identifier Type of Value 01 through Value 10. More information on how derived values are calculated can be found in the Important Measuring Component Type System Events topic in this chapter. For more functional information about derived values please refer to [About Final Measurements](#).

The combination of UOM, TOU and SQI define what a measuring component measures. TOU and SQI are optional, but UOM must be defined for all value identifiers. For example, consider a meter (as illustrated in the image below) with two measuring components, both measuring the same unit of measure (kWh), but each measuring component measures consumption in different time of use (TOU) periods (peak and off-peak).

Another example might be a meter that records both generated KWH and consumed KWH. This meter would be configured to measure both UOM and SQI.

A measurement is recorded each time a measuring component is read. This means that for a meter with two measuring components that is read once a month, two measurements, one for each measuring component, would be recorded each month.

Important Measuring Component Type System Events

The measuring component type supports several business object algorithm system events that relate to calculating the consumption for measuring components of that type:

- **Calculate Interval Consumption:** receives the interval list and performs any necessary calculations on that interval data to compute consumption. Since interval data is already received as consumption data algorithms for this system event are typically limited to application of the appropriate multipliers. Refer to the algorithm type Calculate Interval Consumption (D1-IN-CNSUMP) as an example.
- **Calculate Scalar Consumption:** receives information about the scalar reading and calculates the consumption as appropriate. Algorithms for this event typically support calculating the consumption using a stop and start reading or backing into a reading using consumption and a start reading. Much like the interval counterpart it will apply the appropriate multipliers. Refer to algorithm type Calculate Scalar Consumption (D1-SC-CNSUMP) as an example.
- **Calculate Subtractive Interval Consumption:** receives the interval list and supporting information (e.g. the start reading for the first interval) and either calculates the consumption by subtracting the interval's reading from the prior interval's reading or calculates the reading by adding the current interval's consumption to the prior interval's reading. Refer to algorithm type Calculate Subtractive Interval Consumption (D1-SIN-CNSUM) as an example.
- **Condition Mapping:** receives the details of a single subtractive interval along with the details for its start reading and computes the applicable final condition and reading condition. This is leveraged solely for subtractive interval measuring component types. Refer to algorithm type Subtractive Interval - Condition Mapping (D1-SIN-CNMAP) as an example.

These system events are typically called from within initial measurement processing during the initial stages of the initial measurement lifecycle (e.g. the Pre VEE status of most initial measurement business objects).

In addition to the measuring component type business object algorithms there is an additional system event provided on measuring component type itself:

- **Value Derivation:** receives details of an initial measurement and an associated final measurement. Using these inputs it can compute a value derived either from the primary measurement or one of the other derived values. Refer to algorithm type Derive a quantity using a formula (D1-DERIVAQTY) as an example.

Important Measuring Component System Events

The measuring component business object that is associated to a given measuring component type supports a special system event that is used in the periodic estimation process:

- **Periodic Estimation:** this system event will scan the measuring component's final measurement history to identify missing measurements and create either a To Do, or an estimation initial measurement, or both. More detail about this system event can be found by visiting the following algorithm types: Refer to algorithm type Create Interval IMD and To Do Based Upon Install History (D1-CIITBIH) and Auto-Read Scalar Periodic Estimation (D1-ARSPE) as an example.

Measuring Component Business Object Options

The device business object that is associated to a given device type plays an important role in how a device is processed in a system beyond defining the data associated to that device. Below are a list of business object options that are defined on the device business object and their impact on system processing:

- **Estimation Initial Measurement Data BO:** Is used to identify the appropriate estimation IMD to create.
- **Manual Override IMD BO:** Is used to identify the appropriate manual override IMD to create.
- **System IMD BO:** Is used to identify the appropriate system IMD to create.
- **Measuring Component Consumption Function:** identifies a function that can be executed from any compatible measuring component 360 Degree zone. Each measuring component can support 0 to many of these functions.
- **Interval Initial Measurement Function:** identifies a function that can be executed from any compatible initial measurement zone. Each measuring component can support 0 to many of these functions.

More detail about these options can be found by visiting a measuring component business object and inspecting the business object options.

Configuring Measuring Component Types

This portal is used to display and maintain a Measuring Component.

Refer to [Understanding Measuring Component Types](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Measuring Component**.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component Type:** This zone provides information about the selected Measuring Component Type.

Measuring Component Comparison Types

Understanding Measuring Component Comparison Types

Measuring component comparison types define the details by which measuring component data can be compared to determine the days that most closely resemble a specific day being evaluated. For example, measuring component comparison types can be used on measuring components that store weather data so that comparisons can be made based on temperature. These are used when performing “proxy day” estimations, allowing the application to search for days that are similar to historical data (for instance, the same date from the previous month or previous year) to use as the basis for estimation.

Measuring component comparison types use the following parameters:

- A specific metric to be calculated to enable data comparisons. The “Calculate Comparison Coefficient - Pearson Correlation Coefficient” algorithm, included with the base package can be used to calculate a coefficient based on the linear correlation between two data sets (specifically between weather data stored on a measuring component and on the comparison object).
- The specific object to be compared. This can be either the same measuring component (to compare against historical data for the same measuring component), or a factor profile (to compare against profile data).
- The date range for the comparison period, including the start of the comparison period (current date, same date last year, or both), the time each day through which the comparison will be calculated, and the number of days prior to and after the start date that will be compared with the comparison object.
- Average Difference Eligibility: An average value either above or below the average for the current date that will be eligible for comparison. For example, assume the current date’s average is 75, and the prior day’s average is 72. If the Average Difference Eligibility is set to 3 then the prior day value of 72 will be eligible for comparison to the current day average of 75.
- The maximum number of resulting calculations that should be stored as measuring component comparable periods.
- A template that defines which days are considered like each day of the week (for example, weekdays are like other weekdays, weekend days are like other weekend days). This template is defined as a record for the “Like Day Eligibility Template” extendable lookup.
- Work calendars used to determine if specific data should be compared to other weekend days or to the same date in prior years, and which dates, if any, should be excluded from historical data used for comparison.

Configuring Measuring Component Comparison Types

Refer to [Understanding Measuring Component Comparison Types](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Measuring Component Comparison Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component Comparison Type List:** This zone lists all measuring component comparison type records. Broadcast a record to display the details of the selected record.
- **Measuring Component Comparison Type:** This zone displays details for the selected measuring component comparison type.

Device Configuration Types

Understanding Device Configuration Types

Device Configuration types define the measurements a given device can record. It should be noted that the device configuration type itself does not specify this information but rather the device configuration type will identify the valid list of measuring component types that can be referenced associated to a device.

When creating a new device configuration type there are the following options:

Name	Details	Business Object
Device Configuration Type	This represents configurations for physical meters and communication components. It identifies a list of valid measuring components types.	D1-DeviceConfigurationType
Item Configuration Type	This represents badged items that are installed at a particular service point. Given the nature of items there are no measuring component types associated to this type.	D1-ItemConfigurationType

Refer to [Configuring Consumption Synchronization](#) for more information on how a device configuration type can be set up to synchronize consumption between two related channels of measurement data.

Configuring Device Configuration Types

This portal is used to display and maintain a Device Configuration Type.

Refer to [Understanding Device Configuration Types](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Device Configuration Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Configuration Type List:** This zone lists all Device Configuration Type records. Broadcast a record to display the details of the selected record.
- **Device Configuration Type:** This zone provides information about the selected Device Configuration Type.

Device Types

Understanding Device Types

Device types define information about a class of devices, including properties that apply to all devices of a type. Properties defined for a device type can be overridden for an individual device.

Specifically, device types provide information about:

- How a device can be configured by defining the valid list of device configuration types
- How a device communicates by defining a fallback head end system and a list of valid head end systems.
- How a device records measurement data through the fallback incoming data shift which plays an important role in daylight savings processing. Refer to [Daylight Savings Time Support](#) for more information.
- The consumption profile of an item: the unit of measure consumed and method of calculation (profile or straight line)
- Whether the device is attached to a service point or meter (used with items and device communication equipment)
- Characteristics common to all devices of this type (defined in the **Device Type Characteristics** zone).

When creating a new device type there are the following options:

Name	Details	Business Object
Smart Meter Device Type	These devices measure consumption for a given service point, support remote commands, and remote collection of measurement and event data. These devices are associated to a head end system.	D1-SmartMeterType
Manual Meter Device Type	These devices measure consumption for a given service point but require a visit to the service point to collect the measurement data. They are not associated to head end systems.	D1-ManualMeterType

Item Device Type	<p>These devices represent various items that consume consumption at a constant rate which are not directly metered. As consumption is calculated rather than measured so there is no need for an association to a head end system. Devices of this type can either be created individually for "badged" items or can be listed directly on a service point for "unbadged items."</p> <p>These devices may also be configured as equipment that can be attached to a service point.</p>	D1-ItemType
Communications Component Device Type	<p>These devices provide remote collection of consumption data measured by a manual meter on which they are installed. These devices are associated to a head end system.</p>	D1-CommunicationCompMeterType
Device Communication Equipment Type	<p>These devices provide remote collection of consumption data measured by a manual meter to which they are attached. Devices of this sort are sometimes referred to as Encoding Receiver/Transmitter (ERT) modules, or communication modules.</p> <p>These devices are associated to a head end system.</p>	D1-DvcCommEquipmentType

Device Business Object Options Drive Functionality

The device business object that is associated to a given device type plays an important role in how a device is processed in a system beyond defining the data associated to that device. Below is a list of business object options that are defined on the device business object and their impact on system processing:

- **Device Category:** This defines the type of device and correlates to the core device types that are supported (i.e. smart meter, AMR meter, manual meter, item, or communication component). This value is used by smart meter commands, service order management, and other system processes to make processing decisions.
- **Install Event BO:** This identifies the appropriate install event business object to use when this device is being installed at a service point. Refer to [About Install Events](#) for more information about install events.
- **Valid Command Request BO:** This identifies the commands that are valid for any device of this type. This option can be repeated for as many commands as the device supports. Note: the combination of the device and service provider (aka head end) define the true list of available commands by device.
- More detail about these options can be found by visiting a device business object and inspecting the business object options.

Device Type - Service Quantity

For "badged" and "unbadged" items consumption is not directly measured. Instead, for each item type, the average daily consumption amount is provided. The commodity represented by the daily consumption amount is defined by the item type's unit of measure.

The average daily consumption amount can be effective dated over time to support changes in the consumption profile. This is used in conjunction with the item's calculation method to derive the consumed amount per interval.

Refer to [Multiple Time Zone Support](#) for additional information on how device type service quantities are impacted by multiple time zones.

Valid Device Characteristic Types

The **Valid Device Characteristic Types** zone lists the valid characteristic types that may be instantiated on devices of this type. Characteristics of these types are maintained using the **Device Characteristics** zone in the **Device** portal.

Configuring Device Types

This portal is used to display and maintain a Device Type.

Refer to [Understanding Device Types](#) for more information.

You can access the portal by selecting **Admin**, then **Device**, then **Device Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Type List:** This zone lists all Device Type records. Broadcast a record to display the details of the selected record.
- **Device Type:** This zone provides information about the selected Device Type.
- **Device Type Service Quantity:** This zone displays the list of effective dated service quantities supported by the selected Device Type. This applies only to Items.
- **Device Type Characteristics:** This zone lists characteristics common to all devices of this type.
- **Valid Device Characteristic Types:** This zone lists the valid characteristic types that may be instantiated on devices of the device type. To add or edit valid characteristic types, click **Edit**.

Defining Device Installation Options

Service Point Types

Understanding Service Point Types

Service point types define a specific type of point at which service is delivered.

Specifically, service point types define how the application manages many aspects of the service point's behavior. A service point type may have one or more valid device types defined that limit the types of devices that can be installed at service points of this type.

Service point types are defined by the following:

- **Service Point Business Object:** the business object used by service points of this type
- **Service Point Category:** the types of devices that can be installed at service points of this type. Valid values include:
 - **Meter:** Indicates that a single meter can be installed at service points of this type.
 - **Item:** Indicates that a single "badged" item can be installed at service points of this type.
 - **Multi-Item:** Indicates that one or more "unbadged" items can be installed at service points of this type.
- **Divisions:** one or more divisions associated with service points of this type.
- **Valid Device Types:** the device types considered valid for service points of this type.
- **Valid Field Task Types:** the field task types considered valid for service points of this type. The field task types available when creating field activities can be based on the field task types listed here via the **Restrict Field Task Type by Service Point Type** option on the Service Order Management Master Configuration.

- **Usage Snapshot Configuration:** the configuration(s) to be used to take weekly or monthly usage snapshot(s)
- **Unreported Usage Snapshot Configuration:** the configuration(s) to be used to take weekly or monthly unreported usage snapshot(s)

Configuring Service Point Types

You use the Service Point Type portal to view and maintain service point types.

Refer to [Understanding Service Point Types](#) for more information.

You can access the portal by selecting **Admin, Device Installation, Service Point Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured service point types as well service point types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Point Type List:** This zone lists all service point type records. Broadcast a record to display the details of the selected record.
- **Service Point Type:** This zone provides information about the selected service point type.
- **Valid Field Task Types:** This zone lists the field task types considered valid for the selected service point type.
- **Valid Disconnect Location:** This zone lists disconnection locations considered valid for the selected service point type.

Service Point Quantity Types

Understanding Service Point Quantity Types

Service point quantity types define types of quantities that can be stored for a service point. These quantity types are often infrequently calculated descriptors of a given customer and how they relate, at an aggregate level, to either the customer base as a whole or their particular rate class. For example, a customer quantity may be used to store a scaling factor that describes how a given customer's usage compares to the profiled usage for their rate class.

In a settlement implementation, service point quantity types can be used to define values calculated monthly, annually, etc., such as annual peak load contribution (PLC).

Service quantity types use the following parameters:

- The service type (electric, gas, water, etc.) for service point quantities of this type
- Quantity identifiers related to the current service point quantity type (used to provide shorthand descriptions of the various types of values measured by service point quantities of this type)

Configuring Service Point Quantity Types

Refer to [Understanding Service Point Quantity Types](#) for more information.

You can access the portal by selecting **Admin**, then **Device Installation**, then **Service Point Quantity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Service Point Quantity Type List:** This zone lists all service point quantity type records. Broadcast a record to display the details of the selected record.
- **Service Point Quantity Type:** This zone displays details for the selected service point quantity type.

Measurement Cycles

Understanding Measurement Cycles

Measurement cycles define the schedule for manual meter reading of devices at Service Points in that cycle. Measurement cycles can have one or more associated routes used to collect measurements.

Measurement cycles can also be configured to define when to [create usage transactions](#) for Usage Subscriptions associated to Service Points in the cycle.

For a deeper functional understanding, refer to the [About Route Management](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Measurement Cycles

This portal is used to display and maintain a Measurement Cycle.

Refer to [Understanding Measurement Cycles](#) for more information.

You can access the portal by selecting **Admin**, then **Device Installation**, then **Measurement Cycle**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measurement Cycle List:** This zone lists all Measurement Cycle records. Broadcast a record to display the details of the selected record.
- **Measurement Cycle:** This zone provides information about the selected Measurement Cycle.
- **Measurement Cycle Route List:** This zone lists the measurement cycle routes related to the measurement cycle. Click the **Route** link to view details for a measurement cycle route in the **Measurement Cycle Route** portal.
- **Measurement Cycle Schedule List:** This zone lists the measurement cycle schedules related to the current measurement cycle. Click the **Scheduled Selection Date** link to view details for a measurement cycle schedule in the **Measurement Cycle Schedule** portal.

Configuring Measurement Cycle Routes

The Measurement Cycle Route portal is used to maintain individual measurement cycle routes.

You can access the portal by clicking the **Route** for a specific measurement cycle route in the **Measurement Cycle Route List** zone of the **Measurement Cycle** portal. You are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measurement Cycle Route:** This zone provides information about the selected Measurement Cycle Route.
- **Measurement Cycle Route Characteristics:** This zone lists characteristics for the selected Measurement Cycle Route.

Measurement Cycle and Bill Determinants

The system can be configured to periodically push bill determinants to subscribing systems. In this case, measurement cycles can be configured to define when to create usage transactions for Usage Subscriptions associated to Service Points in the cycle. Even Service Points whose meters are read automatically may reference measurement cycles.

Creating bill determinants (by creating a usage transaction) is performed by an algorithm on the "Complete" state of the SP/Measurement Cycle Schedule Route business object (similar to creating activities as described above).

When the Pending SP/Measurement Cycle Schedule Route records are processed by the D1-PSPSR batch, rather than create a handheld download activity, the algorithm can create a usage transaction (usage transactions are transactions that cause bill determinants to be calculated for the Service Point's Usage Subscription).

If the implementation needs to both manually read the meter and push bill determinants, both algorithms would be plugged in on the SP/Measurement Cycle Schedule Route business object.

Measurement cycle processing is managed by the following three batch processes:

- **Create Pending Measurement Cycle Schedule Routes (D1-CMCS):** This batch process creates Schedule Routes for Measurement Cycle Schedules whose schedule selection date is on or before the batch business date. This process is used if routes have the same schedule each month, quarter, etc. This process simply copies the routes from the Measurement Cycle to the Measurement Cycle Schedule on/after the scheduled selection date.
- **Create Pending SP / Measurement Cycle Schedule Route Records (D1-CSPSR):** This batch process creates a "SP/Measurement Cycle Schedule Route" transaction for every Service Point in the Measurement Cycle Schedule Route that is ready for processing.
- **Process Pending SP / Measurement Cycle Schedule Route Records (D1-PSPSR):** This batch process transitions the Pending "SP/Measurement Cycle Schedule Route" transactions to their Complete state. Custom algorithms can be configured to do any additional necessary work, such as creating a "Meter Read Download" activity. This custom algorithm would be configured as an Enter algorithm on the "Complete" state of the SP/Measurement Cycle Schedule Route business object.

For a deeper functional understanding, refer to the [About Route Management](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Measurement Cycle Schedules

Understanding Measurement Cycle Schedules

Measurement cycle schedules define the dates on which devices are scheduled to be read for a given measurement cycle and the routes used to collect measurements for the measurement cycle.

For a deeper functional understanding, refer to the [About Route Management](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Measurement Cycle Schedules

This portal is used to display and maintain a Measurement Cycle Schedule.

Refer to [Understanding Measurement Cycle Schedules](#) and [Understanding Measurement Cycles](#) for more information.

You can access the portal by selecting **Admin**, then **Device Installation**, then **Measurement Cycle Schedule**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Measurement Cycle Schedule Query:** This zone allows you to query for Measurement Cycle Schedules based on Measurement Cycle and select the desired record.
- **Measurement Cycle Schedule:** This zone provides information about the selected Measurement Cycle Schedule.

Defining Measurement Options

Initial Measurement Data

Configuring the Initial Measurement Algorithms

The behavior of initial measurement data processing can be adjusted by updating parameters in several key algorithms in the lifecycle.

Note: This is not a list of all algorithms and algorithm parameters that can be customized in the initial measurement processing lifecycle. Rather, it is a selection of some of the more impactful parameters.

Initial Measurement Data Seeder Algorithms

- Derive Service Provider and Measuring Component (D1-DER-SPRMC):
 - Enabling a standalone measuring component search allows initial measurement data to be processed without a device identifier. This is useful when profile or temperature data is loaded through the IMD Seeder and a match must be made on measuring component identifiers alone.
 - If measuring component identifiers can be repeated across measuring components for the same device then the error for duplicate measuring components being found can be turned off. This is useful for certain head end systems that will have multiple channels with the same channel identifier. When a duplicate is found the search will fall back on other means for identifier the correct measuring component.
- Perform Date/Time Adjustments and Undercount/Overcount Check (D1-DODTTMADJ):
 - Undercount validation can be turned off completely or left enabled. When left enabled the automatic filling of gaps can be turned off separately.
 - The overcount check can be turned off.
 - The automatic adjustment of the individual interval date/times to an interval boundary can be turned on.

Note:

If your implementation receives initial measurement data with date/times that do not include an explicit time zone and the devices report date/times in standard time, you may need to add the following configuration:

- Navigate to **Admin > Integration > Message Option**
- In the **XAI compliance** option, ensure that the following text is provided:

```
xsd:strict:dstGapInStandardTime
```

This will prevent a date/time reported in standard time that falls on the missing hour of the day Daylight Savings Time is entered from being misinterpreted.

Specific Initial Measurement Data Algorithms

- Normalize measurements (overwrite identical existing Measurements) (D1-NORM-IMD):
 - When the initial measurement data includes measurements that match exactly with the existing final measurements they can either be overwritten or skipped.
 - If logging of changes to final measurements is desired then it must be indicated as such in this algorithm. It is suggested to keep this turned off for high volume initial measurement data such as initial load. See [Configuring Measurement Logging](#) for more details.

Note: Refer to [Configuring Consumption Synchronization](#) for additional parameters that can be adjusted on specific initial measurement data algorithms.

Configuring Measurement Logging

There are two components to logging changes to final measurements:

- **Initial Measurement Finalization:** the "normalization" algorithm on a particular initial measurement data business object will determine how final measurements are updated. For performance reasons certain types of initial measurement data (e.g. initial load) are delivered with a final measurement update method that will skip any logging. This can be controlled by parameters on the algorithm that implements the algorithm type Normalize Measurements for Initial Measurement Data (D1-NORM-IMD). Specifically the "Create Measurement Log on Update (Y/N)" parameter should be set to "Y". As mentioned creating these logs has a performance impact and it is not recommended for use on initial load.
- **Measurement Business Object:** there must be an algorithm for the audit system event configured. The base package delivers the algorithm type Add Measurement Log Record (D1-AMSRMTLOG). It is this algorithm that actually records the log entries.

Logging User Updates to Manual Initial Measurements

By default, manual edits made by users of these zones are not logged on the Log tab. Logging of manual edits to manual initial measurements can be enabled by adding a logging algorithm on an appropriate lifecycle state of the manual initial measurement business objects. The Log User Transaction (D1-LOGUSRTRN) base package algorithm can be used for this. This Enter algorithm is designed to be defined on the Initial state of the manual initial measurement business objects, but it can also be defined on any (non-transitory) Interim or Final state as well.

To ensure logging of any or all manual edits made to manual initial measurements, this algorithm should be specified on any state in which users will make manual edits. This will most often be the Pending or VEE Ready states, but could also include the Error, Exception, or Finalized states.

CAUTION: When defining this algorithm, the user should exercise caution and determine if previous algorithms in the sequence within the state contain any form of transitioning logic that may inadvertently cause this algorithm to be bypassed.

Removing Unwanted Initial Measurements

Over time, implementations can accumulate unnecessary non-final initial measurements which effectively become "stuck" in the system. Examples of these types of initial measurements include:

- Erroneously imported duplicate initial measurements
- Initial measurements that failed validation and were not corrected or replaced
- Initial measurements that triggered service issue monitors that remain unresolved

These initial measurements can also have related VEE Exceptions, To Do Entries, and Service Issue Monitors that remain "stuck" as well. This unnecessary data can impact overall system performance and should be reviewed and removed from time to time.

The Remove Unwanted Initial Measurements feature can be used to identify and close or delete these unwanted non-final initial measurements and any related VEE exceptions, To Do Entries and service issue monitors. This process is initiated by creating Request records which specify the parameters used to locate the non-final initial measurements to be removed. The request in turn initiates a batch process which identifies non-final measurements and related VEE Exceptions, To Do Entries, and/or Service Issue Monitors.

This functionality uses the following system objects:

Table listing objects used by this feature.

Object Type	Object Name	Description
Request Type Business Object	Remove IMDs Request Type (D1-RemoveIMDsType)	Used to define types of initial measurements removal requests. The Remove IMDs Request (D1-RemoveIMDsRequest) request business object (see below) is defined as the "Related Transaction BO" for this business object, meaning that requests created for request types based on this business object use the Remove IMDs Request (D1-RemoveIMDsRequest) request business object.
Batch Control	Remove Non-Final IMDs (D1-RENFI)	Used to identify non-final measurements and related VEE exceptions, To Do Entries and/or Service Issue Monitors (Service Tasks).

Object Type	Object Name	Description
Request Business Object	Remove IMDs Request (D1-RemoveIMDsRequest)	Used to create and process initial measurement removal requests.
Fact Business Object	Remove IMD Object Count (D1-RemoveIMDOjbecCount)	Used to capture details of the initial measurements and related objects to be removed.

Remove Unwanted Initial Measurements Request Types

Requests used to remove initial measurements are based on request types which specify the batch control used to identify and remove the initial measurements.

To create request types used with this feature:

1. Select Menu, **Admin, General, Request Type, Add**.
2. Select "Remove IMDs Request Type" from the **Request Type Business Object** drop-down list, and click **OK**.
3. Enter the following:
 - **Request Type:** A code for the request type
 - **Description:** A description of the request type
 - **Batch Control:** Search for and select the batch control to be used for requests of this type. The default is Remove Non-Final IMDs (D1-RENF), but implementations can create custom versions of this batch control.
4. Click **Save**.

Remove Unwanted Initial Measurements Requests

To create an initial measurement removal request:

1. Select **Menu, Tools, Request, Add**.
2. Select the appropriate request from the **Request Type** drop-down list and click **OK**.
3. Enter the **Submission Parameters** for the request. These include:
 - **Mode:** The mode in which the process will be run. Options include:
 - **Preview:** Returns a count of non-final initial measurements and related objects (VEE Exceptions, To Do Entries, and Service Issue Monitors)
 - **Close:** Transitions non-final initial measurements to the "Discarded" state and completes and/or closes related objects. Details regarding the data impacted by "Close" requests are captured and displayed in the **Object Log** zone.
 - **Delete:** Deletes non-final initial measurements any related objects. Details regarding the data impacted by "Delete" requests are captured and displayed in the **Object Log** zone.
 - **Thread Count:** The number of processing threads allocated to the process
 - **IMD Business Object:** Used to restrict the initial measurements processed to those of a specific business object
 - **IMD Status:** Used to restrict the initial measurements processed to those in a specific non-final state, including Pending, Held, Additional Mapping, Mapping Error, VEE Ready, Defer, Error, VEE Complete, Exception, or Force Complete
 - **IMD Create Date/Time From:** Required. The start date and time of the time period in which initial measurements to be removed were created. For example, to remove initial measurements created between January 1, 2023 and January 31, 2023, the **IMD Create Date/Time From** would be "01-01-2023 12:00 AM".
 - **IMD Create Date/Time To:** Required. The end date and time of the time period in which initial measurements to be removed were created. For example, to remove initial measurements created between January 1, 2023 and January 31, 2023, the **IMD Create Date/Time To** would be "01-31-2023 12:00 AM".
 - **Device Configuration:** Used to restrict the initial measurements processed to those related to a specific device configuration.

4. Click **Save**. The request will then open in the **Request** portal.
5. Click **Submit Batch** to process the request.

Initially requests are created in the "Pending" status. When the request is run (by clicking **Submit Batch**), a batch process based on the batch control defined on the request type is executed.

- If the batch process errors, the request **Status** is set to the "Batch Error".
- If the batch process completes, the request **Status** is set to the "Completed".

Details of the process are captured in the **Submission Information** section, and the **Object Log** zone.

The **Submission Information** section includes:

- **Batch Submission:** Link to the batch job submission for the batch process. Click the link to navigate to the **Batch Job Submission** portal to view details of the batch process.
- **IMD SDE Extract Through Date/Time:** The date and time through which specialized data extracts have been performed for initial measurements impacted by the process.
- **End of Batch Date/Time:** The date and time when the batch process was completed.

The **Object Log** zone contains table with details regarding the initial measurements and related objects processed, including:

- **Object:** The type of object processed (Initial Measurement Data, Service Task, To Do Entry, or VEE Exception)
- **Specialized Data Extract Occurred:** An indicator as to whether or not ("Yes" or "No") occurred for initial measurement data
- **Count:** The number of objects processed.

Example:

Table listing sample results.

Object	Specialized Data Extract Occurred	Count
Initial Measurement Data	No	434
Initial Measurement Data	Yes	134
Service Task		1
To Do Entry		425
VEE Exception		413

Batch Control

The Remove Non-Final IMDs (D1-RENF) batch control identifies and closes or deletes unwanted initial measurements and their related objects. When run, this batch process creates a fact (using the Remove IMD Object Count (D1-RemoveIMDObjectCount) business object) that captures details regarding the batch process and the objects being removed during the process. These details are viewed in the **Object Log** zone in the **Request** portal.

Note that the Request ID is a required parameter for this batch control, meaning that this batch control cannot be run on its own. It can be only run from an initial measurement removal request.

Implementations can create specific versions of this batch control for use when removing specific types of data. For instance, an implementation could create a "Preview" version of this batch control, or a version used only with interval initial measurements.

Implementations can alter the processing of this batch control by creating alternate algorithms for each of the System Events used by this batch process. Refer to [Ad-hoc Processes](#) in the [Plug-in Driven Background Processes](#) section for more information.

Recommendations and Warnings

- We recommend using the **Preview** mode to identify potential initial measurements for removal before processing a request in either the **Close** or **Delete** mode. This allows you to review and verify the data to be removed before closing or deleting it.
- We recommend that access to this feature be limited to system administrators and other power users. Access to this feature can be restricted via the Remove IMDs Request BOAS (D1-RMIMDREQBOAS) application service.

Warning: If used improperly, this feature can inadvertently remove valid operational data (such as initial measurements in "Pending" status awaiting VEE processing). There is no process for "undoing" the removal of initial measurements and related objects using this feature.

Understanding Interval Price Set Types

Interval price set types define properties belonging to a class of interval price sets.

Interval price set types are defined by the following:

- **Service Type:** The service type to which interval price sets and interval prices based on this type will be applied
- **Interval Size:** The size of the intervals for interval prices based on this type, represented as hours:minutes:seconds (HH:MI:SS).
- **UOM:** The unit of measure used to define interval price sets and interval prices based on this type
- **TOU:** The time of use period used to define interval price sets and interval prices based on this type
- **SQI:** The service quantity identifier used to define interval price sets and interval prices based on this type
- **Short-Hand Description:** A short-hand description used for interval price sets of this type

Note: Either a UOM or SQI **must** be defined when creating an interval price set type.

System Data

Interval Price Set Types are based on the following system data:

Data Type	Description
Maintenance Object	Measuring Component Type (D1-MCTYPE)
Business Object(s)	Interval Price Set Type (D1-IntervalPriceType)

Defining Interval Price Set Types

You use the **Interval Price Set Type** portal to display and maintain interval price set types.

Refer to [Understanding Interval Price Set Types](#) for more information./

You can access the portal by selecting **Admin**, select **Interval Price Set**, then select **Interval Price Set Type**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Interval Price Set Type:** This zone displays basic information about interval price set type.

Defining Validation, Editing, and Estimation (VEE) Options

Exception Types

Understanding Exception Types

Exception Types define the groupings of exceptions for an IMD based on their functional similarity. This provides a way to define VEE Exceptions in a distinct enough way to understand the root issue that was generated from the VEE Rule.

For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Exception Types

This portal is used to display and maintain an Exception Type.

Refer to [Understanding Exception Types](#) for more information.

You can access the portal by selecting **Admin**, then **VEE**, then **Exception Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Exception Type List:** displays all of the Exception Types so you can choose the one you want to display in more detail
- **Exception Type:** shows the specific configuration for the selected Exception Type

There are two different options to use when creating an Exception Type:

Name	Details	Business Object
VEE Exception	This will create a "normal" VEE Exception that is attached to an IMD for tracking of conditions triggered in the VEE process.	D1-VEEException
VEE Exception - Monitor Service Point	In addition to tracking the failure in the VEE process, this VEE Exception generates a Service Issue Monitor . This allows for cumulative tracking of VEE Exceptions that can be configured to result in a Service Investigative Order (field work) for the Service Point.	D2-VEEExceptionServiceMonitor

VEE Groups

Understanding VEE Groups

VEE groups are collections of VEE Rules that are applied to initial measurement data. During the VEE process, the system executes the VEE Rules defined in each VEE group. The rules within a VEE group are defined in a specific sequence, allowing control over the order in which the rules are executed.

VEE groups can be associated to a specific measuring component, or to a measuring component type (or both). VEE groups associated with a measuring component type are applied to all measuring components of that type, while those associated to a specific measuring component are applied only to that measuring component. VEE groups associated to a measuring component override those assigned to a measuring component type.

VEE groups can also be referenced by the [Execute VEE Group](#) VEE Rule.

For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring VEE Groups

This portal is used to display and maintain a VEE Group.

Refer to [Understanding VEE Groups](#) for more information.

You can access the portal by selecting **Admin**, then **VEE**, then **VEE Group**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **VEE Group**: Defines basic information about VEE group
- **VEE Rules List**: lists the VEE Rules belonging to the group
- **Referencing VEE Rules List**: lists the VEE Rules that reference the group
- **Referencing VEE Group Factors List**: lists the VEE group factors that reference the group
- **Referencing Measuring Component Type List**: lists the measuring component types that reference the group
- **Referencing Measuring Component List**: lists the measuring components that reference the group

VEE Rules

Understanding VEE Rules

VEE Rules are standard and custom Validation and Estimation rules that perform checking and/or manipulation of initial measurement data. VEE Rules are created for a specific VEE group. For example, if you were configuring two VEE groups and both included a specific VEE Rule, you would need to create two instances of the VEE Rule, one for each group.

The specific validation and estimation processing performed on initial measurement data is defined in individual VEE Rules, each performing a specific set of targeted logic. The base product contains many VEE Rules you can use in your implementation, but you can also create your own custom VEE Rules.

Some VEE Rules generate VEE Exceptions if the initial measurement data fails the conditions specified for the rule. Other rules override measurements, changing measurement values as dictated by the rule's parameters. Some rules can both create exceptions and override the measurement as part of a single process. By convention, VEE Rules change the Post-VEE quantities of initial measurement data, but VEE Rules can change anything on an initial measurement.

Every VEE Rule has an effective period. Rules will only be applied if the initial measurement's start date is within the rule's effective period. For example, an Interval Spike Check rule with a Start Date of 11/15/2010 will only be applied if the start date of the initial measurement is on or after 11/15/2010.

This allows you to update the specifics of a rule without removing the previous version of the rule. For example, you might change the tolerance of an Interval Spike Check rule from 1.2 to 1.5 as of a certain date. However, for initial measurement data for the period prior to the change, you would want to use the tolerance for the original version of the rule (1.2) instead of the new tolerance (1.5).

On almost every VEE Rule, the failure of the rule results in a VEE Exception and the [Exception Type](#) for the failure can be configured on the rule. These Exception Types can also be set to a specific Exception Severity:

- **Information:** Used to highlight minor issues, but not sufficient to cause the initial measurement data to be put into the exception state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues
- **Issues:** Used to report a problem that will prevent the initial measurement data from being finalized. Multiple "issue exceptions" can be created during VEE processing. If at least one issue exists after all rules have been applied, the initial measurement data is transitioned to the exception state
- **Terminate:** Used to report a severe issue that will cause the VEE process to stop and the initial measurement data to be transitioned immediately to the exception state. Only one terminate exception can be issued (as the first one causes VEE processing to stop on an initial measurement data).

For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring VEE Rules

This portal is used to display and maintain a VEE Rule. Also, a list of the specific out-of-the-box rules is included below the instructions for using the portal.

Refer to [Understanding VEE Rules](#), [Understanding VEE Groups](#), and [Understanding Exception Types](#) for more information. For a deeper functional understanding of VEE, refer to the [About VEE](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

You can access the portal by selecting **Admin**, then **VEE**, then [VEE Rule](#). You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **VEE Rule:** this zone displays all of the configuration items specific to this instance of a VEE Rule.
- **Eligibility Criteria List:** this zone displays any VEE Rule Eligibility Criteria that have been setup. These eligibility criteria determine conditionally whether the VEE Rule should be executed or not. Use the Add button to create a new eligibility criteria for the rule you're viewing.

Validation VEE Rules

Below is a list of the validation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Applicable Data Type(s)	Purpose
Consecutive Interval Check	Interval	This validation rule flags any combination of consecutive intervals within Initial Measurement Data based on the values of the data or the condition codes of the data.
Duplicate IMD Check	Interval or Scalar	This rule allows for a duplicate IMD to be flagged.

Dynamic Comparison Validation	Interval or Scalar	This powerful, flexible validation rule compares measurements to historical statistics for the related Service Point. The system will maintain statistics such as the following: sum, min, max, average, median, zero value count, outage count, and standard deviation. Then you define formulas (no programming required) for the comparison of current measurements to these statistics.
Ensure IMD Exists for Sibling MCs	Interval or Scalar	This rule validates that an IMD exists for all of the other measuring components associated to the same Device Configuration as the current measuring component, for the same period of time.
Final Measurement Replacement	Interval or Scalar	This validation rule allows you to define a variety of configuration options to decide if new data should replace existing measurements. The options include value change thresholds, percentage change thresholds, as well as condition code ranking.
High/Low Check	Interval or Scalar	This validation rule compares the total consumption of the current IMD to historical values. The comparison is normalized based on average daily usage (ADU). If the current IMD is too high or too low compared to historical data then an exception is thrown.
Inactive Measurement Check	Interval or Scalar	This validation rule flags any Initial Measurement Data received on a device that is either disconnected, uninstalled, and/or not connected to a Usage Subscription.
Interval Size Validation	Interval	This rule validates that the interval size (in seconds) supplied with the Initial Measurement is equal to the interval size defined on measuring component's type.
Interval Spike Check	Interval	This rule checks for spikes within an IMD and generates an exception if one is found.

Multiplier Check	Interval or Scalar	This rule validates that the register multiplier supplied with the IMD is equal to the multiplier stored on the measuring component. If not, an exception is created using the register multiplier exception type and severity configured on the rule.
Negative Consumption Check	Interval or Scalar	This rule flags any IMD where the total consumption is negative.
Prolonged Estimation Check	Interval or Scalar	This validation rule creates an alert when a device has been estimated for an extended period of time.
Raise Missing Quantity Exception	Interval	This rule flags any missing interval data.
Sum Check	Interval or Scalar	This rule is used to compare the difference between interval data to scalar data for a period of time, or between a set of TOU scalar reads to a "Sum" scalar reading.
Unit of Measure Check	Interval or Scalar	This rule checks the unit of measure (UOM) passed in with the Initial Measurement against the primary unit of measure configured on the measuring component's type.
Zero Consumption Check	Interval or Scalar	This rule checks if the total consumption for the IMD is zero. There is also a check for whether an outage occurred during the same time as the zero consumption to provide ways to avoid exceptions in that case.

Estimation VEE Rules

Below is a list of the estimation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Applicable Data Type(s)	Purpose
Interval Adjustment From Scalar	Interval	This rule performs adjustments to interval values based on the values from the associated scalar data on the same device.
Interval Averaging Estimation	Interval	This rule finds historical interval data from the same measuring component based on a variety of configuration options to use for estimating any missing data within an IMD.

Interval Create Estimation IMD for Gap	Interval	<p>This estimation rule creates a new Estimation IMD to fill gaps between the interval data received from the Head End.</p> <p><i>Note: this estimation rule acts differently from the other rules as it creates a new IMD rather than filling in missing values in an estimation IMD created from periodic estimations.</i></p>
Interval Interpolation Estimation	Interval	<p>This rule attempts to interpolate gaps within an IMD using prior and subsequent intervals as starting points for linear interpolation.</p>
Interval Profile Estimation	Interval	<p>This rule estimates any missing interval data for the IMD based on a referenced Profile Factor.</p>
Interval Proxy Day Estimation	Interval	<p>This rule checks for days with similar temperature and uses the measurement data from those days as the basis of interval estimation for the in-flight initial measurement.</p>
Scalar Calculation From Interval	Scalar	<p>This rule performs adjustments to scalar values based on the values from the associated interval data on the same device.</p>
Scalar Estimation	Scalar	<p>This rule finds historical scalar data from the same measuring component based on a variety of configuration options to use for estimating any missing data within an IMD.</p>
Scalar Profile Estimation	Scalar	<p>This rule estimates any missing scalar data for the IMD based on a referenced Profile Factor.</p>
Scalar Proration	Scalar	<p>This rule prorates the value of a scalar reading that has two valid scalar readings on either side as boundaries. It will also take into account any related interval data within the same period to exclude from the calculation.</p>

Subtractive Interval Adjustment Rule	Subtractive Interval Adjustment Rule	This rule performs adjustments to qualifying interval consumption values for subtractive interval measuring components based on an adjustment target calculated using a start and stop reading for the period that encapsulates the intervals to adjust.
--	--------------------------------------	--

Decision-Making VEE Rules

There are VEE Rules delivered as part of the base product that help with decision-making when executing VEE (listed below). For more information on how each rule executes and can be configured, follow the link provided on the rule.

VEE Rule Name	Purpose
Exception Handler	This rule allows for termination of the VEE process based on a configurable set of exceptions being present for the IMD. This rule also allows a unique To Do Type to be generated based on a group of exceptions.
Execute VEE Group	This rule performs a call to execute a separate VEE Group which includes execution of all VEE Rules within that group.
Successful Termination	This rule allows VEE to be successfully terminated based on a list of exceptions.
VEE Group Matrix (Factor)	This rule provides a way to choose different instances of a VEE Rule using a Factor. This factor leverages characteristics that are defined on Service Point, Device, or Measuring Component.

Validation VEE Rules Consecutive Interval Check

Overview

This rule flags any combination of consecutive intervals within Initial Measurement Data based on the values of the data or the condition codes of the data. It can be used to find faulty meters that are reporting consecutive outage codes, zero measurements, or negative values. It can also be used by water utilities to identify leaks based on the interval never reaching zero.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-CONSINTRV Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ConsecutiveIntervalCheck

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Rule configured to fail for zero values

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	Equal To
Value for Comparison	0
Bottom Range Condition	
Top Range Condition	

Scenario 2: Rule configured to fail for negative values

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	Less Than
Value for Comparison	0
Bottom Range Condition	
Top Range Condition	

Scenario 3: Rule configured to fail for missing condition codes

Parameter Name	Configuration Value
Check performed	Consecutive Condition Values
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	
Value for Comparison	
Bottom Range Condition	Missing
Top Range Condition	Missing

Scenario 4: Rule configured to fail for outage condition codes only if its zero

Parameter Name	Configuration Value
Check performed	Both
Maximum consecutive hours	02:00:00
Look To Prior Measurements	No
Equation Type	Equal To
Value for Comparison	0
Bottom Range Condition	Outage
Top Range Condition	Outage

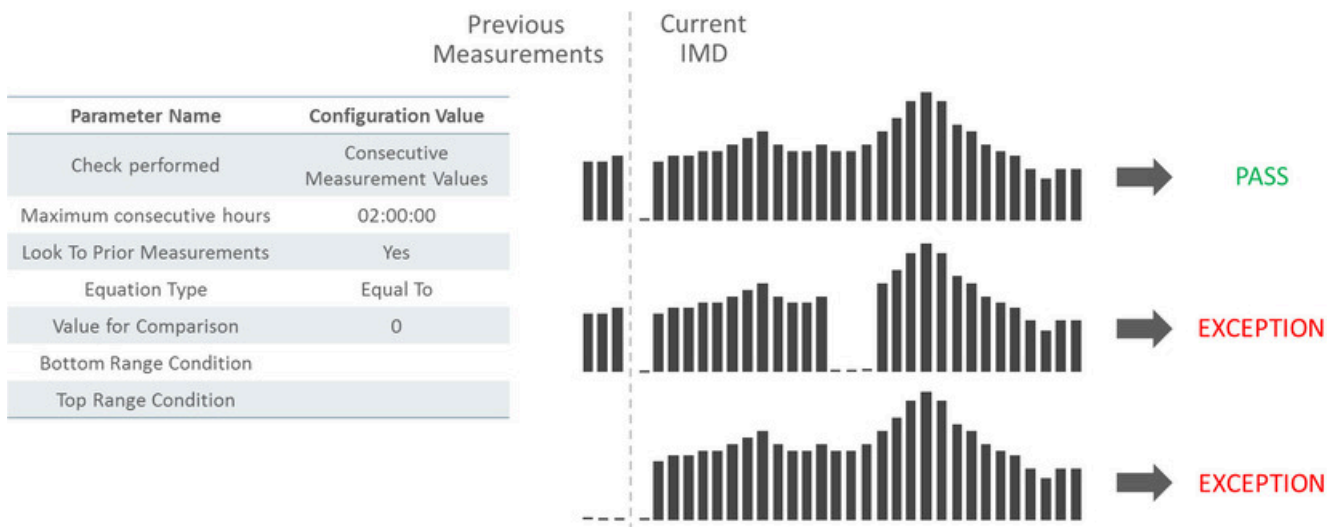

Scenario 5: Rule configured to fail if a long period of consecutive water values are greater than 0.1

Parameter Name	Configuration Value
Check performed	Consecutive Measurement Values
Maximum consecutive hours	20:00:00
Look To Prior Measurements When First Interval Matches Criteria	No
Equation Type	Greater Than
Value for Comparison	0.1
Bottom Range Condition	
Top Range Condition	

Scenario 6: Look back at prior measurements when the first interval matches criteria

Duplicate IMD Check

If the current Initial Measurement Data (IMD) being validated is determined to be a duplicate of an existing IMD for the same measuring component, this rule will produce a VEE exception of the type and severity configured on the VEE Rule. The algorithm logic looks for duplicate IMDs using the following criteria:

- associated to the same measuring component as the current IMD
- utilizes the same IMD business object as the current IMD (for example, Initial Load Scalar)
- references the same To Date/Time (ends on the same date) as the current IMD
- exists in a "Finalized" state
- the contents of pre-VEE are identical to the pre-VEE of the current IMD

If any IMDs are found that meet all of the above criteria, the current IMD is deemed to be a duplicate.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-DUPIMDCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-DuplicateIMDCheck

Dynamic Comparison Validation

This validation rule compares measurements to historical statistics for the related Service Point. The system will maintain statistics such as the following: sum, min, max, average, median, zero value count, outage count, and standard deviation. Setting up these [Measuring Component Statistics](#) is a prerequisite to using the rule.

Users can define formulas (no programming required) for the comparison of current measurements to these statistics. This is powerful rule will allow utilities to look for unusual usage patterns. For example:

- Lowest/highest usage ever
- Current usage is more than three standard deviations from the mean
- Detect unexpected zero usage
- Detect negative usage while ruling out known cases
- Abnormal usage
- Voltage threshold monitoring
-

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-DYNCOMCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-DynCompValidation

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Example 1: Detect new "high water mark"

Historical Statistics	Dynamic Values	Equation			
<p>Statistics MC Type: MC_STATS_13MONTHS</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td>Max</td> <td>15 min</td> <td>4.320</td> </tr> </table>	Max	15 min	4.320	<p>Variable Name: IMD1</p> <ul style="list-style-type: none"> • Source Type: IMD • Set Function: Max <p>Variable Name: CS1</p> <ul style="list-style-type: none"> • Source Type: Channel Statistics • MC Type: MC_STATS_13MONTH • Value: Max 	<p>Equation</p> $IMD1 > CS1 * 1.1$ <p>This equation is comparing the max interval in the new IMD to the max interval from the last 13 months of history from the MC. If greater than 110% of max then fail.</p>
Max	15 min	4.320			

Example 2: High Usage

Historical Statistics	Dynamic Values	Equation												
<p>Statistics MC Type: MC_STATS_LASTMONTH</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td>Average</td> <td>15 min</td> <td>1.630</td> </tr> <tr> <td>Standard Deviation</td> <td>15 min</td> <td>0.519</td> </tr> </table> <p>Statistics MC Type: MC_STATS_LASTYEAR</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td>Average</td> <td>15 min</td> <td>1.893</td> </tr> <tr> <td>Standard Deviation</td> <td>15 min</td> <td>0.851</td> </tr> </table>	Average	15 min	1.630	Standard Deviation	15 min	0.519	Average	15 min	1.893	Standard Deviation	15 min	0.851	<p>Variable Name: IMD1</p> <ul style="list-style-type: none"> • Source Type: IMD • Set Function: Max <p>Variable Name: CS1</p> <ul style="list-style-type: none"> • Source Type: Channel Statistics • MC Type: MC_STATS_LASTMONTH • Value: Average <p>Variable Name: CS2</p> <ul style="list-style-type: none"> • Source Type: Channel Statistics • MC Type: MC_STATS_LASTMONTH • Value: Standard Deviation <p>Variable Name: CS3</p> <ul style="list-style-type: none"> • Source Type: Channel Statistics • MC Type: MC_STATS_LASTYEAR • Value: Average <p>Variable Name: CS4</p> <ul style="list-style-type: none"> • Source Type: Channel Statistics • MC Type: MC_STATS_LASTYEAR • Value: Standard Deviation 	<p>Equation</p> $(IMD1 - CS1) / CS2 > 3$ $AND (IMD1 - CS3) / CS4 > 3$ <p>This equation checks that the standard score of the current max interval is within 3 standard deviations of historical data from last month and last year. If greater than 3 standard deviations, an exception is thrown.</p>
Average	15 min	1.630												
Standard Deviation	15 min	0.519												
Average	15 min	1.893												
Standard Deviation	15 min	0.851												

Example 3: Detect unexpected zero usage (method 1)

Historical Statistics	Dynamic Values	Equation												
<p>Statistics MC Type: MC_STATS_LASTMONTH</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td>Total Count</td> <td>15 min</td> <td>2880</td> </tr> <tr> <td>Zero Count</td> <td>15 min</td> <td>3</td> </tr> </table> <p>Statistics MC Type: MC_STATS_LASTYEAR</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <tr> <td>Total Count</td> <td>15 min</td> <td>2880</td> </tr> <tr> <td>Zero Count</td> <td>15 min</td> <td>0</td> </tr> </table>	Total Count	15 min	2880	Zero Count	15 min	3	Total Count	15 min	2880	Zero Count	15 min	0	<p>Variable Name: IMD1</p> <ul style="list-style-type: none"> • Source Type: IMD • Calc Function: Sum <p>Variable Name: CS_T1</p> <ul style="list-style-type: none"> • Source Type: Channel Statistics • MC Type: MC_STATS_LASTMONTH • Value: Total Count <p>Variable Name: CS_Z1</p> <ul style="list-style-type: none"> • Source Type: Channel Statistics • MC Type: MC_STATS_LASTMONTH • Value: Zero Count <p>Variable Name: CS_T2</p> <ul style="list-style-type: none"> • Source Type: Channel Statistics • MC Type: MC_STATS_LASTYEAR • Value: Total Count <p>Variable Name: CS_Z2</p> <ul style="list-style-type: none"> • Source Type: Channel Statistics • MC Type: MC_STATS_LASTYEAR • Value: Zero Count 	<p>Equation</p> $IMD1 = 0$ $AND CS_Z1 / CS_T1 < 0.01$ $AND CS_Z2 / CS_T2 < 0.01$ <p>This equation finds zero intervals in the current IMD that seem to not fit with historical trends for the customer based on prior counts of zero intervals.</p>
Total Count	15 min	2880												
Zero Count	15 min	3												
Total Count	15 min	2880												
Zero Count	15 min	0												

Example 4: Detect unexpected zero usage (method 2)

Historical Statistics

Statistics MC Type: MC_STATS_LASTMONTH		
Min	15 min	0.43

Statistics MC Type: MC_STATS_LASTYEAR		
Min	15 min	0.52

Dynamic Values

Variable Name: IMD1	Variable Name: CS1
• Source Type: IMD	• Source Type: Channel Statistics
• Calc Function: Min	• MC Type: MC_STATS_LASTMONTH
	• Value: Min
	Variable Name: CS2
	• Source Type: Channel Statistics
	• MC Type: MC_STATS_LASTYEAR
	• Value: Min

Equation

$$IMD1 = 0$$

$$AND CS1 > 0$$

$$AND CS2 > 0$$

This equation finds zero intervals in the current IMD that seem to not fit because the minimum values for the meter historically have never reached zero during comparable periods.

Example 5: Detect negative usage while ruling out known cases

Historical Statistics

Statistics MC Type: MC_STATS_13MONTHS		
Negative Count	15 min	0

Dynamic Values

Variable Name: V1	Variable Name: V2
• Source Type: IMD	• Source Type: Channel Statistics
• Calc Function: Min	• MC Type: MC_STATS_13MONTHS
	• Value: Negative Count

Equation

$$V1 < 0 AND V2 = 0$$

This equation detects negative usage on the current IMD while the prior 13 months shows no cases of negative usage.

Example 6: Abnormal usage

Historical Statistics

Statistics MC Type: MC_STATS_LASTMONTH		
Average	15 min	1.630
Standard Deviation	15 min	0.519

Statistics MC Type: MC_STATS_LASTYEAR		
Average	15 min	1.893
Standard Deviation	15 min	0.851

Dynamic Values

Variable Name: IMD_STD	Variable Name: LM_STD	Variable Name: LY_AVG	Variable Name: LY_STD
• Source Type: IMD	• Source Type: Channel Statistics	• Source Type: Channel Statistics	• Source Type: Channel Statistics
• Calc Function: Standard Deviation	• MC Type: MC_STATS_LASTMONTH	• MC Type: MC_STATS_LASTYEAR	• MC Type: MC_STATS_LASTYEAR
	• Value: Standard Deviation	• Value: Average	• Value: Standard Deviation
Variable Name: IMD_AVG			
• Source Type: IMD			
• Calc Function: Average			
Variable Name: LM_AVG			
• Source Type: Channel Statistics			
• MC Type: MC_STATS_LASTMONTH			
• Value: Average			

Equation

$$IMD_AVG <= 0$$

$$AND ABS(IMD_AVG - LM_AVG) < 0.5$$

$$AND ABS(IMD_AVG - LY_AVG) < 0.5$$

$$AND ABS(IMD_STD - LM_STD) > 1.5$$

$$AND ABS(IMD_STD - LY_STD) > 1.5$$

This equation determines that the average of the current IMD is close to the historical average but that the standard deviation is far off. This points to abnormal usage.

Example 7: Voltage threshold monitoring

Historical Statistics

None

Dynamic Values

Variable Name: VOLT_MAX	Variable Name: VOLT_MIN
• Source Type: IMD	• Source Type: IMD
• Calc Function: Max	• Calc Function: Min

Equation

$$VOLT_MIN < 117$$

$$OR$$

$$VOLT_MAX > 127$$

This equation determines if the voltage data in the current IMD has fallen below or exceeded the bounds that a utility needs to keep customer voltage within. This is usually set to values that catch incorrect voltage before the value drops below the regulatory requirement.

Ensure IMD Exists for Sibling MCs

This rule validates that an IMD exist for all of the other measuring components associated to the same Device Configuration as the current measuring component, for the same period of time.

A check is also performed that all of the Initial Measurements have the same External Source ID (indicating that they all came from the same usage file).

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-ENSIMDMC Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-EnsureIMDExistsForSibling

Final Measurement Replacement

This validation rule allows you to define a variety of configuration options to decide if new scalar or interval data should replace existing measurements. The options include value change thresholds, percentage change thresholds, as well as condition code ranking. One common use for this rule is rejecting trivial measurement changes to prevent very small changes for a bill from being sent to a customer.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-VLMSRCOND Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-FinalMeasurementValidation

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Example 1: Replacement of measurements based solely on value difference

KEY	
	= Regular
	= System Estimated
	= No Read – System
	= No Read – Outage
	= Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Value Change
Value Change Tolerance	0.1
Percentage Change Tolerance	
Condition Code Prioritization by Groups	

Example 2: Percentage change to replace measurement

KEY

- = Regular
- = System Estimated
- = No Read – System
- = No Read – Outage
- = Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Percentage Change
Value Change Tolerance	
Percentage Change Tolerance	50
Condition Code Prioritization by Groups	

Example 3: Partial replacement of estimated data with regular data based on condition range prioritization

KEY

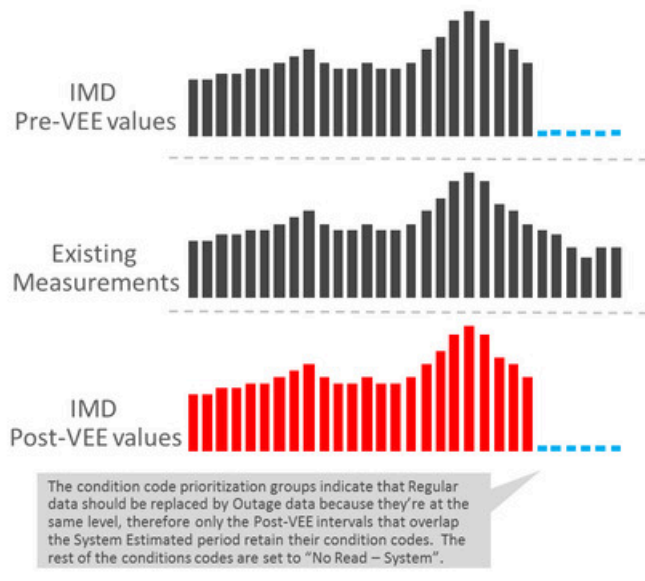

- = Regular
- = System Estimated
- = No Read – System
- = No Read – Outage
- = Super

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Value Change
Value Change Tolerance	0.1
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

Example 4: Partial replacement of regular data with outage data based on condition range prioritization

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	Compare Value Change
Value Change Tolerance	0.1
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

Example 5: Super not replaced by regular (retain a smoothed spike)

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	
Value Change Tolerance	
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

Example 6: Prevent replacement of manually edited data

KEY

- = Regular
- = System Estimated
- = No Read – System
- = No Read – Outage
- = Super
- = User Edited data

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	No
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	
Value Change Tolerance	
Percentage Change Tolerance	
Condition Code Prioritization by Groups	

Example 7: Allow replacement of manually edited data if the condition group is lower than new data

KEY

- = Regular
- = System Estimated
- = No Read – System
- = No Read – Outage
- = Super
- = User Edited data

Parameter Name	Configuration Value
Replacement Method	Reject Based on Configuration
Replacement Condition Value	No Read – System
Replace Manually Edited Data?	No
Use Early and Late MC Type Settings?	
Replacement Evaluation Type	
Value Change Tolerance	
Percentage Change Tolerance	
Condition Code Prioritization by Groups	10: Super 20: Regular, No Read – Outage 30: System Estimate 40: No Read – System

High/Low Check

This validation rule compares the total consumption of the current IMD to historical values. The comparison is normalized based on average daily usage (ADU). If the current IMD is too high or too low compared to historical data then an exception is thrown.

Numerous configuration options are provided including:

- A Historical Pre-Window and Post-Window that determines the number of days to check before and after the period being examined.
- Percentages to control how much of the historical data can be user edited, estimated, or non-normal data.
- What type of historical data to look at first
- What to do when an outage has occurred

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-HILO-CHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-VEERuleHighLowCheck

Inactive Measurement Check

This validation rule flags any Initial Measurement Data received on a device that is either disconnected, uninstalled, and/or not connected to a usage subscription.

- When the 'Check Measurements on Disconnected Device' flag is set to "Yes", the logic will compare the IMD measurements total to the threshold configured. If the total measurements are above the threshold, then logic compares the IMD dates to two things: 1) On/Off Dates related to the Install Event and 2) the Installation and Removal Dates of the Install Event. If the On or Off falls within the dates for an interval IMD, then the logic will only sum intervals that fall during the disconnected periods.
- When the 'Check for Uninstalled Device' flag is set to "Yes", the logic will check for a valid Install Event based on the IMD dates.
- When the 'Check for Missing Usage Subscription' flag is set to "Yes", the logic will check for an active Usage Subscription based on the IMD dates.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INACTVCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-InactiveMeasurementCheck

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

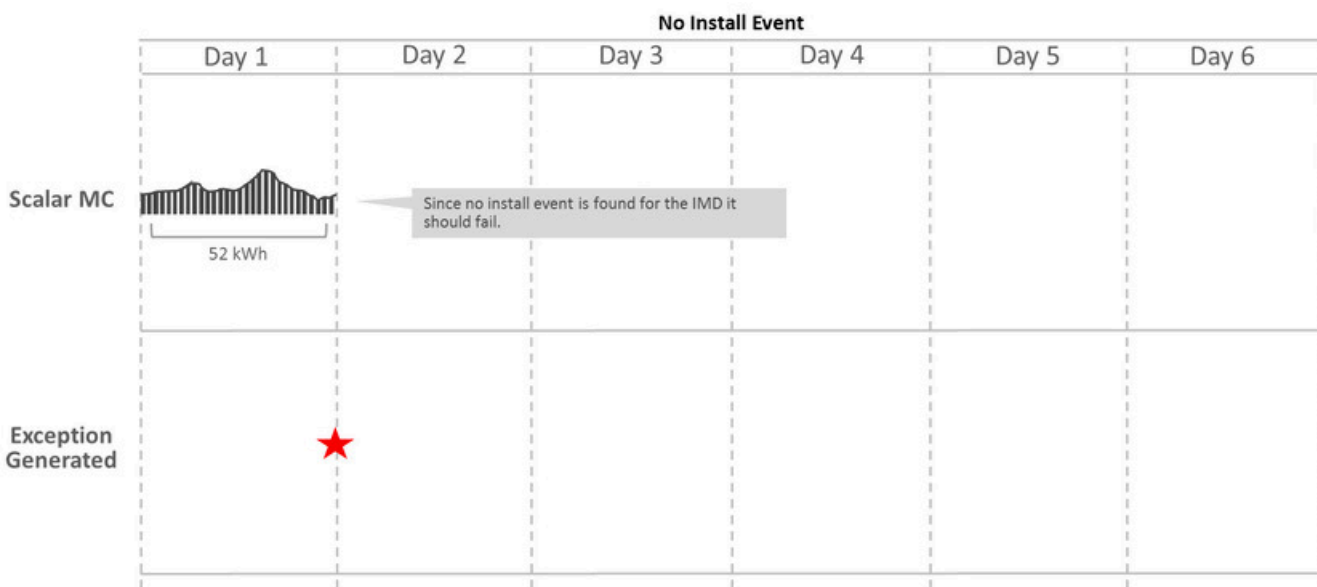

Example 1: Non-zero data during disconnected period

Example 2: Non-zero data after removal date with no new install

Example 3: Data received when device has no Install Event records

Example 4: Data received when not connected to a Usage Subscription record

Interval Size Validation

This rule validates that the interval size (in seconds) supplied with the Initial Measurement is equal to the interval size defined on measuring component's type.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTSIZVAL Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalSizeValidation

Interval Spike Check

This rule looks for spikes by taking the highest interval and the third-highest interval, and determining the percent difference between the two. If the percent difference is larger than the tolerance configured on the rule, the algorithm logs an exception of the type and severity configured on the rule.

The rule can be executed in one of two modes (as configured on the rule):

- The spike check is performed for every 24-hour chunk of data in the initial measurement data set
- The spike check is performed for the entire initial measurement data set

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTSPKCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalSpikeCheck

Multiplier Check

This rule validates that the register multiplier supplied with the Initial Measurement is equal to the multiplier stored on the measuring component.

**Note:**

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-REGMULCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-RegisterMultiplierCheck

Negative Consumption Check

This rule checks if the total consumption of the initial measurement is less than zero. If the rule encounters negative consumption, an exception will be logged if the related Measuring Component Type is not configured to "allow negative consumption", or if the Override MC Type Allow Negative Consumption flag on the rule is set to "Yes".

**Note:**

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-NCON-CHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-NegativeConsumptionCheck

Prolonged Estimation Check

This validation rule can be used on either interval or scalar and will alert you when a device has been estimated for an extended period of time. The IMD must first fall within the condition code range configured on the rule for this to execute. Next the validation finds the 'Most Recent Non-Estimated Read Date Time' from the Measurement Component. If this date plus the 'Days of Estimation Allowable' from the VEE Rule is less than the IMD End Date then a Prolonged Estimation Exception is created.

**Note:**

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-PROESTCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProlongedEstimationCheck

Example Scenario

Below is an example scenario that can be achieved based on configuration of this rule.

Raise Missing Quantity Exception

This rule flags any missing interval data while providing a soft parameter on the algorithm to exclude a condition range if desired.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-RAIMISQTY Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-RaiseMissingQuantityExcp

Sum Check

This rule evaluates whether consumption for the current Initial Measurement Data is within a tolerance of the sum of the consumption during the same period for any measuring components related to the current one. If the values are not within the defined tolerance of each other, and exception is logged.

The rule can be used to evaluate consumption totals for an interval measuring component that has a related scalar measuring component with the same UOM to ensure that the total consumption of the interval measuring component is within a tolerance of that of the scalar value. It can also be used to evaluate consumption totals for scalar TOU meters that have a "check" register (for example, three registers that measure ON-PEAK, OFF-PEAK, and SHOULDER, with a fourth check register that measures the total consumption).

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SUM-CHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-SumCheck

Unit of Measure Check

This rule checks the unit of measure (UOM) passed in with the Initial Measurement against the primary unit of measure configured on the measuring component's type.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-UOMCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-UOMCheck

Zero Consumption Check

This rule checks if the total consumption for the IMD is zero. There is also a check for whether an outage occurred during the same time as the zero consumption to provide ways to avoid To Dos by having a different exception type.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-ZEROCNCHK Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ZeroConsumptionCheck

Estimation VEE Rules

Interval Adjustment From Scalar

This rule adjusts interval Initial Measurement Data based on scalar values using one of two options configured on the VEE Rule. Both options require that a scalar measuring component be related to the current interval measuring component using the Consumption Reference Measuring Component, and that one or more final measurements be present for the related measuring component between the start and end date/times of the current Initial Measurement Data set.

1. Adjust all intervals. In this case, the scalar consumption provides a value that is then used to proportionally adjust all of the intervals in the set. The formula used is (Scalar Consumption / Total Initial Measurement Consumption) * Interval Amount. If the total of all of the intervals had been equal to zero originally, the rule adjusts all of the intervals to the same value.
2. Adjust intervals based on condition. For this option, a range of conditions is configured on the VEE Rule, and the rule adjusts only those intervals with conditions that lie within the configured range. The adjustment is done by applying an adjustment factor to each of the intervals within range.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTADJSCA Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalAdjustmentFrmScalar

Interval Averaging Estimation

The algorithm estimates when the current Measuring Component is eligible. Estimation is performed only if all these conditions are satisfied:

- The Measuring Component is interval.
- The Measuring Component is linked to a Service Point or the VEE Rule's Estimate If Not Attached to SP field is set to "Estimate".
- The Percentage of Missing Intervals is less than the VEE Rule's Maximum Percentage Missing Intervals Threshold.

The algorithm will compute the Total Accumulated Consumption and the Total Number of Intervals using a variety of methods including scanning holidays, similar days of the week, or neighboring days. Once a set of valid comparison days are found then these are used as the basis of creating estimated intervals for the current IMD.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTAVGEST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalAveragingEstimation

Interval Create Estimation IMD for Gap

This rule is very different from other VEE rules in that it does not examine the current initial measurement but rather looks to see if there are any missing measurements prior to the initial measurement being processed (i.e. a gap exists). If so and the scenario meets the configured options it will generate an estimation initial measurement to fill in that gap.

This rule is intended to provide more real-time filling of missing measurements as opposed to running periodic estimation. However, it is still expected that periodic estimation will be used in conjunction with this rule such that any gaps that are not filled in by this rule would eventually be filled in by periodic estimation.

This rule can be configured to perform minimal validation of that gap that is identified and defer to the estimation initial measurement to validate against other initial measurements and final measurements that may overlap the gap. Conversely, it can also be configured to validate the gap and exclude any periods where a final measurement or in progress initial measurement overlaps the gap's duration.

Note:

This estimation rule acts differently from the other rules - it creates a new IMD rather than filling in missing values in an estimation IMD created from periodic estimations.

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-CREESTIMD Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-CreateEstimationIMDRule

Example Scenarios

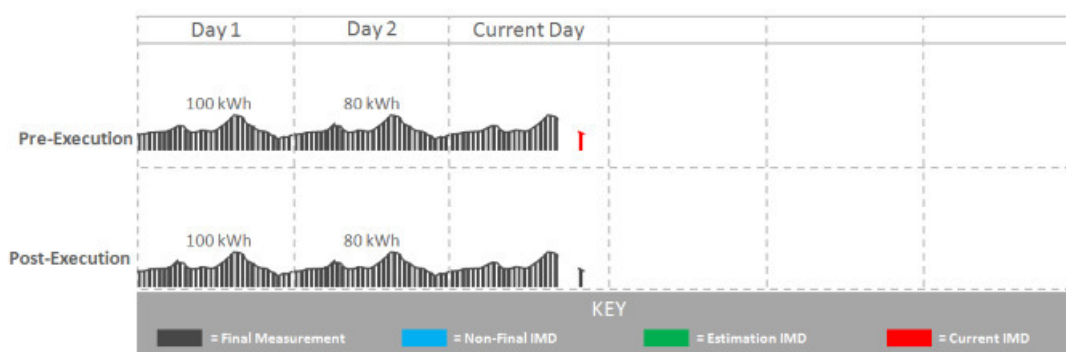

The following are sample scenarios that can be achieved based on configuration of this rule.

Example 1: A 4-hour gap exists and the rule is configured to always fill gaps. Maximum hours are set to 4 and the gap fill is set to "always".

Since the maximum hours has not been exceeded and the rule is configured to always fill the gap, a 4-hour estimation IMD is created to fill the gap.

Example 2: A 4-hour gap exists and the rule is configured to always fill gaps. However, the maximum number of hours to fill is 3.

Since the gap is 4 hours long and the maximum hours to gap fill is 3 hours, no estimation has been created. An exception would be created if the rule were configured this way.

Example 3: A non-contiguous gap exists and the rule is configured to "Skip In-Progress IMDs and Final Measurements" with a maximum number of IMDs set to 2.

In this scenario:

- One interval in the 4-hour gap is covered by a final measurement.
- One interval in the 4-hour gap is covered by an in-progress IMD.
- Two estimation IMDs are generated one to fill each hour not covered by a final measurement or in-progress IMD.

Interval Interpolation Estimation

This rule attempts to interpolate gaps in Initial Measurement Data sets using prior and subsequent intervals as starting points for linear interpolation. A configuration parameter determines the maximum number of consecutive intervals within a gap before that gap can no longer be interpolated.

If a given gap lies at the beginning or end of the Initial Measurement Data set, this algorithm seeks out final measurements immediately before or after the set in an attempt to find two reference measurement values for interpolation. In this situation, assuming that the condition of the measurement retrieved lies in NEITHER of the algorithm parameter ranges you have configured (the measurement is neither "missing" nor an "outage"), this measurement value is then used as the basis for interpolation.

In the event that the gap is the entire length of the Initial Measurement Data set (and the VEE Rule is configured such that this is not too large of a gap), the routine attempts to find final measurements as described above.

If a valid measurement can be found for only one side of a given gap, the interpolation logic assigns each interval in the gap the same value - the value of the measurement retrieved. This is referred to as applying a "flat load".

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTINTEST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalInterpolationEst

Interval Profile Estimation

This rule uses a profile measuring component's interval consumption as a source of values to assign to intervals in the current Initial Measurement Data set that are marked "missing" via the interval's condition. If the interval is marked with a condition indicating "outage", the algorithm skips it.

If a measurement is not available for the profile measuring component on the date/time, the interval is left unchanged.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTPROEST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalProfileEstimation

Interval Proxy Day Estimation

This rule checks for days with similar temperature and uses the measurement data from those days as the basis of interval estimation for the in-flight initial measurement. [Measuring component comparison periods](#) are used as the main driver for determining similar temperature days.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-INTPROXY Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalProxyDayEstimation

Scalar Calculation From Interval

This rule calculates a single consumption amount for a scalar measuring component's Initial Measurement using the total consumption for the same date/time range for a related interval measuring component.

The scalar value replaces any existing value within the Initial Measurement (in the post-VEE list) and updates the condition to the value configured on the VEE Rule. This VEE Rule updates the condition to the value defined in

"Condition Value for High Quality Condition" when the measurement condition value for all underlying interval data and the previous scalar measurement (when Evaluate Condition Of Previous Scalar Measurement is configured as "Yes") is greater than or equal to the "Minimum Condition Quality to Override" (If "Minimum Condition Quality to Override" is defined) otherwise it updates the measurement condition of the Initial Measurement Data to the condition defined in "IMD Created Condition Value".

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCACALINT Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarCalcFromInterval

Scalar Estimation

This rule uses historical data for the same measuring component to derive an estimated value for a scalar Initial Measurement. Depending upon a VEE Rule configuration parameter, the routine uses historical data from a month ago followed by a year ago, or vice-versa. If the data for the first historical period turns out to be usable, the second historical period will not be evaluated. Whether historical data qualifies for use in estimation is configured via the rule parameters in conjunction with the below algorithm parameters.

The rule rejects consumption from a historical period as unusable for estimation if too great a portion of the period is covered by final measurements that are not high-quality. The first pair of parameter values are used when evaluating the acceptable System-Estimated Percentage for historical periods as configured on the VEE Rule. Once an estimated value is calculated, the routine backs into a reading (which involves backing out multipliers and, if the measuring component is subtractive, adding the result to the prior reading).

An interim High/Low can also be configured on this rule.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCALAREST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarEstimation

Scalar Profile Estimation

This VEE rule arrives at a scalar estimate by looking at final measurements for a profile measuring component covering the same date range as the current Initial Measurement. The profile measuring component to be used as a source of measurement data is defined via a profile factor on the rule. This rule is meant primarily for a configuration in which the profile measuring components are interval, although the profile could be scalar as well.

If a measurement already exists in the current Initial Measurement with a condition that lies within the ranges specified in the pairs of algorithm parameters for "system estimate" and "regular", the routine does not attempt to estimate.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCAPROEST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarProfileEstimation

Scalar Proration

This rule prorates the value of a scalar reading that has two valid scalar readings on either side as boundaries.

If the scalar MC does not have a related interval MC and 'Minimum Related Measurement Condition' is defined the algorithm will take into consideration any intervals during the proration period that meet a minimum condition quality defined by the 'Minimum Related Measurement Condition' when performing the proration. This is to keep the prorated scalar estimates in sync with any existing interval measurements. To do this the algorithm will augment the total duration and total quantity being prorated by the related interval MC's qualifying measurements. For example, take the following scenario:

- Scalar proration is executing for a scalar IMD for 01/01 12:00 AM - 01/02 12:00 AM (24 hours)
- The subsequent measurement is for 150 kWh and has a measurement date/time of 01/04 12:00 AM (72 hours)
- The related interval MC has measurements on 01/03 12:00 AM to 01/04 12:00 AM totaling 100 kWh (24 hours)

Therefore the result of the calculation for the scalar IMD from 01/01 12:00 AM to 01/02 12:00 AM would be 25 kWh. Since the interval measurements covered 24 of the 72 total hours of the 150 kWh that would leave 50 kWh to be split among the remaining 48 hours. Which leaves 25 kWh for 01/01 12:00 AM to 01/02 12:00 AM and 25 kWh for 01/02 12:00 AM to 01/03 12:00 AM.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SCLRPRORT Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ScalarProration

Subtractive Interval Adjustment Rule

This rule adjusts qualifying consecutive intervals for a subtractive interval initial measurement (IMD) based on the known consumption between a set of actual readings. The readings can either be leveraged from other intervals within the IMD or from the final measurements when there are no suitable readings within the IMD. The adjustment is done by applying an adjustment factor to each of the qualifying intervals.

The rule supports adjusting multiple sets of qualifying consecutive intervals by calculating a consumption adjustment target and adjustment factor specific to each set of consecutive qualifying intervals.

Intervals are considered to be qualified for adjustment based on condition. A range of conditions is configured on the VEE Rule, and the rule adjusts only those intervals with conditions that lie within the configured range.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SUBINADJV Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-SubIntAdjustmentVEE

Decision-Making VEE Rules Exception Handler

This rule allows you to terminate the VEE process based on a configurable set of exceptions being present for the IMD. This rule also allows a unique To Do Type to be generated based on a group of exceptions.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-AVEER-EEH Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleExceptionHandler

Execute VEE Group

Many implementations need to execute a group of validations for any data being received. For example, you might want to perform device identifier validations, multiplier checks, and UOM checks on all measuring components. One inefficient way to meet this requirement would be to repeat these three rules in multiple VEE groups. However, this solution becomes hard to maintain if changes to the rules are required (or if new "global rules" are introduced) as each group would have to be updated. Instead of this, you can use the "Execute VEE Group" rule to execute a referenced VEE Group. Using the example above, you could create a group called "Rules for All MCs" that contains a device identifier validations rule, a multiplier check rule, and a UOM check rule, and then reference the "Rules for All MCs" group in a Execute VEE Group rule.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-AVEER-RFG Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleReferredVEEGroup

Successful Termination

This rule allows VEE to be successfully terminated based on a list of exceptions.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-AVEER-EST Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleSuccessTermination

VEE Group Matrix (Factor)

Another situation likely to occur in many implementations is where specific rules may need to be applied to measurement data based on specific criteria, such as geography. For example, some geographic territories may have unique VEE Rules in addition to rules that are applied to all geographic territories. The "VEE Group Matrix (Factor)" rule allows for a Factor to determine which VEE Rule gets executed based on defined characteristics.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-AVEER-FCT Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-VEERuleGroupFactor

Prerequisite Setup

Since the prerequisite setup items for this rule are more involved, the following procedure describes these in detail:

1. Create the Characteristic Type and Values to be used by the factor that will be referenced by the rule.
2. Create the Characteristic Source Algorithm to be used by the factor that will be referenced by the rule.
3. Create the VEE Groups to be associated to the characteristic values.
4. Create the Factor that will be referenced by the rule.
5. Create the Factor Values for the factor, each referencing an effective-dated characteristic value/VEE group pairings.
6. Create the rule, referencing the factor

Measuring Component Statistics

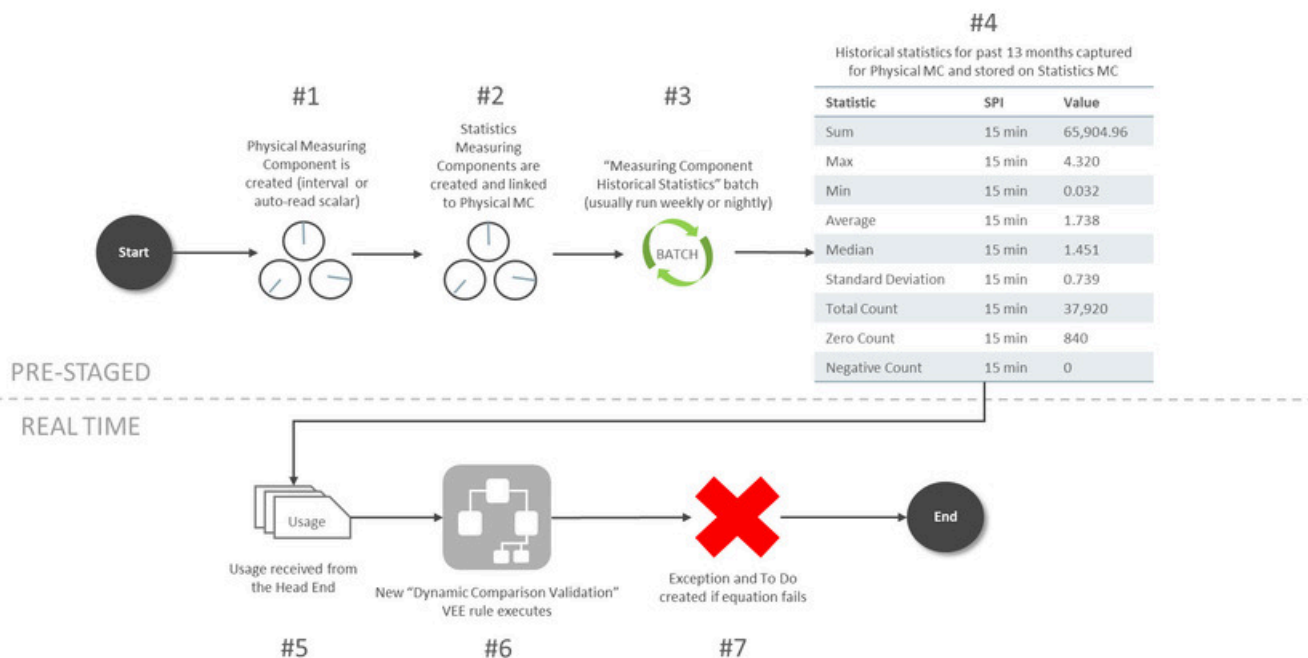

Understanding Measuring Component Statistics

Oracle Utilities Meter Data Management provides a way to stage statistics for Measuring Components in order to speed up VEE processing. These statistics are primarily meant for use in conjunction with the [Dynamic Comparison Validation](#) VEE Rule, but could also be generated for other analytics or reporting.

Some of the potential benefits of using Measuring Component Statistics are:

- Reduce the data volume for VEE queries by up to 1000 times (this is most beneficial when replacing VEE Rules that query historical data such as High/Low)
- Offload heavier processing of historical data to "system downtimes" - potentially nights or weekends

Below is an overview example of how Measuring Component Statistics can be implemented along with the Dynamic Comparison Validation:

The steps for pre-staging Measuring Component Statistics are detailed below:

1. A Physical Measuring Component is created. The algorithm to trigger the creation of Statistics Measuring Components is only set on Interval or Auto-Read Scalar BOs as part of base product.
2. New Statistics Measuring Component are created and linked to the Physical Measuring Component.
3. The Measuring Component Historical Statistics Batch (D1-MCHS) is run based on the schedule you've defined. The suggestion is to run this either nightly or on the weekends during quieter times for overall system processing.

4. A measurement is created for the Statistics Measuring Component that holds historical statistics related to the Physical Meter for a specific period of time (in this example it's set for 13 months).

The steps for how VEE can take advantage of Measuring Component Statistics are detailed below:

1. IMDs are received from the Head End.
2. The [Dynamic Comparison Validation](#) VEE Rule is configured to execute for the meter. This validation uses the historical statistics from the Statistics Measuring Component in order to perform its validation logic.
3. An exception and potentially a To Do is generated based on the failure of the VEE rule.

Storage Impact from Statistics

Much consideration was given to the storage implications when designing Measuring Component Statistics. Below is an outline of the storage impact to customers who choose to calculate and store Channel Statistics. An example impact to a utility with 1 million Physical Meters (each with 4 channels of information) is shown in the far right column:

Area	Additional Data in MDM	Example Impact (assuming utility has 1 million Physical Meters)
Additional MCs <i>Assumption: Statistics are only configured on the primary billing channel MC Type for the majority of your Physical Meters.</i>	1-3 extra MCs per Physical Meter <i>Assumption: customers will only configure Statistics on their primary billing channel MC Type for the majority of their Physical Meters.</i>	1 - 3 million extra MCs <i>This increases the Measuring Component table by an extra 25% to 75% from its size without statistics.</i>
Additional Measurements <i>If 'Statistics Retention Mode' configured as "Only Retain Most Recent Record".</i>	1 extra Measurement per Physical Meter	1 - 3 million extra Measurements for the life of MDM <i>This data is a minuscule fraction compared to the overall AMI data footprint.</i>
Additional Measurements <i>If 'Statistics Retention Mode' configured as "Retain Historical Records".</i>	1 extra Measurement per Physical Meter per week	1 - 3 million extra Measurements per week (52-156 million per year) <i>This data is 0.2-0.5% of the size of the AMI data collected in that same week.</i>

Configuring Measuring Component Statistics

Measuring Component Types

In order to start generating Measuring Component Statistics, two different configurations must occur for [Measuring Component Types](#):

- New Measuring Component Types must be configured that leverage the **Channel Statistics Type** business object. These should be setup as the periods for which Measuring Component Statistics should be calculated. For example, if you would like to be able to reference both last month, last year, as well as the past 13 months as statistics periods, then 3 different Channel Statistics Types must be setup for this. These could be setup as follows:
 - "Last Month" Channel Statistics Type:
 - Calculation Lag Days = 0
 - Calculation Horizon Days = 30
 - "Same Month Last Year" Channel Statistics Type:

- Calculation Lag Days = 365
- Calculation Horizon Days = 395
- "Prior 13 Months" Channel Statistics Type:
- Calculation Lag Days = 0
- Calculation Horizon Days = 395

NOTE: *it's recommended to set the Statistics Retention Mode to "Only Retain Most Recent Record" on the Channel Statistics Type to reduce the amount of data being stored in Oracle Utilities Meter Data Management.*

- For a Physical Measuring Component Type leveraging either "Interval Channel Type" or "Register - Auto-Read Type", the **Related Statistics Measuring Component Types** section must be filled in with the appropriate types that should be created for the Physical Measuring Component.

VEE Rule

If you have a desire to leverage Measuring Component Statistics for VEE, the [Dynamic Comparison Validation](#) VEE Rule section should be referenced. A number of detailed examples of how to implement this rule are provided in this section as well.

Related Batch Controls

There are a few batches directly involved with Measuring Component Statistics:

- **Measuring Component Historical Statistics (D1-MCHS):** this batch monitors any active Statistics Measuring Components to execute the logic for calculating a new set of historical statistics.
- **Statistics Measuring Component Creation (D1-STMCC):** this batch is used to create Statistics Measuring Components on any Physical Measuring Components that were created prior to configuring this module. This is especially useful for existing customers that want to implement Statistics Measuring Components for all of their devices.

Note: Refer to [Understanding Measuring Component Statistics](#) for more information.

Defining Usage Options

Usage Subscription Types

Understanding Usage Subscription Types

Usage Subscription Types define a collection of properties defining a class of Usage Subscriptions. Usage Subscription types also control valid values for various attributes of Usage Subscriptions.

For a deeper functional understanding, refer to the [About Usage Subscriptions](#) or [About Usage Calculation](#) sections of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Usage Subscription Types

This portal is used to display and maintain a Usage Subscription Type.

Refer to [Understanding Usage Subscription Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Subscription Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Subscription Type List:** displays all of the Usage Subscription Types so you can choose the one you want to display in more detail

- **Usage Subscription Type:** shows the specific configuration for the selected Usage Subscription Type

The Usage Subscription Type defines a number of lists for "valid" objects that can be used in conjunction with the overall usage calculation process:

- Valid Usage Recipients
- Valid Service Point Types
- Valid Usage Calculation Groups
- Valid Dynamic Option Types

Integrating Usage Transactions

Requesting Usage Transactions from External Systems

When Oracle Utilities Meter Data Management is deployed with Oracle Utilities Customer Care and Billing usage transactions can be created via a request from Oracle Utilities Customer Care and Billing.

To invoke a usage transaction request, Oracle Utilities Customer Care and Billing invokes a Usage Transaction Request Inbound service script which invokes the Usage Transaction Seeder (D2-UsgTranSeeder) business object. This business object does the following:

- Determines the usage subscription ID based on an external usage subscription ID
- Determines the appropriate usage transaction business object to create. This uses the "How To Create Usage Subscription Related Information" processing method defined for the "Usage Transaction Creation" processing role on the service provider that represents the external system.

For a deeper functional understanding of Usage Transactions, refer to the [About Usage Transactions](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Processing and Sending Usage Transactions to External Systems

When Oracle Utilities Meter Data Management is integrated with a customer information system (such as Oracle Utilities Customer Care and Billing), usage transaction information, including bill determinants and other data can be sent to the customer information system (again, such as Oracle Utilities Customer Care and Billing).

Usage transactions are sent to subscribing systems when they enter the "Sent" state. The "Send Usage" (D2-SEND-USG) Enter algorithm on the Sent state of the base package usage transaction business object (D2-UsageTransaction) determines the method used to send the information, based on the Usage Recipient (service provider) defined on the usage transaction's Usage Subscription. Usage transactions can be sent to service providers via either online real-time processing or periodically via batch processing.

Online Real-Time Processing

To set up the service provider to support online real-time notification of usage transactions, do the following:

- Create one or more Outbound Message Types that reference the outbound message business object to be used to send usage transaction information to the external system. The base package include the following business object for Usage Transaction Outbound Message (D2-UsageTranOutboundMesg).
- Define a Message Sender that will be used to send the message to the external system.
- Add the outbound message type to the service provider's External System and reference the Message sender created above.
- Add a processing method to the service provider as follows:
 - **Processing Role:** Usage Transaction Notification - Online
 - **Processing Method:** How To Send US Related Information
 - **Status:** Active
 - **Default Processing Method:**
 - **Outbound Message Type:** the outbound message type created above

- **Override Processing Method:** outbound message types for specific usage subscription types if applicable

For a deeper understanding of integrating usage transactions with a customer information or Oracle Utilities Customer Care and Billing, refer to the [Configuring the Bill Determinant Interface](#) in the Interface section.

Batch Processing

If Oracle Utilities Meter Data Management is integrated with a customer information system (such as Oracle Utilities Customer Care and Billing) that requests bill determinants, usage transaction processing should be coordinated with the requesting system's billing process.

Requests from a billing system that have been indicated as "batch requests" (such as those produced by Oracle Utilities Customer Care and Billing batch billing process) accumulate in a "calculation deferred" state to be processed specially by the **Usage Transaction Calculate Defer Monitor** batch control (D2-UTCD).

To set up the service provider to support periodic batch processing of usage transactions, use a periodic monitor batch control. These batch programs should invoke the business objects that will contain the usage transaction information. The base package includes the following business object for this: Usage Transaction Outbound Message (D2-UsageTranOutboundMesg).

Next, setup the following configuration:

- Add a processing method to the service provider as follows:
 - **Processing Role:** Usage Transaction Notification - Batch
 - **Processing Method:** How To Send US Related Information
 - **Status:** Active
 - **Default Processing Method:**
 - **Batch Control:** the batch control created above
 - **Override Processing Method:** batch controls for specific usage subscription types if applicable

Errors encountered when processing Usage Transactions can be reprocessed with the following batches:

- Reprocessing usage transaction "seeders" in error (D2-UTSED)
- Reprocessing usage transactions in error (D2-UTID)

If unexpected errors occur that leave usage transactions in an unmonitored state, the **Usage Transaction Monitor** batch control (D2-UT), or one based on this batch control with parameter values tailored to any specific requirements, can be used to process those usage transactions.

For a deeper functional understanding of Usage Transactions, refer to the [About Usage Transactions](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Generating Usage Transactions in Oracle Utilities Meter Data Management

There may be some cases where Usage Transactions should be generated in Oracle Utilities Meter Data Management rather than requested from an external system. Generation of these usage transactions are scheduled around the time when the meter installed on the service point is read.

Base product delivered a batch program that reads all pending measurement cycle schedule routes with selection date on or before the business date and creates as SP measurement cycle schedule route business object instance that stages the creation of these usage transactions.

For additional details refer to the D1-CSPSR batch control and D1-SPMrmtCycScheduleRoute business object.

Usage Transaction Exception Types

Understanding Usage Transaction Exception Types

Usage Transaction Exception Types define the groupings of exceptions for a Usage Transaction based on their functional similarity. This provides a way to define Usage Transaction Exceptions in a distinct enough way to understand the root issue that was generated from the usage calculation rule.

For a deeper functional understanding of Usage Calculation, refer to the [About Usage Calculation](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Usage Transaction Exception Types

This portal is used to display and maintain a Usage Transaction Exception Type.

Refer to [Understanding Usage Transaction Exception Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Transaction Exception Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Transaction Exception Type List:** displays all of the Usage Transaction Exception Types so you can choose the one you want to display in more detail
- **Usage Transaction Exception Type:** shows the specific configuration for the selected Usage Transaction Exception Type

Usage Calculation Groups

Understanding Usage Calculation Groups

Usage calculation groups are collections of usage calculation rules that are used to either calculate bill determinants or validate bill determinants. During the usage transaction process, the system executes the usage calculation rules defined in the usage calculation group referenced on the usage subscription. The rules within a usage calculation group are defined in a specific sequence, allowing control over the order in which the rules are executed.

Usage calculation groups are associated with specific usage subscriptions and usage subscription types (or both). When assigned to usage subscriptions, usage calculation groups contain the usage calculation rules to be used to calculate usage / bill determinants. Usage calculation groups associated with usage subscription types are those groups considered valid for usage subscriptions of that type.

Usage calculation groups can also specify a list of device donfiguration types that are considered valid. Usage calculation groups should only be associated with usage subscriptions for service points related to device configurations of a valid device configuration type.

Usage calculation groups can also be referenced by the [Execute Usage Calculation Group](#) usage calculation rule.

For a deeper functional understanding of usage calculation, refer to the [About Usage Calculation](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Configuring Usage Calculation Groups

This portal is used to display and maintain a usage calculation group.

Refer to [Understanding Usage Calculation Groups](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Calculation Group**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Group:** Defines basic information about usage calculation group
- **Usage Calculation Rules List:** lists the usage calculation rules belonging to the group
- **Referencing Usage Calculation Rules List:** lists the usage calculation rules that reference the group
- **Referencing Usage Subscription Type List:** lists the usage subscription types that reference the group
- **Referencing Usage Subscriptions List:** lists the usage subscriptions that reference the group

Usage Calculation Rules

Understanding Usage Calculation Rules

Usage calculation rules are standard and custom rules that perform calculations on measurement data to generate bill determinants and other values used by external systems, such as billing systems, customer information systems, etc. Usage calculation rules are created for a specific usage calculation group. For example, if you were configuring two usage calculation groups and both included a specific usage calculation rule, you would need to create two instances of the usage calculation rule, one for each group.

The base package includes rules that calculate common bill determinants including:

- Scalar reads
- Time-of-use consumption (by applying a time-of-use map to an interval channel)
- Interval curves (either real or derived)
- Virtually anything else that can be calculated from the information in the system

For a deeper functional understanding of usage calculation, refer to the [About Usage Calculation](#) section of the *Oracle Utilities Meter Solution Business User Guide*.

Usage Transaction Exceptions

On almost every usage calculation rule, the failure of the rule results in a usage transaction exception and the [Usage Transaction Exception Type](#) for the failure can be configured on the rule. These usage transaction exception types can also be set to a specific Exception Severity:

- **Information:** Used to highlight minor issues, but not sufficient to cause the usage transaction to be put into a failure state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues
- **Issues:** Used to report a problem that will prevent the usage transaction from being sent. Multiple "issue exceptions" can be created during usage transaction processing. If at least one issue exists after all rules have been applied, the usage transaction is transitioned to a failure state requiring review and approval.
- **Terminate:** Used to report a severe issue that will cause the usage calculation process to stop and the usage transaction to be transitioned immediately to a failure state requiring review and approval. Only one terminate exception can be issued (as the first one causes calculation processing to stop on for a Usage Transaction). This should be used for cases where manual override / approval isn't accurate. For example, a "Curve Not Continuous" error that says the interval data doesn't cover the full usage period should always be set to Terminate as an Exception Severity.

Rounding Usage Transaction Service Quantities

Several usage calculation rules provide a means for defining the manner in which service quantities are rounded during usage calculations. Service quantity rounding can be defined using the **SQ Rounding Details** which allow configuration of the method by which quantities are rounded (Up, Down, or Nearest) and the number of decimal positions retained after rounding.

Creating Measurement Data Snapshots

Daily Scalar Calculation Rule, Get Interval, Get Item Counts and Consumption, and Get Scalar Details usage calculation rules can be configured to create measurement data snapshots during usage transaction processing. Measurement data snapshots are used by data aggregation in Market Settlements Management.

Measurement data snapshot configuration is done in the **Extract To Measurement Data Snapshots** section, and includes the following options:

- **Measurement Data Snapshot Type:** The measurement data snapshot type for measurement data snapshots created by the usage rule.
- **Usage Transaction ID To Use:** A flag that designates the type of ID to use to identify the usage transaction on the measurement data extract. Options include:
 - **Usage Transaction ID:** The usage transaction's ID
 - **Usage Transaction External ID:** The external ID for the usage transaction. Used when the usage transaction is triggered by external system such as a CIS (or by the billing functionality in Customer To Meter)
- **Extract To Different Usage Subscription:** A flag that designates whether or not the measurement data snapshot should be extracted to a different usage subscription, such as one used by Market Settlements Management. Options include:
 - **No:** The extract will reference the usage subscription for which usage calculations are being processed. This option is used when Meter Data Management and Market Settlements Management are installed in different application environments. In this case, the extract can be exported from Meter Data Management for subsequent import into Market Settlements Management.
 - **Yes:** The extract will reference a different usage subscription such as one used by Market Settlements Management. This option is used when Meter Data Management and Market Settlements Management are installed in the same application environment. In this case, the measurement data snapshot is "exported" within the system to the Settlement Item, where it can be used in data aggregation processing.

When this option is selected, the **Source Identifier Type** and **Target Identifier Type** fields must be configured to define how the system will determine the correct settlement usage subscription to use.

- **Irregular Data Flag Mapping:** Ranges of condition codes used to flag data as "irregular". The value of the **Irregular Data Flag** (based on the IRREGULAR_DATA_FLG lookup) is used to flag data that falls with each range configured. A blank **Irregular Flag** value denotes that the condition range is considered to be "Regular".

See [About Measurement Data Snapshots](#) for more information about measurement data snapshot creation and processing.

Configuring Usage Calculation Rules

This portal is used to display and maintain a usage calculation rule.

Refer to [Understanding Usage Calculation Rules](#), [Understanding Usage Calculation Groups](#), and [Understanding Usage Transaction Exception Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Calculation Rule**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Rule:** Defines the usage calculation rule, including parameters used when executing the rule
- **Eligibility Criteria List:** Lists the eligibility criteria defined for the rule

Pre-Calculation Usage Calculation Rules

The following is a list of the pre-calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose
-----------------------------	-------------------------	---------

<p>Alignment and Delay Usage Calculation Rule</p>	<p>Interval or Scalar</p>	<p>This rule can be used to handle two main needs:</p> <ol style="list-style-type: none"> 1) aligns all measuring components for a Usage Subscription to the same date (whether on the same device or separate devices) 2) delays the usage transaction until the end of the retry window based on the quality of available data and other configured parameters.
<p>Check Existence of Installed Device</p>	<p>Interval or Scalar</p>	<p>This rule checks for the existence of a device installed on the Usage Subscription's Service Point for the usage period. In the case of multi-items this rule also checks that they are effective for the usage period.</p>

Calculation Usage Calculation Rules

The following is a list of the calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose
<p>Apply Math (Interval Data)</p>	<p>Interval</p>	<p>This rule is used to perform calculations on interval data and stores the results in the usage transaction's service quantities. A variety of options are available on this rule that include defining the calculation type, variables to use, as well as the equation to use (math functions and expressions).</p> <p>This rule provides aggregated usage for all selected interval measuring components (filter by TOU, SQI & UOM) associated to a usage subscription.</p> <p>This rule can also multiply total usage by a factor using a custom formula.</p>

Coincident Peak and Individual SP Demand	Interval	<p>This rule is used to calculate the coincident peak demand for all of the service points on the usage subscription and the demand values for each service point at the coincident peak. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point).</p>
Daily Scalar Usage Calculation Rule	Scalar	<p>This rule is used to calculate usage of daily scalar measuring components installed in the Service Points associated with a Usage Subscription for the specified usage period. It creates bill determinants by taking the difference between the beginning and ending reading for the bill period.</p> <p>This rule can also be used to provide register readings by measuring component.</p> <p>For consumption values, only the beginning and ending readings are exported</p> <p>This rule supports date breaks (the normal Get Scalar Data rule does not).</p>
Get Interval Data	Interval	<p>This rule is used to get interval quantities from interval measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Interval' usage period.</p> <p>This rule retrieves the interval data for measuring components associated to a usage subscription by TOU, SQI and UOM.</p> <p>This rule converts the interval data to another interval length or unit of measure.</p>
Get Item Counts and Consumption	Interval or Scalar	<p>This rule finds item-based and multi-item-based Service Points linked to the Usage Subscription for the current usage transaction, summarizes the item counts by item type and Service Point, and calculates item-based consumption.</p>

Get Scalar Details	Scalar	<p>This rule is used to get usage from scalar measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Scalar' usage period.</p> <p>This rule creates bill determinants by summing all scalar readings for the bill period. This rule can also be used to provide register readings by measuring component. All readings are exported by this rule.</p> <p>Note: This rule is used for traditional monthly read meters.</p>
Get Subtractive Interval Details	Interval	<p>This rule is used to get interval quantities from subtractive interval measuring components installed on the service points linked to the usage subscription for the specified 'interval' usage period.</p> <p>It also identifies the start and stop readings for each usage period using subtractive interval readings.</p>
Get TOU Mapped Usage	Interval	<p>This rule is used to get time of use quantities from interval measuring components for devices installed at the Service Points linked to the Usage Subscription for the specified 'Interval' usage period.</p>
Interval Tier Calculation	Interval	<p>This rule calculates the difference between a source and reference vector.</p> <p>This rule loops through each tier that is configured and calculates the imbalance amount associated to that tier level.</p> <p>This rule breaks down that difference into one to many positive or negative tiers, and create a service quantity for each tier calculated.</p>
Profile Accumulation	Interval	<p>This rule is used to manipulate a customer's interval data by adding other vectors to it. Those other vectors are derived from a list of profile factors and corresponding characteristic values stored in a list on the usage transaction.</p>

Rolling Demand	Interval	<p>This rule is used to calculate rolling demand for all of the service points on the usage subscription. Rolling demand can be based on a rolling consumption total, rolling consumption average, or coincident peak demand. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point).</p>
Round and Adjust Usage	Interval or Scalar	<p>This rule copies identified source and target Service Quantities and inserts these as Service Quantities that are rounded and adjusted.</p>
Vector and Service Quantity Math	Interval	<p>This rule is designed to facilitate configuration of complex vector calculations. It is based on a series of underlying services with vectors configured as input to the calculations.</p> <p>Typical uses:</p> <ul style="list-style-type: none"> Perform math using interval data, e.g., take the difference between two curves, find max values, find coincident peaks, multiply a curve by a value, apply TOU maps, etc. Define complex formulas using various interval curves, profile factor values or calculated service quantities (bill determinant values). Support math functions: sin, cos, square root, etc. Store derived curves in memory that can be used in subsequent calculations <p>Please note, this rule is not as efficient as other rules.</p>

Post-Calculation Usage Calculation Rules

Below is a list of the post-calculation usage calculation rules provided as part of base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Applicable Data Type(s)	Purpose
-----------------------------	-------------------------	---------

Usage High/Low Rule	Interval or Scalar	This rule compares the Service Quantities of the Usage Transaction to historical values. If the current value is too high or too low compared to historical data then an exception is thrown.
Validate Against Tolerance	Interval or Scalar	This rule is used to validate the calculated usage against a tolerance value. The tolerance value may either come from the specified value or tolerance factor defined in the usage calculation rule.
Business Flag Hold	Interval or Scalar	This rule can stop a usage transaction from proceeding when there have been business flags for the applicable service points. The hold can either be indefinite or set to expire a configurable amount of time prior to the calculation window ending.

Decision-Making Usage Calculation Rules

There are usage calculation rules delivered as part of the base product that help with decision-making when executing running the usage calculation process. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Usage Calculation Rule Name	Purpose
Execute Usage Calculation Group	This rule performs a call to execute a separate usage calculation group which includes execution of all usage calculation rules within that group.
Exception Handler	This rule is used to terminate execution of the usage processor if exception count criteria specified in the rule is met.

Advanced Aside: Using Factors For Variables

A situation common in some implementations involves converting one unit of measure (UOM) to another. However, the conversion factor used in conversions of this can differ based on many different types of criteria, such as the location of the service point or other characteristics. This sort of calculation can be implemented as a usage calculation rule that accumulates consumption for one UOM and converts the consumption to a different UOM by applying a factor to it.

Factors used for this purpose have a Factor Class of "Number," and use some unique rules:

- Number factors reference a characteristic type (with pre-defined values).
- Number factors reference an algorithm that retrieves or derives the value of the characteristic type at runtime.

Factor values for a Number factor are effective-dated pairings of a characteristic value and a corresponding value. Because these pairings are effective-dated, the value returned from the factor can change over time for each characteristic value. At run time, the rule retrieves / derives the characteristic value for the factor's characteristic type and then finds the value associated with the respective characteristic value. Factors can be related to any real or dynamic attribute, so rules of this type are very flexible. For example:

- **Real Attribute:** you could create a rule that retrieves a specific value based on the location of a service point.
- **Dynamic Attribute:** you could create a rule that retrieves a percentage value based on the amount the customer conserved as compared to the same period in the prior year, returning one value if the amount conserved is between 5% and 10%, another value if the amount conserved is between 10% and 20%, and yet a third value if the amount conserved is greater than 20%. The amount conserved is dynamically calculated at execution time and is compared to the characteristic values defined for the factor, and returns the appropriate value. In this example, if the amount conserved was anything less than 5%, no percentage value would be returned.

Pre-Calculation Usage Calculation Rules

Alignment and Delay Usage Calculation Rule

This rule attempts to delay usage calculation until high quality data for calculating bill determinants have become available. It is especially useful for usage subscriptions having multiple sources of usages such as multiple service points or multiple measuring components on the installed meter. The rule ensures that the usage calculated is based on a common date or alignment date, identified for these sources.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-ALGNDELAY Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-AlignmentandDelay

Check Existence of Installed Device

This rule checks for the existence of a device installed on the Usage Subscription's Service Point for the usage period. In the case of multi-items this rule also checks that they are effective for the usage period.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-CHKEXTDVC Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ChkExistenceofInstalledDvc

Calculation Usage Calculation Rules

Apply Math (Interval Data)

This rule is used to perform calculations on interval data and it stores the results in the usage transaction's service quantities. A variety of options are available on this rule that include defining the calculation type, variables to use, as well as the equation to use (math functions and expressions).

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-APPMATHIN Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ApplyMathInt

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Get the total KWH for the period

Calculation Type = Single Variable

Variable Name = V1, where the following is configured:

- Variable Type = Channel Accumulation
- UOM = KWH
- Set Function = Sum

Scenario 2: Get the higher value between the total KWH or total KVARH

Calculation Type = Math Function

Math Function = Max

Variable Name = V1, where the following is configured:

- Variable Type = Channel Accumulation
- UOM = KWH
- Set Function = Sum

Variable Name = V2, where the following is configured:

- Variable Type = Channel Accumulation
- UOM = KVARH
- Set Function = Sum

Scenario 3: Total KWH multiplied with a factor value

Calculation Type = Mathematical Expression

Mathematical Expression = $V1 * V2$

Variable Name = V1, where the following is configured:

- Variable Type = Channel Accumulation
- UOM = KWH
- Set Function = Sum

Variable Name = V2, where the following is configured:

- Variable Type = Factor
- Factor = factor code that holds the multiplier

Coincident Peak and Individual SP Demand

This rule is used to calculate the coincident peak demand for all of the service points on a usage subscription and the demand values for each service point at the coincident peak. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point).

Interval Data Retrieval Parameters

This rule can be configured to use specific data either directly from a specific device and measuring component on the service point or calculated from more than one devices and/or measuring components on the service point. Each type of data is referred to as a "channel" of data. For example, a service point with solar panels might have separate channels for "Consumed" and "Generated" usage, and the rule could be configured to use data from either or based on calculations involving both.

Parameters used to retrieve interval data for this rule include:

- **Check Missing Intervals:** A flag that indicates if the rule should check for missing intervals during the calculation period.
- **No Meter Condition:** The measurement condition assigned to intervals inserted to fill gaps during periods in which when no meter is installed. If not set, the measurement condition defaults to "No Read - System" (100000).
- **SP Device Filter:** An algorithm used to filter the service point device configuration that will be processed by the rule.
- **Common UOM:** The unit of measure that is common among the multiple channels of data used by the rule, if applicable
- **Common Interval Size:** The interval size used to align service point data of different interval sizes. For instance, if a service point has channels measuring data in both 1-hour and 15-minute intervals, setting this to 01:00:00 (1 hour) would scale the 15-minute data to hourly intervals.
- **Channels:** A list of the data channels measured at the service point. Each should be assigned a variable name and the appropriate UOM, TOU, and SQI.
- **Aggregation Method:** The method by which data from multiple channels will be aggregated. Channels can be combined using a simple formula or using a conditional formula.

To define a single channel for the rule to use, configure the "Vector 1 (IV1)" variable in the **Channels** section and reference that variable in a simple formula.

To configure the rule to use multiple channels, define each as a variable in the **Channels** section and configure either a simple or conditional formula to perform any needed evaluations or calculations on the channels.

Defining Formula Operands

Operands used in both simple and conditional formulas are defined in the Operand Lookup (D1-CoincidentPeakOperandLookup) extendable lookup. Operands used to represent channels should use the values in parentheses in the **Variables** drop-down list in the **Channels** section. For instance, the operand for "Vector 1 (IV1)" should be "IV1", the operand for "Vector 2 (IV2)" should be "IV2", and so on.

Operands can also be simple formulas based on the variables defined in the **Variables** drop-down list in the **Channels** section. For instance, a simple formula in which the values from Vector 1 are subtracted from the values in Vector2 could be defined as "IV2 - IV1".

Calculation Modes

This rule has two main modes: calculating demand for individual service points on a usage subscription (Individual SP Demand), or calculating the coincident peak among all of the service points on a usage subscription (Coincident Peak). The coincident peak calculation can be performed on either all readings, or those designated as "on-peak" or "off-peak" via time of use mapping using the Coincident On-Peak or Coincident Off-Peak function. See [Defining Time of Use Mapping Options](#) for more information about time of use mapping.

Individual SP Demand

The "Individual SP Demand" **Calculate Function** identifies the peak demand for each service point on a usage subscription.

For example, the table below lists sample interval data for three service points belonging to single usage subscription for a 12 hour calculation period. This rule would identify the highest value (peak) for each service point within the calculation period (indicated in bold).

Date/Time	Service Point 1	Service Point 2	Service Point 3
10/27/2022 12:00 PM	12	11	13
10/27/2022 1:00 PM	10	12	12
10/27/2022 2:00 PM	11	14	14
10/27/2022 3:00 PM	13	13	14
10/27/2022 4:00 PM	14	14	14
10/27/2022 5:00 PM	13	15	12
10/27/2022 6:00 PM	12	13	15
10/27/2022 7:00 PM	11	12	13
10/27/2022 8:00 PM	12	13	12
10/27/2022 9:00 PM	13	14	12
10/27/2022 10:00 PM	12	14	13
10/27/2022 11:00 PM	12	12	12

This rule would return the following values in the usage transaction service quantities list, which represent the peak values for each service point during the calculation period:

Date/Time	Demand
10/27/2022 4:00 PM	14
10/27/2022 5:00 PM	15
10/27/2022 6:00 PM	15

Note: This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Coincident Peak / Coincident On-Peak / Coincident Off-Peak

The "Coincident Peak" (or "Coincident On-Peak" or "Coincident Off-Peak") **Calculate Function** identifies the coincident peak demand for all of the service points on the usage subscription and the demand values for each service point at the coincident peak. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point).

The data used in the calculation is based on the specific **Calculate Function** selected:

- **Coincident Peak:** Evaluates all measurements matching the configured unit of measure
- **Coincident On-Peak:** Evaluates measurements matching the configured unit of measure that falls with the "on-peak" TOU period defined in the **Results** section based on a specified TOU Map Template.
- **Coincident Off-Peak:** Evaluates measurements matching the configured unit of measure that falls with the "off-peak" TOU period defined in the **Results** section based on a specified TOU Map Template.

For example, the table below lists sample interval data for three service points belonging to single usage subscription for a 12 hour calculation period. This rule would identify the highest total for all of the service points, as well as the

individual values for each service point at the time of the coincident peak within the calculation period (indicated in bold).

Date/Time	Service Point 1	Service Point 2	Service Point 3	Total
10/27/2022 12:00 PM	12	11	13	36
10/27/2022 1:00 PM	10	12	12	34
10/27/2022 2:00 PM	11	14	14	39
10/27/2022 3:00 PM	13	13	14	40
10/27/2022 4:00 PM	14	14	14	42
10/27/2022 5:00 PM	13	15	12	40
10/27/2022 6:00 PM	12	13	15	40
10/27/2022 7:00 PM	11	12	13	36
10/27/2022 8:00 PM	12	13	12	37
10/27/2022 9:00 PM	13	14	12	39
10/27/2022 10:00 PM	12	14	13	39
10/27/2022 11:00 PM	12	12	12	36

This rule would return the following values in the usage transaction service quantities list, which represent the total at the coincident peak and the peak values for each service point at the coincident peak during the calculation period:

Date/Time	Coincident Peak Demand	SP 1 Demand	SP 2 Demand	SP 3 Demand
10/27/2022 4:00 PM	42	14	14	14

Note: Values for individual service points are for information and reporting purposes only, and cannot be used for billing purposes.

Notes and Examples

Notes and Recommendations

- When using the "Coincident On Peak" or "Coincident Off Peak" **Calculate Function**, you must specify a TOU map template in the **On Peak Off Peak Schedule** drop-down list in the **Calculation Details** section, and specify the appropriate time of use period (On-Peak or Off-Peak, respectively) in the **TOU** field in the **Results** section.
- A recommended practice is to configure a Service Quantity Identifier (SQI) to uniquely identify coincident peak data and specify it in the **SQI** field in the **Results** section.
- Additional detail on the logic of this rule can be found in the Detailed Description of the D1-CALDEMAND Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-CoincidentPeakSPDemandRule

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Calculate demand for individual service points (similar to the example above, based on a single channel)

- **Interval Data Retrieval Parameters:**
 - **Check Missing Intervals:** Yes
 - **No Meter Condition:** No Read - System
 - **Common UOM:** Kilowatt-Hour
 - **Common Interval Size:** 01:00:00
 - **Channels:**
 - **Variable 1:**
 - **Variable Name:** Variable 1 (IV1)
 - **UOM:** Kilowatt-Hour
 - **Aggregation Method:**
 - **Formula Source:** Simple Vector Formula
 - **Simple Vector Formula:** IV1
- **Calculation Details:**
 - **Calculate Function:** Individual SP Demand
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:**
 - **SQI:**
 - **Common Interval Size:** 01:00:00

Scenario 2: Calculate demand for individual service points (based on two channels)

In this scenario, the service point has two channels, one for consumed energy, and one for generated energy (from a solar panel). If the consumed value is greater than the generated value, subtract the generated value from the consumed value. If the generated value is greater than the consumed value, use zero (0).

- **Interval Data Retrieval Parameters:**
 - **Check Missing Intervals:** Yes
 - **No Meter Condition:** No Read - System
 - **Common UOM:** Kilowatt-Hour
 - **Common Interval Size:** 01:00:00
 - **Channels:**
 - **Variable 1:**
 - **Variable Name:** Variable 1 (IV1)
 - **UOM:** Kilowatt-Hour
 - **TOU:**
 - **SQI:** Consumed
 - **Variable 2:**
 - **Variable Name:** Variable 2 (IV2)
 - **UOM:** Kilowatt-Hour
 - **TOU:**
 - **SQI:** Generated
 - **Aggregation Method:**

- **Formula Source:** Conditional Vector Formula
- **Conditional Vector Formula:**
 - **Sequence:** 10
 - **Left Operand:** IV1
 - **Criteria Operator:** >
 - **Right Operand:** IV2
 - **True Action:** Apply True Formula
 - **True Formula:** IV1-IV2
 - **False Action:** Apply False Formula
 - **False Formula:** 0
- **Calculation Details:**
 - **Calculate Function:** Individual SP Demand
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:**
 - **SQI:**

Scenario 3: Coincident Peak (similar to the example above, based a single channel)

- **Interval Data Retrieval Parameters:**
 - **Check Missing Intervals:** Yes
 - **No Meter Condition:** No Read - System
 - **Common UOM:** Kilowatt-Hour
 - **Common Interval Size:** 01:00:00
 - **Channels:**
 - **Variable 1:**
 - **Variable Name:** Variable 1 (IV1)
 - **UOM:** Kilowatt-Hour
 - **Aggregation Method:**
 - **Formula Source:** Simple Vector Formula
 - **Simple Vector Formula:** IV1
- **Calculation Details:**
 - **Calculate Function:** Coincident Peak
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:**
 - **SQI:** Coincident Peak

Scenario 4: Coincident On-Peak (based on a single channel)

- **Interval Data Retrieval Parameters:**
 - **Check Missing Intervals:** Yes
 - **No Meter Condition:** No Read - System
 - **Common UOM:** Kilowatt-Hour
 - **Common Interval Size:** 01:00:00
 - **Channels:**
 - **Variable 1:**
 - **Variable Name:** Variable 1 (IV1)

- **UOM:** Kilowatt-Hour
- **Aggregation Method:**
 - **Formula Source:** Simple Vector Formula
 - **Simple Vector Formula:** IV1
- **Calculation Details:**
 - **Calculate Function:** Coincident On Peak
 - **On Peak Off Peak Schedule:** <TOU map template>
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:** On Peak
 - **SQI:** Coincident On Peak

Daily Scalar Usage Calculation Rule

This rule is used to calculate usage of daily scalar measuring components installed in the Service Points associated with a Usage Subscription for the specified 'Interval' usage period. Only automatically read scalar measuring components with value identifier that matches usage calculation rule's UOM/TOU/SQI will be processed.

If configuring this rule with interval and scalar usage calculation rules under a usage calculation group, it should be executed after interval usage calculation rule and before the scalar usage calculation rule.

This rule calculates usage based on the beginning and ending reading values -- ignoring intermediate readings. This rule will not estimate data based on the usage transaction estimate flag. Frequently read scalar devices must use periodic estimation processes.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETFRESCR Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-CalFrequentlyReadScalar

Get Interval Data

This rule is used to get interval quantities from interval measuring components installed in the service points linked to the usage subscription for the specified 'Interval' usage period. Only measuring components that match the UOM/SQI defined in the usage calculation rule are processed. Measurements within the period are stored in the usage transaction's service quantities' interval data list. The SQ entry's quantity is calculated based on the **Calculate Function** defined in the usage calculation rule. This is done for every entry in the usage period list. Each service quantity recorded by this rule is linked to a service point and measuring component.

By supplying the Axis Conversion parameters on the usage calculation rule, this algorithm will convert the identified measuring component's consumption into the supplied UOM and interval size prior to storing the consumption into the service quantity's interval data list.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETINTDAT Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetIntervalData

Get Item Counts and Consumption

This rule finds item-based and multi-item-based Service Points linked to the Usage Subscription for the current usage transaction, summarizes the item counts by item type and Service Point, and calculates item-based consumption. Once the item detail entries are created, the rule processes goes through them to create usage period SQs.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETITEMCC Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetItemCountsConsumption

Get Scalar Details

This rule is used to get usage from scalar measuring components installed in the Service Points linked to the Usage Subscription for the specified 'Scalar' usage period. By default all scalar measuring components are processed but if specific UOMs/TOUs/SQIs are defined in the usage calculation rule then only applicable measuring components are processed. Measurements within the period are retrieved. The usage transaction request may indicate whether or not 'Estimate' measurements are allowed. If the usage transaction request indicates that 'Estimate' measurements are allowed but an estimated end measurement cannot be found an Estimate initial measurement is created.

The measurement details are stored in the usage transaction's scalar details. The usage is also stored in the usage transaction's service quantities unless otherwise specified in the usage calculation rule (using Build Service Quantity indicator).

This rule can be configured to perform measurement quality assessment, which will result in the population of the measurement quality list with the quantities and corresponding conditions of those measurements (regular, estimated, etc.).

Please note: this rule should not be used with readings occurring daily or more frequently as it will retrieve all of the readings to store in the Usage Transaction. The [Daily Scalar usage calculation rule](#) may be a better option for this use case.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETSCALAR Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetScalar

Get Subtractive Interval Details

This rule is used to calculate the usage for a subtractive interval measuring components. This differs from the Get Interval Data usage calculation rule in that it also retrieves a start and stop reading for each usage period it calculates. The start and stop readings are then used to provide entries into the usage scalar details table which are then made available in the usage transaction sent to the billing system for bill presentment.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-SUBINTADJ Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetSubtractiveInterval

Get TOU Mapped Usage

This rule is used to get time of use quantities from interval measuring components for devices installed at the Service Points linked to the Usage Subscription for the specified 'Interval' usage period. Only measuring components that match the UOM/SQI defined in the usage calculation rule instance are processed.

Measurements within the period are mapped to time of use quantities based on the TOU map defined on the usage calculation rule. If dynamic options are specified in the referenced TOU map and if there are dynamic option events in effect within the usage period then the TOU map associated with the dynamic option is used for the entire dynamic option event period. This calculation is performed for every usage period requested.

The calculated time of use quantities are stored in the usage transaction's service quantities per Service Point and measuring component.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETTOUSG Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-GetTOUUsage

Interval Tier Calculation

This rule calculates the difference between a source and reference vector. It then breaks that difference into one to many positive or negative tiers. For each tier calculated it will create a service quantity with the optional ability to create additional service quantities for the total of all positive tiers and the total of all negative tiers. This rule will loop through each tier that is configured and calculate the imbalance amount associated to that tier level.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-GETINTIER Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-IntervalTierCalculation

Profile Accumulation

This rule is used to manipulate a customer's interval data by adding other vectors to it. Those other vectors are derived from a list of profile factors and corresponding characteristic values stored in a list on the usage transaction.

The typical application of this rule is for customer self-service rate compare, in which a self-service user has selected a set of usage adjustments to apply to their historical consumption to assess the effect on the amount consumed.

This rule algorithm retrieves the customer's usage (the source UOM) for the usage period using one of two options:

- A channel linked to a Usage Subscription
- A usage transaction service quantity

Then it takes each entry in the usage transaction's profile factor list, finds the profile measuring component for each, retrieves the measurement data for the profile, applies axis conversion to align it to the source UOM and target interval size, and adds it to the source vector. Each profile's data is added progressively to arrive at a final vector. The final vector may then be TOU-mapped, and the vector itself may be preserved or discarded.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-DYNPRFLAC Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProfileAccumulation

Profile Service Quantity

This rule intervalizes scalar service quantity values based on a profile measuring component.

This rule first retrieves scalar service quantities, identified by the rule's UOM/TOU/SQI. If multiple service quantities exist for the service point they will be summarized at the service point level. In the case of a split or broken usage period for a service point, the usage period is merged and the quantities are summarized. Each service quantity is subject to intervalization. The profile measuring component is then derived using the profile factor supplied with either the usage subscription or service point as characteristic sources. If the profile is not available, an exception will be created using the exception details on the rule.

If a dynamic option type is provided, the events associated with it are retrieved for the usage transaction period. Any intervalized quantities that coincide with the dynamic option events start/end date time are then recorded in a new usage period service quantity of usage type "Correlated SQ".

If no dynamic option type provided, the intervalized quantities are recorded in a new usage period service quantity of usage type "Profile SQ".

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-PRFSVCQTY Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ProfileServiceQuantity

Rolling Demand

This rule is used to calculate rolling demand for all of the service points on the usage subscription. Demand is calculated from consumption. In electric service markets, these are typically represented by kilowatts (kW) and kilowatt hours (kWh) respectively, where demand values are calculated by multiplying consumption interval values by the number of intervals per hour. For example, the demand associated with a fifteen (15) minute interval value of 25kWh would be 100kW (25 x 4 intervals per hour).

Interval Data Retrieval Parameters

This rule can be configured to use specific data either directly from a specific device and measuring component on the service point or calculated from more than one devices and/or measuring components on the service point. Each type of data is referred to as a "channel" of data. For example, a service point with solar panels might have separate channels for "Consumed" and "Generated" usage, and the rule could be configured to use data from either or based on calculations involving both.

Parameters used to retrieve interval data for this rule include:

- **Check Missing Intervals:** A flag that indicates if the rule should check for missing intervals during the calculation period.
- **No Meter Condition:** The measurement condition assigned to intervals inserted to fill gaps during periods in which when no meter is installed. If not set, the measurement condition defaults to "No Read - System" (100000).
- **SP Device Filter:** An algorithm used to filter the service point device configuration that will be processed by the rule.

- **Common UOM:** The unit of measure that is common among the multiple channels of data used by the rule, if applicable
- **Common Interval Size:** The interval size used to align service point data of different interval sizes. For instance, if a service point has channels measuring data in both 1-hour and 15-minute intervals, setting this to 01:00:00 (1 hour) would scale the 15-minute data to hourly intervals.
- **Channels:** A list of the data channels measured at the service point. Each should be assigned a variable name and the appropriate UOM, TOU, and SQI.
- **Aggregation Method:** The method by which data from multiple channels will be aggregated. Channels can be combined using a simple formula or using a conditional formula.

To define a single channel for the rule to use, configure the "Vector 1 (IV1)" variable in the **Channels** section and reference that variable in a simple formula.

To configure the rule to use multiple channels, define each as a variable in the **Channels** section and configure either a simple or conditional formula to perform any needed evaluations or calculations on the channels.

Defining Formula Operands

Operands used in both simple and conditional formulas are defined in the Operand Lookup (D1-CoincidentPeakOperandLookup) extendable lookup. Operands used to represent channels should use the values in parentheses in the **Variables** drop-down list in the **Channels** section. For instance, the operand for "Vector 1 (IV1)" should be "IV1", the operand for "Vector 2 (IV2)" should be "IV2", and so on.

Operands can also be simple formulas based on the variables defined in the **Variables** drop-down list in the **Channels** section. For instance, a simple formula in which the values from Vector 1 are subtracted from the values in Vector2 could be defined as "IV2 - IV1".

Calculation Modes

This rule has two main modes: calculating rolling demand for a usage subscription based on either a rolling consumption total (Rolled Total) or rolling consumption average (Rolled Average), or calculating the coincident peak among all of the service points on a usage subscription based on either a rolling consumption total (Rolled Total - Coincident Peak) or rolling consumption average (Rolled Average - Coincident Peak). The coincident peak calculation can be performed on either all readings, or those designated as "on-peak" or "off-peak" via time of use mapping using the Coincident On-Peak or Coincident Off-Peak function, See [Defining Time of Use Mapping Options](#) for more information about time of use mapping.

The number of intervals in the rolling total or rolling average is determined via rule configuration. The **Roll Interval Size** parameter (in the **Calculation Details** section) divided by the **Common Interval Size** parameter (in the **Interval Data Retrieval Parameters** section). For example, if **Roll Interval Size** was 01:00:00 (1 hour) and the **Common Interval Size** was 00:15:00 (15 minutes), the rolling total or average would be based on sets of 4 intervals (1 hour divided by 15 minutes).

Rolled Demand Total

The "Rolled Demand Total" **Roll Calculate Function** identifies the peak demand for the usage subscription based on a rolling consumption total.

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

- **Date/Time:** The date and time of each interval
- **Service Point n:** The kWh value for each interval at a specific service point
- **Total:** The combined total of consumption at the usage subscription's service points
- **Rolling Total:** The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Demand:** The demand calculated from the rolling total (calculated by multiplying the running total by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest demand for the usage subscription during the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Demand
10/27/2022 12:00 PM	12	11	23		
10/27/2022 1:00 PM	10	12	22		
10/27/2022 2:00 PM	11	13	24		
10/27/2022 3:00 PM	13	13	26	95	95
10/27/2022 4:00 PM	14	14	28	100	100
10/27/2022 5:00 PM	13	13	26	104	104
10/27/2022 6:00 PM	12	13	25	105	105
10/27/2022 7:00 PM	11	12	23	102	102
10/27/2022 8:00 PM	12	13	25	99	99
10/27/2022 9:00 PM	13	14	27	100	100
10/27/2022 10:00 PM	12	14	26	101	101
10/27/2022 11:00 PM	12	12	24	102	102

This rule would return the following values in the usage transaction service quantities list, which represents the peak demand value during the calculation period:

Date/Time	Demand
10/27/2022 6:00 PM	105

Note: This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Rolled Demand Total - Coincident Peak / Rolled Demand Total - Coincident On Peak / Rolled Demand Total - Coincident Off Peak

The "Rolled Demand Total - Coincident Peak / Rolled Demand Total - Coincident On Peak / Rolled Demand Total - Coincident Off Peak" **Roll Calculate Function** identify the coincident peak demand for all of the service points on the usage subscription. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point). The coincident peak demand is the demand based on the rolling total at the coincident peak.

The data used in the calculation is based on the specific **Roll Calculate Function** selected:

- **Total - Coincident Peak:** Evaluates all measurements matching the configured unit of measure
- **Total - Coincident On Peak:** Evaluates measurements matching the configured unit of measure that falls with the "on peak" TOU period defined in the **Results** section based on a specified TOU Map Template.
- **Total - Coincident Off Peak:** Evaluates measurements matching the configured unit of measure that falls with the "off peak" TOU period defined in the **Results** section based on a specified TOU Map Template.

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

- **Date/Time:** The date and time of each interval
- **Service Point n:** The kWh value for each interval at a specific service point
- **Total:** The combined total of consumption at the usage subscription's service points
- **Rolling Total:** The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Demand:** The demand calculated from the rolling total (calculated by multiplying the running total by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest total for all of the service points within the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Demand
10/27/2022 12:00 PM	12	11	23		
10/27/2022 1:00 PM	10	12	22		
10/27/2022 2:00 PM	11	13	24		
10/27/2022 3:00 PM	13	13	26	95	95
10/27/2022 4:00 PM	14	14	28	100	100
10/27/2022 5:00 PM	13	13	26	104	104
10/27/2022 6:00 PM	12	13	25	105	105
10/27/2022 7:00 PM	11	12	23	102	102
10/27/2022 8:00 PM	12	13	25	99	99
10/27/2022 9:00 PM	13	14	27	100	100
10/27/2022 10:00 PM	12	14	26	101	101

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Demand
10/27/2022 11:00 PM	12	12	24	102	102

This rule would return the following values in the usage transaction service quantities list, which represent the demand at the coincident peak:

Date/Time	Coincident Peak Demand
10/27/2022 4:00 PM	100

Note: This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Rolled Demand Average

The "Rolled Demand Average" **Roll Calculate Function** identifies the peak demand for the usage subscription based on a rolling average (calculated from the rolling total).

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

- **Date/Time:** The date and time of each interval
- **Service Point n:** The kWh value for each interval at a specific service point
- **Total:** The combined total of consumption at the usage subscription's service points
- **Rolling Total:** The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Rolling Average:** The rolling average of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Demand:** The demand calculated from the rolling average (calculated by multiplying the rolling average by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest demand for the usage subscription during the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Rolling Average	Demand
10/27/2022 12:00 PM	12	11	23			
10/27/2022 1:00 PM	10	12	22			
10/27/2022 2:00 PM	11	13	24			
10/27/2022 3:00 PM	13	13	26	95	23.75	23.75
10/27/2022 4:00 PM	14	14	28	100	25	25
10/27/2022 5:00 PM	13	13	26	104	26	26

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Rolling Average	Demand
10/27/2022 6:00 PM	12	13	25	105	26.25	26.25
10/27/2022 7:00 PM	11	12	23	102	25.5	25.5
10/27/2022 8:00 PM	12	13	25	99	24.75	24.75
10/27/2022 9:00 PM	13	14	27	100	25	25
10/27/2022 10:00 PM	12	14	26	101	25.25	25.25
10/27/2022 11:00 PM	12	12	24	102	25.5	25.5

This rule would return the following values in the usage transaction service quantities list, which represents the peak demand value during the calculation period:

Date/Time	Demand
10/27/2022 6:00 PM	26.25

Note: This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Rolled Demand Average - Coincident Peak / Rolled Demand Average - Coincident On Peak / Rolled Demand Average - Coincident Off Peak

The "Average - Coincident Peak / Average - Coincident On-Peak / Average - Coincident Off-Peak" **Calculate Function** identify the coincident peak demand for all of the service points on the usage subscription. The "coincident peak" is the time at which the combined values of multiple service points is the highest (which is not necessarily the peak for each individual service point). The coincident peak demand is the demand based on the rolling average at the coincident peak.

The data used in the calculation is based on the specific **Roll Calculate Function** selected:

- **Rolled Demand Total - Coincident Peak:** Evaluates all measurements matching the configured unit of measure
- **Rolled Demand Total - Coincident On Peak:** Evaluates measurements matching the configured unit of measure that falls with the "on peak" TOU period defined in the **Results** section based on a specified TOU Map Template.
- **Rolled Demand Total - Coincident Off Peak:** Evaluates measurements matching the configured unit of measure that falls with the "off peak" TOU period defined in the **Results** section based on a specified TOU Map Template.

For example, the table below lists sample hourly interval data for two service points belonging to single usage subscription for a 12 hour calculation period. This table includes the following:

- **Date/Time:** The date and time of each interval
- **Service Point n:** The kWh value for each interval at a specific service point
- **Total:** The combined total of consumption at the usage subscription's service points
- **Rolling Total:** The rolling total of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))

- **Rolling Average:** The rolling average of 4 total values (based on a **Roll Interval Size** of 01:00:00 (1 hour) and **Common Interval Size** of 00:15:00 (15 minutes))
- **Demand:** The demand calculated from the rolling average (calculated by multiplying the rolling average by the number of intervals per hour - in this example the total is the same as the demand because this is hourly data).

This rule would identify the highest demand for the usage subscription during the calculation period (indicated in **bold**).

Date/Time	Service Point 1	Service Point 2	Total	Rolling Total	Rolling Average	Demand
10/27/2022 12:00 PM	12	11	23			
10/27/2022 1:00 PM	10	12	22			
10/27/2022 2:00 PM	11	13	24			
10/27/2022 3:00 PM	13	13	26	95	23.75	23.75
10/27/2022 4:00 PM	14	14	28	100	25	25
10/27/2022 5:00 PM	13	13	26	104	26	26
10/27/2022 6:00 PM	12	13	25	105	26.25	26.25
10/27/2022 7:00 PM	11	12	23	102	25.5	25.5
10/27/2022 8:00 PM	12	13	25	99	24.75	24.75
10/27/2022 9:00 PM	13	14	27	100	25	25
10/27/2022 10:00 PM	12	14	26	101	25.25	25.25
10/27/2022 11:00 PM	12	12	24	102	25.5	25.5

This rule would return the following values in the usage transaction service quantities list, which represents the peak demand value during the calculation period:

Date/Time	Demand
10/27/2022 4:00 PM	25

Note: This option should be used for information and reporting purposes only. These values cannot be used for billing purposes.

Notes and Examples

Notes and Recommendations

- When using the "Coincident On Peak" or "Coincident Off Peak" **Roll Calculate Function**, you must specify either a TOU map (in the **TOU Map** field) or a TOU map template (in the **On Peak Off Peak Schedule** drop-down list) in the **Calculation Details** section, and specify the appropriate time of use period (On-Peak or Off-Peak, respectively) in the **TOU** field in the **Results** section.
- A recommended practice is to configure a Service Quantity Identifier (SQI) to uniquely identify coincident peak data and specify it in the **SQI** field in the **Results** section.
- Additional detail on the logic of this rule can be found in the **Detailed Description** of the D1-CALROLDEM Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

D1-CalcRollingDemandRule

Example Scenarios

Below are some example scenarios that can be achieved based on configuration of this rule.

Scenario 1: Calculate demand for services points based on rolling total (based on a single channel)

- **Interval Data Retrieval Parameters:**
 - **Check Missing Intervals:** Yes
 - **No Meter Condition:** No Read - System
 - **Common UOM:** Kilowatt-Hour
 - **Common Interval Size:** 00:15:00
 - **Channels:**
 - **Variable 1:**
 - **Variable Name:** Variable 1 (IV1)
 - **UOM:** Kilowatt-Hour
 - **Aggregation Method:**
 - **Formula Source:** Simple Vector Formula
 - **Simple Vector Formula:** IV1
- **Calculation Details:**
 - **Roll Calculate Function:** Rolled Demand Total
 - **Roll Interval Size:** 01:00:00
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:**
 - **SQI:**

Scenario 2: Calculate demand for service points based on rolling total (based on two channels)

In this scenario, the service point has two channels, one for consumed energy, and one for generated energy (from a solar panel). If the consumed value is greater than the generated value, subtract the generated value from the consumed value. If the generated value is greater than the consumed value, use zero (0).

- **Interval Data Retrieval Parameters:**
 - **Check Missing Intervals:** Yes

- **No Meter Condition:** No Read - System
- **Common UOM:** Kilowatt-Hour
- **Common Interval Size:** 01:00:00
- **Channels:**
 - **Variable 1:**
 - **Variable Name:** Variable 1 (IV1)
 - **UOM:** Kilowatt-Hour
 - **TOU:**
 - **SQI:** Consumed
 - **Variable 2:**
 - **Variable Name:** Variable 2 (IV2)
 - **UOM:** Kilowatt-Hour
 - **TOU:**
 - **SQI:** Generated
- **Aggregation Method:**
 - **Formula Source:** Conditional Vector Formula
 - **Conditional Vector Formula:**
 - **Sequence:** 10
 - **Left Operand:** IV1
 - **Criteria Operator:** >
 - **Right Operand:** IV2
 - **True Action:** Apply True Formula
 - **True Formula:** IV1-IV2
 - **False Action:** Apply False Formula
 - **False Formula:** 0
- **Calculation Details:**
 - **Roll Calculate Function:** Rolled Demand Total
 - **Roll Interval Size:** 01:00:00
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:**
 - **SQI:**

Scenario 3: Calculate demand for services points based on rolling average (based on a single channel)

- **Interval Data Retrieval Parameters:**
 - **Check Missing Intervals:** Yes
 - **No Meter Condition:** No Read - System
 - **Common UOM:** Kilowatt-Hour
 - **Common Interval Size:** 00:15:00
 - **Channels:**
 - **Variable 1:**
 - **Variable Name:** Variable 1 (IV1)
 - **UOM:** Kilowatt-Hour
- **Aggregation Method:**
 - **Formula Source:** Simple Vector Formula
 - **Simple Vector Formula:** IV1

- **Calculation Details:**
 - **Roll Calculate Function:** Rolled Demand Average
 - **Roll Interval Size:** 01:00:00
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:**
 - **SQI:**

Scenario 4: Total - Coincident Peak (based on a single channel)

- **Interval Data Retrieval Parameters:**
 - **Check Missing Intervals:** Yes
 - **No Meter Condition:** No Read - System
 - **Common UOM:** Kilowatt-Hour
 - **Common Interval Size:** 00:15:00
 - **Channels:**
 - **Variable 1:**
 - **Variable Name:** Variable 1 (IV1)
 - **UOM:** Kilowatt-Hour
 - **Aggregation Method:**
 - **Formula Source:** Simple Vector Formula
 - **Simple Vector Formula:** IV1
- **Calculation Details:**
 - **Roll Calculate Function:** Rolled Demand Total, Coincident Peak
 - **Roll Interval Size:** 01:00:00
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:**
 - **SQI:** Coincident Peak

Scenario 5: Average - Coincident On Peak (based on a single channel)

- **Interval Data Retrieval Parameters:**
 - **Check Missing Intervals:** Yes
 - **No Meter Condition:** No Read - System
 - **Common UOM:** Kilowatt-Hour
 - **Common Interval Size:** 00:15:00
 - **Channels:**
 - **Variable 1:**
 - **Variable Name:** Variable 1 (IV1)
 - **UOM:** Kilowatt-Hour
 - **Aggregation Method:**
 - **Formula Source:** Simple Vector Formula
 - **Simple Vector Formula:** IV1
- **Calculation Details:**
 - **Roll Calculate Function:** Rolled Demand Average, Coincident, On Peak
 - **Roll Interval Size:** 01:00:00
 - **Reference TOU Map by Template:** Yes

- **On Peak Off Peak Schedule:** <TOU map template>
- **Results:**
 - **UOM:** Kilowatt
 - **TOU:** On Peak
 - **SQI:** Coincident On Peak

Round and Adjust Usage

This rule copies identified source and target Service Quantities and inserts these as period Service Quantities that are rounded and adjusted. This rule captures the source and target Service Quantity identifiers, rounding method, and Service Quantity bucket to hold the adjustment. The usage calculation rule also has an option to validate the difference between the source and target service quantities.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-RNDADJUSG Algorithm Type.

Business Object

D2-RoundAndAdjustUsage

Vector and Service Quantity Math

This rule is designed to facilitate configuration of complex vector and scalar quantity calculations. It is based on a series of underlying services, including Axis Conversion, Apply Formula (most importantly), and Apply TOU Map. It can be configured to accept as input up to five vectors - where a single vector can represent the combination of all measuring components with linkages to the Usage Subscription with the configured UOM/SQI. It can also accept a list of scalar variables that can be taken in as factor values, usage transaction service quantities, set functions on a vector, or numeric values.

Vectors can be combined using a simple formula expression, or using condition formula expressions. Both interval values and interval conditions can be referenced. The result is interval-by-interval processing of the vector formula. The resulting final vector can be stored, TOU mapped, and/or subjected to a final set function (such as sum or max).

This rule stores service quantities of type "other" - meaning that the service quantities created by this rule do not have linkages to a specific Service Point or measuring component, given the potentially diverse sources of the data taken as input by this rule that lead to the final quantity.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-MATH Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

D2-UsageHighLowRule

Validate Against Tolerance

This rule is used to validate the calculated usage against a tolerance value. The tolerance value may either come from the specified value or tolerance factor defined in the usage calculation rule.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-VALUSGTOL Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ValAgainstTol

Business Flag Hold

This rule can be used to place a hold on a usage transaction until the business flags related to the usage transactions service points can be investigated. The hold can be placed in one of two ways:

- **Calculation Window Based:** holds will remain until either a user manually bypasses the usage exception error or the current date is within a configurable tolerance of the calculation window end (aka the retry until date time).
- **Indefinite:** holds require a user to manually bypass the usage exception that is generated.

Defining which business flags should result in a usage transaction is a matter of identifying which business flag types, priorities, and confidences should be included.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-AUR-IBFH algorithm type.

D2-BusinessFlagHold

Decision-Making Usage Calculation Rules

Execute Usage Calculation Group

This rule performs a call to execute a separate usage calculation group which includes execution of all usage calculation rules within that group. It is especially useful in cases where repeating the same rule over and over would be hard to maintain.

For example, you may want to calculate a straightforward kWh sum for every usage calculation group. Creating a separate CALC_KWH_SUM usage calculation group for this one calculation allows you to isolate the configuration points. Then the CALC_KWH_SUM usage calculation group can be referenced in every other usage calculation group that needs this sort of service quantity.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-AUSGR-RFG Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D1-UsageRuleReferredUsageGroup

Exception Handler

This rule evaluates the exception list that was accumulated during the execution of the calculation rules against exception criteria configured on this rule. This used to terminate the execution of usage calculation group processor if there are far too many exceptions hit during the execution.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-UREXPCHAN Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Detailed Configuration Examples

Demand Calculation Options Using Interval Data

There are a number of ways to calculate a demand value from interval data when retrieving bill determinants for CIS. A few examples of demand calculations are listed below:

Scenario1: Use interval data for demand at a common block size: the [Vector and Service Quantity Math](#) usage calculation rule can be used to calculate demand from the interval data. Below is one example of configuration to handle demand calculation based on 30 minute blocks:

Usage Calculation Rule field	Value	Notes
Vector 1 // Type	Physical Channels Links to Usage Subscription	
Vector 1 // Unit of Measure	Kilowatt-Hours	Use your own UOM here - this is just as example.
Vector 1 // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Vector Processing // Common Interval Size	00:30:00	This configuration rolls up all channels (whether 5 minute, 15 minute, or 30 minute interval data) into a common interval size.
Vector Processing // Vector Formula Source	Simple Vector Formula	
Vector Processing // Simple Vector Formula	IV1*2	This is multiplying the common 30 minute interval size by 2 to achieve an hourly value.
Result // Unit of Measure	Kilowatts	Use your own UOM here - this is just as example.

Result // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Result // Insert Primary SQ Entry	Yes	
Result // SQ Entry Quantity Source	Set Function Against Derived Vector	
Result // Set Function Against Derived Vector	Max	This function pulls the max value based on the configuration in the "Vector Processing" section.

Scenario 2: Use interval data for demand by TOU period: This example is very similar to the last and again leverages the [Vector and Service Quantity Math](#) usage calculation rule. However, instead of calculating a single demand value for the entire period it will calculate a demand value for each TOU period:

Usage Calculation Rule field	Value	Notes
Vector 1 // Type	Physical Channels Links to Usage Subscription	
Vector 1 // Unit of Measure	Kilowatt-Hours	Use your own UOM here - this is just as example.
Vector 1 // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Vector Processing // Common Interval Size	00:30:00	This configuration rolls up all channels (whether 5 minute, 15 minute, or 30 minute interval data) into a common interval size.
Vector Processing // Vector Formula Source	Simple Vector Formula	
Vector Processing // Simple Vector Formula	IV1*2	This is multiplying the common 30 minute interval size by 2 to achieve an hourly value.
Result // Unit of Measure	Kilowatts	Use your own UOM here - this is just as example.
Result // Service Quantity Identifier	Consumed	Use your own SQI here - this is just as example.
Result // Insert Primary SQ Entry	No	
Result // Apply TOU Map To Derived Vector	Yes	
Result // TOU Map	(your TOU Map)	Select the TOU Map you'd like to apply.

Result // Time Of Use Calculate Function	Max	This function pulls the max value based on the configuration in the "Vector Processing" section and then buckets it based on the selected TOU Map.
---	-----	--

Usage Calculation Types

Understanding Usage Calculation Types

Usage calculation types define calculations executed at a customer level where there may be more than one calculation per usage subscription. For example, a customer may have a usage subscription for producing billing determinants but there may be additional calculations that will be executed on a much less frequent basis (annually, quarterly, etc). Usage calculation types provide a way to leverage a single usage subscription to drive multiple different calculations.

Usage calculation types use the following parameters:

- **Request Type:** Used to drive the creation and processing of the usage transactions for all usage subscriptions that are valid for the usage calculation type.
 -  **Note:** Request types for usage calculation types should be based on the Usage Calculation Request Type business object (D2-UsageCalculationReqType)
- **Service Point Quantity Creation:** Details of the quantities created by usage calculations of this type, including service point quantity type, and UOM, TOU, and SQI.
- **Applicable Usage Subscription Types:** A list of usage subscription types for which this usage calculation type is applicable. Each usage subscription type is defined by an effective date range, the usage transaction business object used for the usage calculation, the result UOM/TOU/SQI, and the usage calculation group used to perform the calculations.

Configuring Usage Calculation Types

You use the **Usage Calculation Type** portal to maintain and view usage calculation types.

Refer to [Understanding Usage Calculation Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Calculation Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Calculation Type List:** This zone lists all usage calculation type records. Broadcast a record to display the details of the selected record.
- **Usage Calculation Type:** This zone displays details for the selected usage calculation type.

Usage Subscription Quantity Types

Understanding Usage Subscription Quantity Types

Usage subscription quantity types define types of quantities that can be stored for a usage subscription. These quantity types are often infrequently calculated descriptors of a given customer and how they relate, at an aggregate level, to either the customer base as a whole or their particular rate class. For example, a customer quantity may be used to store a scaling factor that describes how a given customer's usage compares to the profiled usage for their rate class.

In a settlement implementation, usage subscription quantity types can be used to define values calculated monthly, annually, etc., such as annual peak load contribution (PLC).

Usage subscription quantity types use the following parameters:

- **Service Type:** The service type (electric, gas, water, etc.) for service point quantities of this type.
- **Usage Subscription Quantity Business Object:** The business object used for usage subscription quantities of this type.
- **Usage Subscription Quantity Identifiers:** Value identifiers related to the current usage subscription quantity type (used to provide shorthand descriptions of the various types of values measured by usage subscription quantities of this type).

Configuring Usage Subscription Quantity Types

You use the **Usage Subscription Quantity Type** portal to display and maintain usage subscription quantity types.

Refer to [Understanding Usage Subscription Quantity Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Usage Subscription Quantity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Usage Subscription Quantity Type List:** This zone lists all usage subscription quantity type records. Broadcast a record to display the details of the selected record.
- **Usage Subscription Quantity Type:** This zone displays details for the selected usage subscription quantity type.

Dynamic Option Types

Understanding Dynamic Option Types

Dynamic options specify terms that override how usage is normally calculated, such as a critical peak period that affects the TOU mapping of interval consumption. Dynamic option types store information common to dynamic options of a specific type.

There are two classes of dynamic options:

- **Interval Set:** Used to represent dynamic option types that provide a set of intervals that will be included in a calculation.
- **Usage Event:** Used to represent dynamic option types that provide a specific period of time during which a dynamic option is applicable.

Interval Set dynamic option types also define key information about the interval data they represent, including:

- **Unit of Measure:** Identifies the quantity that Interval Set dynamic options and Interval Set dynamic option events based on this type are measuring.
- **Interval Size:** Defines the size of the intervals for Interval Set dynamic option events of this type, represented as hours:minutes:seconds (HH:MI:SS).

Configuring Dynamic Option Types

This portal is used to display and maintain a Dynamic Option Type.

Refer to [Understanding Dynamic Option Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Dynamic Option Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Dynamic Option Type List:** displays all of the Dynamic Option Types so you can choose the one you want to display in more detail
- **Dynamic Option Type:** shows the specific configuration for the selected Dynamic Option Type

Contact Types

Understanding Contact Types

Contact types define the properties of a class of entities (businesses, persons).

Configuring Contact Types

This portal is used to display and maintain a Contact Type.

Refer to [Understanding Contact Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Contact Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Contact Type List:** displays all of the Contact Types so you can choose the one you want to display in more detail
- **Contact Type:** shows the specific configuration for the selected Contact Type

Bill Cycle

Understanding Bill Cycle

Bill cycle identifies window period when a customer is going to be billed and when the bill determinants are going to be calculated.

Configuring Bill Cycle

This portal is used to display and maintain a Bill Cycle.

Refer to [Understanding Bill Cycle](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **Bill Cycle**.

The following zones may appear as part of the portal's **Main** tab page:

- **Bill Cycle List:** displays all of the Bill Cycles so you can choose the one you want to display in more detail.
- **Bill Cycle:** shows the specific configuration for the selected Bill Cycle.
- **Bill Cycle List:** lists the bill cycle schedules of the current bill cycle.

Defining Time of Use Mapping Options

Time of Use Groups

Understanding Time of Use Groups

Time of Use (TOU) Groups are groups of TOUs that are associated to TOU templates that limit the TOUs available for use in a TOU schedule. These TOUs will be available as the default, holiday, and schedule TOUs within the template.

Each TOU in the group is given a priority. The priority is important in a few ways:

- The [TOU Overlay](#) 360 Degree zone uses these priorities to decide which TOUs will be rendered as a unique shade and which will fall into a category of "other" when the maximum number of distinct TOUs to graph has been reached.
- These priorities are available for use in customized logic.

Configuring Time of Use Groups

This portal is used to display and maintain a TOU Group.

Refer to [Understanding Time of Use Groups](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **TOU Group**.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Group List:** This zone lists all TOU Group records. Broadcast a record to display the details of the selected record.
- **TOU Group:** This zone provides information about the selected TOU Group.

Time of Use Map Templates

Understanding Time of Use Map Templates

Every TOU map references a TOU map template that defines the rules for generating TOU data from that TOU map. Specifically, TOU map templates define:

- The TOU group (defines the valid TOU periods for the template) used for the TOU map
- The default TOU period used for periods not explicitly defined. (This means you don't have to specify dates and times for all periods. For example, if your default TOU period is "Off Peak" you only need to define dates and days and times for On Peak or other TOU periods.)
- The specific date ranges, days of the week, and time periods designated for each TOU period.

The system periodically generates TOU map data for TOU maps by interpreting the rules defined template.

Attributes used to define TOU map templates include the following:

- **TOU Group:** the TOU group used by the map template Default TOU: the default TOU for the map template (from the TOU Group). This is the TOU used when creating TOU map data for dates not accounted for in the TOU Schedules section.
- **Work Calendar:** the work calendar used to identify holidays. On each holiday the Holiday TOU will be used. For additional information see [Defining Work Calendar](#) in the Oracle Utilities Application Framework *Administrative User Guide*.
- **Holiday TOU:** the TOU used for holidays (from the TOU Group)
- **Holiday Template:** the TOU map template used for holidays (if applicable)
- **Interval Size:** the size of the intervals for TOU map data created from the map template, represented as hours:minutes:seconds (HH:MI:SS).
- **TOU Schedules:** date ranges (including month, day, and time ranges) and which TOU periods apply to each

Refer to [Understanding Referencing Master Data by Identifiers](#) for information on how admin configuration can reference a TOU map by a TOU template to ease migration of data between environments.

TOU Map Template Interval Size

TOU map templates can also specify an interval size (in seconds-per-interval, or SPI). This value specifies the duration of the individual TOU map data records, and also controls the values allowed in the Start and End Times. For example, if a TOU map template sets the interval size at 15 minutes, Start and End times must be in units of the interval size (10:00, 10:15, 10:30, etc.).

A TOU map template can be used to generate TOU map data for TOU maps whose SPI is divisible by the template's SPI. For example, a 60 minute template can be used to generate TOU data for TOU maps with SPIs of 60 minutes, 15 minutes, 5 minutes, etc. This means separate map templates are not needed for every SPI.

Holidays

Many utilities categorize consumption on holidays differently than on the day of week on which the holiday falls. For example, holiday consumption might be categorized as Off-Peak regardless of the day it falls on. TOU map templates can define rules for different TOU periods for holidays in two ways. Both options require that the template references a Work Calendar that identifies each of the holidays throughout the year. In addition they require either:

- A Holiday TOU that will be used for each holiday for the duration of that holiday (e.g. Off Peak)
- A Holiday TOU Map Template that defines the TOUs that should be used for holidays that fall during different seasons within the year (e.g. Off Peak Summer, Off Peak Winter)

Important Time of Use Template System Events

The time of use template supports the following business object algorithm system events:

- **Derive TOU:** receives a date time and determines the TOU code for that date time based on the configuration of the time of use template schedule. See the Derive Time Of Use For Date Time (D2-DERTOU-DT) algorithm type as an example.

Configuring Time of Use Map Templates

This portal is used to display and maintain a TOU Map Templates.

Refer to [Understanding Time of Use Map Templates](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **TOU Map Template**.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Map Template List:** This zone lists all TOU Map Template records. Broadcast a record to display the details of the selected record.
- **TOU Map Template:** This zone provides information about the selected TOU Map Template.

Time of Use Map Types

Understanding Time of Use Map Types

TOU Map Types define important properties of TOU maps of the type, including the interval size and the valid TOU map templates.

Attributes used to define TOU map types include the following:

- **Time Zone:** the time zone to be used when generating the TOU map data. Refer to [Multiple Time Zone Support](#) for more information about how time zones impact TOU map data in multiple time zone environments.
- **Interval Size:** the size of the intervals for TOU map data created from maps of this type, represented as hours:minutes:seconds (HH:MI:SS). The interval size cannot be larger than the interval size defined on the Default TOU Map Template or any of the Override TOU Map Templates.
- **Default TOU Map Template:** the default TOU map template used by maps of this type
- **Override TOU Map Templates:** one or more TOU map templates that can be used as an override on TOU maps of this type.

TOU Map Type Interval Size

The SPI of a TOU map must divide evenly into the SPI of any measuring component that uses the map (because the system joins the date/time of the measurement to the date/time of the TOU data). This means that it is possible to use a 15 minute TOU map with a 60 minute measuring component. However, it is not OK to have a 60 minute TOU map used with a 15 minute measuring component because the join will miss 3 out of 4 measurements.

However, it is important to note that the TOU mapping process is at its most efficient when the measurement data that is being mapped is of the same interval size as the TOU schedule it is being mapped against. When there are

differences in the interval size the process must first convert the measurement data into the appropriate interval size for the TOU Map prior to applying the TOU Map.

This means that for each TOU Map Template you should have sufficient TOU Map Types to cover the various interval sizes that will be supported by your measurement data. For example, if you have measuring components with interval sizes of 15 minutes, 30 minutes, and 60 minutes then for each TOU Map Template there should be TOU Map Types with interval sizes of 15 minutes, 30 minutes, and 60 minutes.

Default and Override TOU Map Templates

While most TOU maps will use the TOU map template defined on the TOU map type, TOU maps also support a fallback/override pattern used in other areas of the system.

- A TOU map's TOU map type defines the default (or "fallback") TOU map template that's used to generate its TOU data.
- A TOU map's type defines the TOU map templates that can be referenced on individual TOU maps to override the "fallback" template.
- An individual TOU map can have an override template. If the TOU map doesn't have an override template, the fallback template defined on the TOU map type is used to generate the map's TOU data.

Important Time of Use Map System Events

The TOU Map business object that is associated to a given TOU map type supports a special system event that is used in the generation of TOU map data:

- **Create TOU Map Data:** receives a date range and for that date range it will create the appropriate TOU map data for the TOU map. See the Create TOU Map Data (D2-CRETMD-CT) algorithm type as an example.

Configuring Time of Use Map Types

This portal is used to display and maintain a TOU Map Types.

Refer to [Understanding Time of Use Map Types](#) for more information.

You can access the portal by selecting **Admin**, then **Usage**, then **TOU Map Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **TOU Map Type List:** This zone lists all TOU Type records. Broadcast a record to display the details of the selected record.
- **TOU Map Type:** This zone provides information about the selected TOU Map Type.

Defining Communications Options

Device Event Types

Understanding Device Event Types

Device Events

Device event types define properties common to specific types of events.

Device event types represent different types of events that can take place relative to a device. Examples of device events include power outages, power restoration, tampering alerts, and other events.

Device event types can be defined by the following attributes:

- **Standard Event Name:** the "standard" name of the event type. Device vendors may have their own specific names for device events. Only a single active device event type may be mapped to a given standard name at any time.
- **Device Event Category:** a category (defined as an Extendable Lookup) used to group device event types.
- **Reporting Category:** a category used to group device event types for reporting purposes.
- **Activity Type:** the activity type for activities created for device events of this type.

Device Event Mapping

The first step to device event type configuration is defining the list of standard event names that will be processed by the system. This is done by populating the Standard Event Name extendable lookup (D1-StdEventNameLookup). More information about this extendable lookup can be found in [About Device Events](#).

With the fully defined list of Standard Event Names each head-end specific event name (which is also called an external event name) that the system will receive from a given head-end should be mapped to a standard event name. This mapping is configured using a device event mapping extendable lookup. Each head-end system should have its own extendable lookup to define event name mapping in order to prevent possible conflicts between mappings. Each of these business objects should be defined as a child of the parent business object Device Event Mapping (D1-DeviceEventMappingLookup).

For example, head-end systems A and B might both use the same event name, such as the code "1", but this event might need to be mapped to "outage" for head-end system A but "tamper" for head-end system B.

The device event mapping extendable lookup business object is configurable. Each Oracle Utilities Smart Grid Gateway adapter includes a device event mapping lookup business object for the supported head-end system.

Lastly, each device event type is associated to a standard name. This means that as each device event that is received will go through the following mapping steps:

1. The head end specific event name is mapped to a standard event name using the head end specific device event mapping extendable lookup
2. The standard event name is mapped to a device event type
3. The device event type is used to select the appropriate device event business object

Device Event - Additional Processing

Certain device event business objects can be used to update master data as a result of device events received into the system. For example, when a utility's field worker arms a meter, the resulting device event can trigger an update to the device's arming status in the Oracle Utilities application. This processing is initiated by the Execute - Additional Processing system event

algorithm during the Additional Processing status of the business object's lifecycle.

The following base package business objects are configured to execute additional processing:

If a standard device event requires additional processing, the algorithms that execute the processing should be specified in the Additional Processing Algorithms list on the Standard Event Name extendable lookup for the event. The base package includes the additional processing algorithm Arm Meter (D1-ARM-METER).

Only a subset of base package device event business objects are configured to execute additional processing

Description	Business Object Name
Device Event Communication Response	D1-DeviceEventComResp
Standard Device Event	D1-StandardDeviceEvent

If additional processing is required for any business objects not listed above it can easily be added by configuring the algorithm Executer - Additional Processing System Event (D1-EXTADDDPRC) in the Additional Processing status.

Reader Remarks

Reader remark types define properties common to specific types of reader remarks.

Reader remarks are a type of device event used to capture and/or record specific events or circumstances encountered when a meter reader is manually reading scalar meters. Reader remark types represent the different types of remarks that meter readers can record. Examples of reader remark types include evidence of tampering, broken seals, damaged meter, dog on premises, and other notices.

When creating a new device type there are the following options:

Name	Details	Business Object
Reader Remark Type	Provides the configuration for a reader remark type	D1-ReaderRemarkType

Field Activity Remarks

Field activity remark types define properties common to specific types of field activity remarks.

Field activity remarks are a type of device event used to capture and/or record specific events or circumstances encountered when a field worker is performing field work at a service point. Field activity remarks represent can represent situations that are found as well as actions that were taken in the field.

When creating a new device type there are the following options:

Name	Details	Business Object
Device Field Remark Type	Provides the configuration for a field activity remark type	D1-DeviceFieldRemarkType

Configuring Device Event Types

This portal is used to display and maintain a Device Event Type.

Refer to [Understanding Device Event Types](#) for more information.

You can access the portal by selecting **Admin**, then **Communication**, then **Device Event Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Device Event Type List:** This zone lists all Device Event Type records. Broadcast a record to display the details of the selected record.
- **Device Event Type:** This zone provides information about the selected Device Event Type.

Activity Types

Understanding Activity Types

Activities are records of a communication or event related to a device, measuring component, service point or other entity in the system. Examples of activities include smart meter command request, field activities, meter read downloads (for manually read meters) or the combined event of a "last gasp" and "power up" message sent by devices when they detects they experience an outage.

Each type of activity is assigned to an activity type category, please refer to [About Activities](#) for more information about the activity type categories supported by base product.

Activities Orchestrate Communication

Certain types of activities such as request orchestrators, field activities, and command requests coordinate a large number of child transactions that represent the communication to and from an external application. The following diagram depicts a two-way communication with an external system:

Each object in the sequence diagram has a distinct set of duties within the context of the communication:

- **Orchestrating Activity:** controls the overall intent of the communication. For example it may "Start Service" which would include initiating one-to-many specific activities to install the meter and begin the flow of the metered commodity to the service point.
- **Specific Activity:** can be initiated from an orchestrating activity or directly. These activities represent a single task to be carried out such as installing a meter or a remote disconnect smart meter command.
- **Communication Out:** orchestrates the communication to the external application and provides robust handling for any errors that might occur during that communication.
- **Outbound Message:** represents the message payload sent to the external system and the synchronous response.
- **Communication In:** orchestrates the handling of an asynchronous or unsolicited response from an external system.
- **Completion Event:** carries out the results of the communication. For example, in the case of a remote connect it would create the appropriate on off history entry for the device's installation event.

The following diagram involves many of the same objects but instead represents a one-way communication with an external system. All objects maintain the same duties described above with the addition of the communication out handling the synchronous response which contains the result of the message.

Important Activity Type System Events

The activity type supports several business object algorithm system events that relate to calculating the consumption for measuring components of that type:

- **Customer-Device Compatibility:** receives information about the activity being analyzed and returns an indication of whether the customer and device are compatible. This system event is primarily used in service order management. See algorithm type Ensure Device-Usage Calculation Group Compatibility (D2-ENSDVCCMP) as an example.
- **Override Device / Task:** receives information about the activity such as whether the device is installed at a service point, whether the service point is connected, where it is disconnected (if applicable), and the installation event status override. Based on those inputs it should determine the output device configuration type as well as the field activity business object and field task type. This system event is primarily used in service order management. See algorithm type Evaluate Smart Meter Opt-Out for Device Installation (D2-EVSMOPDV) as an example.

Service Order Activity and Service Order Field Activity Types and Divisions

Service order activity types and service order field activity types can specify a Division, to represent the specific operating company associated with activities of that type. If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", users can only access service order activities or service order field activities with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

Note: In Oracle Utilities Customer to Meter, the **Control By CIS Division** setting on the **Main** tab on the **Installation Options** portal is used to restrict data access based on divisions.

See [Understanding Divisions](#) for more information about divisions.

Activity Type Maintenance Category

Activity types can be assigned an Activity Type Maintenance Category to specify that they should be maintained using the [SOM Activity Type](#) portal rather than the standard [Activity Type](#) portal. This option is used with the following categories of activity types:

- Field Activity Types
- Non-Dispatchable Activity Types
- Orchestration Maintenance Types
- Request Orchestration Types

Assigning activity types to the "Service Order Management Activity Type" Activity Type Maintenance Category is done via the Activity Type Maintenance Category business object option on the appropriate activity type business objects.

Configuring Activity Types

You use the **Activity Type** portal to view and maintain activity types.

Refer to [Understanding Activity Types](#) for more information.

You can access the portal by selecting **Admin, Communication, Activity Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured activity types as well activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Field Task By Device Condition:** This zone is used to configure field tasks such as Turn On Device or Turn Off Device, based on the device condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Update Device \(D1-UPDDVC\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

- **Field Task By Service Point Condition:** This zone is used to configure field tasks such as "Install Device" or "Connect SP", based the service point condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Create Specific Activity \(D1-CRSPACT\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

Configuring Service Order Management Activity Types

You use the **SOM Activity Type** portal to view and maintain activity types whose business object has the Activity Type Maintenance Category business object option set to DISO (Service Order Management Activity Type).

Refer to [Understanding Activity Types](#) for more information.

You can access the portal by selecting **Admin, Communication, SOM Activity Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured service order management activity types as well activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Field Task By Device Condition:** This zone is used to configure field tasks such as Turn On Device or Turn Off Device, based on the device condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Update Device \(D1-UPDDVC\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes" , only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

- **Field Task By Service Point Condition:** This zone is used to configure field tasks such as "Install Device" or "Connect SP", based the service point condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Create Specific Activity \(D1-CRSPACT\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

Communication Types

Understanding Communication Types

Communication types define properties common to a specific type of communication. This single admin object covers both communication in and communication out types.

Communication types include types of communications between an application and an external system such as a head-end system or the work management system. These are outbound communications such as smart meter command requests or field activities as well as inbound communications such as a message response that indicates the results of a request.

Communication types typically provide configuration around exception handling:

- **To Do Type and Role:** identifies the To Do to be created when an error is encountered
- **Retry Frequency:** defines how often the communication should be retried. As many errors can be due to connectivity the ability to retry provides automatic resolution.
- **Maximum Retries:** provides an upper limit to the number of times a communication can be re-attempted
- Each communication type can have its own unique set of fields, please refer to the embedded help for that communication type for more details on those fields.

Configuring Communication Types

This portal is used to display and maintain a Communication Type.

Refer to [Understanding Communication Types](#) for more information.

You can access the portal by selecting **Admin**, then **Communication**, then **Communication Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Communication Type List:** This zone works differently than the typical zone that list types in that it displays both those communication types that have been configured as well as those communication types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Communication Type:** This zone provides information about the selected Communication Type

Service Task Types

Understanding Service Task Types

Service tasks types define properties common to specific types of service tasks.

Service task types represent types of tasks that can be performed by users of other Oracle Utilities applications, such as Oracle Utilities Customer Self Service or Oracle Utilities Network Management System. Examples of service tasks include self service meter reads, in which users enter their own meter reads via the Customer Self Service application, and service issue monitor types used when determining if service investigation is needed for a service point.

When creating a new record, the following options are available:

Name	Details	Business Object
Service Issue Monitor Type	The service issue monitor type defines the parameters for when a service investigative order should be created. It can also optionally define the completion parameters for that indicate the investigative order was successful in its purpose.	D1-ServiceIssueMonitorType
Self-Service Rate Compare Scenario Request Type	A simple description of a rate compare scenario request type.	D2-RateCompareScenarioRqstType
Self-Service Meter Read Task Type	Provides the default settings for meter reads created through self service.	D2-SSMeterReadTaskType

Configuring Service Task Types

This portal is used to display and maintain a Service Task Type.

Refer to [Understanding Service Task Types](#) for more information.

You can access the portal by selecting **Admin**, then **Customer**, then **Service Task Type**

The following zones may appear as part of the portal's **Main** tab page:

- **Service Task Type List:** This zone lists all Service Task Type records. Broadcast a record to display the details of the selected record.
- **Service Task Type:** This zone provides information about the selected Service Task Type.

Smart Grid Gateway Adapters

Oracle Utilities Smart Grid Gateway (SGG) Adapters support communication with various third-party head end systems to provide the following functionality:

- **Payload Processing:** Receiving usage and device event payloads from the head end system (also referred to as Measurement Data and Device Event Loading and Processing)
- **Smart Meter Command Processing:** Sending/receiving messages to/from third-party applications to initiate smart meter commands from Smart Grid Gateway

Smart Grid Gateway Implementations

Oracle Utilities Smart Grid Gateway Adapters can be implemented in one of two manners:

- **Middleware Implementations** use Oracle Service Bus (OSB) for payload processing and Oracle Business Process Execution Language (BPEL) to communicate with head end systems when initiating smart meter commands. Middleware implementations can be used **only** with on-premises implementations of Oracle Utilities Smart Grid Gateway.
- **Native Implementations** use batch processing for payload processing, and specific communication business objects to communicate with head end systems when initiating smart meter commands. Native implementations can be used with **either** on-premises implementations of Oracle Utilities Smart Grid Gateway, or with Oracle Utilities cloud services such as Oracle Utilities Meter Solution Cloud Service or Oracle Utilities Customer Cloud Service.

The following sections provide details about each type of implementation.

Smart Grid Gateway Adapter Middleware Implementations

Note: Unless otherwise noted, the contents of this section apply to middleware (on-premises) implementations of Oracle Utilities Smart Grid Gateway only, and do NOT apply to native implementations or Oracle Utilities cloud services. See [Smart Grid Gateway Adapter Native Implementations](#) for more information about Smart Grid Gateway Adapter native implementations and implementing Smart Grid Gateway adapters with Oracle Utilities cloud services.

Oracle Utilities Smart Grid Gateway (SGG) Adapters support communication with various third-party head-end systems. Smart Grid Gateway uses Oracle Service Bus (OSB) and Oracle Business Process Execution Language (BPEL) to facilitate communication with the head-end systems. Most if not all of the functionality shown below is available in each SGG Adapter.

Measurement Data and Device Event Loading: Data parsing and transformation via Oracle Service Bus from head-end system format into the Oracle Utilities Service and Measurement Data Foundation unified format for measurement data and device events.

Measurement Data and Device Event Processing: Configurable mapping for head-end system status codes and device event names to Oracle Utilities Service and Measurement Data Foundation standard values.

Smart Meter Command Processing: Sending/receiving messages to/from third-party applications to initiate smart meter commands from SGG. Most head-end systems support the following types of commands and communications:

- **Device Status Check:** Business objects and BPEL processes to support issuing device status check commands.
- **Meter Commissioning:** Business objects and BPEL processes to support issuing meter commissioning commands (including registration and installation commands).
- **Meter Decommissioning:** Business objects and BPEL processes to support issuing meter decommissioning commands.
- **Meter Retirement:** Business objects and BPEL processes to support issuing meter retire (deregistration) commands.
- **On-Demand Read:** Business objects and BPEL processes to support issuing on-demand read commands.
- **Remote Connect:** Business objects and BPEL processes to support issuing remote connect commands.
- **Remote Disconnect:** Business objects and BPEL processes to support issuing remote disconnect commands.

This information in this guide describes how to configure, extend, and test the Smart Grid Gateway Adapters for individual head-end systems. The following head-end systems each have a specific SGG Adapter that can be configured: Itron OpenWay, Landis+Gyr, Networked Energy Services, MV90 for Itron, Sensus RNI, and Silver

Spring Networks. Customers also can create their own customized adapter for using Smart Grid Gateway with a specific head-end system. See [Creating a Custom Adapter for Smart Grid Gateway](#) for more information.

Configuring Smart Grid Gateway Adapters

This section describes how to configure Oracle Utilities Smart Grid Gateway Adapters for each supported head-end system. Use the cross-references below to go to the adapter of interest.

[Itron OpenWay](#)

[Landis+Gyr](#)

[Networked Energy Services](#)

[MV90 for Itron](#)

[Sensus RNI](#)

[Silver Spring Networks](#)

Note: This section applies to middleware (on-premises) implementations of Oracle Utilities Smart Grid Gateway only. This section does NOT apply to native implementations or Oracle Utilities cloud services. See [Smart Grid Gateway Adapter Native Implementations](#) for more information about Smart Grid Gateway Adapter native implementations and implementing Smart Grid Gateway adapters with Oracle Utilities cloud services.

Itron OpenWay

The Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay supports communication with the Itron OpenWay application, including measurement data and device event loading, and command messaging in support of commissioning, connect, disconnect, decommissioning, status check, and on-demand read commands. The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Versions	7.0 Itron OpenWay Operations Center SR 5.3, 5.4
Protocol	Proprietary
Market(s)	Worldwide
Architecture	RF Mesh

Itron OpenWay Adapter Processing

This section provides details concerning the OSB processing, BPEL Processes, and Oracle Utilities Application Framework (OUAF) objects that are supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway (SGG) service format. Payloads contain measurements and meter events in some head-end specific format. OSB then places each service call into a Java Message Service (JMS) queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel. A service then creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Measurement and device event data must be requested from the Itron OpenWay head-end system via Scheduled Read commands. See [Scheduled Read Commands](#) on page 715 for more information.

Scheduled Read Commands

Note: This section applies to **both** middleware and native implementations of the Smart Grid Gateway Adapter for Itron OpenWay.

Measurement and device event data must be requested from the Itron OpenWay head-end system via Scheduled Read commands. Schedule read commands are used to request meter reads and/or device events for a group of devices for a specified date and time. Scheduled read commands can be created such that recurring requests based on the same command parameters are sent to the head-end system at regular intervals. For example, a command could be configured to request daily (24 hour) scalar meter readings once per day for a specified group of devices. Another command could be configured to request weekly (168 hours) device events once per week for a group of devices.

Scheduled read commands should be created for all devices from which meter readings and/or device events are to be uploaded via Oracle Utilities Smart Grid Gateway. Separate scheduled read commands can be created for specific groups and for specific types of data. For example, for a given group of scalar devices, you might create separate commands to request scalar usage data and to request device events from the same group (both of which can be based on different recurrence patterns). The specifics concerning request specifics and recurrence patterns should be based on the requirements of the implementation.

Attributes used to define a schedule read command include the following:

- **Status:** the status of the activity
- **Schedule Read Type:** the type of scheduled read
- **Schedule Information:** information about the schedule for the read, including:
 - **One Time Read:** indicates if the request is a one-time request. One-time requests have a defined date/time range during which request and recurrences can take place.
 - **One Time Start Date Time:** specifies the start time for one-time requests (applicable only if **One Time Read** is set to “Yes”)
 - **One Time End Date Time:** specifies the end time for one-time requests (applicable only if **One Time Read** is set to “Yes”)
 - **First Daily Measurement Time:** Indicates starting time for measurements for each day. This field, along with the value from **IMD Length**, will be used to determine when interrogation requests should be made. For example, if the **First Daily Measurement Time** is set to 08:00AM and **IMD Length** is set to 12 hours (12:00:00) then there would be two requests made per day:
 - 8:00AM - 8:00PM
 - 8:00PM - 8:00AM
 - **Interrogation Buffer:** This parameter impacts when interrogation requests are sent. It is entered in the format of hours:minutes:seconds. For example, if set to 1 hour (01:00:00) for our above example, the first request of the day for 8:00AM - 8:00PM would be sent to Itron OpenWay at 7:00PM. The buffer time will decrease if the activity is monitored after 7:00PM, so if the monitor process is executed at 7:30PM the buffer time would only be 30 minutes and if the monitor process were not executed until after 8:00PM there would be no buffer time at all.
 - **IMD Length:** Defines the number of hours, minutes and seconds of data that should be retrieved for each request. It is entered in the format of hours:minutes:seconds. This number must be divisible into 24 since it will determine how many requests will be made per day (i.e. if set to 8 hours (08:00:00) there will be 3 requests per day).
 - **Disable Extended IMD Length Recovery:** By default the schedule read activity will attempt to "catch-up" when interrogation requests have been missed by requesting the entire period from the last interrogation request made. Setting this parameter to "Yes" will turn off this functionality and interrogation requests will only be made in for the exact amount of time defined in the **IMD Length**
 - **Range of Recurrence:** indicates how to define request recurrences. Valid values include “Maximum Recurrence”, “No End Date”, and “Recurrence End Date”
 - **Maximum Recurrence:** The activity will make a set number of requests, once the set number has been reached the activity will expire. When selected, **Maximum Recurrences** must also be provided.
 - **No End Date:** The activity will never expire and will continue to make requests until it is manually transitioned to inactive.

- **Recurrence End Date:** The activity will continue to make requests until a specified date. When selected, **Recurrence End Date Time** must also be provided.

Note: When “No End Data” is selected, the recurrences of the request continue until a user manually changes the status of the command.

- **Maximum Recurrence:** defines the maximum number of recurrences before the command’s status is changed to “Inactive”.
- **Recurrence End Date Time:** The date after which no more recurrences are attempted. After this date and time, the command’s status is changed to “Inactive”.
- **Group:** the group of devices used by requests for the command
 - **Group Type:** indicates the type of device group to use for the command. Valid options include Application Group or Configuration Group.
 - **Application Group/Configuration Group Name:** defines the specific group (based on the group type).

Note: Groups referenced by Scheduled Read commands and the devices that belong to each are defined in Itron OpenWay head-end system. Each group to be used with these commands must also be defined in either the “Itron — Application Group Lookup” or “Asset Specification” extendable lookup. See the Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay Configuration Guide for more information about these extendable lookups.

- **Default Read Parameters:** specifies details concerning the data to be requested. The read parameters define the exact data that will be requested from the meters. Please consult the Itron OpenWay documentation for the specifics of each parameter.
 - **Interrogation Window Hours:** the number of hours used to calculate when to submit requests. For example, to submit requests once per day, this should be set to 24. To submit requests once per week (7 days), this should be set to 168. The current date time (or the Latest Request End Date Time) plus this equals interrogation window end date time.
- **Override Read Parameters:** an alternative set of parameters that can be defined. To leverage this group each parameter must be provided, no parameter is allowed to be left blank. This set of parameters will be used when the request end time is equal to the **First Daily Measurement Time**. For example, a schedule read with a **First Daily Measurement Time** of 12:00AM and an **IMD Length** 12 hours (12:00:00) would make the following requests each day:
 - 12:00AM - 12:00PM
 - 12:00PM - 12:00AM

The **Override Read Parameters** would be used for the 2nd request where the request end time of 12:00AM matches the **First Daily Measurement Time** of 12:00AM. If an extended request is made to "catch up" (i.e. it makes a request that is larger in duration than the configured **IMD Length**), and the request start and request end date time includes the **First Daily Measurement Time** then the **Override Read Parameters** will be used.

- **Outbound Communication Exception Handling Overrides:** parameters used to control retry attempts and expiration for the outbound communication. These parameters take precedence over their outbound communication counterparts
- **Last Read Details:** details concerning the most recent read request sent for the command. This information is used to calculate the time for the next request (based on the **Interrogation Window Hours** parameter).
 - **Latest Request Start Date Time:** the start date and time of the last request
 - **Latest Request End Date Time:** the end date and time of the last request
 - **Recurrence Count:** the number of recurrences of the last request

About Ad Hoc Requests

While scheduled read commands are typically configured to create recurring requests for meter reads and device events, users can also submit ad hoc requests for a specific date and time range based on the parameters of a currently active scheduled read command. This is useful if meter read data or device events are needed before the next request for a command would be submitted based on the command’s recurrence settings.

Ad hoc requests are created as separate one-time request commands, with a start and end time based on parameters supplied by the user when initiating the ad hoc request. The group and read parameters for ad hoc requests are the same as those for the command used to send the ad hoc request.

Error Handling

If errors occur when processing scheduled read commands, errors are logged as follows:

- If there is a single error it will create a single log entry
- If there is more than one error, the log entry will perform a count of devices and create a single error message stating the number of devices that were in error.

Initial Measurements

The usage data received from the AMI head-end system as a file in Itron OpenWay XML format is loaded into Oracle Utilities as initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. **SGG-D8-ITRONXML-BASE** contains components responsible for “actual” processing of incoming data. It should not be modified during configuration. This project can be upgraded without affecting the customization and environment settings added to SGG-D8-ITRONXML-CM.
2. **SGG-D8-ITRONXML-CM** allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-D8-ITRONXML-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
destinationRootElementEvent	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false

Element	Description	Valid Values
filterUsage	Determines if usage should be filtered.	true false
filterRegisterSource	Determines if source register data should be filtered.	true false

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D8-ITRONXML-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue

Parameter	Description	Default Value
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **Itron - UOM Code to Standard UOM Mapping** extendable lookup (D8-HeadendUOMLookup) are passed into the system for processing.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/ or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (DIRT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Itron OpenWay can send real-time events such as meter outage alarms to Oracle Utilities Smart Grid Gateway. These events are referred to as exceptions in the Itron architecture, and are sent to the BPEL ExceptionSubscriberService service by Itron OpenWay without requiring an explicit request from Oracle Utilities Smart Grid Gateway. Exceptions are loaded as device events data and provided to the edge applications.

The required functionality is delivered in the base product as two OSB projects:

1. **SGG-D8-EXCEPTION-BASE** contains components responsible for “actual” processing of incoming data. It should not be modified during configuration. This project can be upgraded without affecting the customization and environment settings added to the SGG-D8-EXCEPTION-CM project.
2. **SGG-D8-EXCEPTION-CM** allows the customization and simplifies the future upgrades.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the device event data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false

Publishing Events

The Itron OpenWay adapter can be configured to publish device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Device Event Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D8-EXCEPTION-CM OSB project are used in publishing device events data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.

- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Device Event Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Device event data is published in the “native” device event data format (the format of the device event seeder business object). This format includes normalized device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: In addition, filtering can NOT be applied to device events published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Events

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **Itron - Device Event Mapping** extendable lookup (D8-DeviceEventMappingLookup) are passed into the system for processing.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (DIRT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D8-EXCEPTION-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

Note: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The Itron OpenWay adapter base package includes the following initial measurement and device event business objects:

Business Object Name	Description
D8-InterrogateByGroup	Itron - Interrogate By Group Performs a Schedule Read for a group of devices (either Application or Configuration) in the Itron OpenWay API.
D8-InterrogateByGroupResult	Itron - Interrogate by Group Result This BO is the inbound asynchronous response to an Interrogate By Group (Schedule Read) outbound communication.
D8-InitialLoadIMDInterval	Itron - Initial Load IMD - Interval Used when loading Itron OpenWay interval measurements into the system for the first time.
D8-InitialLoadIMDScalar	Itron - Initial Load IMD - Scalar Used when loading Itron OpenWay scalar measurements into the system for the first time.
D8-ScheduleRead	Itron - Schedule Read Requests IMD and Event data from the Itron OpenWay Network. This data will later be returned and placed in files to be uploaded.

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related web service from the head-end system. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each Itron OpenWay command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	Itron - Reconnect Meter	Itron - Reconnect Meter Result	Connect Device Completion Event
Remote Disconnect	Itron - Disconnect Meter	Itron - Disconnect Meter Result	Disconnect Device Completion Event
Device Commissioning	Itron - Add Meter Definition		Device Commissioning Completion Event
Device Decommissioning	Itron - Deregister Meter		Device Decommissioning Completion Event
On-Demand Read (Scalar)	Itron - Contingency Read (Scalar)	Itron - Contingency Read Result (Scalar)	Create IMD Completion Event

Command	Outbound Communication	Inbound Communication	Completion Event
On-Demand Read (Interval)	Itron - Contingency Read (Interval)	Itron - Contingency Read Result (Interval)	Create IMD Completion Event
Scheduled Read (Scalar)	Itron - Interrogate by Group (Scalar)	Itron - Interrogate by Group Result (Scalar)	Create IMD Completion Event
Scheduled Read (Interval)	Itron - Interrogate by Group (Interval)	Itron - Interrogate by Group Result (Interval)	Create IMD Completion Event
Device Status Check	Itron - Ping by Endpoints (Status Check)	Itron - Get Ping by Endpoints Result	

Device Communication Base Package Business Objects

The Itron OpenWay Adapter base package includes the following communication business objects:

Business Object Name	Description
D8-AddMeterDefinitions	Itron - Add Meter Definition (Commission)
D8-DeregisterMeter	Itron - Deregister Meter (Decommission)
D8-DetectLoadSideVoltageByMtr	Itron - Detect Load Side Voltage
D8-DetLoadSideVoltageMtrRslt	Itron - Detect Load Side Voltage Result
D8-DisconnectMeter	Itron - Disconnect Meter (Remote Disconnect)
D8-DisconnectMeterResult	Itron - Disconnect Meter Result
D8-PingByEndpoints	Itron - Ping By Endpoints (Device Status Check)
D8-PingByEndpointsMDResponse	Itron - Multi-Device Ping Response
D8-PingByEndpointsMultiDevice	Itron - Ping By Endpoints Multi-Device
D8-PingByEndpointsResponse	Itron - Ping By Endpoints Response
D8-ReadDisconStateByMtr	Itron - Read Disconnect State
D8-ReadDisconStateMtrRslt	Itron - Read Disconnect State Result
D8-ReadInterval	Itron - Contingency Read (Interval)
D8-ReadResult	Itron - Contingency Read Result
D8-ReadScalar	Itron - Contingency Read (Scalar)
D8-ReconnectMeter	Itron - Reconnect Meter (Remote Connect)
D8-ReconnectMeterResult	Itron - Reconnect Meter Result

Itron OpenWay Event Data Mapping

The Itron OpenWay event file format maps as follows into the business object, D1-DeviceEventMappingLookup:

Itron OpenWay Flat File Field	Device Event Seeder BO Element	Comments
Transaction ID (from Header record)	External Source Identifier	This is the file name.
Device Identifier	External Device Identifier	
Event Name	External Event Name	
Event Creation Date/Time	Event Date/Time	
Device Type	External Device Type	This element has no real bearing on the device type within MDM/SGG. Its valid values include (although the element itself is free-form): Meter Collector Router
Service Location ID	External Service Location ID	
Communication Module Serial Number	External Communication Module Identifier	
Event Category ID	External Event Category	
Event Severity	External Event Severity	Valid values include (although the element itself is free-form): Alert Information
Status Value	External Status Value	This represents additional information that relates to the event itself.
Status Date/Time	External Status Date/Time	The date & time at which the additional information referenced above had occurred.

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Outbound Message Types

Acknowledgment and response messages are sent and received validating that commands have been transmitted.

Outbound Message Type	Description
D8ITRECO	D8 Itron Remote Connect

Inbound / Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The Oracle Utilities Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway adapter for Itron OpenWay includes the following inbound web services:

Inbound Web Service	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Used for upload of device events. The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event. If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.
D1-DeviceStatusCheck	Device Status Check This service is invoked by the integration layer to instantiate a Device Status Check command.
D1-InitialLoadIMD	Used by OSB to instantiate an IMD The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.
D1-RemoteConnect	Remote Connect This service is invoked by the integration layer to instantiate a Remote Connect command.

Inbound Web Service	Description
D1-RemoteDisconnect	Remote Disconnect This service is invoked by the integration layer to instantiate a Remote Disconnect command.
D8-DetLoadSideVoltageMtrRslt	Itron - Detect Load Side Voltage by Meter Result
D8-DisconnectMeterResult	Itron - Disconnect Meter Result Service
D8-InterrogateByGroupResult	Itron - Interrogate By Group Result XIA
D8-PingByEndpointsMDResponse	Itron - Ping By Endpoints Multi-Device Response XAI Inbound
D8-PingByEndpointsResponse	Itron - Ping By End Response inbound web service
D8-ReadDisconStateMtrRslt	Itron - Read Disconnect State by Meter Result Service
D8-ReadResult	Itron - Contingency Read Result
D8-ReconnectMeterResult	Itron - Reconnect Meter Result Service

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

The Oracle Utilities Smart Grid Gateway adapter for Itron OpenWay includes the following message senders:

Message Sender	Description
D8-RemoteCon	D8 Remote Connect

BPEL Processes

These processes are responsible for performing the conversion from Oracle Utilities format to Itron OpenWay format, invoking process callouts and invoking the remote endpoint to trigger the device events. BPEL modules are divided into “Composites,” or collections of business logic.

OnDemandRead Composite Process — The OnDemandRead composite invokes a sequence of web methods that call the head-end system to retrieve meter reading data and send it back to the OUAF layer. In the case of Itron OpenWay, this is accomplished using the ContingencyReadByEndpoints/GetContingencyReadByEndpointsResult services defined in the Data service WSDL.

ConnectDisconnect Composite Process — This composite is responsible for triggering the Connect and Disconnect events on the head-end system. A second, asynchronous reply sends the results back into the OUAF layer when the head-end system signals a change in the status of the device. The Itron OpenWay Adapter uses the ReconnectMeter/GetReconnectMeterResult web service pair to connect, and the DisconnectMeter/GetDisconnectMeterResult web service pair to disconnect. Each of these services is defined in the Control service WSDL.

CommissionDecommission Composite Process — Commissioning and Decommissioning of devices, sometimes referred to as “Provisioning,” is handled by the CommissionDecommission composite. Commissioning invokes the AddMeterDefinitions web service and Decommissioning uses the DeregisterMeters web service. Both are defined in the Provisioning service.

DeviceStatusCheck Composite — This composite uses the PingByEndpoints and GetPingByEndpointsResult web services to check the health of a device. These Itron OpenWay services are defined in the Control.Diagnostic service.

Common Composite — The Common composite contains three main classes of operations: Proxies, ProcessCallouts, and utility functions. Proxies are usually simple mediators that forward a web service call to a preset endpoint. In this Adapter they have two additional roles. First, they interrogate a composite property and determine whether the supported version of head-end software is 3.70 or 3.90. Some of the proxies will also append the callback URL for the StatusChanged service. Proxies are convenient because they allow head-end URLs and security to be set in a single composite. In this case, they also offer a common location to make these checks. ProcessCallouts are points of customization which allow users to modify data and/or initiate some external business process. Utility functions serve as a central location for business logic needed by multiple composites.

Web Services

The following web services are all defined in the Itron OpenWay head-end system:

- **CommissionDecommissionService**
 - **BPEL Process:** CommissionDecommission
 - **Operation:** AddMeterDefinitions
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/CommissionDecommission/CommissionDecommissionService
- **CommissionDecommissionService**
 - **BPEL Process:** CommissionDecommission
 - **Operation:** DeregisterMeters
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/CommissionDecommission/CommissionDecommissionService
- **ConnectDisconnectService**
 - **BPEL Process:** ConnectDisconnect
 - **Operation:** ReconnectMeter
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/ConnectDisconnect/ConnectDisconnectService
- **ConnectDisconnectService**
 - **BPEL Process:** ConnectDisconnect
 - **Operation:** DisconnectMeter
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/ConnectDisconnect/ConnectDisconnectService
- **DeviceStatusCheckService**
 - **BPEL Process:** DeviceStatusCheck
 - **Operation:** DeviceStatusCheck
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/DeviceStatusCheck/DeviceStatusCheckService
- **OnDemandReadService**
 - **BPEL Process:** OnDemandRead
 - **Operation:** ContingencyReadByEndpoints
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/<EM_PARTITION>/OnDemandRead/OnDemandReadService

Itron OpenWay Web Services

The following table describes Itron OpenWay web services and operations used for the Oracle Utilities Smart Grid Gateway command messaging:

Smart Grid Gateway Command	AMI Adapter Business Objects	Itron OpenWay Web Services	Itron OpenWay Operations
Device Commissioning	D8-AddMeterDefinitions	ProvisioningService	AddMeterDefinitions
Device Decommissioning	D8-DeregisterMeter	ProvisioningService	DeregisterMeters
Remote Connect	D8-ReconnectMeter	ControlService	ReconnectMeter
	D8-DetectLoadSideVoltageByMtr	DiagnosticService	DetectLoadSideVoltageByMeter
	D8-ReadDisconStateByMtr		ReadDisconnectStateByMeters
Remote Disconnect	D8-DisconnectMeter	ControlService	DisconnectMeter
Device Status Check	D8-PingByEndpoints	ControlService	PingByEndpoints
			GetPingByEndpointsResult
On-Demand Read	D8-ReadInterval	DataService	ContingencyReadByEndpoints
	D8-ReadScalar		GetContingencyReadByEndpointsResult
	D1-InitialLoadIMD		InterrogateByGroup
	D1-DeviceEventSeeder		GetInterrogateByGroupResult
		DataSubscriberService (Async Response)	DataArrived
Event Loading	D1-DeviceEventSeeder	ExceptionSubscriberService	ExceptionsArrived

Configuring an Itron OpenWay Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay to communicate with the Itron OpenWay application.

Master Configurations

Master Configurations are sources of global parameter records used by a system implementation. This section describes the master configuration that is specific to Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay. Refer to the Oracle Utilities Meter Data Management / Smart Grid Gateway documentation for more information about other master configurations used by Oracle Utilities Smart Grid Gateway.

Itron Version Master Configuration

This master configuration specifies the version of the Itron head-end system with which the system is communicating. The configuration options are Itron OpenWay 3.70, Itron OpenWay 3.90, and Itron OpenWay 6.10. Only one version can be specified at a time.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the Itron OpenWay application in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Device Event Seeder
D1-DeviceStatusCheck	Device Status Check
D1-InitialLoadIMD	Used by OSB to instantiate an IMD
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
D8-DetLoadSideVoltageMtrRslt	Itron - Detect Load Side Voltage by Meter Result
D8-DisconnectMeterResult	Disconnect Meter Result Service
D8-InterrogateByGroupResult	Itron - Interrogate By Group Result
D8-PingByEndpointsMDResponse	Itron - Ping By Endpoints Multi-Device Response XAI Inbound
D8-PingByEndpointsResponse	Itron - Ping By Endpoints Response inbound web service
D8-ReadDisconStateMtrRslt	Itron - Read Disconnect State by Meter Result Service
D8-ReadResult	Itron - Contingency Read Result
D8-ReconnectMeterResult	Itron - Reconnect Meter Result Service

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests. A message sender should be configured for each command.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
D8-ITRON_IBG	Itron Interrogate By Group
D8-COMM	Itron Commission
D8-DCOMM	Itron Decommission
D8-DLSV	Itron Detect Load Side Voltage
D8-IPBE	Itron Ping By Endpoints
D8-RCONN	Itron Remote Connect
D8-RDCONN	Itron Remote Disconnect
D8-RDSS	Itron Read Disconnect State

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction:http://xmlns.oracle.com/ouaf/Itron/<OPERATION>
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Itron/<SERVICE>
- where:
 - <OPERATION>: the operation performed by the message sender (see Operation column in the table above)
 - <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
 - <PASSWORD>: the password used to log into WebLogic Enterprise Manager
 - <EM_SERVER>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
 - <EM_SERVER_PORT>: the port where the WebLogic Enterprise Manager is installed
 - <SERVICE>: the service invoked by the message sender (see Service column in the table above)

How to Use Enterprise Manager to Locate the URL for the Message Sender

Follow this procedure to find the correct URL for the command associated with a message sender:

1. Open Enterprise Manager and use the navigation pane to open the dashboard of the service used by the message sender:
2. The top bar of the dashboard contains several buttons and icons. One of these is a “world” icon with a puzzle piece over it. Click this icon to display a list of the WSDLs and endpoint URIs for the service:
3. Click the service’s WSDL URL link to see the WSDL in the browser, or right click and save it to your machine.

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
D8-CONREAD	Itron Contingency Read By Endpoints
D8-INTRGRP	Itron Interrogate By Group
D8-COMM	Itron Commission
D8-DCOMM	Itron Decommission
D8-DSC	Itron Device Status Check
D8-DSCMD	Itron Device Status Check Multi Device
D8-DLSV	Itron Detect Load Side Voltage
D8-RCOONN	Itron Remote Connect
D8-RDCONN	Itron Remote Disconnect
D8-RDSS	Itron Read Disconnect State

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the Itron OpenWay head end must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - Itron OpenWay:

- **External System:** Itron OpenWay
- **Description:** Itron OpenWay
- **Outbound Message Types:**

Outbound Message Type	Message Sender
D8-INTRGRP	D8-ITRON_IBG
D8-COMM	D8-COMM
D8-DCOMM	D8-DCOMM

Outbound Message Type	Message Sender
D8-DSC	Message sender associated with the Device Status Check Outbound Message Type
D8-DSCMD	Message sender associated with the Device Status Check Multi Device Outbound Message Type
D8-DLSV	D8-DLSV
D8-RCONN	D8-RCONN
D8-RDCONN	D8-RDCONN
D8-RDSS	D8-RDSS

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D8-Request.xsl
- **Response XSL:** D8-Response.xsl

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the Itron OpenWay head end must be present in your system. If this are not present in your configuration, add it. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about creating service providers.

Service Provider - Itron OpenWay:

- **Service Provider:** Itron OpenWay
- **Description:** Itron OpenWay
- **External Reference ID:** Itron OpenWay
- **External System:** Itron OpenWay
- **Our Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **Pre-Commissioning Device ID Type:**
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the Itron OpenWay service provider. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

UOM Translation

UOM mapping processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the Itron OpenWay service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1-HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	D8-AddMeterDefinitions	Commission
Device Decommission	Device Removal	D8-DeregisterMeter	Decommission
Device Status Check	Device Status Check	D8-PingByEndpoints	Device Status Check
Load Check*	Load Check	D8-DetectLoadSideVoltageByMtr	Detect Load Side Voltage by Meter
Multi-Devie Status Check	Multi-Devie Status Check	D8-PingByEndpointsMultiDevice	Read Disconnect State By Meters
On-Demand Read (Scalar)	On-Demand Read (Scalar)	D8-ReadScalar	On Demand Read — Scalar
Remote Connect	Remote Connect	D8-ReconnectMeter	Connect
Remote Disconnect	Remote Disconnect	D8-DisconnectMeter	Disconnect

* The Load Check processing method can be used to ensure that it is safe to connect a meter. The load check processing method is executed during the Connection Ready state of the Remote Connect activity and can be configured to detect the possibility of a load side voltage at the meter, or to check the disconnect meter switch on the meter.

If the Read Disconnect State business object is used as the processing method, you should configure the disconnect switch state values that indicate the state of the switch. These values are defined on the D8-DisconnectSwitchStateLookup extendable lookup, and are then added in the Disconnect Switch State Error Values

section of the Itron - Read Disconnect State Result Inbound communication type. See [Itron OpenWay Disconnect Switch State Lookup](#) for more information.

Configuring Endpoint URIs

Part of the configuration process is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands. The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head-end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoint URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The Itron OpenWay endpoint override DVM (D8-EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the Itron OpenWay adapter and the command used with each:

DVM Key	Commands
DataService390	Scheduled Read (Scalar)
	Scheduled Read (Interval)
	On-Demand Read (Scalar)
	On-Demand Read (Interval)
ProvisioningService370	Device Commissioning
ProvisioningService390	Device Decommissioning
ControlService370	Device Status Check (if using v3.70)
	Remote Connect (if using v3.70)
	Remote Disconnect (if using v3.70)
ControlService390	Remote Connect (if using v3.90)
	Remote Disconnect (if using v3.90)
DiagnosticService390	Device Status Check (if using v3.90)
ProcessCallout	User Exit Functions

Note:

The numbers in the keys above (370 and 390) designate the version of the Itron OpenWay head-end system.

Only a single version of each key should be defined, based on the version of the Itron OpenWay head-end system

To define an override Endpoint URI for the Itron OpenWay adapter, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is <http://server:port/soa/composer>.

2. Select the D8-EndpointOverrides.dvm in the left panel.

- In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
- In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list. The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.
4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:
 - **key**: The DVM key for the Endpoint URI you wish to define (see the table above).
 - **EndpointURI**: The override Endpoint URI.
6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.
8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Itron OpenWay Extendable Lookups

Note: This section applies to **both** middleware and native implementations of the Smart Grid Gateway Adapter for Itron OpenWay.

This section outlines some of the extendable lookups that must be configured for use with the Itron OpenWay adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Application Group Lookup

The Itron OpenWay head-end system allows users to define addressable groups of meters based on criteria such as a geographic identifier or zip code. These application groups can be represented in Oracle Utilities Smart Grid Gateway by using the Itron OpenWay Application Group Lookup. The groups defined for this lookup are used with Scheduled Read commands. Each value defined for the Itron OpenWay Application Group extendable lookup should include the following:

- **Application Group**: The application group name as defined in the Itron OpenWay head-end system.
- **Description**: A description of the application group.

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system. Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name**: The event name used by the head-end system
- **Description**: A description of the device event
- **Status**: The status of the lookup value (can be Active or Inactive)
- **Standard Event Name**: The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

Disconnect Switch State Lookup

Some utilities may require verification of the load on a meter to ensure that it is safe to connect the meter. One method of doing this is to check the disconnect switch on the meter to see if it is connected or armed. To use this method, the Itron OpenWay Disconnect Switch State extendable lookup should be configured to list the possible states of the meter disconnect switch. Each value defined for the Itron OpenWay Interval Disconnect Switch State extendable lookup should include the following:

- **Switch State:** The Itron OpenWay disconnect switch state code
- **Description:** A description of the disconnect switch state code.

UOM Code to Standard UOM Mapping

Usage received from a utility's head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-End Unit of Measure:** The unit of measure code used by the Itron OpenWay application
- **Description:** A description of the unit of measure code.
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Unit of Measure:** The unit of measure defined in the system.
- **Time of Use:** An optional time of use period, defined in the system, used to further distinguish the unit of measure.
- **Service Quantity Identifier:** An optional service quantity identifier, defined in the system, used to further distinguish the unit of measure.
- **Unit of Measure Magnitude Conversion:**
 - **Magnitude Multiplier:** An optional; multiplier used to convert raw values received from the head-end system to values appropriate for use with the system. For example, if a reading or interval data is received in Wh, a multiplier of ".001" would convert Wh to kWh. If not provided or left blank, no conversion is performed.

Interval Status Code to Condition Mapping

Interval usage received from the Itron OpenWay application can include Itron OpenWay interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The Itron OpenWay Interval Status Code to Condition Mapping extendable lookup is used to determine how to map Itron OpenWay interval status codes to standard status codes when receiving usage from the Itron OpenWay application. Each value defined for the Itron OpenWay Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The Itron OpenWay interval status code
- **Description:** A description of the interval status code.
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.

Other Extendable Lookups

Business Object Name	Description
D8-DvcStatusMappingLookup	Itron - Device Status Lookup
D8-FailureReasonLookup	Itron - Failure Reason Lookup
D8-ItronVersions	Itron - Versions Lookup

Business Object Name	Description
D8-JobStatusLookup	Itron - Job Status
D8-ResultLookup	Itron - Result Lookup
D8-RptSelfReadOptionLookup	Itron - Report Self Read Option Lookup

Using the Itron OpenWay Test Harness

Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay includes a test harness that can be configured to simulate a general head-end system for testing the two-way commands. The test harness includes a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. See [Using Smart Grid Gateway Test Harnesses](#) for more information.

Landis+Gyr

The Oracle Utilities Smart Grid Gateway Adapter for Landis+Gyr supports communication with the Landis+Gyr Gridstream Command Center, including measurement data and device event loading, and command messaging in support of commissioning, connect, disconnect, decommissioning, and on-demand read. The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Version	Gridstream Command Center 7.5, 8.1, 8.4, 8.5
Smart Meter Command Format	MultiSpeak v3.1
Bulk Usage/Event Data Format	California Metering Exchange Protocol (CMEP)
Market(s)	North America, portions of Asia Pacific, Sweden, Australia, New Zealand, and Latin America.
Commodities Supported	Electricity, Gas, Water
Architecture	PLC and RF

Landis+Gyr Adapter Processing

This section provides details concerning the OSB processing, BPEL Processes, and Oracle Utilities Application Framework (OUAF) objects that are supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway (SGG) service format. Payloads contain measurements and meter events in some head-end specific format. OSB then places each service call into a Java Message Service (JMS) queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel. A service then creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Initial Measurements

The usage data exported from the AMI head-end system as a file in Landis+Gyr format is loaded into Oracle Utilities as initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. **SGG-D3-USAGE-BASE** - contains components responsible for “actual” processing of incoming data. It should not be modified during configuration. This can be upgraded without affecting the customization and environment settings added to SGG-D3-USAGE-CM.
2. **SGG-D3-USAGE-CM** allows for customization and simplifies future upgrades.

When importing non-interval usage data, separate initial measurements can be created for difference measurement types. For instance, if the data includes Power Factor or Volt data, separate initial measurements are created for each of these. See [Non-Interval 'Plain' XML to IMD Mapping](#) on page 767 for more information about specific units of measure that trigger the creation of separate initial measurements.

The runtime configuration settings for the SGG-D3-USAGE-CM project are stored in the EnvironmentSettings.xq XQuery file. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRawIMD	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
modifyResultXMLInput	Specifies the name of an XQuery document (without the "xq" extension) used to map additional fields from the "plain" XML format to the result XML format sent as initial measurement data. See Mapping Additional Fields on page 768 for more information.	
dateTimeInUTC	Indicates whether the Landis+Gyr system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device.	true false

Element	Description	Valid Values
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterUsage	Determines if usage should be filtered.	true false

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D3-USAGE-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue

Parameter	Description	Default Value
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **Landis+Gyr UOM Code to Standard UOM Mapping** extendable lookup (D3-HeadendUOMLookup) are passed into the system for processing.

Note: Filtering of scalar initial measurement data is not supported in the Landis+Gyr adapter.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/ or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (DIRT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be

processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Device Events

The device event data exported from the head-end system as a file in Landis+Gyr format is loaded into Oracle Utilities as a Device Event. One of your configuration tasks is to customize the device events processing. The required functionality is delivered in the base product as two OSB projects:

1. **SGG-D3-EVENT-BASE** containing components responsible for "actual" processing of incoming data. It can be upgraded in future without affecting the customization and environment settings that done in SGG-D3-EVENT-CM project.
2. **SGG-D3-EVENT-CM** allows the customization and simplifies the future upgrades.

The runtime configuration settings for the SGG-D3-EVENT-CM project are stored in the EnvironmentSettings.xq XQuery file. You can use this file to adjust device event data processing. For example, if you want to load raw data you would specify "true" for the content of the populateRaw element. The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the device event data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
modifyResultXMLInput	Specifies the name of an XQuery document (without the ".xq" extension) used to map additional fields from the "plain" XML format to the result XML format sent as device event data. See Mapping Additional Fields on page 768 for more information.	
dateTimeInUTC	Indicates whether the Landis+Gyr system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device.	true false
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false

Publishing Events

SGG can be configured to publish device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Device Event Publishing

Publishing data is enabled by referencing a publisher business service in the `publishServices/service` element in the `EnvironmentSettings.xq` file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D3-EVENT-CM OSB project are used in publishing device events data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the `EnvironmentSettings.xq` file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Device Event Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Device event data is published in the “native” device event data format (the format of the device event seeder business object). This format includes normalized device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: In addition, filtering can NOT be applied to device events published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600

Parameter	Description	Default Value
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Events

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to "true" as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **Landis+Gyr Device Event Mapping** extendable lookup (D3-DeviceEventMappingLookup) are passed into the system for processing.

Subscribing to Real-Time Device Events

The Landis+Gyr Command Center provides the ability to "subscribe" to device events from within their online interface. This is done by creating a subscriber in Command Center with an associated callback URL as well as a list of events types that subscriber is interested to receive. When an event that is subscribed to occurs it is sent to the callback URL in real time.

Within L+G Events are configured with one of three "alarm" settings. These settings determine how often the events will be sent to subscribers:

1. Alarm: immediately delivered from the meter
2. Advisory: sent based upon a delivery schedule
3. Log Only: sent only upon request (not applicable for our implementation real time event processing)

Command Center will communicate the events using a CIM format that describes the message as a noun/verb combination. The details of the event itself will be contained within a "payload" element of the standard structure. The payload will be formatted using the EndDeviceEvent message structure. This message identifies device events using a CIM 4-part category number. These numbers are four period separated numbers that will describe the type of device and the event. For example: 3.33.1.257 is for "Tamper attempt suspected".

- Segment 1: End Device event domain code (e.g. 3. meter/10. collector/11. router/12. HAN device)
- Segment 2: End Device Event Domain Part Codes (e.g. 1. Access/2. Battery)
- Segment 3: End Device Event Type Codes (e.g. 1. Alarm/2. Alarm Mgt)
- Segment 4: End Device Event Index (e.g. 1. Abort/2. Access Attempt)

Refer to the Landis+Gyr documentation for details about the CIM Category Numbers. CIM Category Numbers must be mapped to standard device event names using the Landis+Gyr Device Event Mapping extendable lookup.

SGG receives these messages through a BPEL composite that saves the incoming request as a file to be picked up by OSB.

The **AMIEventSubscriber** composite is responsible for receiving the event messages based on subscriptions defined in the L+G Command Center. The callback URL configured for the subscription in the Command Center should point to this BPEL composite.

The following OSB projects parse individual device events from the message and perform the validation and mapping of the information to the Device Event Seeder Format.

1. **SGG-D3-CIM-EVENT-BASE** contains components responsible for "actual" processing of incoming data. It can be upgraded in future without affecting the customization and environment settings that done in SGG-D3-CIM-EVENT-CM project.
2. **SGG-D3-CIM-EVENT-CM** allows the customization and simplifies the future upgrades.

The runtime configuration settings for the SGG-D3-CIM-EVENT-CM project are stored in the EnvironmentSettings.xq XQuery file. You can use this file to adjust device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the device event data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false

Processing statistics are gathered for any real time events that are received (even if there is just one event in the message) in the same manner as device events received via the flat-file interface.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (DIRT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending

these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D3-CIM-EVENT-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

Note: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The Landis+Gyr adapter base package includes the following initial measurement business objects:

Business Object Name	Description
D3-InitialLoadIMDInterval	Landis+Gyr Initial Load IMD - Interval Used when loading Landis+Gyr interval measurements into the system for the first time.
D3-InitialLoadIMDScalar	Landis+Gyr Initial Load IMD - Scalar

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related web service from the head-end system. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each Landis+Gyr command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect (This command has sub-commands)	Initiate MR by Mtr Num	Reading Changed Notification	Connect Device
	Initiate Connect Disconnect	Connect Disconnect State Changed Notification	Create IMD Completion Event

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Disconnect (This command has sub-commands)	Initiate Connect Disconnect Initiate MR by Mtr Num	Connect Disconnect State Changed Notification Reading Changed Notification	Disconnect Device Create IMD Completion Event
Device Commissioning (Registration)	L+G Add Meter to Inventory		Device Commissioning
Device Commissioning (Installation)	L+G Meter Exchange Notification		Device Commissioning
Device Decommissioning	Meter Remove Notification		Device Decommissioning
Device Deregistration	L+G Meter Retire Notification		Device Deregistration
On-Demand Read (Scalar)	Initiate MR by Mtr Num	Reading Changed Notification	Create IMD Completion Event
On-Demand Read (Scalar) - CIM	CIM Meter On Demand Read (Scalar)	CIM Meter On Demand Read Response	Create IMD Completion Event
On-Demand Read (Interval)	Initiate MR by Mtr Num	Reading Changed Notification	Create IMD Completion Event
On-Demand Read (Interval) - CIM	CIM Meter On Demand Read (Interval)	CIM Meter On Demand Read Response	Create IMD Completion Event
Device Status Check	CIM Ping	CIM Ping Response	
Demand Reset	Schedule Demand Reset (Multispeak)	Schedule Demand Reset Response (Multispeak)	Create IMD Completion Event

Device Registration Commission Commands

Landis+Gyr device commission commands can be used to “register” the device and notify the L+G head-end system that meters have been added to inventory. Device commission commands of this type have the “Registration-Only Mode” flag set to “Yes”. An Enter algorithm on the “Commission Ready” state evaluates the Registration-Only Mode of the command and if set to “Yes”, the command skips the default “Waiting for Measurement” state and is transitioned to the “Execute Completion Event” state, and an activity log entry is created.

Only the device registration request is sent to the head-end system for device commission commands of this type.

Device registration commands are typically created when new devices are added to inventory in an asset management system such as Oracle Utilities Operational Device Management.

Device Installation Commission Commands

Landis+Gyr device commission commands can be used to notify the L+G head-end system that meters have been installed or exchanged. An Enter algorithm on the “Commission Ready” state evaluates the “Is Installation Check Unnecessary” flag of the command and if set to “False”, the algorithm creates an “L+G Meter Exchange Notification” outbound communication and sends an installation notification to the head-end system.

Device Deregistration Commands

The Landis+Gyr adapter supports the Device Deregistration command (based on the D1-DeviceDeregistration business object). This command sends a communication that deregisters the device in the head-end system, and is most often used when retiring a device. The specific message sent is defined for the Device Deregistration processing role for the L+G head-end system service provider.

Device deegistration commands are typically created when devices are retired in an asset management system such as Oracle Utilities Operational Device Management.

Unit of Measure Filtering for On-Demand Reads

Readings returned via On-Demand Read commands are filtered on the combination of Unit of Measure/Time of Use/Service Quantity Identifiers (UOM/TOU/SQI) configured for the device and measuring component. When filtering is enabled, only readings that match a configured UOM/TOU/SQI combination are processed. All others are filtered out.

Filtering is enabled by default via the “Opt Out Of Filtering” parameter (set to "false" by default) on the D3-CCOMPEV (Create IMD Completion Event) algorithm on the Create Completion Events status of the D3-ReadingChgNotification (Reading Changed Notification - SOA based) business object.

The D3-VALDVCFIL (Check if Device has any Filtering errors) algorithm on the Validate status of the D3-ReadingChgNotification (Reading Changed Notification - SOA based) business object is used to check for errors related to filtering. The value of the “Opt Out Of Filtering” parameter on this algorithm must match the value of the parameter on the D3-CCOMPEV algorithm. The parameters should both be set to either "false" (the default) or "true" (if filtering is to be disabled).

Demand Reset Commands

For on-demand read commands associated with Demand Reset commands, filtering is enabled by default via the “Opt Out Of Filtering” parameter (set to "false" by default) on the D3-SDRCCE (Create Schedule Demand Reset Completion Event) algorithm on the Create Completion Events status of the D3-ScheduleDemandResetResponse (Schedule Demand Response(Multispeak)) business object.

The D3-VALSDRCCE (Check if Device has any Filtering errors - Schedule Demand Reset) algorithm on the Validate status of the D3-ScheduleDemandResetResponse (Schedule Demand Response(Multispeak)) business object is used to check for errors related to filtering. The value of the “Opt Out Of Filtering” parameter on this algorithm must match the value of the parameter on the D3-SDRCCE algorithm. The parameters should both be set to either "false" (the default) or "true" (if filtering is to be disabled).

CIM Commands

For CIM-based on-demand read commands, filtering is enabled by default via the “Opt Out Of Filtering” parameter (set to "false" by default) on the D3-CCMPEVCIM (Create CIM Completion Event) algorithm on the Create Completion Events status of the D3-CIMMeterReadingsResponse (CIM Meter On Demand Read Response SOA Based) business object.

The D3-VALCEVCIM (Check if Device has any Filtering errors CIM Completion Event) algorithm on the Validate status of the D3-CIMMeterReadingsResponse (CIM Meter On Demand Read Response SOA Based) business object is used to check for errors related to filtering. The value of the “Opt Out Of Filtering” parameter on this algorithm must match the value of the parameter on the D3-CCMPEVCIM algorithm. The parameters should both be set to either "false" (the default) or "true" (if filtering is to be disabled).

Device Communication Base Package Business Objects

The Landis+Gyr Adapter base package includes the following communication business objects:

Business Object Name	Description	Protocol
D3-AddMeterToInventoryMultiSp	L+G Add Meter to Inventory (MultiSpeak)	MultiSpe
D3-CIMGetLPData	CIM Meter On Demand Read (Interval)	CIM

Business Object Name	Description	Protocol
D3-CIMMeterOnDemandRead	CIM Meter On Demand Read (Scalar)	CIM
D3-CIMMeterReadingResponse	CIM Meter On Demand Read Response	CIM
D3-CIMPing	CIM Ping	CIM
D3-CIMPingResponse	CIM Ping Response	CIM
D3-ConnectDisconStateChgNtf	Connect Disconnect State Changed Notification	MultiSpe
D3-InitiateConnectDisconnect	Initiate Connect Disconnect	MultiSpe
D3-InitiateMRByMtrNbr	Initiate Meter Read By Meter (MultiSpeak)	MultiSpe
D3-MeterAddNotificationMultiSp	Meter Add Notification (MultiSpeak)	MultiSpe
D3-MeterExNotificationMultiSp	L+G Meter Exchange Notification	MultiSpe
D3-MeterRetireNotification	L+G Meter Retire Notification	MultiSpe
D3-MtrRmvNotifMultiSpeak	Meter Remove Notification (MultiSpeak)	MultiSpe
D3-ReadingChgNotification	Reading Changed Notification	MultiSpe
D3-ScheduleDemandReset	Schedule Demand Reset (Multispeak)	MultiSpe
D3-ScheduleDemandResetResponse	Schedule Demand Reset Response (Multispeak)	MultiSpe

Landis+Gyr Event Data Mapping

The Landis+Gyr event file format maps as follows into the business object, D1-DeviceEventMappingLookup:

Landis+Gyr Flat File Field	Device Event Seeder BO Element	Comments
Transaction ID (from Header record)	External Source Identifier	This is the file name.
Device Identifier	External Device Identifier	
Event Name	External Event Name	
Event Creation Date/Time	Event Date/Time	
Device Type	External Device Type	This element has no real bearing on the device type within MDM/SGG. Its valid values include (although the element itself is free-form): Meter Collector Router

Landis+Gyr Flat File Field	Device Event Seeder BO Element	Comments
Service Location ID	External Service Location ID	
Communication Module Serial Number	External Communication Module Identifier	
Event Category ID	External Event Category	
Event Severity	External Event Severity	Valid values include (although the element itself is free-form): Alert Information
Status Value	External Status Value	This represents additional information that relates to the event itself.
Status Date/Time	External Status Date/Time	The date & time at which the additional information referenced above had occurred.

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Outbound Message Types

Acknowledgment and response messages are sent and received validating that commands have been transmitted. These notifications are based on the following outbound message types.

Outbound Message Type	Description
D3-ADDMTRINV	Add Meter to Inventory
D3-COMMS	Commission Device
D3-CONNECT	Connect Device
D3-DECOMMS	Decommission
D3-DEMRESET	Demand Reset
D3-DERDEV	Deregister Device
D3-DISCONN	Disconnect Device
D3-DVCSTCHK	Device Status Check

Outbound Message Type	Description
D3-INITMRN	Initiate Meter Read by Meter Number
D3-INITMTR	Initiate Meter Read by Meter Number
D3-MTRADDNOT	Meter Add Notification Outbound Message Type
D3-MTREX	Meter Exchange Notification OB MSG
D3-MTRRMV	Meter Remove Notification

Inbound / Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The Oracle Utilities Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway adapter for Landis+Gyr includes the following inbound web services:

Inbound Web Service	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Used for upload of device events. The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event. If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.
D1-InitialLoadIMD	Used for initial measurement upload. The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.
D3-CIMMeterReadingsResponse	CIM Meter On Demand Read Response Retrieve response from CIM On Demand Read command

Inbound Web Service	Description
D3-CIMPingResponse	CIM Ping Response Retrieve response from CIM Device Status Check command
D3-ConDisconStChgNotification	Initiate Connect Disconnect response. Retrieve response from the Initiate Connect Disconnect command.
D3-ReadingChangedNotification	Reading Changed Notification Notification that a Landis+Gyr device reading has changed.
D3-ScheduleDemandResetResponse	Scheduled Demand Reset Response Retrieve response from Demand Reset command

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

The Oracle Utilities Smart Grid Gateway adapter for Landis+Gyr includes the following message senders:

Message Sender	Description
D3-Comms	Commission Device
D3-Connect	Connect Device
D3-Decomm	Decommission Device
D3-Decomms	Decommissioning Sender
D3-DemReset	Demand Reset
D3-DerDevice	Deregister Device
D3-Disconnec	Disconnect Device
D3-InitMTR	Initiate Meter Read by Meter Number Outbound Message
D3-MTREXMS	Meter Exchange Notification Message Sender
D3-RTSender	Real Time Sender
D3-RTSnd	Real-time Sender (Landis+Gyr)
D3-SDemReset	SG Demand Reset

BPEL Processes

These processes are responsible for performing the conversion from Oracle Utilities format to MultiSpeak 3.0 format, invoking process callouts and invoking the remote endpoint to trigger the device events.

OnDemandRead Composite Process: Invokes the remote endpoint to trigger the on-demand read event. An asynchronous reply responds to the OUAF layer when the reading arrives.

ConnectDisconnect Composite Process: Invokes the remote endpoint to trigger the connect/disconnect event. An asynchronous reply responds to the OUAF layer when confirmation of the requested event arrives.

CommissionDecommission Composite Process: Invokes the remote endpoint to trigger the commission or decommission event. After the synchronous call completes, one of the following second business callout services is invoked to determine if the related “received” or “completed” callout should be executed:

- isExecutingCommissionReceivedCallout
- isExecutingCommissionCompletedCallout
- isExecutingDecommissionReceivedCallout
- isExecutingDecommissionCompletedCallout
- isExecutingAddMeterToInventoryReceivedCallout
- isExecutingAddMeterToInventoryCompletedCallout
- isExecutingMeterExchangeNotificationReceivedCallout
- isExecutingMeterExchangeNotificationCompletedCallout

CIMOnDemandRead Composite Process: Invokes the remote endpoint to trigger the CIM on-demand read event. An asynchronous reply responds to the OUAF layer when the reading arrives.

CIMDeviceStatusCheck Composite Process: This process is similar to CIM OndemandRead BPEL process. SGG uses the result of On Demand Read command to identify the status of the meter. If reads are successfully returned, then meter is running healthy otherwise it is considered as meter inactive/dead.

DemandReset Composite Process: Invokes the remote endpoint to trigger the demand reset event. An asynchronous reply responds to the OUAF layer when the reading arrives.

LGProcessCallout Composite: This business callout provides a point at which customers and implementers can incorporate custom business logic and transformations. This composite includes the WSDLs and processing logic for all of the MultiSpeak processes. The default implementation of each method is a direct return of the input.

Web Services

These web services are all defined in the Landis+Gyr head end system. The WSDLs were added to a Meta Data Storage (MDS) layer in OUAF and all references to the WSDL point to this MDS location.

Web Service	Related BPEL Process	Description
MR_CB	OnDemandRead CommissionDecommission DemandReset	This web service is defined by the Landis+Gyr head end system’s implementation of MR_Server. The WSDL defines the interface for requesting a meter reading from the head end system. The actual definition can be obtained from L&G or downloaded from multispeak.org. Build 3.0aa is appropriate if obtained from MultiSpeak. Default endpoint must be changed in configuration: http://demo.turtletech.com/Multispeak/webapi/MR_CB.asmx

Web Service	Related BPEL Process	Description
CD_CB	ConnectDisconnect	<p>This web service is defined by the Landis+Gyr implementation of CB_CD.</p> <p>The WSDL defines the interface for requesting a meter's connection or disconnection on the head end system.</p> <p>This web service defines the interface for reporting a connection or disconnection by the head end system.</p> <p>This web service is only invoked by the head end system; not OUAF.</p> <p>Only the CDStateChangedNotification web method is implemented in the composite.</p> <p>Default endpoint must be changed in configuration: http://demo.turtletech.com/Multispeak/webapi/CD_CB.asmx</p>
CIMService	CIMOnDemandRead CIMDeviceStatusCheck	<p>This web service is defined by the L+G head end's implementation of AMIRequest Server.</p> <p>The WSDL defines the interface for requesting a meter reading from the head end system.</p> <p>The actual definition should be obtained from L&G or downloaded from L&G SDK for CIM 2.0.</p>
LGProcessCallout	OnDemandRead ConnectDisconnect CommissionDecommission	<p>Imported from LGProcessCallout Composite</p> <p>Default endpoint must be changed in configuration: http://127.0.0.1:8000/soa-infra/services/default/LGProcessCallout/LGProcessCallout</p>

Landis+Gyr Command Center Web Services

The following table describes the Land+Gyr Command Center web services and operations used for the Oracle Utilities Smart Grid Gateway command messaging:

Smart Grid Gateway Command	AMI Adapter Business Objects	Landis+Gyr Web Services	Landis+Gyr Operations
Device Commissioning	D3-MeterAddNotificationMultiSp	MR	MeterAddNotification
Device Decommissioning	D3-MtrRmvNotifMultiSpeak	MR	MeterRemoveNotification
Remote Connect/ Remote Disconnect	D3-InitiateConnectDisconnect	CD	InitiateConnectDisconnect
On-Demand Read	D3-InitiateMRByMtrNbr	MR	InitiateMeterReadByMeterNumber

Smart Grid Gateway Command	AMI Adapter Business Objects	Landis+Gyr Web Services	Landis+Gyr Operations
On-Demand Read (CIM)	D3-CIMGetLPData D3-CIMMeterOnDemandRead	CIMService	ScheduleDemandRead
Demand Reset	D3-ScheduleDemandReset	MR	CIM

Configuring a Landis+Gyr Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway Adapter for Landis+Gyr to communicate with the Landis+Gyr Command Center software.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the L+G Command Center in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Device Event Seeder
D1-InitialLoadIMD	IMD Seeder
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
D3-ConDisconStChgNotification	Initiate Connect Disconnect Response
D3-CIMMeterReadingsResponse*	CIM Meter On Demand Read Response
D3-CIMPingResponse	CIM Ping Response
D3-ReadingChangedNotification*	Reading Changed Notification
D3-ScheduleDemandResetResponse	Scheduled Demand Reset Response

*The Landis+Gyr adapter supports both MultiSpeak and CIM On Demand Read commands. You only need to configure the inbound service for the protocol you wish to use.

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
D3-Comms	Commission Device
D3-Connect	Connect Device
D3-Decomm	Decommission Device
D3-InitMTR	Initiate Meter Read by Meter Number Outbound Message
D3-RTSender	Real Time Sender
D3-RTSnd	Real-time Sender (Landis+Gyr)
D3_CIMODR	L+G CIM On Demand Read
D3_CIMPING	L+G CIM Ping
D3_SCHDEMRES	L+G Schedule Demand Reset

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tabsysuser00:

- **HTTP Header:** SOAPAction: http://xmlns.oracle.com/ouaf/multispeak_3.0/ <OPERATION>
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http:// <EM_SERVER> : <EM_SERVER_PORT> /soa-infra/services/D3/ <SERVICE> / <SERVICE>

where:

- <OPERATION> : the operation performed by the message sender (see Operation column in the table above)

- **<USER_ID>** : the user ID used to log into WebLogic Enterprise Manager
- **<PASSWORD>** : the password used to log into WebLogic Enterprise Manager
- **<EM_SERVER_IP>** : the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- **<EM_SERVER_PORT>** : the port where the WebLogic Enterprise Manager is installed
- **<SERVICE>** : the service invoked by the message sender (see Service column in the table above)

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
D3-ADDMTRINV	Add Meter to Inventory
D3-COMMS	Commission Device
D3-CONNECT	Connect Device
D3-DECOMMS	Decommission
D3-DEMRESET	Demand Reset
D3-DERDEV	Deregister Device
D3-DISCONNEN	Disconnect Device
D3-DVCSTSCHK	Device Status Check
D3-INITMRN	Initiate Meter Read by Meter Number
D3-INITMTR	Initiate Meter Read by Meter Number
D3-MTRADDNOT	Meter Add Notification Outbound Message Type
D3-MTRES	Meter Exchange Notification OB MSG
D3-MTRRMV	Meter Remove Notification

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the L+G Command Center must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - Landis+Gyr:

- **External System:** LG
- **Description:** Landis+Gyr
- **Outbound Message Types:**

Outbound Message Type	Description	Message Sender
D3-ADDMTRINV	Add Meter to Inventory	Message sender associated with the Add Meter to Inventory Outbound Message Type
D3-COMMS	Commission Device	Message sender associated with the Commission Device Outbound Message Type
D3-CONNECT	Connect Device	Message sender associated with the Connect Device Outbound Message Type
D3-DECOMMS	Decommission	Message sender associated with the Decommission Device Outbound Message
D3-DEMRESET	Demand Reset	Message sender associated with the Demand Reset Outbound Message Type
D3-DERDEV	Deregister Device	Message sender associated with the Deregister Device Outbound Message Type
D3-DISCONNED	Disconnect Device	Message sender associated with the Disconnect Device Outbound Message Type
D3-DVCSTSCHK	Device Status Check	Message sender associated with the Device Status Check Outbound Message Type
D3-INITMRN	Initiate Meter Read by Meter Number	Message sender associated with the Initiate Meter Read By Meter Number Outbound Message Type
D3-INITMTR	Initiate Meter Read by Meter Number	Message sender associated with the Initiate Meter Read By Meter Number Outbound Message Type
D3-MTRADDNOT	Meter Add Notification Outbound Message Type	Message sender associated with the Meter Add Notification Outbound Message Type
D3-MTRESX	Meter Exchange Notification OB MSG	Message sender associated with the Meter Exchange Notification Outbound Message Type

Outbound Message Type	Description	Message Sender
D3-MTRRMV	Meter Remove Notification	Message sender associated with the Meter Remove Notification Outbound Message Type

Note: The following apply to the above outbound message types*:

- **Processing Method:** Real-time
- **Message XSL:** D3-Request.xml (*use D3-DRRequest.xml for the Demand Reset command)
- **Response XSL:** D3-Response.xml (*use D3-DRResponse.xml for the Demand Reset command)

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the L+G Command Center must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about creating service providers.

Service Provider - Landis+Gyr:

- **Service Provider:** LG
- **Description:** Landis+Gyr
- **External Reference ID:** L+G
- **External System:** Landis+Gyr
- **Out Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the L+G service provider. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

UOM Translation

UOM mapping processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the L+G service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1–HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	D3-AddMeterToInventoryMultiSp	Add Meter to Inventory
Device Commission	Device Installation	D3-MeterExNotificationMultiSp	Meter Exchange Notification
Device Decommission	Device Removal	D3-MtrRmvNotifMultiSpeak	Decommission Meter Remove Notification
Device Deregistration	Device Deregistration	D3-MeterRetireNotification	Deregister Device
On-Demand Read (Scalar), Multispeak and CIM	On-Demand Read (Scalar)	MS: D3-InitiateMRByMtrNbr CIM: D3-CIMMeterOnDemandRead	MS: Initiate Meter Read by Meter Number CIM: CIM On Demand Read
On-Demand Read (Interval)	On-Demand Read (Interval)	D3-CIMGetLPData	CIM On Demand Read
Demand Reset	Demand Reset	D3-ScheduleDemandReset	Demand Reset
Device Status Check	Device Status Check	D3-CIMPing	Device Status Check
Remote Connect	Remote Connect	D3-InitiateConnectDisconnect	Connect Device
Remote Disconnect	Remote Disconnect	D3-InitiateConnectDisconnect	Disconnect Device

Configuring Endpoint URIs

Part of the configuration process is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands. The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head-end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoint URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The Landis+Gyr endpoint override DVM (D3–EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the Landis+Gyr adapter and the command used with each:

DVM Key	Commands
CIMService	On-Demand Read (Scalar) - CIM On-Demand Read (Interval) - CIM Device Status Check
CD_CB	Remote Connect Remote Disconnect
Metering	Device Commissioning (Registration)
MR_CB	Device Commissioning Device Decommissioning Device Commissioning (Installation) Device Deregistration On-Demand Read (Scalar) On-Demand Read (Interval)
LGProcessCallout	User Exit Functions

To define an override Endpoint URI for the Landis+Gyr adapter, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is <http://server:port/soa/composer>.

2. Select the D3–EndpointOverrides.dvm in the left panel.
 - In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
 - In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list). The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.
4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:
 - **key**: The DVM key for the Endpoint URI you wish to define (see the table above).
 - **EndpointURI**: The override Endpoint URI.
6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.

8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Landis+Gyr Extendable Lookups

Note: This section applies to **both** middleware and native implementations of the Smart Grid Gateway Adapter for Landis+Gyr.

This section outlines some of the extendable lookups that must be configured for use with the Landis+Gyr adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

CIM Response Status Extendable Lookup

The CIM Response Status extendable lookup is used to map descriptions to response status codes received from the L+G Command Center. Each value defined for the CIM Response Status extendable lookup should include the following:

- **Response Status:** The CIM status code for the response status
- **Description:** A description of the response status
- **Status:** The status of the lookup value (can be Active or Inactive)

CIM Data Source Extendable Lookup

The CIM Data Source extendable lookup is used to map descriptions to data sources defined in the L+G Command Center. Each value defined for the CIM Data Source extendable lookup should include the following:

- **Data Source:** The CIM code for the data source
- **Description:** A description of the data source
- **Status :** The status of the lookup value (can be Active or Inactive)

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system. Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name:** The event name used by the head-end system
- **Description:** A description of the device event
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Standard Event Name:** The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

UOM Code to Standard UOM Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-end UOM:** The unit of measure code used by the head-end system.
- **Unit of Measure:** The unit of measure defined in the system.
- **Description:** A description of the unit of measure code.

Interval Status Code to Condition Mapping

Interval usage received from the Landis+Gyr Command Center can include interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The Landis+Gyr Interval Status Code to Condition Mapping extendable lookup is used for this purpose. Each value defined for the Landis+Gyr Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The interval status code
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.
- **Description:** A description of the interval status code.

Using the Landis+Gyr Test Harness

Oracle Utilities Smart Grid Gateway Adapter for Landis+Gyr (LG) includes a test harness that can be configured to simulate the Landis+Gyr Gridstream Command Center head-end system for testing the two-way commands. The test harness is Multispeak 3.0 standard compliant and includes a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. See [Using Smart Grid Gateway Middleware Test Harnesses](#) on page 846 for more information.

Landis+Gyr Interval Data Mapping

This section describes how data in Landis+Gyr import files is mapped to the XML document format created by OSB and sent to Oracle Utilities Smart Grid Gateway.

When Landis+Gyr data is processed, it is initially received in a tilde-separated file format, which is converted into a "plan" XML format before being converted into the "result" XML format which is sent to the IMD Seeder and/or Device Event Seeder inbound services.

Non-Interval Usage with Additional Fields

The following is a sample file of non-interval usage that contains additional fields.

```
ID~PremiseID~ESIID~Provisioned~Meter~kWh~DateTime~Peak~PeakDateTime~Dmd~TouA~TouB~TouC~TouD~TouE~Volts~P
EMED01~SL002~~~96968280~34315.000~08042010120000AM~2.66~03122009063000AM~~34315.000~0.000~0.000~0.000~0.
EMED01~SL001~~~96968285~33693.000~08042010120000AM~2.62~03122009061500AM~~33693.000~0.000~0.000~0.000~0.
```

This data is mapped to the "plain" XML format.

XML 'Plain' XML Format

The "Plain" XML contain elements to hold the extra fields (highlighted in bold).

```
<?xml version="1.0" encoding="utf-8"?>
<xs:schema attributeFormDefault="unqualified" elementFormDefault="qualified"

Non-Interval Usage to 'Plain' XML Mapping

The following table shows the mapping between fields in incoming non-interval data and child elements of MeterReads/MeterRead element in the "Plain" XML format:

L+G Interval Structure Field	"Plain" XML element
ID	RecordType
Premise ID	Premise
ESIID	ESIID
Provisioned	Provisioned
Meter	MeterID
kWh	kWh
Date/Time of initial Read	FirstIntervalDateTime
Peak	Peak
Peak Date/Time	PeakDateTime
Dmd	Dmd
TouA	TouA
TouB	TouB
TouC	TouC
TouD	TouD
TouE	TouE
Volts	Volts
PF	PF
<extraFieldName1>	ExtraFields/ExtraField/FieldName with value of <extraFieldName1> ExtraFields/ExtraField/FieldValue with value in <extraFieldName1>
<extraFieldName2>	ExtraFields/ExtraField/FieldName with value of <extraFieldName2> ExtraFields/ExtraField/FieldValue with value in <extraFieldName2>

L+G Interval Structure Field	"Plain" XML element
<extraFieldName3>	ExtraFields/ExtraField/FieldName with value of <extraFieldName3> ExtraFields/ExtraField/FieldValue with value in <extraFieldName3>
<extraFieldNameN>	ExtraFields/ExtraField/FieldName with value of <extraFieldNameN> ExtraFields/ExtraField/FieldValue with value in <extraFieldNameN>
RawData	A record content from incoming file.

'Plain' XML to IMD Mapping

The following table outlines how data from the "plain" XML format is mapped to the InitialLoadIMD format when the Landis+Gyr record type is set to "MEPMD01" (interval usage).

"Plain" XML element	InitialLoadIMD element	Note
Record Type	N/A	
RecordVersion	N/A	
Premise ID	N/A	
ESIID	N/A	
Provisioned	N/A	
Meter ID	dvcIdN	as is
Purpose	N/A	
Commodity	N/A	
Units	externalUOM	as is
CalcConst	mcm	as is
Interval	spi	Transform from DDHHMM to SPI
Count	N/A	
FirstIntervalDateTime	stDt	Convert to OUAF date/time format
Data	msrs	Value -> msrs/mL/q
Status -> msrs/mL/sts/stsL/st		
N/A	imdType	'D1IL

"Plain" XML element	InitialLoadIMD element	Note
Origin	externalId	the origin attribute in "Plain" XML (incoming file name)
N/A	serviceProviderExternalId	L+G
RawData	rawData	Vendor-specific "raw" data

Non-Interval 'Plain' XML to IMD Mapping

The following table outlines how non-interval data in the "plain" XML format is mapped to the InitialLoadIMD format when the Landis+Gyr record type is set to "EMED01" (non-interval usage).

"Plain" XML Element	InitialLoadIMD element	Notes
RecordType	N/A	
Premise	N/A	
ESIID	N/A	
Provisioned	N/A	
MeterID	dvcIdN	as is
kWh	enQty	as is
	uom	KWH
TimeStamp	enDt	Convert to OUAF date/time format This should be mapped to enDt. Relevant only to non-interval data.
Peak	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KW
PeakDateTime	enDt	Convert to OUAF date/time format
Dmd	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KW and 'Dmd' in "<mcIdN>
TouA	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KWH and 'kWh Rate A' in "<mcIdN>

"Plain" XML Element	InitialLoadIMD element	Notes
TouB	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KWH' and 'kWh Rate B' in "<mcIdN>
TouC	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KWH and 'kWh Rate C' in "<mcIdN>
TouD	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KWH and 'kWh Rate D' in "<mcIdN>
TouE	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with KWH and 'kWh Rate E' in "<mcIdN>
Volts	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with Volts
PF	enQty	as is A separate IMD Seeder will be created with <uom> in IMD Seeder populated with PF
N/A	imdType	D1IL
Origin	externalId	the origin element in "Plain" XML (incoming file name)
N/A	serviceProviderExternalId	L+G This is a constant. There is no such field in incoming structure.
RawData	rawData	Vendor-specific "raw" data When the "populateRawIMD" parameters in the EnvironmentSettings.xq file is set to true.

Mapping Additional Fields

Measurement and device event files received from the Landis+Gyr head-end system can include additional fields containing data to be imported into Oracle Utilities Smart Grid Gateway. These additional fields must be mapped to elements within the XML document processed by OSB and sent to Smart Grid Gateway.

This mapping can be performed through use of a custom XQuery document, specified in the EnvironmentSettings.xq file via the "modifyResultXMLInput" parameter.

The following sample XQuery documents illustrate how additional fields can be mapped into the XML format sent to Smart Grid Gateway.

Sample XQuery — Initial Measurements

The following XQuery is an example that shows a transformation that passes in a root element with 3 children (the “result” XML, the “plain” XML, the environment settings) that returns a modified “result” XML. For testing purposes, it changes the original value in the <enQty> “result” element and replaces it with a value from the “plain” XML depending on an environment setting variable. The <serviceProviderExternalId> value was also replaced by a hard-coded value.

```

declare namespace lan = "http://xmlns.oracle.com/LandisGyrUsage";
declare namespace xf = "http://tempuri.org/D3/lgimd";
declare namespace soap = "http://schemas.xmlsoap.org/soap/envelope/";
declare function xf:modifyResultXML($modifyResultXMLInput as element(*)) as element(*)
{
  <InitialLoadIMDList>
  {
    for $InitLoadIMD in $ modifyResultXMLInput/InitialLoadIMDList/
    InitialLoadIMD
    return
      <InitialLoadIMD>
      <preVEE>
      <dvcIdN>{ data($InitLoadIMD/preVEE/dvcIdN) }</dvcIdN>
      <externalId>{ data($InitLoadIMD/preVEE/externalId) }</externalId>
      <uom>{ data($InitLoadIMD/preVEE/uom) }</uom>
      <mcIdN>{ data($InitLoadIMD/preVEE/mcIdN) }</mcIdN>
      <enDt>{ data($InitLoadIMD/preVEE/enDt) }</enDt>
      {
        if ($modifyResultXMLInput/EnvironmentSettings/test1="true")
        then <enQty>{ data($modifyResultXMLInput/lan:MeterReads/
lan:MeterRead/lan:ExtraFields/lan:ExtraField[lan:FieldName
= 'EF4']/lan:FieldValue) }</enQty>
        else <enQty>{ data($modifyResultXMLInput/lan:MeterReads/
lan:MeterRead/lan:ExtraFields/lan:ExtraField[lan:FieldName= 'EF2']/
lan:FieldValue) }</enQty>
      }
      <imdType>{ data($InitLoadIMD/preVEE/imdType) }</imdType>
      </preVEE>
      <serviceProviderExternalId>NewSPId</serviceProviderExternalId>
      </InitialLoadIMD>}</InitialLoadIMDList>
};
declare variable $modifyResultXMLInput as element(*)external;
xf:modifyResultXML($modifyResultXMLInput)

```

Sample XQuery — Device Events

The following XQuery is an example that shows a transformation that passes in a root element with 3 children (the "result" XML, the "plain" XML, and the environment settings) and returns a modified "result" XML. For testing purposes, it changes the original value in the <externalCommunicationModuleIdentifier> "result" element and replaces it with a value from the "plain" XML depending on an environment setting variable. The <externalServiceLocationId> value is also replaced by a hard-coded value.

```

declare namespace lan = "http://xmlns.oracle.com/LandisGyrEvent";
declare namespace xf = "http://tempuri.org/D3/event";
declare namespace soap = "http://schemas.xmlsoap.org/soap/envelope/";
declare function xf:modifyResultXML($modifyResultXMLInput as element(*)) as element(*)
{
  <DeviceEventSeeder>

```

```

    <externalSenderId>{data ($modifyResultXMLInput/DeviceEventSeeder/
externalSenderId) }</externalSenderId>
    <deviceIdentifierNumber>{ data ($modifyResultXMLInput/DeviceEventSeeder/
deviceIdentifierNumber) }</deviceIdentifierNumber>
    <externalEventName>{ data ($modifyResultXMLInput/DeviceEventSeeder/
externalEventName) }</externalEventName>
    <eventDateTime>{ data ($modifyResultXMLInput/DeviceEventSeeder/
eventDateTime) }</eventDateTime>
    <externalSourceIdentifier>{ data ($modifyResultXMLInput/
DeviceEventSeeder/externalSourceIdentifier)
}</externalSourceIdentifier>
    <eventInformation>
    <externalEventCategory>{data ($modifyResultXMLInput/DeviceEventSeeder/
eventInformation/externalEventCategory)
}</externalEventCategory>
    <externalEventSeverity>{data ($modifyResultXMLInput/DeviceEventSeeder/
eventInformation/externalEventSeverity)
}</externalEventSeverity>
    <externalDeviceType>{data ($modifyResultXMLInput/DeviceEventSeeder/
eventInformation/externalDeviceType)
}</externalDeviceType>
    <externalServiceLocationId>{1234 }</externalServiceLocationId>
    {
    if ($modifyResultXMLInput/EnvironmentSettings/testA="true")
    then <externalCommunicationModuleIdentifier>{ data ($modifyResultXMLInput/
lan:DeviceEvents/lan:DeviceEvent/lan:DeviceType) }</
externalCommunicationModuleIdentifier>
    else <externalCommunicationModuleIdentifier>{data ($modifyResultXMLInput/
lan:DeviceEvents/lan:DeviceEvent/lan:CategoryId) }</
externalCommunicationModuleIdentifier>
    }
    <externalStatusValue>{data ($modifyResultXMLInput/DeviceEventSeeder/
eventInformation/externalStatusValue)
}</externalStatusValue>
    <externalStatusDateTime>{data ($modifyResultXMLInput/DeviceEventSeeder/
eventInformation/externalStatusDateTime) }</externalStatusDateTime>
    </eventInformation>
  </DeviceEventSeeder>
};
declare variable $modifyResultXMLInput as element(*) external;
xf:modifyResultXML ($modifyResultXMLInput)

```

MV90 for Itron

The Oracle Utilities Smart Grid Gateway MV-90 Adapter for Itron uses Oracle Service Bus (OSB) to facilitate communication between Oracle Utilities Smart Grid Gateway and MV-90. The following functionality is included:

Measurement Data Loading - Data parsing and transformation from MV-90 binary format into the Oracle Utilities Service and Measurement Data Foundation unified format.

Measurement Data Processing - Configurable mapping for MV-90 status codes to Oracle Utilities Service and Measurement Data Foundation standard values, along with configurable device event creation based on MV-90 status codes.

The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Version	SGG supports the .mv9 binary, mainframe data format.
Protocol	Binary file format.

Attribute	Details
Market(s)	Worldwide, but largely USA.
Architecture	AMR

MV90 Adapter Processing

This section provides details concerning the OSB processing and OUAF objects supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data Loading

The initial measurement data load and subsequent device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway service format. Payloads contain measurements in a head-end specific format OSB then places each service call into a JMS queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel then a service creates initial measurements with data in a common format with head-end-specific processing as needed.

Initial Measurements

The usage data exported from the AMI head-end system as a file in MV-90 format is loaded into Oracle Utilities as Initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. **SGG-D5-USAGE-BASE** contains components responsible for the actual processing of incoming data. It should not be modified during configuration. This project can be upgraded without affecting the customization and environment settings added to the SGG-D5-USAGE-CM project.
2. **SGG-D5-USAGE-CM** allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-D5-USAGE-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRawIMD	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	

Element	Description	Valid Values
filterUsage	Determines if usage should be filtered.	true false
usePhysicalChannel	Optional value. Determines whether the physical channel ID is passed to the IMD seeder to create the measuring component identifier number. If this is set to false, the MV90 LOGCHAN field is used.	true false (default)
fieldForDvcIdN	Optional value. Specifies which field is used as the value for the device ID.	DC_RECID DC_CUSTID DC_METERID (default)
MV90ScalarChannelSuffix	Optional value. Holds a suffix value to be added to the measuring component identifier number when a scalar IMD is created for register reads. Default value is “_S”	
processMV90ScalarData	Optional value. Determines if register reads are processed.	true false (default)
usePulseMultiplierAndOffset	Optional value. If set to "true", specifies the pulse values are multiplied by the pulse mutlipler.	true false (default)
	 Note: This setting only applies to MV90 files that have a Pulse datatype.	

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D5-USAGE-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Usage

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **MV90 UOM Code to Standard UOM Mapping** extendable lookup (D5-UOMtoStdUOMCodeMapLookup) are passed into the system for processing.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (D1RT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Initial Measurement Data Load with Register Reads

In the MV90 format, measurement data can include interval data as well as register reads that can be used to create scalar measurements. For information on configuring the adapter for loading scalar data based on register reads, see [Override Processing Methods for Scalar Initial Measurement Data](#).

Base Package Business Objects

The MV-90 Adapter for Itron base package includes the following initial measurement business objects:

Business Object Name	Description
D5-InitialLoadIMDInterval	MV-90 Initial Load IMD
D5-InitialLoadIMDScalar	MV90 - Initial Load IMD - Scalar

Configuring an MV90 Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway MV-90 Adapter for Itron to receive usage from an MV-90 system.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including incoming usage.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-InitialLoadIMD	IMD Seeder
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the MV-90 system must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - MV-90:

External System: MV90

Description: MV90 - Mainframe File Format

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the MV-90 system must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Meter Data Management / Smart Grid Gateway documentation for more information about creating service providers.

Service Provider - MV-90:

- **Service Provider:** MV90
- **Description:** Head-End System for MV90
- **External Reference ID:** MV90
- **External System:** MV90 - Mainframe File Format
- **Out Name/ID in Their System:** MV90
- **AMI Device ID Type:** Serial Number
- **AMI Measuring Component ID Type:**

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the MV90 service provider. Refer to the Oracle Utilities Meter Data Management / Smart Grid Gateway documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Override Processing Methods for Scalar Initial Measurement Data

In the MV-90 format, meter read start and stop values can represent either a calculated read based on the interval data that is included in the MV90 data, or a register read that has been logged using a separate channel. When the values represent a register read the application can create a second file for the scalar initial measurements. The creation of a scalar initial measurement file is triggered by the Register Type flag, DC_REGTYPE, in the MV-90 data and the processMV90ScalarData variable in the EnvironmentSettings.xq file. The following register read values are valid for the DC_REGTYPE field:

Value	Description
V	Visual energy readings
D	Visual demand and energy readings
E	Encoder register readings (energy only).
B	Both encoder and visual energy readings.
C	Calculate stop meter readings from the encoder base reading

In order to configure your adapter to create scalar initial measurements based on register reads, first define new measuring component types and register measuring components. Then use the new measuring component types to specify override processing methods on the Initial Measurement Creation processing method for your service provider.

Measuring Component Types for Scalar Reads: To create initial measurement data for register reads, first create new measuring component types to represent the registers. These will be used to create measuring components for scalar reads.

Example Measuring Component Type

- **Measuring Component Type:** MV90_SCALAR_REG
- **Description:** MV90 Scalar Register
- **Measuring Component Business Object:** Register
- **Measurement Business Object:** Measurement
- **Service Type:** Electric Service
- **Allow Negative Consumption:** Allowed
- **Consumptive/Subtractive:** Subtractive
- **Read Method:** Automatic Read

Other attributes such as Value Identifiers, VEE Groups, and so on, should be defined based on requirements

Register Measuring Components for Scalar Reads: Use the new measuring component types to create measuring components for the scalar measurements created by the register read process. You must create a corresponding register measuring component for each interval channel for which you will receive scalar reads. The channel number for the registers must be based on the channel numbers of the corresponding interval channels, plus the suffix defined in the “MV90ScalarChannelSuffix” environment setting. The default value for this setting is “_S”. These registers must also be added to the device configuration used by the interval channels (in other words, both measuring components - interval and scalar - must be on the same device). The following table shows examples of these values for the measuring components:

Device Type/Serial Number	MV-90 Interval Channel Number	MV-90 Scalar Register Channel Number
MV90 Electric/00001	1	1_S
MV90 Electric/00002	1	1_S
MV90 Electric/00003	1	1_S

Override Processing Methods for MV-90 Service Provider: Add an override processing method to the Initial Measurement Creation processing method for the MV90 service provider for each register measuring component type. The business object for each override processing method should be “D5-InitialLoadIMDScalar”. The following tables shows examples of the override processing methods:

Measuring Component Type	Business Object
MV90 Scalar Register	D5-InitialLoadIMDScalar
Measuring Component Type 2	D5-InitialLoadIMDScalar
Measuring Component Type n	D5-InitialLoadIMDScalar

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

UOM Translation

UOM translation processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map MV90 UOM codes to standard UOM codes when receiving usage from the MV-90 system.

Configuring MV90 Extendable Lookups

Note: This section applies to **both** middleware and native implementations of the Smart Grid Gateway MV90 Adapter for Itron.

This section outlines some of the extendable lookups that must be configured for use with the MV-90 Adapter for Itron. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Interval Status Code to Event Mapping

The MV-90 Adapter for Itron does not accept device events from an MV-90 system, but can create device events based on specific interval status codes in an incoming usage reading. The MV-90 Interval Status Code to Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when creating device events based on interval status codes received with usage from the MV-90 system.

Each value defined for the Interval Status Code to Event Mapping extendable lookup should include the following:

- **MV90 Interval Status:** The interval status code used by the MV-90 system
- **Description:** A description of the MV-90 interval status code
- **Event Duration Mode:** The duration type for the event. Can be either “Individual” or “Continuous” (used for events with a duration, such as an outage).

- **Device Event Type:** The Device Event Type for the device event created for this interval status code. For status codes with an Event Duration Mode or “Continuous” this is the start event, or the first of the paired events created for this status code.
- **End Event Type:** The Device Event Type for the “end” device event created for this interval status code. For status codes with an Event Duration Mode or “Continuous” this is the start event, or the last of the paired events created for this status code.

Example: The MV-90 “Low Voltage” status code could be configured to create a “Low Voltage” device event as follows:

- **MV90 Interval Status:** <MV-90 interval status code for low voltage>
- **Description:** Low Voltage detected for meter
- **Event Duration Mode:** Individual
- **Device Event Type:** Low Voltage
- **End Event Type:** N/A

Example: The MV-90 “Power Outage” status code could be configured to create a “Last Gasp” device event, and a “Power Restoration” event as follows:

- **MV90 Interval Status:** <MV-90 interval status code for outage>
- **Description:** Outage
- **Event Duration Mode:** Continuous
- **Device Event Type:** Last Gasp
- **End Event Type:** Power Restoration

UOM Code to Standard UOM Code Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-end UOM:** The unit of measure code used by the head-end system.
- **Unit of Measure:** The unit of measure defined in the system.
- **Description:** A description of the unit of measure code.

Other Extendable Lookups

Business Object Name	Description
D5 - ChanelStatusCodeLookup	MV-90 Channel Status Code Lookup
D5-IntStsCdToCndMapPrLookup	Condition Mapping with Priority

Networked Energy Services

The Oracle Utilities Smart Grid Gateway Adapter for Networked Energy Services (NES) supports two-way communication with the NES server. Communications include measurement data and device event loading, and command messaging in support of commissioning, connect, disconnect, decommissioning, and on-demand read. The adapter uses Oracle Service Bus (OSB) and Oracle Business Process Execution Language Process Manager (BPEL PM) to facilitate communication between Oracle Utilities Smart Grid Gateway and NES. The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Version	Networked Energy Services 5.3

Attribute	Details
Protocol	Proprietary (NES specific)
Market(s)	Worldwide
Architecture	ANSI and IEC, PLC

Networked Energy Services Adapter Processing

This section provides details concerning the OSB processing, BPEL Processes, and Oracle Utilities Application Framework (OUAF) objects that are supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway (SGG) service format. Payloads contain measurements and meter events in some head-end specific format. OSB then places each service call into a Java Message Service (JMS) queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel. A service then creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Initial Measurements

Usage data is exported from the head-end system as a file in NES format and is loaded into Oracle Utilities as initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. **SGG-D4-USAGE-BASE** contains components responsible for the actual processing of incoming data. This should not be modified during configuration.
2. **SGG-D4-USAGE-CM** allows you to segment your customizations so that future upgrades of base functionality implemented in SGG-D4-USAGE-BASE do not affecting the customization and environment settings.

The runtime configuration settings for the SGG-D4-USAGE-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	

Element	Description	Valid Values
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterUsage	Determines if usage should be filtered.	true false

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D4-USAGE-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue

Parameter	Description	Default Value
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **NES UOMCode Mapping Extendable Lookup** extendable lookup (D4-HeadendUOMLookup) are passed into the system for processing.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/ or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (DIRT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

The device event data exported from the head-end system as a file in NES format is loaded into Oracle Utilities as a Device Event. One of your configuration tasks is to customize the device events processing.

The required functionality is delivered in the base product as two OSB projects:

1. **SGG-D4-EVENT-BASE** contains components responsible for the actual processing of incoming data. This should not be modified during configuration.
2. **SGG-D4-EVENT-CM** allows you to segment your customizations so that future upgrades of base functionality implemented in SGG-D4-EVENT-BASE do not affecting the customization and environment settings.

The runtime configuration settings for the SGG-D4-EVENT-CM project are stored in the EnvironmentSettings.xq XQuery file. You can use this file to adjust device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the device event data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
serviceProviderExternalId	The External ID of the NES service provider.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false

Publishing Events

The NES adapter can be configured to publish device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Device Event Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D4-EVENT-CM OSB project are used in publishing device events data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Device Event Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Device event data is published in the “native” device event data format (the format of the device event seeder business object). This format includes normalized device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: In addition, filtering can NOT be applied to device events published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Events

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **NES Device Event Mapping** extendable lookup (D4-DeviceEventMappingLookup) are passed into the system for processing.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (DIRT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D4-EVENT-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

Note: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The NES adapter base package includes the following device, initial measurement, and device event business objects:

Business Object Name	Description
D4-InitialLoadIMDInterval	NES Initial Load IMD Interval

Business Object Name	Description
D4-InitialLoadIMDScalar	NES Initial Load MD Scalar
D4-SmartMeter	Smart Meter - NES
D4-EventExtractScheduler	NES Event Extract Scheduler
D4-PayloadExtractScheduler	Payload Extract Scheduler
D4-UsageExtractScheduler	NES Usage Extract Scheduler

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related web service from the head-end system. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each NES command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	Retrieve Meter Information	Read Load Status Notification	Create IMD
	Read Load Status	Read Billing Data On-Demand Notification	Connect Device
	Read Billing Data On-Demand	Connect Load Notification	
	Connect Load		
Remote Disconnect	Disconnect Load	Disconnect Load Notification	Create IMD
	Read Billing Data On-Demand	Read Billing Data On-Demand Notification	Disconnect Device
Device Commissioning	Add Meter Request	Set ATM Configuration Notification	Device Commissioning
	Set ATM Configuration		
Device Decommissioning	Decommission Meter Request	Decommission Meter Notification	Device Decommissioning
On-Demand Read (Scalar)	Read Billing Data On-Demand	Read Billing Data On-Demand Notification	Create IMD
On-Demand Read (Interval)	Read Load Profile On-Demand	Read Load Profile On-Demand Notification	Create IMD

Commissioning and Decommissioning Communications

Commissioning a previously decommissioned NES device requires a different process than commissioning a new device.

When you commission a device for the first time, a commissioning command is sent to BPEL to create the meter in NES using the DeviceManager.CreateMeter command. If Automatic Topology Management is selected then the DeviceManager.SetATMConfiguration command is also sent.

When you decommission a device, BPEL sends the DeviceManager.Move command to NES for the device. In NES you need to confirm that the device has been moved to a non-DC tree. You then need to manually delete the device from the non-DC tree. To permanently decommission the device you must delete it by using the DeviceManager.Delete command from the NES interface.

To recommission a device that has been previously decommissioned, you need to log into NES and manually move the meter from the non-DC tree to the DC tree that it belonged to previously. This will not be possible if the device has been deleted from within NES.

Device Communication Base Package Business Objects

The NES base package includes the following communication business objects:

Meter Commissioning

Business Object	Description
D4-AddMeterRequest	Add Meter Request
D4-GenericAMIDeviceIdentifier	Generic AMI Device Identifier
D4-RetrieveMeterIdentifier	Retrieve Meter Identifier
D4-RetrieveMeterInfo	Retrieve Meter Information
D4-SetATMConfigNotification	Set ATM Configuration Notification
D4-SetATMConfiguration	Set ATM Configuration

Meter Decommissioning

Business Object	Description
D4-DecommMeterNotification	Decommission Meter Notification
D4-DecommMeterRequest	Decommission Meter Request

On-Demand Read

Business Object	Description
D4-ReadBillingData	Read Billing Data On-Demand
D4-ReadBillingDataNtf	Read Billing Data On-Demand Notification
D4-ReadLoadProfile	Read Load Profile On Demand
D4-ReadLoadProfileNtf	Read Load Profile On-Demand Notification

Business Object	Description
D4-ReadLoadStatus	Read Load Status
D4-ReadLoadStatusNtf	Read Load Status Notification

Remote Connect

Business Object	Description
D4-ConnectLoad	Connect Load
D4-ConnectLoadNtf	Connect Load Notification

Remove Disconnect

Business Object	Description
D4-DisconnectLoad	Disconnect Load
D4-DisconnectLoadNtf	Disconnect Load Notification

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Outbound Message Types

Acknowledgment and response messages are sent and received validating that commands have been transmitted.

Outbound Message Type	Description
D4-ADDMETREQ	Add Meter Request
D4-CONLOAD	Connect Load
D4-DECMETREQ	Decommission Meter Request
D4-DISCONLD	Disconnect Load
D4-HNLBATEVT	NES - Handle Batch Event
D4-HNLBATUSG	NES - Handle Batch Usage
D4-RDLOADST	Read Load Status
D4-READLP	Read Load Profile

Outbound Message Type	Description
D4-READOUT	Read Billing Data
D4-RETMETID	Retrieve Meter Identifier
D4-RETRIEVE	Retrieve Meter Information
D4-SETATMCFG	Set ATM Configuration

Inbound / Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The Oracle Utilities Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway Adapter for NES uses the following inbound web services to import usage and device events:

Inbound Web Service	Description
D1-DeviceEventSeeder	Used for upload of device events. The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event. If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.
D1-InitialLoadIMD	Used for initial measurement upload. The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.

The Oracle Utilities Smart Grid Gateway Adapter for NES includes the following inbound web services for receiving communications from the NES:

Inbound Web Service Name	Description
D4-ConnectLoadNotification	Connect Load Notification
D4-DecommMeterNotificationXAI	Meter Decommission Notification
D4-DisconnectLoadNotification	Disconnect Load Notification

Inbound Web Service Name	Description
D4-ReadBDNotificationXAI	Read Billing Data On-Demand Notification
D4-ReadingATMConfigNotification	Get Response Initiate Read By Meter Number
D4-ReadLoadStatusNotification	Read Load Status Notification
D4-ReadLPNotificationXAI	Read Load Profile On-Demand Notification

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

The Oracle Utilities Smart Grid Gateway Adapter for NES includes the following message senders:

Message Sender	Description
D4-ADDMETREQ	Add Meter Request
D4-CONLOAD	Connect Load
D4-DECOMMIS	Device Decommissioning
D4-DISCONLD	Disconnect Load
D4-HNLBATEVT	NES Handle Batch Event
D4-HNLBATUSG	NES Handle Batch Usage
D4-RDLOADST	Read Load status
D4-READBILLD	NES On-Demand Read (Scalar)(2)
D4-READLP	Read Load Profile
D4-RETMETID	Retrieve Meter Identifier
D4-RETRIEVE	Retrieve Meter Information
D4-ReadBill	Read Billing Data
D4-SETATMCFG	Set ATM Configuration

BPEL Processes and Web Services

These processes are responsible for performing the conversion from Oracle Utilities format to NES format, invoking process callouts and invoking the remote endpoint to trigger the device events.

All web services receive XML from an incoming service then transform the call to a format which is recognized by the NES system.

CreateMeter: Receives the incoming XML from the message sender service, transforms it to the NES API parameters node, passes it to the DeviceManager.Create NES API web service method then collects XML from CreateMeter to be returned to Oracle Utilities Smart Grid Gateway.

Messages

CreateMeter RequestMessage: Contains the parameters which are formatted from Oracle Utilities Smart Grid Gateway to match the incoming XML for the NES API DeviceManager.Create method.

CreateMeter ResponseMessage: Contains the Device ID that is used when the DeviceManager.Create method validates the security key and the XML parameters successfully.

Related Processes

Meter Commissioning

ConnectLoadRemoteConnect

Receives the incoming XML from the D4-CONLOAD (Connect Load) message sender in Oracle Utilities Smart Grid Gateway and transforms to NES format.

GrabBatchEvents

Retrieves the un-processed events from the event repository; transforms each batch to replace GUID identifiers with a readable form, and finally prepares a new file for OSB before deleting the batch of events. The scheduled call to this service can contain the preferred dates to query for or can accept the default which is the previous day usage.

Messages

GrabBatchEventsSoapIn

GrabBatchEventsSoapOut

GrabBatchUsage

Retrieves the un-processed usage from the usage repository; transforms each batch to replace GUID identifiers with a readable form, and finally prepares a new file for OSB before deleting the batch of usage. The scheduled call to this service can contain the preferred dates to query for or can accept the default which is the previous day usage.

Messages

GrabBatchUsageSoapIn

GrabBatchUsageSoapOut

Related Processes

Connection

Event Management

Usage Processing

MeterDecommissioning

Receives the incoming XML from the message senderOutbound service and transforms to NES API parameters node to be passed to the DeviceManager.Move NES API web service method. The process then collects the return XML to be returned to Oracle Utilities Smart Grid Gateway.

Messages

MeterDecommissioningRequestMessage: This message is the input for the Move method. The method contains the parameters conveniently formatted from Oracle Utilities Smart Grid Gateway to match the incoming XML for the NES API DeviceManager.Move method.

MeterDecommissioningResponseMessage: This message contains status stating that the DeviceManager.Create method validated the security key and the XML parameters are accepted successfully. If the status is SUCCEEDED, it also contains Tracking ID for the call, Device ID and StatusType ID.

Related Processes

Meter Decommissioning

PerformCommand

This web service facilitates most of the communication between Oracle Utilities Smart Grid Gateway and the NES system. If your implementation requires functionality that was not delivered as part of the base package this web service will play an integral part in managing those customizations.

PerformCommand executes a command which generates the events that advance the Oracle Utilities Smart Grid Gateway lifecycle then returns the output string to the caller. The output might be a tracking ID or information about a device.

Messages

PerformCommandSoapIn: The sXmlParameters input is prepared from within Oracle Utilities Smart Grid Gateway to execute primarily a group of five commands, these are Read Load Status, On-Demand Read, Connect Load, Disconnect Load and Set ATM Configuration.

PerformCommandSoapOut:

The return from PerformCommand is the xml from the DeviceManager.PerformCommand for Read Load Status, On-Demand Read, Connect Load, Disconnect Load and Set ATM Configuration.

ReceivePanoramixEvents

This web service is actually never called by the implementation, but rather it is called by NES and is needed when configuring the NES server.

ReceivePanoramixEvents obtains the APIKey from the NES authentication service, then, with the event definition ID from the parameter list for this service, switches to the branch for the event definition to begin any specific processing. For example, an on-demand read completion event means that the BPEL PM process needs to retrieve the usage using the RESULTID found in the event xml. All events and usage to be passed on to Oracle Utilities Smart Grid Gateway must first be transformed to replace the GUID with a readable form items. This involves using the BPEL PM DVM lookup functionality.

Event Management

PrePerformCommandCallout / PostPerformCommandCallout

These web services are hooks designed to allow customization of messages just prior and just after sending them to the NES server. Your implementation may wish to modify the data for special purposes. This is the one of the only places where modification of BPEL PM code is allowed.

ReceivedPanoramixEventsCallout

This web service is a hook designed to allow customization of messages just prior and just after sending them to the NES server. Your implementation may wish to modify the data for special purposes. This is one of the only places where modification of BPEL PM code is allowed.

ReadBillingDataOnDemand

This web service method, initiate a call to NES system with formatted inbound xml parameter. First it transforms the Parameters received from the calling system in to NES system recognizable format. Then it invokes a call to the NES system's Device Manager Service. When the call is invoked the system receives the return XML from DeviceManager stating the status of the command execution and, if succeeded, the tracking ID of this call.

Messages

ReadBillingDataOnDemandRequestMessage: Contains the input parameter for DeviceManager Perform Command to read billing data OnDemand. It formats parameters from the calling system to match incoming XML for the NES DeviceManager.PerformCommand method.

ReadBillingDataOnDemandResponseMessage: Transforms the response xml from NES system format to Oracle Utilities Smart Grid Gateway format.

Related Processes

On Demand Reads

ReadLoadProfileOnDemand

This web service method, initiate a call to NES system's Device Manager Service with formatted inbound xml parameter. First it transforms the Parameters received from the calling system in to NES system recognizable format. Then it invokes a call to the NES system thru Device Manager Service. After invoking the call, the system receives the response message from DeviceManager stating the status of the command execution and, if succeeded, the tracking ID of this call.

Messages

ReadLoadProfileOnDemandRequestMessage: This message is for interval on demand read request to the NES system. Transforms the incoming XML from Oracle Utilities Smart Grid Gateway to NES recognizable format.

ReadLoadProfileOnDemandResponseMessage: Transforms the response xml for ReadLoadProfileOnDemandRequest from NES system format to Oracle Utilities Smart Grid Gateway format.

Related Processes

On Demand Reads

ReadLoadStatusRemoteConnect

Receives the incoming XML from the D4-RDLOADST (Read Load Status) message sender in Oracle Utilities Smart Grid Gateway and transforms to NES format.

RemoteDisconnect

Receives the incoming XML from the D4-DISCONLD (Disconnect Load) message sender in Oracle Utilities Smart Grid Gateway and transforms to NES format.

RetrieveMeterInfo

Initiates a call to the Request Management Service with formatted inbound xml parameters. First it transforms the Parameters received from the calling system in to NES system recognizable format. Then it invokes a call to the NES system thru Request Management Service and retrieves a response with Meter Information.

Messages

RetrieveMeterInformationRequestMessage: Contains the input parameter for DeviceManager Perform Command to retrieve meter information. It also formats parameters from the calling system to match incoming XML for the NES DeviceManager.PerformCommand method.

RetrieveMeterInformationResponseMessage: Transforms the response xml from NES system format to Oracle Utilities Smart Grid Gateway format.

Related Processes

Remote Disconnect

Remote Connect

RetrieveMeterIdentifier

Receives a call from Oracle Utilities Smart Grid Gateway for RetrieveMeterIdentifier process and invokes the RetrieveByParameter method in the NES system's DeviceManager service.

Converts incoming Oracle Utilities Smart Grid Gateway formatted input to sXmlParameters in NES format then invokes RetrieveMeterIdentifier.

Messages

RetrieveMeterIdentifierRequestMessage: Transforms the xml received from the calling system to match incoming XML for the NES API DeviceManager.RetrieveByParameter method. This method requires the Type of ID and the associated ID as input.

RetrieveMeterIdentifierResponseMessage: When the XML is synchronously returned from the head-end system for the RetrieveByParameter call, the DEVICEID node is only included in the APIPAYLOAD if the status of the call is Succeeded.

Related Processes

Meter Commissioning

SetATMConfiguration

This web service method is specific to set Automated Topology Management (ATM) configuration command which assigns the Meter to the Data Concentrator.

Converts incoming Oracle Utilities Smart Grid Gateway formatted input to sXmlParameters in NES format then invokes the DeviceManager PerformCommand. A connection should establish to begin the NES command processing.

Messages

SetATMConfigurationRequestMessage: This message is the input for the SetATMConfiguration method. The method contains the parameters conveniently formatted from Oracle Utilities Smart Grid Gateway to match the incoming XML for the NES API DeviceManager.PerformCommand method where the COMMANDID is Constants.DeviceCommands.SET_ATM_CONFIGURATION

SetATMConfigurationResponseMessage: when the XML is synchronously returned from the head-end system for the PerformCommand call, the COMMAND node is only included in the APIPAYLOAD if the status of the call is Succeeded.

NES Web Services

The following table describes NES web services and operations used for the Oracle Utilities Smart Grid Gateway command messaging:

Smart Grid Gateway Commands	AMI Adapter Business Objects	NES Web Services	NES Operations
Device Commissioning	D4-AddMeterRequest	DeviceManager	Create
	D4-RetrieveMeterIdentifier		RetrieveByParameter
	D4-SetATMConfiguration		PerformCommand: SET_ATM_CONFIGURATION
Device Decommissioning	D4-DecommMeterRequest	DeviceManager	PerformCommand: MOVE_DEVICE_ADD
Remote Connect	D4-ConnectLoad	DeviceManager	Retrieve
	D4-ReadLoadStatus		PerformCommand: CONNECT_LOAD
	D4-RetrieveMeterInfo		READ_LOAD_STATUS

Smart Grid Gateway Commands	AMI Adapter Business Objects	NES Web Services	NES Operations
Remote Disconnect	D4-DisconnectLoad	DeviceManager	PerformCommand: DISCONNECT_LOAD
On-Demand Read	D4-ReadBillingData	DeviceManager	PerformCommand Command ID: READ_BILLING_DATA_ON_DEMAND (Scalar) READ_LOAD_PROFILE_ON_DEMAND (Interval)

Configuring a Networked Energy Services Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway NES Adapter to communicate with the NES software.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the NES in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Device Event Seeder
D1-InitialLoadIMD	IMD Seeder
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
D4-ConnectLoadNotification	Connect Load Notification
D4-DecommMeterNotificationXAI	Meter Decommission Notification
D4-DisconnectLoadNotification	Disconnect Load Notification
D4-ReadBDNotificationXAI	Read Billing Data On-Demand Notification
D4-ReadingATMConfigNotification	Get Response Initiate Meter Read By Meter Number

Inbound Web Service Name	Description
D4-ReadLoadStatusNotification	Read Load Status Notification
D4-ReadLPNotificationXAI	Read Load Profile On-Demand Notification

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
D4-ADDMETREQ	Add Meter Request
D4-CONLOAD	Connect Load
D4-DECOMMIS	Device Decommissioning
D4-DISCONLD	Disconnect Load
D4-HNLBATEVT	NES Handle Batch Event
D4-HNLBATUSG	NES Handle Batch Usage
D4-RDLOADST	Read Load status
D4-READBILLD	NES On-Demand Read (Scalar)(2)
D4-READLP	Read Load Profile
D4-RETMETID	Retrieve Meter Identifier
D4-RETRIEVE	Retrieve Meter Information
D4-ReadBill	Read Billing Data
D4-SETATMCFG	Set ATM Configuration

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction: http://xmlns.oracle.com/ouaf/echelon/<OPERATION>
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/D4/<SERVICE>/<SERVICE>

where:

- <OPERATION>: the operation performed by the message sender (see Operation column in the table above)
- <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
- <PASSWORD>: the password used to log into WebLogic Enterprise Manager
- <EM_SERVER>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- <EM_SERVER_PORT>: the port where the WebLogic Enterprise Manager is installed
- <SERVICE>: the service invoked by the message sender (see Service column in the table above)

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
D4-ADDMETREQ	Add Meter Request
D4-CONLOAD	Connect Load
D4-DECMETREQ	Decommission Meter Request
D4-DISCONLD	Disconnect Load
D4-HNLBATEVT	NES - Handle Batch Event
D4-HNLBATUSG	NES - Handle Batch Usage
D4-RDLOADST	Read Load Status
D4-READLP	Read Load Profile
D4-READOUT	Read Billing Data
D4-RETMETID	Retrieve Meter Identifier
D4-RETRIEVE	Retrieve Meter Information

Outbound Message Type	Description
D4-SETATMCFG	Set ATM Configuration

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the NES must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - NES:

- **External System:** NES
- **Description:** NES
- **Outbound Message Types::**

Outbound Message Type	Message Sender
D4-ADDMETREQ	D4-ADDMETREQ
D4-CONLOAD	D4-CONLOAD
D4-DECMETREQ	D4-DECOMMIS
D4-DISCONLD	D4-DISCONLD
D4-HNLBATEVT	D4-HNLBATEVT
D4-HNLBATUSG	D4-HNLBATUSG
D4-RDLOADST	D4-RDLOADST
D4-READLP	D4-READBILLD
D4-READOUT	D4-READLP
D4-RETMETID	D4-RETMETID
D4-RETRIEVE	D4-RETRIEVE
D4-SETATMCFG	D4-SETATMCFG

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D4-Request.xml
- **Response XSL:** D4-Response.xml

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the NES must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about creating service providers.

Service Provider - NES

- **Service Provider:** NES
- **Description:** NES
- **External Reference ID:** NES
- **External System:** D4-NES
- **Out Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the NES service provider. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

UOM Translation

UOM mapping processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the NES service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1–HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	D4-SetATMConfiguration	Set ATM Configuration
Device Decommission	Device Removal	D4-DecommMeterRequest	Decommission Meter Request
On-Demand Read (Scalar)	On-Demand Read (Scalar)	D4-ReadBillingData	Read Billing Data
On-Demand Read (Interval)	On-Demand Read (Interval)	D4-ReadLoadProfile	Read Load Profile
Device Status Check	Device Status Check	D4-ReadLoadStatus	Read Load Status
Remote Connect	Remote Connect	D4-ConnectLoad	Connect Load
Remote Disconnect	Remote Disconnect	D4-DisconnectLoad	Disconnect Load

Other Processing Methods

This section outlines details for other processing methods used by the NES adapter.

Processing Role	Default Business Object	Default Outbound Message Type
NES Add Meter Request	D4-AddMeterRequest	Commission
NES Retrieve Meter Identifier	D4-RetrieveMeterIdentifier	Commission Retrieve Meter Identifier
NES Retrieve Meter Information	D4-RetrieveMeterInfo	Retrieve Meter Info

Configuring Endpoint URIs

Part of the configuration process is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands. The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head-end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoint URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The NES endpoint override DVM (D4-EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the NES adapter and the command used with each:

DVM Key	Commands
DeviceManager	Remote Connect Remote Disconnect Device Commissioning Device Decommissioning On-Demand Read (Scalar) On-Demand Read (Interval)
EventManager	On-Demand Read (Scalar) On-Demand Read (Interval)
GatewayManager	Remote Connect Remote Disconnect Device Commissioning Device Decommissioning On-Demand Read (Scalar) On-Demand Read (Interval)
SettingManager	Remote Connect Remote Disconnect Device Commissioning Device Decommissioning On-Demand Read (Scalar) On-Demand Read (Interval)
UserManager	Remote Connect Remote Disconnect Device Commissioning Device Decommissioning On-Demand Read (Scalar) On-Demand Read (Interval)
ProcessCallout	User Exit Functions

To define an override Endpoint URI for the NES adapter, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is <http://server:port/soa/composer>.

2. Select the D4-EndpointOverrides.dvm in the left panel.

- In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
- In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list. The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.
4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:
 - **key**: The DVM key for the Endpoint URI you wish to define (see the table above).
 - **EndpointURI**: The override Endpoint URI.
6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.
8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Networked Energy Services Extendable Lookups

Note: This section applies to **both** middleware and native implementations of the Smart Grid Gateway Adapter for Networked Energy Services.

This section outlines some of the extendable lookups that must be configured for use with the NES adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system. Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name**: The event name used by the head-end system
- **Description**: A description of the device event
- **Status**: The status of the lookup value (can be Active or Inactive)
- **Standard Event Name**: The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

UOM Code to Standard UOM Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-end UOM**: The unit of measure code used by the head-end system.
- **Unit of Measure**: The unit of measure defined in the system.
- **Description**: A description of the unit of measure code.

Interval Status Code to Condition Mapping

Interval usage received from the NES can include NES interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The NES Interval Status Code to Condition Mapping extendable lookup is used to determine how to map NES interval status codes to standard status codes when receiving usage from the NES.

Each value defined for the NES Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The NES interval status code
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.
- **Description:** A description of the interval status code.
- **Priority:** The priority of the interval status code, represented as a numeric value where larger numbers correlate to higher priorities.

Other Extendable Lookups

Business Object	Description
D4-EntityTypeLookup	Entity Type
D4-ExtServiceReturnCodeLookup	External Service Return Code
D4-GatewayTypeLookup	Gateway Type
D4-IDTypeLookup	ID Type
D4-InformationReturnCodeLookup	Information Return Code
D4-LoadVoltageStatusTypeLookup	Load Voltage Status Type
D4-TaskPriorityLookup	Task Priority
D4-TimeZoneManagerLookup	Time Zone Manager

Configuring NES Usage and Event Extract Processing

Usage and events received from the NES server must be requested from Oracle Utilities Smart Grid Gateway.

Extract requests for usage and events are triggered by a batch process, and sent to the NES via middleware. The NES compiles a batch of usage or events and sends it to BPEL services to create a file to be processed by Oracle Service Bus (OSB) services, it is then loaded as SGG events and/or usage.

This section describes the processing performed by the extract request process, and the configuration steps involved.

Extract Request Processing

This section provides a detailed description of the extract request process.

- The “Usage / Event Extract Scheduler Monitor” batch process (D1-EXTSC) checks for “NES Usage Extract Scheduler” or “NES Event Extract Scheduler” activities that are in the “Active” state, and transitions these to the “Send Request” state. It also updates the “Latest Request Start Date/Time” and “Latest Request End Date/Time” fields on the activity based on the date and time of the request.
- When the activity enters the “Send Request” state, an Enter algorithm (either “Usage Extract Scheduler Send Request” (D4-USGSNDREQ) or “Event Extract Scheduler Send Request” (D4-EVTSNDREQ)) sends a request via a message sender to the middleware (via the GrabBatchUsage or GrabBatchEvent BPEL services), which in turn send the request to the NES server.

- After the request is sent, the “NES Usage Extract Scheduler” or “NES Event Extract Scheduler” activity to set back to the “Active” state.
- The NES server calls the BPEL services “GrabBatchEvents” and “GrabBatchUsage.” BPEL then routes the incoming events or usage to a file system, which is used by OSB components to process the usage or events.

Extract Request Configuration Steps

This section outlines the objects that must be configured to support batch extracts of usage and events from an NES head-end system. To configure the NES Adapter to support sending extract requests for usage and events, you must do the following:

- Create message senders (one for usage, one for events) to send extract requests.
- Create Outbound Message Types (one for usage, one for events) for extract requests.
- Associate the message senders and Outbound Message Types to the External System used with the head-end system service provider
- Create “NES Usage Extract Scheduler Type” and “NES Event Extract Scheduler Type” activity types.
- Create “NES Usage Extract Scheduler” and “NES Event Extract Scheduler” activities.

The following sections provide details for configuring these object. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders, Outbound Message Types, and External Systems.

Note: Configuration of the OSB and BPEL services used by this process is done when installing and configuring the OSB and BPEL components of the NES Adapter.

Message Sender - NES Handle Batch Event

Create a message sender for event extracts as follows:

Main Tab:

- **Message Sender:** Enter a code for the batch event message sender (D4-HNLBATEVT)
- **Description:** NES Handle Batch Event
- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes messages via HTTP real-time)
- **Active:** True (checked)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction:http://xmlns.oracle.com/ouaf/NES/GrabBatchEvents
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/NES/HandleBatchEvent/BatchEventHandler

where:

- <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
- <PASSWORD>: the password used to log into WebLogic Enterprise Manager
- <EM_SERVER>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- <EM_SERVER_PORT>: the port where the WebLogic Enterprise Manager is installed

Message Sender - NES Handle Batch Usage

Create a message sender for usage extracts as follows:

Main Tab:

- **Message Sender:** Enter a code for the batch usage message sender (D4-HNLBATUSG)
- **Description:** NES Handle Batch Usage
- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDNR (Sender routes messages via HTTP real-time)
- **Active:** True (checked)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction:http://xmlns.oracle.com/ouaf/NES/GrabBatchUsage
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/NES/HandleBatchUsage/BatchUsageHandler

where:

- <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
- <PASSWORD>: the password used to log into WebLogic Enterprise Manager
- <EM_SERVER>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- <EM_SERVER_PORT>: the port where the WebLogic Enterprise Manager is installed

Outbound Message Type - NES Handle Batch Event

Create an Outbound Message Type for event extract requests as follows:

- **Outbound Message Type:** Enter a code for the batch event Outbound Message Type (D4-HNLBATEVT)
- **Description:** NES Handle Batch Event
- **Business Object:** D1-OutboundMessage
- **Priority:** - Priority 20 (or lower)

Outbound Message Type - NES Handle Batch Usage

Create an Outbound Message Type for usage extract requests as follows:

- **Outbound Message Type:** Select a code for batch usage Outbound Message Type (D4-HNLBATUSG)
- **Description:** NES Handle Batch Usage
- **Business Object:** D1-OutboundMessage
- **Priority:** Priority 20 (or lower)

External Systems

Add the event and usage extract Outbound Message Types and message senders to the external system used for the NES head-end system as follows:

- **External System:** NES
- **Description:** NES
- **Outbound Message Types:**

Outbound Message Type	Message Sender
D4-HNLBATEVT	D4-HNLBATEVT
D4-HNLBATUSG	D4-HNLBATUSG

Note: The following apply to the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D4-Request.xsl
- **Response XSL:** D4-Response.xsl

Activity Type - NES Event Extract Scheduler

Create an Activity Type for event extract requests as follows:

- **Activity Type:** Enter a code for the activity type (NES-EVENT-EXTRACT)
- **Description:** Enter a description for the activity type (NES Event Extract Scheduler Type)
- **Related Transaction BO:** NES Event Extract Scheduler
- **Activity Type Status:** Active
- **Outbound Message Type:** NES Handle Batch Event
- **External System:** The external system used for the NES head-end system
- **Exception Handling:**
 - **To Do Type:** Activity To Do Type
 - **To Do Role:** System Default Role
 - **Retry Frequency:** Select retry frequency in case if Activity reaches an error state (00:03:00)
 - **Maximum Retries:** Select max number of times the activity will be retried - since it reached the error state (1)
 - **Discard Reason:** Select from the dropdown if available.

Activity Type - NES Usage Extract Scheduler

Create an Activity Type for usage extract requests as follows:

- **Activity Type:** Enter a code for the activity type (NES-USAGE-EXTRACT)
- **Description:** Enter a description for the activity type (NES Usage Extract Scheduler Type)
- **Related Transaction BO:** NES Usage Extract Scheduler
- **Activity Type Status:** Active
- **Outbound Message Type:** NES Handle Batch Usage
- **External System:** The external system used for the NES head-end system
- **Exception Handling:**
 - **To Do Type:** Activity To Do Type
 - **To Do Role:** System Default Role
 - **Retry Frequency:** Select retry frequency in case if Activity reaches an error state (00:03:00)
 - **Maximum Retries:** Select max number of times the activity will be retried - since it reached the error state (1)
 - **Discard Reason:** Select from the dropdown if available.

Activity - NES Event Extract Scheduler

Initiate an Activity for event extract requests as follows:

1. Select **Main->Communication->Activity+**
2. Select "NES Event Extract Scheduler Type" from the **Activity Type** drop-down list.
3. Enter the number of hours for each extract request in the **Number of Hours of Data Request** field. The default is 24.
4. *Optional:* Enter start and end dates and times for the first extract request in the **Current Request Start Date/Time** and **Current Request End Date/Time** fields.

Note that these are optional fields. If not populated, the values are populated as follows:

- **Current Request Start Date/Time:** taken from the last request stop date/time (which is populated by the "Event Extract Scheduler Send Request" algorithm (D4-EVTSNDREQ))

- **Current Request End Date/Time:** the Current Request Start Date/Time plus the number of hours in the **Number of Hours of Data Request** field.

Activity - NES Usage Extract Scheduler

Initiate an Activity for usage extract requests as follows:

1. Select **Main->Communication->Activity+**
2. Select "NES Usage Extract Scheduler Type" from the **Activity Type** drop-down list.
3. Enter the number of hours for each extract request in the **Number of Hours of Data Request** field. The default is 24.
4. *Optional:* Enter start and end dates and times for the first extract request in the **Current Request Start Date/Time** and **Current Request End Date/Time** fields.

Note that these are optional fields. If not populated, the values are populated as follows:

- **Current Request Start Date/Time:** taken from the last request stop date/time (which is populated by the "Usage Extract Scheduler Send Request" algorithm (D4-USGSNDREQ))
- **Current Request End Date/Time:** the Current Request Start Date/Time plus the number of hours in the **Number of Hours of Data Request** field.

Executing Extract Requests

To schedule and execute usage and device event extract requests, set up the "Usage / Event Extract Scheduler Monitor" batch process (D1-EXTSC) to run at a frequency appropriate to when you wish to retrieve usage and device events from the NES. For example, to retrieve usage and device events on a daily basis, schedule the "Usage / Event Extract Scheduler Monitor" batch process (D1-EXTSC) to run once every 24 hours.

Sensus

The Oracle Utilities Smart Grid Gateway Adapter for Sensus RNI supports communication with the Sensus Regional Network Interface (RNI), including measurement data and device event loading, and command messaging in support of commissioning, connect, disconnect, decommissioning, status check, and on-demand read. The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Version	Sensus RNI 4.4, 4.5.1, 4.10, 4.12, 4.14
Protocol	MultiSpeak 3.0 & 4.1. RNI 3.1 and the SGG Sensus RNI adapter support MultiSpeak 4.1
Market(s)	Worldwide
Architecture	Long range radio WAN (mesh)

Sensus Adapter Processing

This section provides details concerning the OSB processing, BPEL Processes, and Oracle Utilities Application Framework (OUAF) objects that are supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway (SGG) service format. Payloads contain measurements and meter events in some head-end specific format. OSB then places each service call into a Java Message Service (JMS) queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective

services in parallel. A service then creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Initial Measurements

The usage data exported from the AMI head-end system as a file in Sensus RNI format is loaded into Oracle Utilities as Initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. **SGG-D6-USAGE-BASE** contains components responsible for “actual” processing of incoming data. It should not be modified during configuration. This can be upgraded without affecting the customization and environment settings added to SGG-D6-USAGE-CM.
2. **SGG-D6-USAGE-CM** allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-D6-USAGE-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRawIMD	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
dateTimeInUTC	Indicates whether the Sensus RNI system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device.	true false
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterUsage	Determines if usage should be filtered.	true false
useExternalTOU	Indicates whether or not an externally reference TOU period should be used when processing measurement data.	true false

Element	Description	Valid Values
scalarExpanding	<p>Defines the number of register reads to process in scalar payloads. When defined, Sensus payload processing uses this setting to ensure that all the scalar reads included in a payload will be processed.</p> <p>Default value is 2.</p>	

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D6-USAGE-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	<p>JNDI name of queue to publish SGG payloads.</p> <p>This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.</p>	DataRakerQueue

Parameter	Description	Default Value
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **Sensus UOM Code to Standard UOM Mapping** extendable lookup (D6-HeadendUOMLookup) are passed into the system for processing.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/ or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (DIRT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

The device event data exported from the head-end system as a file in Sensus RNI format is loaded into Oracle Utilities as a Device Event. One of your configuration tasks is to customize the device events processing.

The required functionality is delivered in the base product as two OSB projects:

1. **SGG-D6-EVENT-BASE** contains components responsible for “actual” processing of incoming data. It can be upgraded in future without affecting the customization and environment settings that done in SGG-D6-EVENT-CM project.
2. **SGG-D6-EVENT-CM** allows the customization and simplifies the future upgrades.

The runtime configuration settings for the SGG-D6-EVENT-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the event data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
dateTimeInUTC	Indicates whether the Sensus RNI system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device.	true false
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false

Publishing Events

The Sensus adapter can be configured to publish device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Device Event Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D6-EVENT-CM OSB project are used in publishing device events data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Device Event Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Device event data is published in the “native” device event data format (the format of the device event seeder business object). This format includes normalized device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: In addition, filtering can NOT be applied to device events published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Events

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **Sensus Device Event Mapping** extendable lookup (D6-DeviceEventMappingLookup) are passed into the system for processing.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (DIRT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D6-EVENT-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

Note: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The Sensus RNI adapter base package includes the following device and initial measurement business objects:

Business Object Name	Description
D6-InitialLoadIMDInterval	Sensus Initial Load IMD - Interval Used when loading Sensus interval measurements into the system for the first time.
D6-InitialLoadIMDScalar	Sensus Initial Load IMD - Scalar
D6-SmartMeter	Sensus Smart Meter

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related web service from the head-end system. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each Sensus RNI command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	Sensus – Initiate Connect Disconnect	Sensus – Connect / Disconnect State Change	Connect Device Completion Event
Remote Disconnect	Sensus – Initiate Connect Disconnect	Sensus – Connect / Disconnect State Change	Disconnect Device Completion Event
Device Commissioning	Sensus – Meter Add Notification		Device Commissioning Completion Event
Device Decommissioning	Sensus – Meter Remote Notification		Device Decommissioning Completion Event
On-Demand Read (Scalar)	Sensus – Initiate Meter Read By Meter ID	Sensus – Reading Changed Notification	Create IMD Completion Event
On-Demand Read (Interval)	Interval data not supported		
Device Status Check	Sensus – Initiate Outage Detection	Sensus – Outage Detection Event Notification	

Unit of Measure Filtering for On-Demand Reads

Readings returned via On-Demand Read commands are filtered on the combination of Unit of Measure/Time of Use/Service Quantity Identifiers (UOM/TOU/SQI) configured for the device and measuring component. When filtering is enabled, only readings that match a configured UOM/TOU/SQI combination are processed. All others are filtered out.

Filtering is enabled by default via the “Opt Out Of Filtering” parameter (set to "false" by default) on the D6-CCOMPEV (Create IMD Completion Event) algorithm on the Create Completion Events status of the D6-ReadingChgNotification (Sensus - Reading Changed Notif SOA based) business object.

The D6-VALDVCFIL (Check if Device has any Filtering errors) algorithm on the Validate status of the D6-ReadingChgNotification (Sensus - Reading Changed Notif SOA based) business object is used to check for errors related to filtering. The value of the “Opt Out Of Filtering” parameter on this algorithm must match the value of the parameter on the D6-CCOMPEV algorithm. The parameters should both be set to either "false" (the default) or "true" (if filtering is to be disabled).

Device Communication Base Package Business Objects

The Sensus RNI Adapter base package includes the following communication business objects:

Business Object Name	Description
D6-ConnectDisconStateChgNtf	Sensus - Connect/Disconnect State Change
D6-InitiateConnectDisconnect	Sensus - Initiate Connect Disconnect
D6-InitiateMeterByMeterId	Sensus - Initiate Meter Read By Meter ID
D6-InitiateOutageDetection	Sensus - Initiate Outage Detection
D6-MeterAddNotification	Sensus - Meter Add Notification
D6-MeterRemoveNotification	Sensus - Meter Remove Notification
D6-OutageDetectEvtNotification	Sensus - Outage Detection Event Notification
D6-ReadingChgNotification	Sensus - Reading Changed Notification
D6-UnsolicitedEvtNotification	Sensus - Unsolicited Event Notification

Sensus Event Data Mapping

The Sensus event file format maps as follows into the business object, D1-DeviceEventMappingLookup:

Sensus Flat File Field	Device Event Seeder BO Element	Comments
Transaction ID (from Header record)	External Source Identifier	This is the file name.
Device Identifier	External Device Identifier	
Event Name	External Event Name	
Event Creation Date/Time	Event Date/Time	
Device Type	External Device Type	This element has no real bearing on the device type within MDM/SGG. Its valid values include (although the element itself is free-form): Meter Collector Router
Service Location ID	External Service Location ID	

Sensus Flat File Field	Device Event Seeder BO Element	Comments
Communication Module Serial Number	External Communication Module Identifier	
Event Category ID	External Event Category	
Event Severity	External Event Severity	Valid values include (although the element itself is free-form): Alert Information
Status Value	External Status Value	This represents additional information that relates to the event itself.
Status Date/Time	External Status Date/Time	The date & time at which the additional information referenced above had occurred.

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Outbound Message Types

Acknowledgement and response messages are sent and received validating that commands have been transmitted.

Outbound Message Type	Description
D6-CONDISCON	Sensus Initiate Connect Disconnect
D6-INITMTR	Initiate Meter Read By Meter ID
D6-INTOUTDET	Initiate Outage Detection Request

Inbound / Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The Oracle Utilities Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway adapter for Sensus RNI includes the following inbound web services:

Inbound Web Service	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	<p>Used for upload of device events.</p> <p>The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event.</p> <p>If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.</p>
D1-InitialLoadIMD	<p>Used for initial measurement upload.</p> <p>The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.</p>
D1-DeviceStatusCheck	<p>Device Status Check</p> <p>This service is invoked by the integration layer to instantiate a Device Status Check command.</p>
D1-InitialLoadIMD	<p>Used by OSB to instantiate an IMD</p> <p>This inbound web service is used by OSB to instantiate an Initial Measurement Data for incoming interval usage in the Sensus format.</p>
D1-RemoteConnect	<p>Remote Connect</p> <p>This service is invoked by the integration layer to instantiate a Remote Connect command.</p>
D1-RemoteDisconnect	<p>Remote Disconnect</p> <p>This service is invoked by the integration layer to instantiate a Remote Disconnect command.</p>
D6-ConDisconStChgNotification	<p>Initiate Connect Disconnect response.</p> <p>Retrieve response from the Initiate Connect Disconnect command.</p>
D6-OutageDetectionEventNotification	<p>Initiate Outage Detection Response</p> <p>Retrieve response from the Initiate Outage Detection Event Notification command.</p>
D6-ReadingChangedNotification	<p>Reading Changed Notification</p> <p>Notification that a Sensus device reading has changed.</p>

Inbound Web Service	Description
D6-UnsolicitedEventNotification	Unsolicited Event Response Retrieve unsolicited notifications when an event triggers an alarm on the meter.

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

The Oracle Utilities Smart Grid Gateway adapter for Sensus RNI includes the following message senders:

Message Sender	Description
D6-CONDISCON	Sensus Initiate Connect/Disconnect
D6-INTOUTDET	Initiate Outage Detection Request
D6-InitMID	Initiate Meter Read By Meter ID Outbound Message

BPEL Processes

These processes are responsible for performing the conversion from Oracle Utilities format to MultiSpeak 4.1 format, invoking process callouts and invoking the remote endpoint to trigger the device events.

OnDemandRead Composite Process — Invokes the remote endpoint to trigger the on-demand read event. An asynchronous reply responds to the OUAF layer when the reading arrives.

ConnectDisconnect Composite Process — Invokes the remote endpoint to trigger the connect/disconnect event. An asynchronous reply responds to the OUAF layer when confirmation of the requested event arrives.

CommissionDecommission Composite Process — Invokes the remote endpoint to trigger the commission or decommission event. After the synchronous call completes, a one of the following second business callout services is invoked to determined if the related “received” or “completed” callout should be executed:

- isExecutingCommissionReceivedCallout
- isExecutingCommissionCompletedCallout
- isExecutingDecommissionReceivedCallout
- isExecutingDecommissionCompletedCallout

DeviceStatusCheck Composite — Invokes the remote endpoint to trigger the initiate outage detection event. An asynchronous reply responds to the OUAF layer when confirmation of the requested event arrives.

ProcessCallout Composite — This business callout provides a point at which customers and implementers can incorporate custom business logic and transformations. This composite includes the WSDLs and processing logic for all of the MultiSpeak processes. The default implementation of each method is a direct return of the input.

Web Services

These web services are all defined in the Sensus RNI head end system. The WSDLs were added to a Meta Data Storage (MDS) layer in OUAF and all references to the WSDL point to this MDS location. These web services have HTTP security by default. You may need to modify the security as a part of your implementation.

Web Service	Related BPEL Process	Description
CB_ServerService	ConnectDisconnect	<p>This web service defines the return interface, the means by which the status is returned to the calling system.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the CDStateChangeNotification web method is implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Sensus/ConnectDisconnect/CB_ServerService</p>
CB_Server	OnDemandRead	<p>This web service defines the return interface, the means by which the reading is returned to the calling system.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the ReadingChangedNotification web method is implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Sensus/OnDemandRead/CB_Server</p>
OA_ServerService	DeviceStatusCheck	<p>This web service defines the asynchronous return for InitateOutageDetectionEventRequest for solicited responses. It is also used for unsolicited alarms.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the ODEventNotification, PingURL, and GetMethods web methods are implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Sensus/DeviceStatusCheck/OA_ServerService</p>

Sensus RNI Web Services

The following table describes the Sensus RNI web services and operations used for the Oracle Utilities Smart Grid Gateway command messaging:

Smart Grid Gateway Command	AMI Adapter Business Objects	Sensus Web Services	Sensus Operations
Device Commissioning	D6-MeterAddNotification	MR	MeterAddNotification
Device Decommissioning	D6-MeterRemoveNotification	MR	MeterRemoveNotification

Smart Grid Gateway Command	AMI Adapter Business Objects	Sensus Web Services	Sensus Operations
Remote Connect/ Remote Disconnect	D6-InitiateConnectDisconnect	CD	InitiateConnectDisconnect
	D6-ConnectDisconStateChgNtf	CB	CDStatesChangedNotification (async reply)
Device Status Check	D6-InitiateOutageDetection	OD	InitiateOutageDetectionEventRequest
	D6-OutageDetectEvtNotification	OA	ODEventNotification (async reply)
On-Demand Read	D6-InitiateMeterByMeterId	MR	InitiateMeterReadingsByMeterID
	D6-ReadingChangedNotification	CB	ReadingChangedNotification (async reply)

Configuring a Sensus Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway Adapter for Sensus RNI to communicate with the Sensus RNI.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the Sensus Regional Network Interface (RNI) in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-DeviceEventSeeder	Device Event Seeder
D1-DeviceStatusCheck	Device Status Check
D1-InitialLoadIMD	IMD Seeder
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
D6-ConDisconStChgNotification	Initiate Connect Disconnect Response
D6-OutageDetectionEventNotification	Initiate Outage Detection Response
D6-ReadingChangedNotification	Reading Changed Notification
D6-UnsolicitedEventNotification	Unsolicited Event Response

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
D6-CONDISCON	Sensus Initiate Connect/Disconnect
D6-INTOUTDET	Initiate Outage Detection Request
D6-InitMID	Initiate Meter Read By Meter ID Outbound Message

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction:<OPERATION>
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Sensus/<SERVICE>
- where:
 - <OPERATION>: the operation performed by the message sender (see Operation column in the table above)
 - <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
 - <PASSWORD>: the password used to log into WebLogic Enterprise Manager
 - <EM_SERVER_IP>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
 - <EM_SERVER_PORT>: the port where the WebLogic Enterprise Manager is installed
 - <SERVICE>: the service invoked by the message sender (see Service column in the table above)

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
D6-CONDISCON	Sensus Initiate Connect Disconnect
D6-INITMTR	Initiate Meter Read By Meter ID
D6-INTOUTDET	Initiate Outage Detection Request

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the Sensus RNI must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - Sensus:

- **External System:** Sensus
- **Description:** Sensus
- **Outbound Message Types:**

Outbound Message Type	Description	Message Sender
D6-CONDISCON	Sensus Initiate Connect Disconnect	D6-CONDISCON
D6-INITMTR	Initiate Meter Read By Meter ID	D6-InitMID
D6-INTOUTDET	Initiate Outage Detection Request	D6- INTOUTDET

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D6-Request.xml
- **Response XSL:** D6-Response.xml

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the Sensus RNI must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Meter Data Management / Smart Grid Gateway documentation for more information about creating service providers.

Service Provider - Sensus:

- **Service Provider:** Sensus
- **Description:** Sensus
- **External Reference ID:** Sensus
- **External System:** Sensus
- **Our Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the Sensus service provider. Refer to the Oracle Utilities Meter Data Management / Smart Grid Gateway documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

UOM Translation

UOM mapping processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the Sensus service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1–HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	D6-MeterAddNotification	Commission
Device Decommission	Device Removal	D6-MeterRemoveNotification	Decommission
Device Status Check	Device Status Check	D6-InitiateOutageDetection	Initiate Outage Detection Request

Command	Processing Role	Default Business Object	Default Outbound Message Type
On-Demand Read (Scalar)	On-Demand Read (Scalar)	D6-InitiateMeterByMeterId	Initiate Meter Read by Meter ID
Remote Connect	Remote Connect	D6-InitiateConnectDisconnect	Connect Device
Remote Disconnect	Remote Disconnect	D6-InitiateConnectDisconnect	Disconnect Device

Configuring Endpoint URIs

Part of the configuration process is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands. The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head-end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoint URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The Sensus endpoint override DVM (D6-EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the Sensus adapter and the command used with each:

DVM Key	Commands
MR_Server	Device Commissioning Device Decommissioning On-Demand Read (Scalar)
CD_Server	Remote Connect Remote Disconnect
OD_Server	Device Status Check
ProcessCallout	User Exit Functions

To define an override Endpoint URI for the Sensus adapter, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.
The URL for the SOA Composer is `http://server:port/soa/composer`.
2. Select the D6-EndpointOverrides.dvm in the left panel.
 - In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
 - In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list. The panel also displays a list of previously defined keys.
3. Click the **Create Session** button (above the left panel) to begin an editing session.
4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:
 - **key**: The DVM key for the Endpoint URI you wish to define (see the table above).
 - **EndpointURI**: The override Endpoint URI.
6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.
8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Sensus Extendable Lookups

Note: This section applies to **both** middleware and native implementations of the Smart Grid Gateway Adapter for Sensus.

This section outlines some of the extendable lookups that must be configured for use with the Sensus adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system. Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name**: The event name used by the head-end system
- **Description**: A description of the device event
- **Status**: The status of the lookup value (can be Active or Inactive)
- **Standard Event Name**: The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

UOM Code to Standard UOM Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-end UOM**: The unit of measure code used by the head-end system.
- **Unit of Measure**: The unit of measure defined in the system.
- **Description**: A description of the unit of measure code.
- **Status**: The status of the lookup value (can be Active or Inactive)

Interval Status Code to Condition Mapping

Interval usage received from the Sensus RNI can include Sensus interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The Sensus Interval Status Code to Condition Mapping extendable lookup is used to determine how to map Sensus interval status codes to standard status codes when receiving usage from the Sensus RNI.

Each value defined for the Sensus Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The Sensus interval status code
- **Description:** A description of the interval status code.
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.

Other Extendable Lookups

Business Object Name	Description
D6-CDReasonCodeLookup	Sensus Connect/Disconnect Reason Code
D6-LoadActionCodeLookup	Sensus Load Action Code
D6-OutageEventTypeLookup	Sensus Outage Event Type
D6-SensusTimeUnits	Sensus Time Units
D6-ServiceTypeMappingLookup	Sensus Service Type Mapping

Using the Sensus Test Harness

Oracle Utilities Smart Grid Gateway Adapter for Sensus RNI includes a test harness that can be configured to simulate a general head-end system for testing the two-way commands. The test harness includes a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. See [Using Smart Grid Gateway Test Harnesses](#) for more information.

Silver Spring Networks

The Oracle Utilities Smart Grid Gateway Adapter for Silver Spring Networks supports communication with the Silver Spring Networks UtilityIQ application, including measurement data and device event loading, and command messaging in support of commissioning, connect, disconnect, decommissioning, status check, and on-demand read. The following table describes the attributes of the adapter:

Attribute	Details
Currently Supported Versions	UtilityIQ Version 4.10, 4.12, 4.14, 5.0, 5.1
Protocol	Proprietary
Market(s)	Worldwide
Architecture	RF WAN (mesh) based on Access Points

Silver Spring Networks Adapter Processing

This section provides details concerning the OSB processing, BPEL Processes, and Oracle Utilities Application Framework (OUAF) objects that are supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway (SGG) service format. Payloads contain measurements and meter events in some head-end specific format. OSB then places each service call into a Java Message Service (JMS) queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel. A service then creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Initial Measurements

The usage data exported from the AMI head-end system as a file in Silver Spring Networks XML format is loaded into Oracle Utilities as initial measurement data. The following OSB projects, delivered in the base product, help manage the usage processing:

1. SGG-D7-SSNXML-BASE contains components responsible for “actual” processing of incoming data. It should not be modified during configuration. This project can be upgraded without affecting the customization and environment settings added to SGG-D7-SSNXML-CM.
2. SGG-D7-SSNXML-CM allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-D7-SSNXML-CM project are stored in the xquery file EnvironmentSettings.xq. You can use this file to adjust initial measurement data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRawIMD element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the initial measurement data is populated as raw data. Valid values are:	true false
callPreProcessing	Determines if the preprocessing proxy service is called. Valid values are:	true false
callPostProcessing	Determines if the postprocessing proxy service is called. Valid values are:	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
destinationRootElementEvent	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false
filterUsage	Determines if usage should be filtered.	true false

Publishing Initial Measurement Data

The SGG adapter can be configured to publish initial measurement data for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Initial Measurement Data Publishing

Publishing data is enabled by referencing a publisher business service in the `publishServices/service` element in the `EnvironmentSettings.xq` file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D7-SSNXML-CM OSB project are used in publishing measurement data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the `EnvironmentSettings.xq` file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Initial Measurement Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Initial measurement data is published in the “native” initial measurement data format (the format of the initial measurement seeder business object). This format includes normalized unit of measure and condition codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: Initial measurement data published through this feature is published prior to validation, estimation, and editing (VEE) processing. In addition, filtering *cannot* be applied to data published through this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600

Parameter	Description	Default Value
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **SSN - UOM Code to Standard UOM Mapping** extendable lookup (D7-HeadendUOMLookup) are passed into the system for processing.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the project. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Prioritized Initial Measurement Processing

The SGG adapter prioritizes processing of initial measurements created from smart meter commands and/ or completion events by setting the Execution Method flag in these types of initial measurements to “Real Time” (DIRT). In addition, initial measurements received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Initial Measurement Data Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Device Events

The device event data exported from the head-end system as a file in Silver Spring Networks CSV format is loaded into Oracle Utilities as a device event. One of your configuration tasks is to customize the device events processing.

The required functionality is delivered in the base product as two OSB projects:

1. SGG-D7-CSV-BASE contains components responsible for “actual” processing of incoming data. It can be upgraded in future without affecting the customization and environment settings that done in SGG-D7-CSV-CM project.
2. SGG-D7-CSV-CM allows the customization and simplifies the future upgrades.

The runtime configuration settings for the SGG-D7-CSV-CM project are stored in the EnvironmentSettings.xq XQuery file. You can use this file to adjust device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the device event data is populated as raw data. Valid values are:	true false
callPreProcessing	Determines if the preprocessing proxy service is called. Valid values are:	true false
callPostProcessing	Determines if the postprocessing proxy service is called. Valid values are:	true false
destinationRootElement	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered. Valid values are:	true false

Publishing Events

The Silver Spring Networks adapter can be configured to publish device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Device Event Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-D7-CSV-CM OSB project are used in publishing device events data to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Device Event Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems. Device event data is published in the “native” device event data format (the format of the device event seeder business object). This format includes normalized device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: In addition, filtering can NOT be applied to device events published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Events

The SGG adapter can be configured to filter initial measurement data passed into SGG and the Oracle Utilities Meter Data Management application. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **SSN - Device Event Mapping** extendable lookup (D7-DeviceEventMappingLookup) are passed into the system for processing.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (D1RT). In addition,

device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D7-CSV-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.
5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** column.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

Note: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The Silver Spring Networks adapter base package includes the following device and initial measurement business objects:

Business Object Name	Description
D7-InitialLoadIMDInterval	SSN - Initial Load IMD - Interval Used when loading Silver Spring Network (SSN) interval measurements into the system for the first time.
D7-InitialLoadIMDScalar	SSN - Initial Load IMD - Scalar Used when loading Silver Spring Network (SSN) scalar measurements into the system for the first time.
D7-SmartMeter	SSN — Smart Meter

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports.

The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related web service from the head-end system. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each Silver Spring Networks command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	SSN-Connect or Disconnect	SSN – Connect or Disconnect Response Remote Provisioning Job (Get Status)	Connect Device Completion Event
Remote Disconnect	SSN-Connect or Disconnect	SSN – Connect or Disconnect Response	Disconnect Device Completion Event
Device Commissioning (see Note below)	SSN- Replace Location		Device Commissioning Completion Event
Device Decommissioning	SSN- Replace Device At Location (Decomm)		Device Decommissioning Completion Event
On-Demand Read (Scalar)	SSN – Add Meter Read Job (Scalar)	SSN – Meter Read Response (Scalar)	Create IMD Completion Event
On-Demand Read (Interval)	SSN – Add Meter Read Job (Interval)	SSN – Meter Read Response (Interval)	Create IMD Completion Event
Device Status Check	SSN – Add Ping job	SSN – Ping Job Response	

Note: Service points must be provisioned in the Silver Spring Networks (Itron AMM) system before the Device Commissioning command can be used.

Unit of Measure Filtering for On-Demand Reads

Readings returned via On-Demand Read commands are filtered on the combination of Unit of Measure/Time of Use/Service Quantity Identifiers (UOM/TOU/SQI) configured for the device and measuring component. When filtering is enabled, only readings that match a configured UOM/TOU/SQI combination are processed. All others are filtered out.

Filtering is enabled by default via the “Opt Out Of Filtering” parameter (set to "false" by default) on the D7-CCOMPEV (Create Completion Event Scalar) algorithm on the Create Completion Events status of the D7-MeterReadResponseScalar (SSN - Meter Read Response (Scalar)) business object (for scalar on-demand read commands), and/or on the D7-CCOMPEVIN (Create Completion Event Interval) algorithm on the Create Completion Events status of the D7-MeterReadResponseInterval (SSN - Meter Read Response (Interval)) business object (for interval on-demand read commands).

When filtering is enabled, the “Filter if invalid external MC identifier” parameter on the D7-CCOMPEV and D7-CCOMPEVIN algorithms controls what should happen if a measuring component cannot be found using the MC Identifier Number sent from the head end system. When set to 'Yes' and no measuring component is found, the initial measurement will be filtered. When set to 'No' and no measuring component is found, the system will attempt to find the measuring component using the UOM and TOU. The value of the “Filter if invalid external MC identifier” on these algorithms must match the value of the “Error if invalid external MC identifier” parameter on the D1-DER-

SPRMC algorithm on the IMD Seeder (D1-IMDSeeder) business object. The parameters should both be set to either "yes" or "no".

The D7-VALDVCFLS (SSN - Check if Device has any Filtering errors (Scalar)) algorithm on the Validate status of the D7-MeterReadResponseScalar (SSN - Meter Read Response (Scalar)) business object is used to check for errors related to filtering for scalar on demand read commands. The value of the “Opt Out Of Filtering” parameter on this algorithm must match the value of the parameter on the D7-CCOMPEV algorithm. The parameters should both be set to either "false" (the default) or "true" (if filtering is to be disabled). The value of the “Filter if invalid external MC identifier” on this algorithm must match the value of the “Error if invalid external MC identifier” parameter on the D1-DER-SPRMC algorithm on the IMD Seeder (D1-IMDSeeder) business object. The parameters should both be set to either "yes" or "no".

The D7-VALDVCFLI (SSN - Check if Device has any Filtering errors (Interval)) algorithm on the Validate status of the D7-MeterReadResponseInterval (SSN - Meter Read Response (Interval)) business object is used to check for errors related to filtering for interval on demand read commands. The value of the “Opt Out Of Filtering” parameter on this algorithm must match the value of the parameter on the D7-CCOMPEVIN algorithm. The parameters should both be set to either "false" (the default) or "true" (if filtering is to be disabled). The value of the “Filter if invalid external MC identifier” on this algorithm must match the value of the “Error if invalid external MC identifier” parameter on the D1-DER-SPRMC algorithm on the IMD Seeder (D1-IMDSeeder) business object. The parameters should both be set to either "yes" or "no".

Receiving Results via JMS Queue

Some Silver Spring Networks commands can be configured to return results to a JMS queue, eliminating the need for the system to periodically poll for completed commands. This feature is enabled by setting the **Receive Job Results via JMS** parameter to "Yes" on the communication type used by the command.

The table below lists the commands that support this feature and the communication type business objects that correspond to each.

Command	Communication Type Business Object
Connect/Disconnect	D7-ConnectDisconnectType
Device Status Check	D7-AddPingJobType
On-Demand Read (Interval)	D7-AddMeterReadJobIntervalType
On-Demand Read (Scalar)	D7-AddMeterReadJobScalarType

The JMS queue to which command results are sent (all commands send results to the same JMS queue) is defined during installation. Refer to **Deploying the SOA Adapter for Silver Spring Networks** in the *Oracle Utilities Smart Grid Gateway Installation Guide* for details about creating JMS queues.

Device Communication Base Package Business Objects

The Silver Spring Networks Adapter base package includes the following communication business objects:

Business Object Name	Description
D7-AddMeterReadJobInterval	SSN - Add Meter Read Job (Interval)
D7-AddMeterReadJobScalar	SSN - Add Meter Read Job (Scalar)
D7-AddPingJob	SSN - Add Ping Job
D7-ConnectDisconnect	SSN - Connect or Disconnect

Business Object Name	Description
D7-ConnectDisconnectResp	SSN - Connect or Disconnect Response
D7-GetStatus	SSN - Get Status
D7-GetStatusResponse	SSN - Get Status Response
D7-MeterReadResponseInterval	SSN - Meter Read Response (Interval)
D7-MeterReadResponseScalar	SSN - Meter Read Response (Scalar)
D7-PingJobResponse	SSN - Ping Job Response
D7-ReplaceDeviceAtLocForDecomm	SSN - Replace Device At Location (Decomm)
D7-ReplaceLocation	SSN - Replace Location

Silver Spring Networks Event Data Mapping

The Silver Spring event file format maps as follows into the business object, D1-DeviceEventMappingLookup:

Silver Spring Flat File Field	Device Event Seeder BO Element	Comments
Transaction ID (from Header record)	External Source Identifier	This is the file name.
Device Identifier	External Device Identifier	
Event Name	External Event Name	
Event Creation Date/Time	Event Date/Time	
Device Type	External Device Type	This element has no real bearing on the device type within MDM/SGG. Its valid values include (although the element itself is free-form): Meter Collector Router
Service Location ID	External Service Location ID	
Communication Module Serial Number	External Communication Module Identifier	
Event Category ID	External Event Category	
Event Severity	External Event Severity	Valid values include (although the element itself is free-form): Alert Information

Silver Spring Flat File Field	Device Event Seeder BO Element	Comments
Status Value	External Status Value	This represents additional information that relates to the event itself.
Status Date/Time	External Status Date/Time	The date & time at which the additional information referenced above had occurred.

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Outbound Message Types

Acknowledgment and response messages are sent and received validating that commands have been transmitted.

Outbound Message Type	Description
D7-COMMS	Replace Device At Location
D7-OB MSG TY	Outbound Message Type SSN

Inbound/Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The Oracle Utilities Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound web services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway adapter for Silver Spring Networks includes the following inbound web services:

Inbound Web Service	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response

Inbound Web Service	Description
D1-DeviceEventSeeder	<p>Used for upload of device events.</p> <p>The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event.</p> <p>If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.</p>
D1-DeviceStatusCheck	<p>Device Status Check</p> <p>This service is invoked by the integration layer to instantiate a Device Status Check command.</p>
D1-InitialLoadIMD	<p>Used by OSB to instantiate an IMD</p> <p>The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.</p>
D1-RemoteConnect	<p>Remote Connect</p> <p>This service is invoked by the integration layer to instantiate a Remote Connect command.</p>
D1-RemoteDisconnect	<p>Remote Disconnect</p> <p>This service is invoked by the integration layer to instantiate a Remote Disconnect command.</p>
D7-ConnectDisconnectResponse	<p>Connect Disconnect Response</p> <p>Retrieves response for Remote provisioning Job Connect or Disconnect commands.</p>
D7-GetStatusResponse	<p>D7-GetStatusResponse</p> <p>Retrieve response from the Get Status command.</p>
D7-MeterReadResponseInterval	<p>SSN - Meter Read Response (Interval)</p>
D7-MeterReadResponseScalar	<p>SSN - Meter Read Response (Scalar)</p>
D7-PingJobResponse	<p>SSN - Ping Response</p> <p>Retrieves response from the Ping Job Response command.</p>

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

These processes are responsible for performing the conversion from Oracle Utilities format to Silver Spring Networks format, invoking process callouts and invoking the remote endpoint to trigger the device events.

OnDemandRead Composite Process — Provides access points to edge application and handles data between edge application and head end system. It invokes sequence of web methods to head end system and retrieves meter read and send it back to Edge application.

ConnectDisconnect Composite Process — Performs the conversion from Oracle Utilities format to SSN format, invokes process callouts, and invokes the remote endpoint to trigger the connect event. A second, asynchronous reply will call back into the OUAF layer when the status change is completed at the head-end system. Another asynchronous reply will call back into the OUAF layer to send Meter Read Results.

CommissionDecommission Composite Process — Performs the conversion from Oracle Utilities format to SSN UIQ format, invokes process callouts, and invokes the remote endpoint to trigger the commission or decommission of meter.

DeviceStatusCheck Composite — Performs the conversion from Oracle Utilities format to SSN format, invokes process callouts, and makes a call via a proxy to the head-end system starting the Meter Ping operation. In an ideal scenario, the job status is returned as completed and the results are acquired and sent back to OUAF. If the job takes longer, OUAF will initiate a second request that will poll the head end system for the job status. When the job is completed, the results are returned to OUAF.

Common Composite — Contains two main classes of operations: Proxies and ProcessCallouts. Proxies are simple mediators that forward a web service call to a preset endpoint. No transformations are performed. They are convenient because they allow head end URLs and security to be set in a single composite. ProcessCallouts are points of customization which allow users to modify data and/or initiate some external business process.

BulkRequest Composite — Provides access points to requesting application. It decouples the bulk request into single commands for each meter/device in the request and sends it to edge application for processing.

Web Services

The following web services are all defined in the Silver Spring Networks head-end system:

- **CommissionDecommissionService**
 - **BPEL Process:** CommissionDecommission
 - **Operation:** ReplaceDeviceAtLocation
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/CommissionDecommission/CommissionDecommissionService
- **CommissionDecommissionService**
 - **BPEL Process:** CommissionDecommission
 - **Operation:** ReplaceLocation
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/CommissionDecommission/CommissionDecommissionService
- **ConnectDisconnectService**
 - **BPEL Process:** ConnectDisconnect
 - **Operation:** AddRemoteProvisioningJob
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/ConnectDisconnect/ConnectDisconnectService
- **DeviceStatusCheckService**
 - **BPEL Process:** DeviceStatusCheck
 - **Operation:** AddPingJob
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/DeviceStatusCheck/DeviceStatusCheckService
- **AddMeterReadJobService**
 - **BPEL Process:** AddMeterRead

- **Operation:** AddMeterReadJob
- **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/OnDemandRead/AddMeterReadJobService
- **OnDemandReadService**
 - **BPEL Process:** OnDemandRead
 - **Operation:** GetJobStatus
 - **Endpoint URL:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/OnDemandRead/OnDemandReadService

Silver Spring Networks Utility IQ Web Services

The following table describes the Silver Spring Networks Utility IQ web services and operations used for the Oracle Utilities Smart Grid Gateway command messaging:

Smart Grid Gateway Command	AMI Adapter Business Objects	Silver Spring Networks Web Services	Silver Spring Networks Operations
Device Commissioning	D7-ReplaceLocation	Device Manager	findDevice ReplaceLocation
Device Decommissioning	D7-ReplaceDeviceAtLocForDecomm	Device Manager	findDevice ReplaceDeviceAtLocation
Remote Connect/ Remote Disconnect	D7-ConnectDisconnect D7-GetStatus	Device Manager Job Manager DeviceResults	findDevice addRemoteProvisioningJob getJobStatusForDevice getRemoteProvisioningResultsByJobID findJob getJobStatus getMeterReadResultsByJobID
Device Status Check	D7-AddPingJob	Device Manager Job Manager DeviceResults	findDevice addPingJob, getJobStatus getPingResultsByJobID
On-Demand Read	D7-AddMeterReadJobInterval D7-AddMeterReadJobScalar	Device Manager Job Manager DeviceResults	findDevice addMeterReadJob getJobStatus getMeterReadResultsByJobID

Configuring a Silver Spring Networks Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway Adapter for Silver Spring Networks to communicate with the Silver Spring Networks UtilityIQ.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the Silver Spring Networks UtilityIQ application in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Device Event Seeder
D1-DeviceStatusCheck	Device Status Check
D1-InitialLoadIMD	Used by OSB to instantiate an IMD
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
D7-ConnectDisconnectResponse	Connect Disconnect Response
D7-GetStatusResponse	Get Status Response
D7-MeterReadResponseInterval	SSN - Meter Read Response (Interval)
D7-MeterReadResponseScalar	SSN - Meter Read Response (Scalar)
D7-PingJobResponse	SSN - Ping Response

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests. An message sender should be configured for each command.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
D7-DECOMM	SSN Replace Device at Location for Decommission
D7-COMM	SSN Replace Location - Commission
D7-ADDJOB	SSN Add Meter Read Job
D7-ADDPING	SSN Add Ping Job
D7-CONNECT	SSN Connect Device
D7-GTSTATUS	SSN Get Status

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction:http://xmlns.oracle.com/ouaf/ssn/<OPERATION>
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/SSN/<SERVICE>
- where:
 - <OPERATION>: the operation performed by the message sender (see Operation column in the table above)
 - <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
 - <PASSWORD>: the password used to log into WebLogic Enterprise Manager
 - <EM_SERVER_IP>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
 - <EM_SERVER_PORT>: the port where the WebLogic Enterprise Manager is installed
 - <SERVICE>: the service invoked by the message sender (see Service column in the table above)

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
D7-COMMS	Replace Device At Location
D7-OB MSG TY	Outbound Message Type SSN

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the Silver Spring Networks UtilityIQ must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System - Silver Spring Networks:

- **External System:** Silver Spring Networks
- **Description:** Silver Spring Networks
- **Outbound Message Types:**

Outbound Message Type	Description
D7-OB MSG TY	Outbound Message Type SSN

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** D7-Request xsl
- **Response XSL:** D7-Response.xsl

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the Silver Spring Networks UtilityIQ must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about creating service providers.

Service Provider - Silver Spring Networks:

- **Service Provider:** Silver Spring Networks
- **Description:** Silver Spring Networks
- **External Reference ID:** Silver Spring Networks
- **External System:** Silver Spring Networks
- **Our Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **Pre-Commissioning Device ID Type:**
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including as bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to a given head-end system.

The following types of processing methods must be configured for the Silver Spring Networks service provider. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the Silver Spring Networks service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1–HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	D7-ReplaceLocation	Commission
Device Decommission	Device Removal	D7-ReplaceDeviceAtLocForDecomm	Decommission
Device Status Check	Device Status Check	D7-AddPingJob	Get Status
On-Demand Read (Scalar)	On-Demand Read (Scalar)	D7-AddMeterReadJobScalar	Read Meter Data
On-Demand Read (Interval)	On-Demand Read (Interval)	D7-AddMeterReadJobInterval	Read Meter Data
Remote Connect	Remote Connect	D7-ConnectDisconnect	Connect Device
Remote Disconnect	Remote Disconnect	D7-ConnectDisconnect	Disconnect Device

Configuring Endpoint URIs

Part of the configuration process is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands. The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head-end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoint URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The Silver Springs Network endpoint override DVM (D7–EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the Silver Springs Network adapter and the command used with each:

DVM Key	Commands
DeviceResults4.4	Remote Connect
DeviceResults4.7	Remote Disconnect
DeviceResults4.10	On-Demand Read (Scalar) On-Demand Read (Interval) Device Status Check
DataAggregation4.4	Not used in this version.
DataAggregation4.7	
DataAggregation4.10	
DeviceManager4.4	Device Commissioning
DeviceManager4.7	Device Decommissioning
DeviceManager4.10	Remote Connect Remote Disconnect On-Demand Read (Scalar) On-Demand Read (Interval) Device Status Check
JobManager4.4	Remote Connect
JobManager4.7	Remote Disconnect
JobManager4.10	On-Demand Read (Scalar) On-Demand Read (Interval) Device Status Check
ProcessCallout	User Exit Functions

Note:

The numbers in the keys above (4.4, 4.7, and 4.10) designate the version of the Silver Springs Network IQ head-end system.

Only a single version of each key should be defined, based on the version of the Silver Springs Network IQ head-end system

To define an override Endpoint URI for the Silver Springs Network adapter, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is <http://server:port/soa/composer>.

2. Select the D7–EndpointOverrides.dvm in the left panel.

- In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
- In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list. The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.
4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:
 - **key**: The DVM key for the Endpoint URI you wish to define (see the table above).
 - **EndpointURI**: The override Endpoint URI.
6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.
8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Silver Spring Networks Extendable Lookups

Note: This section applies to **both** middleware and native implementations of the Smart Grid Gateway Adapter for Silver Spring Networks.

This section outlines some of the extendable lookups that must be configured for use with the Silver Spring Networks adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system. Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name**: The event name used by the head-end system.
- **Description**: A description of the device event.
- **Status**: The status of the lookup value (can be Active or Inactive).
- **Standard Event Name**: The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

UOM Code to Standard UOM Mapping

Usage received from a utility’s head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The UOM Code to Standard UOM Mapping extendable lookup is used for this purpose. Each value defined for the UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-End Unit of Measure**: The unit of measure code used by the head-end system.
- **Description**: A description of the unit of measure code.
- **Status**: The status of the lookup value (can be Active or Inactive).

- **Unit of Measure:** The unit of measure defined in the system.

Interval Status Code to Condition Mapping

Interval usage received from the Silver Spring Networks UtilityIQ can include Silver Spring Networks interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The Silver Spring Networks Interval Status Code to Condition Mapping extendable lookup is used to determine how to map Silver Spring Networks interval status codes to standard status codes when receiving usage from the Silver Spring Networks UtilityIQ.

Each value defined for the Silver Spring Networks Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The Silver Spring Networks interval status code
- **Description:** A description of the interval status code.
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.

Other Extendable Lookups

Business Object Name	Description
D7-ActivationStatusLookup	SSN - Activation Status
D7-ChannelStatusLookup	SSN - Channel Status
D7-DataTimeZoneLookup	SSN - Data Time Zone
D7-DeviceStatusLookup	SSN - Device Status
D7-ExecutionStatusLookup	SSN - Execution Status
D7-HeadendSQILookup	SSN - Head-End SQI to Standard SQI
D7-HeadendTOULookup	SSN - Head-End TOU to Standard TOU
D7-IntervalStatusLookup	SSN - Interval Status
D7-MeterConnectionStatusLookup	SSN - Meter Connection Status
D7-MeterReadTypeLookup	SSN - Meter Read Type
D7-OldAdminStateNameLookup	SSN - Old Admin State Name
D7-PriorityLookup	SSN - Priority Status
D7-ProvisioningActionLookup	SSN - Provisioning Action
D7-ProvisioningCommandStatus	SSN - Provisioning Command Status
D7-ProvisioningDataType	SSN - Provisioning Data Type
D7-ReadModeLookup	SSN - Read Mode
D7-RegisterReadSourceLookup	SSN - Register Read Source

Business Object Name	Description
D7-RegisterStatusLookup	SSN - Register Status
D7-SSNVersionLookup	SSN - Version
D7-StatusFlagNameLookup	SSN - Status Flag Name

Using the Silver Spring Networks Test Harness

Oracle Utilities Smart Grid Gateway Adapter for Silver Spring Networks (SSN) includes a test harness that can be configured to simulate the Silver Spring Networks UtilityIQ head-end system for testing the two-way commands. The test harness includes a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. See [Using Smart Grid Gateway Test Harnesses](#) for more information.

Using Smart Grid Gateway Middleware Test Harnesses

The Oracle Utilities Smart Grid Gateway Adapter includes middleware test harnesses for each supported head end system. The test harnesses can be configured to simulate a head-end system for initial testing of one-way or two-way commands. The test harnesses are Multispeak 3.0 standard compliant and include a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. This section describes the general components of the test harnesses.

Note: This section applies to middleware implementations of Oracle Utilities Smart Grid Gateway **only**. This section does NOT apply to native implementations or Oracle Utilities cloud services. See [Smart Grid Gateway Adapter Native Implementations](#) for more information about Smart Grid Gateway Adapter native implementations and implementing Smart Grid Gateway adapters with Oracle Utilities cloud services.

Test Harness Design

Each test harness is divided into two main layers: a front end and back end layer. The front end set of services implements the head-end system interfaces, which receive requests corresponding to the specifications shown in the list below. Each of these services calls into the "back end" layer of the test harness, which defines meters and sets their attributes. These meters are stored in a file within the test harness called meterdb.xml.

Note: The meterdb.xml file can be modified pre-deployment, but not post-deployment. However, the test harness retains an in-memory "database" of the meters in the file. The in-memory representation can be modified using the utility web services. Note that any changes to the in-memory structure will be lost when the server is restarted or the test harness composite is redeployed.

Locating the WSDL for the Test Harness

Follow these procedures to locate the test harness web service definition language (WSDL):

How to Use Enterprise Manager to Locate the WSDL

1. Open Enterprise Manager and use the navigation pane to open the dashboard of the test harness composite:
2. The top bar of the dashboard contains several buttons and icons. One of these is a “world” icon with a puzzle piece over it. Click this icon to display a list of the WSDLs and endpoint URIs for the composite:
3. Click the UtilService WSDL URL link to see the WSDL in the browser, or right click and save it to your machine

Depending on your requirements, it may be necessary to download the associated schema found in the wsdl:types section. The URL can be pasted into a browser tab and downloaded in the same manner as the WSDL. The main schema has imported schemas that may also be required.

How to Use a Direct URL to locate the WSDL

The WSDL can be accessed without Enterprise Manager by understanding the paths used on the SOA server. In general, they have the following form:

```
http://{server name}:{port number}/soa-infra/services/{partition}/
{Composite}/{Web Service}?WSDL
```

For example, the test harness WSDL can be found at the following locations for each SGG adapter.

Itron OpenWay:

```
http://{server name}:{port number}/soa-infra/services/Itron_Test/
ItronTestHarness/UtilService? WSDL
```

Landis+Gyr:

```
http://{server name}:{port number}/soa-infra/services/LG_Test/LGTestHarness/
UtilService?WSDL
```

Sensus RNI:

```
http://{server name}:{port number}/soa-infra/services/Sensus_Test/Sensus/
UtilService?WSDL
```

Silver Spring Networks:

```
http://{server name}:{port number}/soa-infra/services/SSN_Test/
SSNTestHarness/UtilService?WSDL
```

Web Services

This section describes the web services included in the test harness BPEL composite for each supported head-end system.

General Services

This section describes the general services of the test harness composite.

LoadMeterIndex

This web service loads the data store from the internal file. By default, if the store is already in memory, it will NOT reload. This behavior can be overridden with the forceReload parameter.

Input — LoadMeterIndexInput

Part: payload

Element: LoadMeterIndexRequest

Parameter	Description
forceReload	A switch telling the system whether to reload the meter index from the configuration file. Default is false.

Output — LoadMeterIndexOutput

Part: payload

Element: LoadMeterIndexResult

Parameter	Description
loaded	A boolean value for whether or not the index was reloaded from the configuration file

Fault — UtilityFault (see [UtilityFault](#) on page 849 for more details).

ViewAuditTrail

This web service returns the audit log for the entire session.

Input — ViewAuditTrailInput

Part: payload

Element: ViewAuditTrailRequest

Output — ViewAuditTrailOutput

Part: payload

Element: ViewAuditTrailResult

An Entry consisting of a timestamp and an Operation. Each entry may have an associated meter object showing the latest update.

Fault — See [UtilityFault](#) on page 849, above.

UtilityFault

Fault with similar mapping to SGG/OUAF faults:

Typically, the faultCode, faultString, faultActor, and detail/text elements will be populated.

Locate Meter Services

This section describes the locate meter web services of the test harness composite.

FindMeters

This web service queries the data store for one or more meters. The difference between GetMeter and FindMeters is GetMeter can return at most one meter and it must match the provided ID exactly. GetMeter will throw an error if the ID is not found. FindMeters can return more than one meter (when using the regex) and will not throw an error when the ID does not match any of the meters in the index.

Input — FindMetersInput

Part: payload

Element: FindMetersRequest

Parameter	Description
id	The meter ID for which to search
isRegex	The provided id can be a regex value when this parameter is true. Hint: to search for all meters in the system, use ".*" for the ID.

Output — FindMetersOutput

Part: payload

Element: FindMetersResult

Zero or more meter objects can be returned from the search

Fault — See [UtilityFault](#) on page 849. Unlike other methods, FindMeters does not throw an exception if the meter is not found. As such, it can be used to test for the existence of a Meter prior to querying for it.

IsMeterDefined

This web service queries whether a particular meter is defined in the data store.

Input — IsMeterDefinedInput

Part: payload

Element: IsMeterDefinedRequest

Parameter	Description
id	The meter ID for which to search

Output — IsMeterDefinedOutput

Part: payload

Element: IsMeterDefinedResult

Whether or not the provided ID is part of the index.

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

GetMeter

This web service returns all the attributes of a single meter from the in-memory data store. The difference between GetMeter and FindMeters is GetMeter can return at most one meter and it must match the provided ID exactly. GetMeter will throw an error if the ID is not found. FindMeters can return more than one meter (when using the regex) and will not throw an error when the ID does not match any of the meters in the index.

Input — GetMeterInput

Part: payload

Element: GetMeterRequest

Parameter	Description
id	The meter ID for which to search

Output — GetMeterOutput

Part: payload

Element: GetMeterResult

The meter object requested by the ID.

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

Meter Administration Services

This section describes the meter administration services of the test harness composite.

AddMeters

This web service adds a set of meters to the in-memory data store. This will not permanently add it to the control file.

Input — AddMetersInput

Part: payload

Element: AddMetersRequest

Parameter	Description
id	The identification code for the meter.
macID	A MAC address that must be unique within the system.
utility	An informational string.
serviceType	One of the valid ServiceType values (see schema). "Electric" is the only option at this time.
isCommissioned	Whether or not the meter is in a commissioned state.
loadActionCode	One of the possible LoadActionCode values used in Connect and Disconnect (see schema).
outageEventType	One of the possible OutageEventType values used in Device Status Check (see schema).
executionStatus	One of the possible ExecutionStates (see schema). These values control how the meter will respond to commands.
groupName	The name linking multiple meters together into a set.
jobExecutionStatus	One of the possible Job Execution Status values (see schema). This attribute determines how requested jobs perform.

Parameter	Description
updateIfExisting	Whether or not to update the meter with the provided values if it already exists in the index.
Comment	An informational string describing the purpose of the meter.
Channels	A listing of unit of measures supported by this meter.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.

Output — AddMetersOutput

Part: payload

Element: AddMetersResult

Whether or not each meter was added to the index.

Fault — See [UtilityFault](#) on page 849

RemoveMeter

This web service removes a meter from the in-memory data store. This will not permanently remove it from the control file.

Input — RemoveMeterInput

Part: payload

Element: RemoveMeterRequest

Parameter	Description
id	The ID for the meter to be removed

Output — RemoveMeterOutput

Part: payload

Element: RemoveMeterResult

Whether or not the meter was removed from the index.

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

AddMeterChannel

This web service adds a new channel to a single meter.

Input — AddMeterChannelInput

Part: payload

Element: AddMeterChannelRequest

Parameter	Description
id	The identification code for the meter.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.

Output — AddMeterChannelOutput

Part: payload

Element: AddMeterChannelResult

Whether or not the channel was added to the index.

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

RemoveMeterChannel

This web service removes a Channel from a meter.

Input — RemoveMeterChannelInput

Part: payload

Element: RemoveMeterChannelRequest

Parameter	Description
id	The ID for the meter to be removed.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.

These three parameters are combined to locate a unique channel

Output — RemoveMeterChannelOutput

Part: payload

Element: RemoveMeterChannelResult

Whether or not the channel was removed from the meter.

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

ReadScalarMeter

This web service generates a scalar reading for each channel of a given meter.

Input — ReadScalarMeterInput

Part: payload

Element: ReadScalarMeterRequest

Parameter	Description
id	The ID for the meter to be read

Output — ReadScalarMeterOutput

Part: payload

Element: ReadScalarMeterResult

Zero or more scalar readings for the given meter.

Parameter	Description
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.
value	A random number representing the scalar reading.

Meter Attribute Administration Services

This section describes the meter administration services of the test harness composite.

GetLoadActionCode

This web service queries whether the given meter is connected or disconnected. This method is used by the Connect/Disconnect service. The values for load action code are:

- Connect
- Disconnect

Input — GetLoadActionCodeInput

Part: payload

Element: GetLoadActionCodeRequest

Parameter	Description
id	The ID for the meter for which the load action code status should be retrieved

Output — GetLoadActionCodeOutput

Part: payload

Element: GetLoadActionCodeResult

The connection status of the requested meter.

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

SetLoadActionCode

This web service updates the load action code for a given meter. This method is used by the Connect/Disconnect service. The values for load action code are:

- Connect
- Disconnect

Input — SetLoadActionCodeInput

Part: payload

Element: SetLoadActionCodeRequest

Parameter	Description
id	The ID for the meter for which the load action code status should be set.
value	The new value of LoadActionCode to set on the meter.

Output — SetLoadActionCodeOutput

Part: payload

Element: SetLoadActionCodeResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

IsCommissioned

This web service queries the commissioning status for a given meter. This service is used by the Commission/Decommission process. The commissioning attribute can be true or false.

Input — IsCommissionedInput

Part: payload

Element: IsCommissionedRequest

Parameter	Description
id	The ID for the meter for which the Commissioned status should be retrieved

Output — IsCommissionedOutput

Part: payload

Element: IsCommissionedResult

The value of the Commissioned status attribute for the requested meter.

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

SetCommission

This web service updates the commissioning status for a given meter. This service is used by the Commission/Decommission process. The commissioning attribute can be true or false.

Input — SetCommissionedInput

Part: payload

Element: SetCommissionedRequest

Parameter	Description
id	The ID for the meter for which the Commissioned status should be set
value	The new value of Commissioned status to set on the meter

Output — SetCommissionedOutput

Part: payload

Element: SetCommissionedResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

GetExecutionStatus

This web service queries the status of the property controlling the overall execution of the command. The possible values of execution status are:

- Success - The command should complete successfully
- ResponseTimeout - The asynchronous response will never arrive
- SyncOperationFail - A simulated fault will occur in the during the initial request
- AsyncOperationFailure - A simulated fault will occur in the asynchronous response

Input — GetExecutionStatusInput

Part: payload

Element: GetExecutionStatusRequest

Parameter	Description
id	The ID for the meter for which the ExecutionStatus should be retrieved

Output — GetExecutionStatusOutput

Part: payload

Element: GetExecutionStatusResult

The value of the ExecutionStatus attribute for the requested meter.

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

SetExecutionStatus

This web service updates the property controlling the overall completion of the command. The possible values of execution status are:

- Success - The command should complete successfully
- ResponseTimeout - The asynchronous response will never arrive
- SyncOperationFail - A simulated fault will occur in the during the initial request
- AsyncOperationFailure - A simulated fault will occur in the asynchronous response

Input — SetExecutionStatusInput

Part: payload

Element: SetExecutionStatusRequest

Parameter	Description
id	The ID for the meter for which the ExecutionStatus should be set
value	The new value of ExecutionStatus to set on the meter

Output — SetExecutionStatusOutput

Part: payload

Element: SetExecutionStatusResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault — See [UtilityFault](#) on page 849. Thrown when meter id is not found.

Creating a Custom Adapter for Smart Grid Gateway

Customers can create their own customized adapter for using Smart Grid Gateway with a specific head-end system. This can be done using the Oracle Utilities Smart Grid Gateway Adapter Development Kit. This section describes the Adapter Development Kit and its components.

Note: Unless otherwise noted, the contents of this section apply to middleware implementations of Oracle Utilities Smart Grid Gateway **only**, and do NOT apply to native implementations or Oracle Utilities cloud services. See [Smart Grid Gateway Adapter Native Implementations](#) for more information about Smart Grid Gateway Adapter native implementations and implementing Smart Grid Gateway adapters with Oracle Utilities cloud services.

Adapter Development Kit Overview

The Oracle Utilities Smart Grid Gateway (SGG) Adapter Development Kit provides a starting point for customers to create their own customized adapter for using SGG with a specific head-end system. SGG uses Oracle Service Bus (OSB) and Oracle Business Process Execution Language (BPEL) to facilitate communication with other head-end systems. The following functionality can be configured:

Measurement Data and Device Event Loading: Data parsing and transformation via Oracle Service Bus from the smart meter format into the Oracle Utilities Service and Measurement Data Foundation unified format for measurement data and device events.

Measurement Data and Device Event Processing: Configurable mapping for meter status codes and device event names to Oracle Utilities Service and Measurement Data Foundation standard values.

Commissioning Communication: Business objects and BPEL processes to support the Meter Add Notification message.

Connect Communication: Business objects and BPEL processes to support Initiate Connect/Disconnect and Connect/Disconnect State Change Notification messages.

Disconnect Communication: Business objects and BPEL processes to support Initiate Connect/Disconnect and Connect/Disconnect State Change Notification messages.

Decommissioning Communication: Business objects and BPEL processes to support Meter Removal Notification message.

On-Demand Read: Business objects and BPEL processes to support Initiate Meter Read by Meter Number and Reading Changed Notification messages.

Device Status Check: Business objects and Oracle BPEL processes to support the outbound Initiate Outage Detection communication, the inbound Outage Detection Event Notification communication, and the processing of Event Notifications.

What Does the Adapter Development Kit Provide?

The Oracle Utilities Smart Grid Gateway Adapter Development Kit includes the following:

Sample Oracle Service Bus Processes: A file parsing and transformation process framework, delivered as an Oracle Service Bus (OSB) configuration, that can be used as a reference for creating the functionality to import usage readings and device events from a specific head-end system.

Sample Oracle Business Process Execution Language Processes: A set of sample communication processes that support Remote Connect, Remote Disconnect, Commission, Decommission, Device Status Check, and On-Demand Read commands delivered as an Oracle Business Process Execution Language (BPEL) project.

Oracle Utilities Smart Grid Gateway Business Objects: Business objects to support measurement data and device event loading and two-way commands such Commission, Decommission, Remote Connect, Remote Disconnect, and Device Status Check.

Sample Two-Way Communication Test Harness: A head-end system emulator delivered as a BPEL composite.

Demonstration Data: A set of sample data provided in the demonstration database that can be used with the adapter processes as delivered (prior to any customization you might perform as part of your implementation).

Adapter Development Kit Processing

This section provides details concerning the OSB processing, BPEL Processes, and OUAF objects supplied as part of the base package. This information illustrates how the base package objects were designed, and can serve as the basis for any customizations you create as part of your implementation.

Initial Measurement Data and Device Event Loading

The initial measurement data load and subsequent device event processing use OSB to poll for, parse, and transform the head-payloads into the Oracle Utilities Smart Grid Gateway service format. Payloads contain measurements and meter events in some head-end specific format OSB then places each service call into a JMS queue within the Oracle Utilities applications. The JMS client consumes the entries and invokes the respective services in parallel then a service creates initial measurements with data in a common format with head-end-specific processing as needed. A second service creates device events with data in a common format.

Initial Measurements and Device Events

The usage and event data exported from the AMI head-end system is loaded into Oracle Utilities as initial measurement and device event data. You can customize processing of this by configuring the following base product OSB projects:

1. **SGG-DG-CSV-BASE** contains components that are not to be changed on customer site. They implement functions specific to the CSV format processing such as validation and transformation.
2. **SGG-DG-CSV-CM** allows for customization and simplifies future upgrades.
3. **SGG-DG-XML-BASE** contains components that are not to be changed on customer site. They implement functions specific to the IMD and event upload format processing such as validation and transformation.
4. **SGG-DG-XML-CM** allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-DG-CSV-CM project are stored in the EnvironmentSettings.xq query file. You can use this file to adjust initial measurement and device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the SGG-DG-CSV-CM EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRaw	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementEvent	Holds the name of inbound web service for the device event seeder.	
destinationRootElementIMD	Holds the name of inbound web service for the IMD seeder.	

The runtime configuration settings for the SGG-DG-XML-CM project are stored in the EnvironmentSettings.xq xquery file. You can use this file to adjust initial measurement and device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the SGG-DG-XML-CM EnvironmentSettings.xq file:

Element	Description	Valid Values
populateRawIMD	Determines if the initial measurement data is populated as raw data.	true false
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElement	Holds the name of inbound web service for the IMD seeder.	

For additional information about the sample OSB implementation included in the Oracle Utilities Smart Grid Gateway Adapter Development Kit, see [Oracle Service Bus Processing](#) on page 868.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the MinimumAge property in the “InboundProxyService” proxy service for the SGG-DG-CSV-CM and SGG-DG-XML-CM projects. The MinimumAge property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

Processing Data in the Adapter Development Kit Native Format

Usage and event data exported from the AMI head-end system can be loaded into Oracle Utilities in the “native” initial measurement and device event data formats (the format of the initial measurement and device event seeder business objects). You can customize processing of this by configuring the following base product OSB projects:

1. **SGG-DG-SEEDER-BASE** contains components that are not to be changed on customer site. They implement functions specific to the IMD and event upload format processing such as validation and transformation.
2. **SGG-DG-SEEDER-CM** allows for customization and simplifies future upgrades.

The runtime configuration settings for the SGG-DG-SEEDER-CM project are stored in the EnvironmentSettings.xq xquery file. You can use this file to adjust initial measurement and device event data processing. For example, if you want to load raw data you would specify “true” for the content of the populateRaw element.

The following table describes the elements included in the SGG-DG-SEEDER-CM EnvironmentSettings.xq file:

Element	Description	Valid Values
callPreProcessing	Determines if the preprocessing proxy service is called.	true false
callPostProcessing	Determines if the postprocessing proxy service is called.	true false
destinationRootElementInterval	Holds the name of inbound web service for the interval IMD seeder.	
destinationRootElementScalar	Holds the name of inbound web service for the scalar IMD seeder. In most cases it is the same as destinationRootElementInterval.	
destinationRootElementEvent	Holds the name of inbound web service for the device event seeder.	
publishServices/service	Specifies the name of the business service within the OSB project used to publish data for external systems (such as Oracle DataRaker).	
filterEvents	Determines if events should be filtered.	true false
filterUsage	Determines if usage should be filtered.	true false

See [The Adapter Development Kit Native Format](#) on page 916 for more information about the ADK “native” format.

Publishing Initial Measurement Data and Device Events

The Adapter Development Kit can be configured to publish initial measurement data and device events for use in Oracle DataRaker or other external systems. This functionality is supported through a combination of OSB components and BPEL composites.

Enabling Data Publishing

Publishing data is enabled by referencing a publisher business service in the publishServices/service element in the EnvironmentSettings.xq file as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

The following components provided with the SGG-DG-SEEDER-CM OSB project are used in publishing measurement data and device events to Oracle DataRaker:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This is the business service that should be specified in the EnvironmentSettings.xq file.
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Configuring Publishing Output

The SGGDRIntegration BPEL composite handles publishing the data to Oracle DataRaker or other systems.

Initial measurement and device event data is published in the “native” initial measurement data format (the format of the initial measurement and device event seeder business objects). This format includes normalized unit of measure, condition, and device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: Initial measurement data published via this feature is published prior to VEE processing. In addition, filtering can NOT be applied to initial measurement or device event data published via this feature.

The following parameters can be used to configure details of how the data is provided to Oracle DataRaker, including the directory where files are posted for Oracle DataRaker to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging

Parameter	Description	Default Value
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Filtering Initial Measurement Data

The Adapter Development Kit can be configured to filter initial measurement data passed into Oracle Utilities Smart Grid Gateway and Meter Data Management. Filtering data is enabled by setting the <filterUsage> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterUsage>true</filterUsage>
```

When filtering is enabled, only measurements whose <externalUOM> matches one of the values defined in the **ADK - UOM Code to Standard UOM Mapping** extendable lookup (DG-HeadendUOMLookup) are passed into the system for processing.

Filtering Events

The Adapter Development Kit can be configured to filter device events passed into Oracle Utilities Smart Grid Gateway and Meter Data Management. Filtering data is enabled by setting the <filterEvents> element in the EnvironmentSettings.xq file to “true” as follows:

```
<filterEvents>true</filterEvents>
```

When filtering is enabled, only device events whose <externalEventName> matches one of the values defined in the **ADK - Device Event Mapping** extendable lookup (DG-DeviceEventMappingLookup) are passed into the system for processing.

Prioritized Device Event Processing

The SGG adapter prioritizes processing of device events created from smart meter commands and/or completion events by setting the Execution Method flag in these types of device events to “Real Time” (DIRT). In addition, device events received with the Execution Method flag set to “Real Time” will be processed in real time rather than via batch processing. See **Device Event Prioritization** in the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* for more information.

Configuring Payload Processing Notifications

By default, Payload Statistics, Payload Error Notification, and Payload Summary notification activities are sent to the Notification Queue within Oracle Service Bus. Smart Grid Gateway adapters can be configured to restrict sending these activities by defining optional JCA transport dynamic properties in the appropriate OSB project. The following optional JCA transport dynamic properties can be used to control if these notification activities are sent:

- **SGG_SEND_STATISTICS**: Controls sending Payload Statistic activities (true: send, false: do not send)
- **SGG_SEND_ERROR**: Controls sending Payload Error Notification activities (true: send, false: do not send)
- **SGG_SEND_SUMMARY**: Controls sending Payload Summary activities (true: send, false: do not send)

When these properties are set to false, the corresponding payload notification will not be sent to the JMS Queue. Note these properties are not populated by default, and default to true if omitted.

To create these properties:

1. Navigate to the SGG-D3-CIM-EVENT-CM project in the Oracle Service Bus Console.
2. Expand the **Proxy Services** folder.
3. Select the **InboundProxyService** proxy service (not the Pipeline or WSDL).
4. Click **Create** to create a new session.

5. Select **Transport Details**.
6. Click the plus sign in the **Dyanmic EndPoint Properties** section. An empty row will appear.
7. Enter the property you wish to define in the **Property** column.
8. Enter "false" in the **value** colulmn.
9. Repeat steps 6-8 for each property you wish to define.
10. Click **Activate** to save and activate your changes.

Note: These properties are only used if the SGG_EXT_ID_PATTERN is not present or the regular expression captures nothing. The SGG_EXT_ID_PATTERN will override these properties when the regular expression captures group data.

Base Package Business Objects

The adapter development kit base package includes the following device and initial measurement business objects:

Business Object Name	Description
DG-InitialLoadIMDInterval	Generic Initial Load IMD - Interval Used when loading customized adapter interval measurements into the system for the first time.
DG-InitialLoadIMDScalar	Generic Initial Load IMD - Scalar
DG-SmartMeter	ADK — Smart Meter

Device Communication

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, device status check, or an on-demand read. The designated BPEL process transforms the request from Oracle Utilities format to MultiSpeak format and invokes the related head-end system web service. The head-end system then returns a reply, and the BPEL process transforms the reply message back to the appropriate format so that Oracle Utilities can receive the response.

Communication Flows

The table below lists the communications created for each Adapter Development Kit command:

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	ADK - Initiate Connect or Disconnect	ADK - Connect/ Disconnect State Change	Connect Device Create IMD
Remote Disconnect	ADK - Initiate Connect Disconnect	ADK - Connect/ Disconnect State Change	Disconnect Device Create IMD
Device Commissioning	ADK - Meter Add Notification		Device Commissioning
Device Decommissioning	ADK - Meter Remove Notification		Device Decommissioning
On-Demand Read (Scalar)	ADK - Initiate Meter Read by Meter ID	ADK - Reading Changed Notification	Create IMD

Command	Outbound Communication	Inbound Communication	Completion Event
On-Demand Read (Interval)	ADK - Initiate Meter Read by Meter ID	ADK - Reading Changed Notification	Create IMD
Device Status Check	ADK - Initiate Outage Detection	ADK - Outage Detection Event Notif	

Unit of Measure Filtering for On-Demand Reads

Readings returned via On-Demand Read commands are filtered on the combination of Unit of Measure/Time of Use/Service Quantity Identifiers (UOM/TOU/SQI) configured for the device and measuring component. When filtering is enabled, only readings that match a configured UOM/TOU/SQI combination are processed. All others are filtered out.

Filtering is enabled by default via the "Opt Out Of Filtering" parameter (set to "false" by default) on the DG-CCOMPEV (Create IMD Completion Event) algorithm on the Create Completion Events status of the DG-ReadingChgNotification (ADK - Reading Changed Notification) business object.

The DG-VALDVCFIL (Check if Device has any Filtering errors) algorithm on the Validate status of the DG-ReadingChgNotification (ADK - Reading Changed Notification) business object is used to check for errors related to filtering. The value of the "Opt Out Of Filtering" parameter on this algorithm must match the value of the parameter on the DG-CCOMPEV algorithm. The parameters should both be set to either "false" (the default) or "true" (if filtering is to be disabled).

Device Communication Base Package Business Objects

The adapter development kit base package includes the following communication business objects:

Business Object Name	Description
DG-ConnectDisconStateChgNtf	Generic - Connect/Disconnect State Change
DG-InitiateConnectDisconnect	Generic - Initiate Connect Disconnect
DG-InitiateMeterByMeterId	Generic - Initiate Meter Read By Meter ID
DG-InitiateOutageDetection	Generic - Initiate Outage Detection
DG-MeterAddNotification	Generic - Meter Add Notification
DG-MeterRemoveNotification	Generic - Meter Remove Notification
DG-OutageDetectEvtNotification	Generic - Outage Detection Event Notification
DG-ReadingChgNotification	Generic - Reading Changed Notification

Event Data Mapping

The head-end system event file format can map as follows into the business object, D1-DeviceEventMappingLookup:

Head-End System Flat File Field	Device Event Seeder BO Element	Comments
Transaction ID (from Header record)	External Source Identifier	This is the file name.

Head-End System Flat File Field	Device Event Seeder BO Element	Comments
Device Identifier	External Device Identifier	
Event Name	External Event Name	
Event Creation Date/Time	Event Date/Time	
Device Type	External Device Type	This element has no real bearing on the device type within MDM/SGG. Its valid values include (although the element itself is free-form): Meter Collector Router
Service Location ID	External Service Location ID	
Communication Module Serial Number	External Communication Module Identifier	
Event Category ID	External Event Category	
Event Severity	External Event Severity	Valid values include (although the element itself is free-form): Alert Information
Status Value	External Status Value	This represents additional information that relates to the event itself.
Status Date/Time	External Status Date/Time	The date & time at which the additional information referenced above had occurred.

External System

You must create an External System for each external system to which Oracle Utilities Smart Grid Gateway will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch or Real-time)
- The corresponding message senders
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

Inbound / Outbound Service Configuration

The inbound/outbound message utility allows you to configure your system to receive information from and to send information to external applications using XML. The adapter for Smart Grid Gateway uses one inbound web service to map device events. This is the same inbound web service used by the D1 application.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send.

The Oracle Utilities Smart Grid Gateway Adapter Development Kit includes the following inbound web services:

Inbound Web Service	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	<p>Used for upload of device events.</p> <p>The Device Event Seeder business object serves as a means of adding device events both from outside the application and from online. Its pre-processing algorithms determine the device event type - which in turn defines the device event BO that should be used to create the device event.</p> <p>If a device event type can't be determined, the device event is created using this BO. Such a device event can then be re-processed - and if successful, a new device event is created.</p>
D1-InitialLoadIMD	<p>Used for initial measurement upload.</p> <p>The IMDSeeder business object is used to determine the type of initial measurement business object to instantiate when receiving usage readings from a head-end system.</p>
D1-DeviceStatusCheck	<p>Device Status Check</p> <p>This service is invoked by the integration layer to instantiate a Device Status Check command.</p>
D1-InitialLoadIMD	<p>Used by OSB to instantiate an IMD</p> <p>This inbound web service is used by OSB to instantiate an Initial Measurement Data for incoming interval usage in the Generic format.</p>
D1-RemoteConnect	<p>Remote Connect</p> <p>This service is invoked by the integration layer to instantiate a Remote Connect command.</p>
D1-RemoteDisconnect	<p>Remote Disconnect</p> <p>This service is invoked by the integration layer to instantiate a Remote Disconnect command.</p>
DG-ConDisconStChgNotification	<p>Initiate Connect Disconnect response.</p> <p>Retrieves asynchronous response from Initiate Connect Disconnect command.</p>

Inbound Web Service	Description
DG-OutageDetectionEventNotification	Initiate Outage Detection Response Retrieve response from the Initiate Outage Detection Event Notification command.
DG-ReadingChangedNotification	Reading Changed Notification Notification that a device reading has changed.

Message Senders

Message senders define the details of how messages are sent to an external system. As in the case of outbound communication business objects and outbound message types, the set of message senders you need to create is based on the types of messages the system is designed to accept.

The Oracle Utilities Smart Grid Gateway Adapter Development Kit includes the following message senders:

Message Sender	Description
DG-COMM	Generic Adapter Commission
DG-DCOMM	Generic Adapter Decommission
DG-INTOUDET	Generic Adapter — Initiate Outage Detection Request
DG-XAISender	Commission / Decommission Sender

BPEL Processes

These processes are responsible for performing the conversion from Oracle Utilities format to MultiSpeak 4.1 format, invoking process callouts and invoking the remote endpoint to trigger the device events.

OnDemandRead Composite Process: Invokes the remote endpoint to trigger the on-demand read event. An asynchronous reply responds to the OUAF layer when the reading arrives.

ConnectDisconnect Composite Process: Invokes the remote endpoint to trigger the connect/disconnect event. An asynchronous reply responds to the OUAF layer when confirmation of the requested event arrives.

CommissionDecommission Composite Process: Invokes the remote endpoint to trigger the commission or decommission event. After the synchronous call completes, a one of the following second business callout services is invoked to determined if the related “received” or “completed” callout should be executed:

- isExecutingCommissionReceived-Callout
- isExecutingCommissionCompleted-Callout
- isExecutingDecommissionReceived-Callout
- isExecutingDecommissionCompleted-Callout

DeviceStatusCheck Composite: Invokes the remote endpoint to trigger the initiate outage detection event. An asynchronous reply responds to the OUAF layer when confirmation of the requested event arrives.

ProcessCallout Composite: This business callout provides a point at which customers and implementers can incorporate custom business logic and transformations. This composite includes the WSDLs and processing logic for all of the MultiSpeak processes. The default implementation of each method is a direct return of the input.

For additional information about the BPEL processes included in the Oracle Utilities Smart Grid Gateway Adapter Development Kit, see [Business Processing Execution Language Processing](#) on page 884.

Web Services

These web services are all defined in the head-end system. The WSDLs were added to a Meta Data Storage (MDS) layer in OUAF and all references to the WSDL point to this MDS location. These web services have HTTP security by default. You may need to modify the security as a part of your implementation.

Web Service	Related BPEL Process	Description
CB_ServerService	ConnectDisconnect	<p>This web service defines the return interface, the means by which the status is returned to the calling system.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the CDStateChangeNotification web method is implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Generic Adapter/ConnectDisconnect/CB_ServerService</p>
CB_Server	OnDemandRead	<p>This web service defines the return interface, the means by which the reading is returned to the calling system.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the ReadingChangedNotification web method is implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Generic Adapter/OnDemandRead/CB_Server</p>
OA_ServerService	DeviceStatusCheck	<p>This web service defines the asynchronous return for InitiateOutageDetectionEventRequest for solicited responses.</p> <p>This web service is only be invoked by the head end system, not OUAF. Only the ODEventNotification, PingURL, and GetMethods web methods are implemented in the composite.</p> <p>The endpointURI format is: http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Generic Adapter/DeviceStatusCheck/OA_ServerService</p>

For additional information about the web services included in the Oracle Utilities Smart Grid Gateway Adapter Development Kit, see [Business Processing Execution Language Processing](#) on page 884.

Oracle Service Bus Processing

This chapter describes how to use Oracle Service Bus (OSB) and the components of the Oracle Utilities Smart Grid Gateway Adapter Development Kit to develop an adapter for importing usage reading and device events.

OSB Overview

The examples in this chapter provide an implementer with the information required to create a customized adapter using the Oracle Utilities Smart Grid Gateway Adapter Development Kit. Customized adapters are required in situations where a productized Smart Grid Gateway adapter is not available for a particular head-end system. The examples below explain how to receive and process inbound meter usage and events. The examples contain two parts: the incoming file parsing functionality implemented in Java, and an easy, configurable and customizable Oracle Service Bus (OSB) configuration, including an implementation of post-parsing functionality.

OSB Prerequisites

Development of an Oracle Utilities Smart Grid Gateway adapter requires a number of technical skills as well as a development environment.

Required Technical Skills

The following technical skills are required for developing an adapter using the development kit:

- Experience in Java programming
- Experience in development using XQuery and XPath
- Experience in XML programming
- Experience in OSB development and administration
- Understanding of Oracle Utilities Service and Measurement Data Foundation (SMDF) architecture

Environment Requirements

Development of the Oracle Utilities Smart Grid Gateway adapter requires an environment configured as follows:

- The Oracle WebLogic server must be installed.
- The OSB must be installed.
- An OSB domain must be created.
- Java Messaging Service (JMS) queues for Initial Measurement Data (IMD) and Notification messages must be created.
- The `spl-d1-osb-2.0.1.jar` containing the `com.splwg.d1.sgg.osb.common` Java package must be available. This is a single jar for all vendor-specific adapters.
- The archive `sgg-osb-generic-adapter.zip` must be available. This file is downloaded as a part of adapter development kit deployment. It contains the `FileParser` folder with sample source code and the `com.splwg.dg.sgg.osb.configuration.jar` file with sample OSB projects.

OSB Related Documentation

For more information about using the adapter development kit and Oracle Service Bus, see the following Oracle documents:

- *Oracle Fusion Middleware User's Guide for Technology Adapters*
- *Oracle Fusion Middleware Administrator's Guide for Oracle Service Bus*
- *Oracle Fusion Middleware Developing Applications for Oracle WebLogic Server*
- *Oracle Fusion Middleware User's Guide for Oracle JDeveloper*
- *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide*
- *Oracle Utilities Meter Data Management / Smart Grid Gateway Administrative User Guide*

OSB Processing Terms and Acronyms

This section lists several terms and acronyms used throughout this chapter.

Term	Definition
AMI	Advanced Metering Infrastructure

Term	Definition
CSV	Comma-Separated Values
FA	File Adapter. Oracle JCA File Adapter.
FP	File Parser, Java code that parses input file and generates Plain XML
GA	Smart Grid Gateway generic adapter
GFP	Generic File Processor, Java code that is invoked by FA. It communicates with FP
IMD	Initial Measurement Data
IMD XML	The final XML containing the IMD.
JAR	Java Archive
JAXB	Java Architecture for XML Binding
JCA	Java Connector Architecture
JDeveloper	Freeware Oracle integrated development environment for development of Java-based SOA and Java EE applications
JMS	Java Message Service
MDB	Message Driven Bean
SMDF	Service and Measurement Data Foundation
OSB	Oracle Service Bus
OAAF	Oracle Utilities Application Framework
Plain XML	An intermediate XML containing all of the values from the inbound file. It is necessary because OSB Message Flow can handle only XML.
PPS	Processing Proxy Service, OSB proxy service where the validation and transformation of Plain XML is implemented. It is necessary to catch errors that occurred before Plain XML is transformed to IMD or Device Event seeder structures.
RFD	Rejected File Descriptor, File containing information about a portion of input file that was a cause of error.
RPPS	Result Processing Proxy Service, OSB proxy service where processing of transformation result is implemented. It is necessary to catch errors that occurred after Plain XML is transformed to IMD or Device Event seeder structures.
SGG	Smart Grid Gateway
Weblogic	Oracle J2EE Application Server

Term	Definition
WSD	Web Session Directory
XML	eXtensible Markup Language
XPath	Programming language for selecting nodes from an XML document
XQuery	Programming language to query XML.

Oracle Utilities Smart Grid Gateway Adapters

This section contains detailed information on the different components that make up an Oracle Utilities Smart Grid Gateway adapter and the application logic that is needed to implement one.

Adapter Components

The following table lists the adapter components:

Component	Description
JCA File Adapter (FA)	Technology adapter for reading and writing files on the local file system. It is responsible for polling files from incoming folder and passing it to the Generic File Processor.
Generic File Processor (GFP)	Framework component that is implemented in Java. It is responsible for instantiation of the File Parser, getting Plain XML from it, and passing it to OSB message Flow. It also performs payload statistics related functionality such as gathering data and generating notification messages.
File Parser (FP)	<p>Component implemented in Java. It is specific to every different incoming format. It is responsible for parsing the incoming file, breaking the payload into logical parts (debatching), generating Plain XML for every logical part, and returning XML back to invoking GFP.</p> <p>Plain XML could be any logical subset of data that can be mapped to IMD. It is an intermediate format/schema between the raw data and IMD XML. The Plain XML schema must be defined by the file parser developer.</p> <p>Raw data is read in portions from the input file and converted to Plain XML before passing to OSB message flow. The reason for data being read in portions is as follows:</p> <p>Assume that an input file contains readings for 100 Measuring Components. You would want to read the input file in portions for two particular reasons.</p> <ol style="list-style-type: none"> 1. Reading data of exactly one measuring component ensures that it is mapped appropriately to one IMD at a time. 2. Reading data in portions ensures that the entire file is not loaded into memory, which could cause resource issues.
Inbound Proxy Service	OSB proxy service that contains FA-related configuration settings. It statically routes all messages to Processing proxy Service.

Component	Description
Processing Proxy Service (PPS)	OSB proxy service that validates and transforms Plain XML. This service is necessary for catching errors that occur before Plain XML is transformed to IMD or Device Event seeder structures.
Result Processing Proxy Service (RPPS)	OSB proxy service that processes transformed data. This service is necessary for catching errors that occur after Plain XML is transformed to IMD or Device Event seeder structures.

Processing Life Cycle

This section outlines the life cycle from the initial input file to the initial measurement output. Refer to [OSB Processing Terms and Acronyms](#) on page 869 for descriptions of the abbreviations and acronyms used in this chapter.

See the [Logic Sequence Diagram](#) for general description of how the components interact.

OSB Processes

1. The JCA File Adapter starts reading the file.
2. FA instantiates and initializes the GFP.
3. FA invokes GFP passing an open stream to the incoming file.
4. GFP sends **D1-PayloadStatistics** notification message to FA.
5. GFP instantiates and initializes (if it is not done yet) the FP that is defined in the Inbound Proxy properties for parsing the file.
6. GFP invokes the FP (See [File Parser Processes](#) on page 872 below).
7. In case of error in FP it invokes GFP. GFP sends **D1-PayloadErrorNotif** notification message to FA.
8. GFP gets the Plain XML as a return from FP.
9. GFP returns the Plain XML to the FA.
10. The Plain XML is passed via InboundProxyService to Processing Proxy service (PPS). In PPS's message flow, the Plain XML is validated and transformed to IMD XML.
11. PPS passes the IMD to Result Processing Proxy service (RPPS). RPPS publishes the IMD XML to a JMS queue, which is then picked up by Message Driven Bean (MDB).
12. OSB processes 3 through 9 are repeated until FP returns NULL on process 9.
13. GFP sends **D1-PayloadSummary** notification message to FA.

File Parser Processes

1. FP starts reading the input stream
2. FP instantiates a JAXB object of the type of Plain XML. The JAXB related interfaces and implementation classes are generated by using JDeveloper (See *Oracle Fusion Middleware User's Guide for Oracle JDeveloper or Generating Java Classes from XML Schemas* on page 883).
3. FP reads the input stream in segments until it hits a logical end of data with which it could create a Plain XML.
4. FP populates the data that is read into the Plain XML JAXB object.
5. FP marshals the JAXB object into Plain XML and passes back GFP. If the end of file (EOF) is reached FP passes back NULL.
6. File parser processes 2 through 5 are performed for every invocation by GFP.

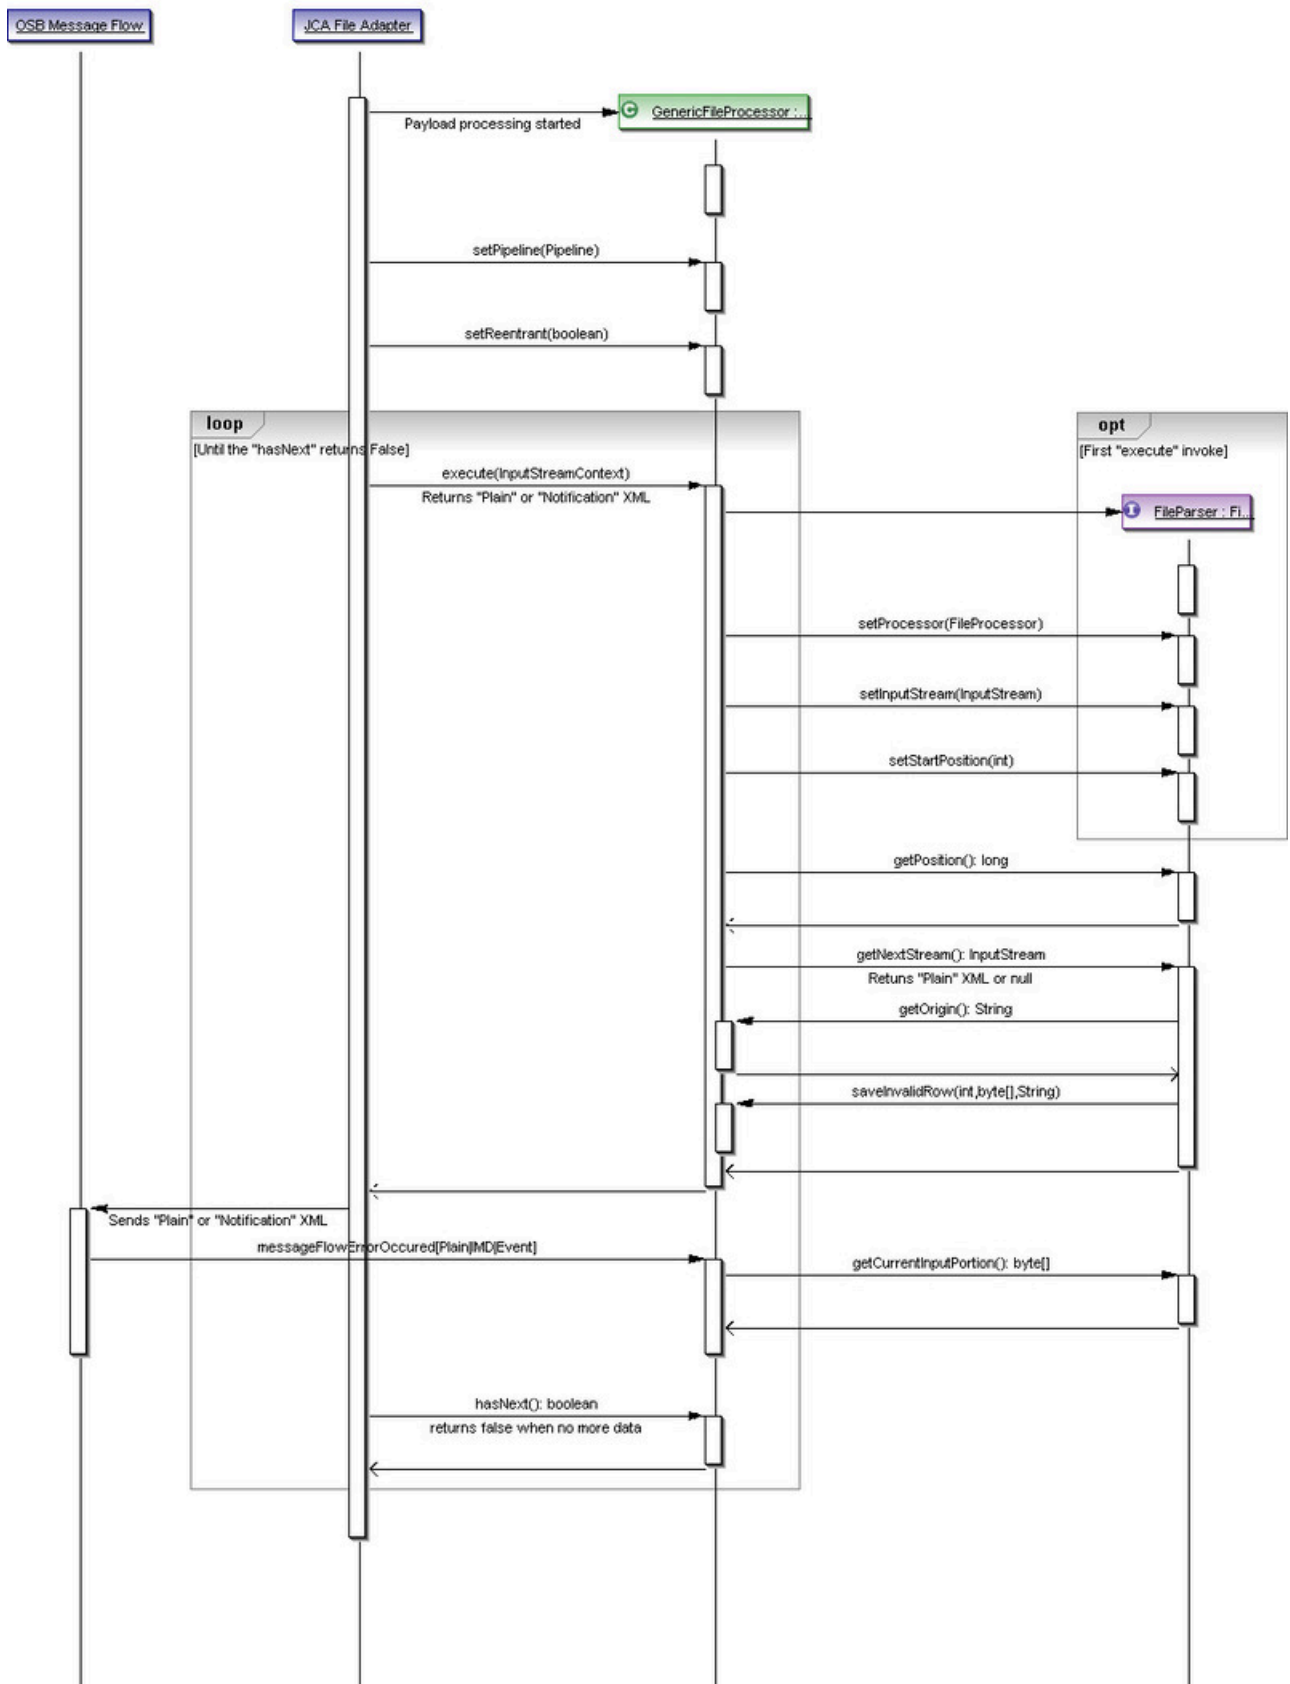

Java Project

The source code in the example files contains an implementation of functionality to parse an incoming payload in Comma Separated Values (CSV) and XML formats. This implementation can be used as a reference for creating a project that is specific to your head-end system. The descriptions below are mostly related to CSV parsing

functionality as it is a more complex and interesting example. The XML related parsing example is provided only to illustrate how XML-based input formats may also be processed.

Logic Sequence Diagram

The sequence diagram below is helpful for understanding the File Parser functionality. The custom class must implement the `FileParser` and `FileParser2` Java interfaces described in the SGG D1 jar to be qualify as a file parser. For more information, see [FileParser Interface](#) on page 881 and [FileParser2 Interface](#) on page 882.

When FA finds a file in the input directory, it instantiates and calls GFP which in turn starts an interaction with the FP. The interaction can be categorized into the following three phases:

1. Instantiation and Initialization

- setProcessor()
- setInputStream()
- setStartPosition()

2. Transaction

- getPosition()
- getNextStream()

3. Exception Handling

- getCurrentInputPortion()

Instantiation and Initialization Phase

The GFP is instantiated and receives an Input Stream when a file gets into the input directory. At that point an instance of the FP is instantiated. Certain methods, as specified above, are invoked on the FP to initialize.

Transaction Phase

Once the FP is initialized, GFP uses the FP instance to generate the Plain XML structure. This happens with the invocation of getNextStream() method on the FP.

On every invocation, the FP returns exactly one Plain XML. The FP invocations continues until NULL is returned from the FP. NULL indicates the end of file and an indication that parsing is complete for a specific file. GFP stops invoking getNextStream() for a particular input file when it receives a NULL from the FP.

FP uses the file input stream to read the file in portions. It could read byte-by-byte or line-by-line, but at the end of each getNextStream() method call it would have read only so much that is sufficient to create one Plain XML structure. For example, in an input file, if there is sufficient data for only one Plain XML then the first call to getNextStream() would return a Plain XML and the next one would return NULL. But if there is more than one, getNextStream() calls would continue to return Plain XML structures for every incoming portion until end of file is reached.

Exception Handling Phase

Exception handling inside the FP can be categorized into two phases: **Reactive** and **Recovery**:

Reactive Phase

This phase involves catching an exception and reporting it to the GFP. It is achieved by invoking saveInvalidRow() method on the GFP (this.fileProcessor).

Note that when an exception occurs, no further parsing is done and NULL is passed back from getNextStream().

If one fails to return NULL, errors such as “Simultaneous good and bad result returned by the File Parser” can be found in the Weblogic server log.

When an exception is reported to the GFP, it does three things:

1. Creates an XML payload D1-PayloadErrorNotif and passes it to the OSB message flow. The message is published to the Notification Queue from inside PPS of the BASE OSB project.
2. It increments the “transaction error occurred” variable by invoking the utility method inside the D1 jar. All the errors occurring during the lifetime of a file parsing are captured and are reported through the message D1-PayloadSummary - which is again published to Notification Queue.
3. Finally, it creates a data file in the error directory with the portion of raw data that is read when the error occurred. It also creates a Rejected File Descriptor (RFD) file. The raw input portion is available by utilizing getCurrentInputPortion() method, which is discussed below.

As noted in the above image, the saveInvalidRow() method takes three input parameters:

1. The position at which the parsing started. It will be written to an RFD file. This is helpful in identifying the location of an error in the input file.
2. The raw data that will be written into error data file. It should be in the same to the incoming file format and it should contain data that is read since current invocation of getNextStream() method is started. It will allow correcting troubled data and place “fixed” file into an incoming folder for further re-processing.
3. The error message that is reported in D1-PayloadErrorNotif message. Note, the content of the error message has to be defined by the file parser developer.

Recovery Phase

This phase must not be confused with recovering from a handled exception discussed above. This case is when file parsing gets completely interrupted by power failure or network interruption.

Preparation for recovery: GFP maintains an internal index to the current read position of the file. This is achieved by GFP by invoking getPosition() method on the FP before every getNextStream() method call.

```
public long getPosition() {
    long retVal = this.fileProcessor.getCurrentInputPosition();
    return retVal;
}
```

Recovery: In case of an interruption and subsequent restore, GFP sets the start position on the File Parser. For instance, if the failure had occurred at byte 415, the start position would be set to 415 so that FP starts to read from that point and not from 0. The value 415 can be referred to as the recovery point.

```
public void setStartPosition(long position) {
    this.startPosition = position;
}
```

When the file parser starts parsing again, two things must occur to ensure that it starts parsing from the recovery point:

1. Store the recovery point to the startPosition field.
2. Incorporate skip logic to start the pointer from the recovery point.

Java Implementation

The Java component of the project includes the following classes and packages:

1. **com.splwg.dg.osb.common.FileParserGenGeneric** class is a super class with members that are common for CSV and XML related functionality. It implements the com.splwg.d1.sgg.osb.common.FileParser interface (see [FileParser Interface](#) on page 881). The implementation of com.splwg.d1.sgg.osb.common.FileParser2 (see [FileParser2 Interface](#) on page 882) has been added to define the IMD & Event Upload Statistics related functionality.
2. **com.splwg.dg.osb.csv.FileParserCSV** class contains the implementation of the parsing functionality for CSV formats. It performs the following logic:
 - Parses the incoming payload.
 - Transforms incoming data to Usage or Event related structures based on incoming data type.
 - Extends those structures with file information and external service provider identifier.
 - Returns one by one that structures as a stream to caller.
3. **com.splwg.dg.osb.plain** package contains JAXB related interfaces and implementation classes corresponding to the Plain XML Schema
4. **com.splwg.dg.osb.xml.FileParserXML** class contains the implementation of parsing functionality for the “IMD and Event Online Upload” XML format (See the *Oracle Utilities Service and Measurement Data Foundation User’s Guide*). It performs the following logic:
 - Parses the incoming payload.
 - Extracts information about current device.
 - Breaks the incoming data to separate initial measurement data structures.

- Extends those structures with device information, file information and external service provider identifier.
- Returns one by one the structures as a stream to caller.

Implementation Details

This section provides an overview of the implementation details. See the comments in the source code for more detailed information.

OSB Configuration

This section outlines the OSB projects provided with the Adapter Development Kit.

OSB Project Summary

The OSB Configuration consists of four projects. These projects can be categorized by either functionality or content:

Functionality by Incoming File Format

CSV format processing:

- SGG-DG-CSV-BASE
- SGG-DG-CSV-CM

XML format processing:

- SGG-DG-SEEDER-BASE
- SGG-DG-SEEDER-CM
- SGG-DG-XML-BASE
- SGG-DG-XML-CM

Content (by purpose of content)

Content containing business logic implementation:

- SGG-DG-CSV-BASE
- SGG-DG-SEEDER-BASE
- SGG-DG-XML-BASE

Content containing configuration settings related to the objects and variables required during the processing of payloads:

- SGG-DG-CSV-CM
- SGG-DG-SEEDER-CM
- SGG-DG-XML-CM

Project Contents

The following table describes the contents of each of these projects:

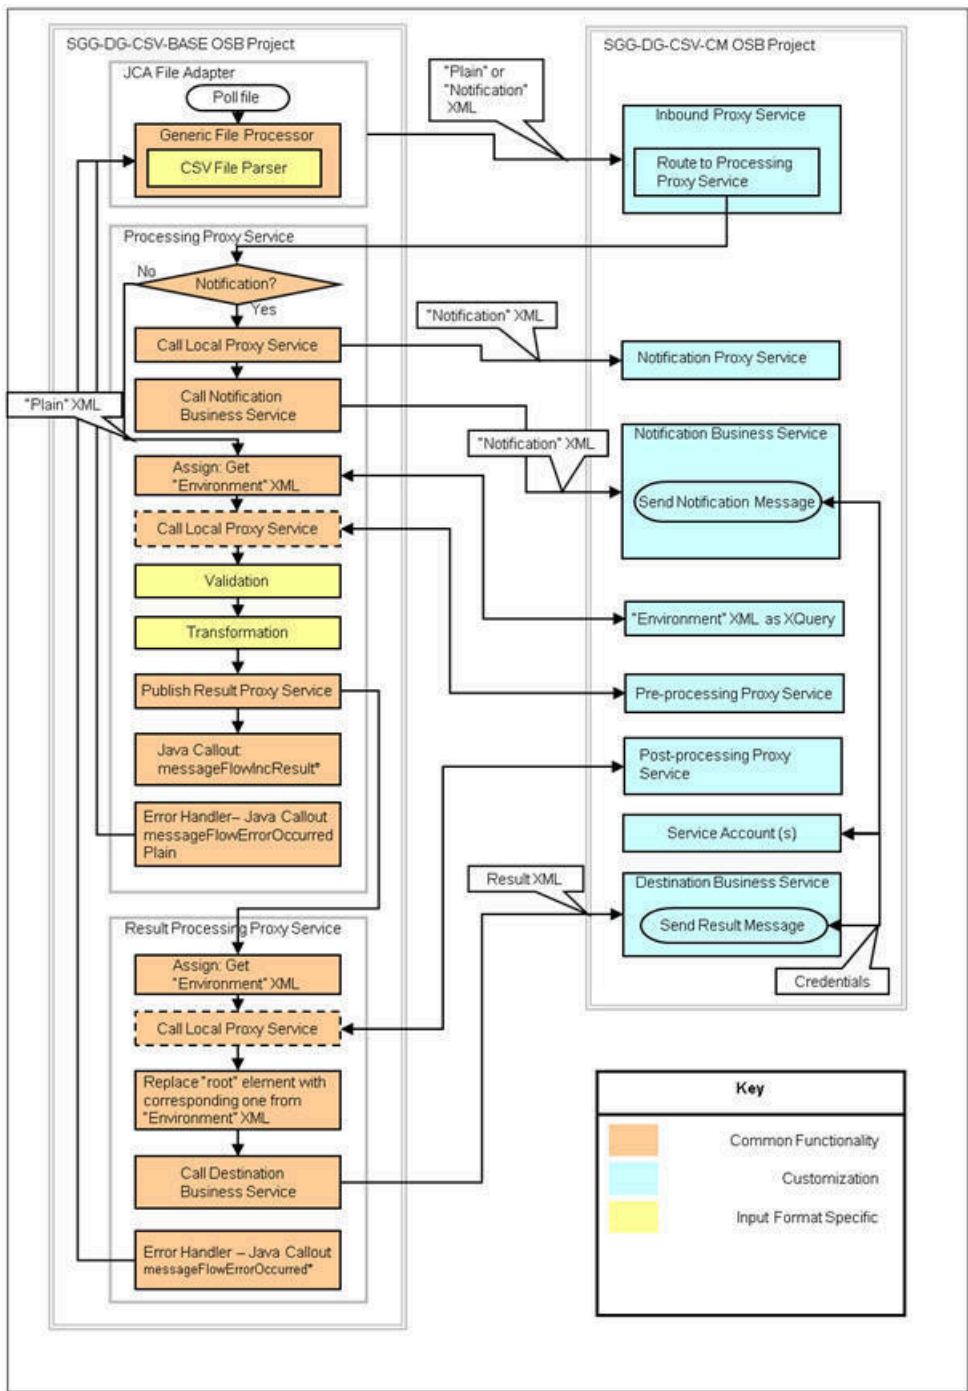

Project	Description
SGG-DG-CSV-BASE	<p>Contains the components responsible for “actual” processing of data coming in CSV format. It can be upgraded in future releases without affecting the customization and environment settings that are stored in the SGG-DG-CSV-CM project. This project performs the following functions:</p> <ul style="list-style-type: none"> • Processes notification messages that are sent from the GFP. • Calls the customizable local service proxies for pre- and post-processing of passed data • Validates passed data against the XSD schema for Plain XML format • Transforms passed Plain XML into D1-InitialLoadIMD or D1-DeviceEventSeeder formats according to type of incoming data. • Sends result structures to destination JMS queue. • Updates statistic information via calling the messageFlowIncResultIMD or messageFlowIncResultEvent method accordingly. • Handles errors that occur to provide information to the File Processing component. Error handling contains separate handlers for two stages: before and after the Plain XML is transformed to the final XML structure. The separation is necessary to make Java calls to appropriate methods (messageFlowErrorOccurredPlain, messageFlowErrorOccurredIMD or messageFlowErrorOccurredEvent) according to the current processing stage and data type.
SGG-DG-CSV-CM	<p>Contains environment related configuration settings. It allows the customization and simplifies the future upgrades as well (See Configuring the OSB Project on page 881 for example values).</p>
SGG-DG-XML-BASE	<p>Contains the components responsible for “actual” processing of data coming in XML format. It can be upgraded in future releases without affecting the customization and environment settings that are in SGG-DG-XML-CM project. This project performs the following functions:</p> <ul style="list-style-type: none"> • Processes notification messages that are sent from GFP. • Calls the customizable local service proxies for pre- and post-processing of passed data. • Validates passed data. • Transform passed data. In current tutorial a simple XQuery code is used just to show the functionality available for transformation. • Sends result structures to destination JMS queue in form of acceptable by the D1-DeviceEventSeeder and/or D1-InitialLoadIMD inbound web services. • Updates statistic information via calling messageFlowIncResultIMD method. • Handles errors to provides information to GFP. Error handling contains separate handlers for two stages: before and after the Plain XML is transformed to the final XML structure. The separation is necessary to make a Java calls to appropriate methods (messageFlowErrorOccurred or messageFlowErrorOccurredIMD) according to the current processing stage.

Project	Description
SGG-DG-XML-CM	Contains environment related configuration settings. It allows the customization and simplifies future upgrades as well.
SGG-DG-SEEDER-BASE	<p>Contains the components responsible for processing of data coming in “native” XML format. It can be upgraded in future releases without affecting the customization and environment settings that are in SGG-DG-SEEDER-CM project. This project performs the following functions:</p> <ul style="list-style-type: none"> • Processes notification messages that are sent from GFP. • Calls the customizable local service proxies for pre- and post-processing of passed data. • Validates passed data. • Splits payload into individual initial measurements and/or device events. • Sends result structures to destination JMS queue in form of acceptable by the D1-InitialLoadIMD and/or D1-DeviceEventSeeder inbound web services. • Updates statistic information via calling messageFlowIncResultIMD method. • Handles errors to provides information to GFP. Error handling contains separate handlers for two stages: before and after the Plain XML is transformed to the final XML structure. The separation is necessary to make a Java calls to appropriate methods (messageFlowErrorOccurred or messageFlowErrorOccurredIMD) according to the current processing stage.
SGG-DG-SEEDER-CM	Contains environment related configuration settings. It allows the customization and simplifies future upgrades as well.

OSB Project Implementation Details

This section provides an overview of the implementation details. For more detailed information see the comments contained in the source code.

The following diagram shows the major processes and the data flow implemented in the OSB Configuration projects. The implementation description that follows is related to CSV parsing.

Setting Up the Adapter Environment

This section contains detailed information about the setting up of an environment with an example adapter.

Setting Up the Java Project

1. Open the sgg-osb-generic-adapter.zip file and extract the FileParser folder into a temporary location on your hard disk.
2. Create a Java project in JDeveloper and import source code into it from the folder extracted previously.
3. Add the spl-d1-osb-2.0.1.jar file to the project's Libraries and Classpath properties.
4. Deploy the project as a jar file to the destination OSB domain's lib folder.

Note: The WebLogic server should be restarted after jar file is copied to lib folder. For more details, see *Oracle Fusion Middleware Developing Applications for Oracle WebLogic Server*.

Configuring the OSB Project

1. Open the `sgg-osb-generic-adapter.zip` file and extract the `com.splwg.dg.sgg.osb.configuration.jar` file into a temporary location on your hard disk.
2. Ensure that OSB is running in the domain that is created for the adapter.
3. Import resources by using the OSB Administration Console via the **System Administration > Import/Export > Import Resources** menu item from the extracted `com.splwg.dg.sgg.osb.configuration.jar` file. Note that conflicts may occur during import. They will be fixed in the following steps.
4. Check and change the JCA Transport Configuration properties of the `SGG-DG-CSV-CM/Proxy Services/InboundProxyService` proxy service according to the deployment environment:

Where:

- **Endpoint Properties/SGG_INPUT_PARSER** is a name of class that implements file parsing functionality. See a Java project mentioned early.
 - **Endpoint Properties/SGG_ERROR_FOLDER** is a folder where a rejected transaction from incoming file will be placed in case when the parsing or validation is failed.
 - **Endpoint Properties/SGG_SP_EXT_REF_ID** is a value corresponding to the target Service Provider's external reference id on OUAF side. It is used in the XML structures related to the IMD & Event Upload Stats functionality. Also, this value will be placed into `D1-InitialLoadIMD/serviceProviderExternalId` and `D1-DeviceEventSeeder/externalSenderId` elements.
 - **Activation Spec Properties/IncludeFiles** is the naming convention that the Oracle File Adapter uses to poll for inbound files.
 - **Activation Spec Properties/PhysicalArchiveDirectory** is a folder where to archive successfully processed files.
 - **Activation Spec Properties/PhysicalDirectory** is an input folder to be polled.
5. Change the Endpoint URI in the Transport Configuration section of the `SGG-DG-CSV-CM/Business Services/DestinationBusinessService` business service according to the deployment environment with value containing URI for JMS server and queue where IMD or Device Event structures will be sent (see *Oracle Fusion Middleware Administrator's Guide for Oracle Service Bus* for more detail.):
 6. Change the Endpoint URI in the Transport Configuration section of the `SGG-DG-CSV-CM/Business Services/NotificationBusinessService` business service according to the deployment environment:
 7. Update the credentials stored in the `SGG-DG-CSV-CM/Service Accounts/DestinationServiceAccount` service account according to the deployment environment with user ID and password required to access JMS server:
 8. Repeat steps 4-7 for the `SGG-DG-XML-CM` project

Additional Information

This section contains additional information about the Adapter Development Kit.

Processing Large Input Files

In some environments, the OSB project may begin processing a large input file before it has been completely copied to the input directory. To prevent this, configure the `MinimumAge` property in the “`InboundProxyService`” proxy service. The `MinimumAge` property specifies the minimum age of files to be retrieved, based on the last modified time stamp. This enables large files to be completely copied to the input directory before they are retrieved for processing.

FileParser Interface

This section provides the source code of the `FileParser` interface used by the Java class delivered with the Java package described earlier in this section.

```
package com.splwg.dl.sgg.osb.common;
import java.io.IOException;
import java.io.InputStream;
/** <p>
 * FileParser component is responsible for processing the input
 * stream and returning a Plain XML containing all data from
```

```

* incoming transaction in a shape expected by the following
* Oracle Service Bus message flow.
* </p>
*/
public interface FileParser {
    /**
     * Returns the next message in Plain XML format
     * or null if there are no more messages
     * @return next message as InputStream
     */
    InputStream getNextStream() throws IOException;
    /**
     * Returns the current position in the currently
     * parsed source input stream
     * @return the position in source input stream after
     * last incoming row was read and parsed
     */
    long getPosition();
    /**
     * Sets source stream
     * @param input the Input Stream that should be parsed
     */
    void setInputStream(InputStream input);
    /**
     * Sets "owner" FileProcessor
     * @param owner the Instance of FileProcessor that will
     * be notified about current processing via call to
     * utility methods (saveInvalidRow and setParseFinishNote)
     */
    void setProcessor(FileProcessor owner);
    /**
     * Sets the position from which the parsing of source
     * stream should be started.
     * It is necessary if last time the processing of
     * current file has been interrupted
     * @param position the starting position
     */
    void setStartPosition(long position);
    /**
     * Returns the byte array that contains a portion of an incoming
     * file that most recently has been read and converted to Plain XML.
     * It should be in the same format as incoming file. The header and
     * tail records, if there are, should be included and updated according
     * to the content
     */
    byte[] getCurrentInputPortion();
    /**
     * Returns type of currently generated transaction - USAGE or EVENT
     */
    FileProcessor.TransactionType getCurrentTransactionType();
    /**
     * Returns the number of successfully generated transactions of given type
     */
    int getTransactionCount(FileProcessor.TransactionType type);
    /**
     * Returns the number of expected transactions in input stream
     * Returns -1 if information not available
     */
    int getTotalExpected();
}

```

FileParser2 Interface

This section provides the source code of the FileParser2 interface used by the Java class delivered with the Java package described earlier in this section. This interface has been added to include a way for the File Processor to retrieve the file creation date which can be stored inside the incoming file.

```
package com.splwg.dl.sgg.osb.common;
import java.util.Date;
public interface FileParser2 extends FileParser {
    /**
     * FileProcessor usage method
     * Returns the File creation date and time stamp stored
     * in the file
     * Returns null if information not available
     */
    Date getCreationDateTime();
}
```

FileProcessor Interface

This section contains a portion of the FileProcessor interface related to the file parsing functionality.

```
package com.splwg.dl.sgg.osb.common;
public interface FileProcessor {
    public enum TransactionType {
        USAGE, EVENT
    }
    /**
     * FileParser usage method
     *
     * @return a string containing the name of currently processed inbound file
     */
    String getOrigin();
    /**
     * FileParser usage method Creates a file in the Error Folder and saves
     * passed row parameter to it
     *
     * @param position
     *         the number representing the position in file where invalid
     *         raw data is started
     * @param row
     *         the byte array containing an invalid raw data in vendor
     *         specific format the same with format of incoming file
     * @param failCause
     *         the string showing the cause of fail It will be used while
     *         logging the fail message.
     */
    void saveInvalidRow(long position, byte[] row, String failCause);
    /**
     * FileParser usage method
     * Returns the current offset in input file
     */
    long getCurrentInputPosition();
}
```

Generating Java Classes from XML Schemas

In JDeveloper you can use JAXB (Java Architecture for XML Binding) to generate Java classes from XML schemas. JAXB is an easy way to incorporate XML data and processing functions in Java applications without having to know XML. You can generate a JAXB 1.0 or 2.0 content model, including the necessary annotations, from an XML schema.

When the JAXB binding compiler is run against an XML schema, JAXB packages, classes, and interfaces are generated. You can then use the generated JAXB packages and the JAXB utility packages in a binding framework to unmarshal, marshal, and validate XML content.

To generate Java classes from XML schemas with JAXB:

1. From the main menu choose **File > New > Business Tier > TopLink/JPA** and select either JAXB 1.0 or 2.0 Content Model from XML Schema to open the compilation dialog.
2. Select the schema file and optionally the JAXB customization file to use and the package to which the generated classes will be added.

The JAXB package and generated classes are added to the Application Resources folder.

Business Processing Execution Language Processing

This section describes the Business Process Execution Language (BPEL) processes included in the Oracle Utilities Smart Grid Gateway Adapter Development Kit that support two-way communication between the adapter and the head-end system. The ideas and general practices described in this section can be applied to any other adapter.

WSDLs, Endpoints, and Messages

WSDLs are Web Service Definition Language files that describe a web service. New services must utilize the WSDLs to determine the structure of requests and responses. For remote services, they contain the locations to access the services. For both remote and local (hosted) services, the files will contain the definitions for each web service including names, arguments, exceptions, and the structure of the input and output messages.

In Oracle Service Oriented Architecture (SOA), WSDLs can be classified as a “service” or as a “reference.” Services are hosted on the SOA server; that is, the implementation of the web service is on the local application server. Referenced services are implemented on a different server. This distinction is also relevant to the composite level. Services are implemented in the current composite. References are located elsewhere, possibly on the same app server, but in a different composite.

An “endpoint” is simply the URL for a web service. Since web services communicate via HTTP, each will have a unique URL. Once a service’s endpoint is known, a message service can be targeted to it.

How to locate WSDLs and Endpoints

There are two ways to locate WSDLs in an installed Adapter: through Enterprise Manager and by using a direct URL. Only “hosted” WSDLs can be located in this way. Referenced (remote) WSDLs must be either located in source code or obtained from the hosted location.

How to Use Enterprise Manager to Locate WSDLs and Endpoints:

1. Open Enterprise Manager and use the navigation pane to open the Dashboard of the desired composite.
2. The top bar of the Dashboard contains several buttons and icons. One of these is an “earth” icon with a puzzle piece over it. Click this icon to display the WSDL and endpoint URIs for the composite.
3. Click the URL link to see the WSDL in the browser, or right click and save it to your machine for use in developing new services.

Depending on the requirements, It may be necessary to download the associated schema or WSDL file(s). Schemas are available within the WSDL’s “types” element. Find associated WSDL URLs within the import element. That URL can be pasted into a browser tab.

The endpoint for the service is also visible in this window. It is this URL that should be added to message sender configuration. For example:

The value HTTP Header/SOA Action is taken from the service’s WSDL. Locate the `wsdl:definitions/wsdl:binding/wsdl:operation/soap:operation` element for the web method being invoked. An attribute called `soapAction` will contain the value for this field. A shortcut to this field is using Enterprise Manager's Testing framework (locate the Test tab from the dashboard view for the composite). Once the WSDL is parsed, the SOAP Action will appear in a field on the request tab:

The values **HTTP Login User** and **HTTP Login Password** should be set to a valid WebLogic user that has access to the module. The **HTTP Method** should always be set to POST and the HTTP URL 1 should be set to the value of the endpoint above.

How to Use a Direct URL to Locate WSDLs and Endpoints

The WSDLs can be accessed without Enterprise Manager by understanding the paths used on the SOA server. In general, they have the form:

```
http://{server name}:{port number}/soa-infra/services/{partition}/
{Composite}/{Web Service}
```

Composite Components

This section outlines several important logical features of the BPEL composites.

Composite Properties

Most composites contain properties within the main file, composite.xml. They are essentially global constants that can be preconfigured with default values and changed at deployment time. They can be accessed post-deployment in Enterprise Manager.

Typically, these properties represent timeouts and boolean properties for activating or deactivating functionality. Other uses might include setting default values of constants such as URLs. They are accessed with the `ora:getPreference()` BPEL function.

They can be changed during development, at deployment time, or after deployment using different techniques for each.

Development Changes

At development time, properties can be created at will within the “component” sections of the composite.xml file. The image below shows an example of the properties found in DeviceStatusCheck:

```
<component name="DeviceStatusCheck">
  <implementation.bpel src="DeviceStatusCheck.bpel" />
  <property name="bpel.preference.isExecutingInitODRequestReceivedCallout">true</property>
  <property name="bpel.preference.isExecutingInitODEventRequestCompleted">true</property>
  <property name="bpel.preference.isExecutingODEventNotificationArrived">true</property>
  <property name="bpel.preference.timeout.callback.years">0</property>
  <property name="bpel.preference.timeout.callback.months">0</property>
  <property name="bpel.preference.timeout.callback.days">0</property>
  <property name="bpel.preference.timeout.callback.hours">0</property>
  <property name="bpel.preference.timeout.callback.minutes">0</property>
  <property name="bpel.preference.timeout.callback.seconds">45</property>
  <property name="bpel.preference.OD_ServerCallbackEndpoint">http://127.0.0.1:8001/soa-infra/serv
  <property name="bpel.preference.externalSenderID">DSC Sensus</property>
  <property name="partnerLink.OD_ServerProxy.idempotent" type="xs:string"
    many="false">false</property>
</component>
```

Properties must be prefixed with “bpel.preference.” The BPEL process associated with them (see the `implementation.bpel` element) can use the `ora:getPreference()` method to extract the value. When accessing the values, the “bpel.preference” prefix is dropped.

Pre-Deployment Changes

While the values of properties cannot be changed at runtime, they can be altered using the configuration plan each composite uses for deployment. Most configuration plans will contain multiple property elements within the “component” section. Modifying the value in the replace element and redeploying the composite will change the behavior of the property:

```

<component name="DeviceStatusCheck">
  <property name="bpel.preference.isExecutingInitODRequestReceivedCallout">
    <replace>true</replace>
  </property>
  <property name="bpel.preference.isExecutingInitODEventRequestCompleted">
    <replace>true</replace>
  </property>
  <property name="bpel.preference.isExecutingODEventNotificationArrived">
    <replace>true</replace>
  </property>
  <property name="bpel.preference.timeout.callback.years">
    <replace>0</replace>
  </property>
  <property name="bpel.preference.timeout.callback.months">
    <replace>0</replace>
  </property>
  <property name="bpel.preference.timeout.callback.days">
    <replace>0</replace>
  </property>
</component>

```

When the composite is deployed, the properties will contain the values in the “replace” elements.

Post-Deployment Changes

After deployment, changes can still be made to the values of the properties through Enterprise Manager.

1. In the Enterprise Manager navigation window, open WebLogic Domain/{domain name}. Right click on the domain and select **System MBean Browser**.
2. A new navigation pane opens in the window on the right. Select **Application Defined MBeans/oracle.soa.config/Server: {domain name}/SCAComposite/{Composite} [1.0]/SCAComposite.SCAComponent/{Component}** to access the controls for a particular component. A “component” is a single BPEL or Mediator within a larger SOA composite

A list of options will open in the right pane.

3. Select **Properties**.

The Property sheet shows a list of all the properties. Opening one allows editing of the property value.

4. Click **Apply** to save any changes.

Proxies

Proxy web services make no changes to the data going through the system and are just used to centralize endpoint configuration. The message structures are identical to those of the head-end system. Data is passed through without modification. Mediator objects within the Common composite are used to move data from Oracle Utilities Smart Grid Gateway to the head-end system.

Process Callouts

Some services are designated as “Process Callouts.” These services allow integrators direct access to the XML coming to and from the head-end system. They are useful in the event the integrator needs to provide custom enrichment or transformation of the inbound or outbound data. Because process callouts are generally located before and after calls to the head-end system or when data arrives, they can also serve as an “event” trigger if the integrator requires additional processing logic. The services define identical inputs and outputs and are based on head-end schema definitions. To use a callout, the integrator should create a web service implementing one or more of the WSDLs defined in the Common composite. Other composites should then be configured to target the new Callout-type service.

A typical example is for re-rendering the meter identifier being sent to the head-end system. If the standard meter ID should be modified, a process callout service is a candidate for making this change. Note that because the schema is based off the head-end system's definition, deviations from the schema are not allowed.

Configuring and Customizing Adapter BPEL Processes

This section outlines how to configure and customize the Oracle Business Process Execution Language (BPEL) processes provided with the Adapter Development Kit to work with your implementation.

Editing Configuration Files

This section outlines the changes that need to be made in various configuration and build files to enable the application servers used in your implementation to communicate with each other, and to support the specifics of your head-end system. These files are also used in packaging and deploying the processes.

Server Definitions

In order for your adapter to work properly, you must set up the application servers that run the components used by the adapter to communicate with each other as follows:

- The Oracle Utilities Smart Grid Gateway application server must be able to send and receive messages to and from the SOA Suite application server.
- The SOA Suite application server must be able to send and receive messages to and from the head-end system application server, and the Oracle Utilities Smart Grid Gateway application server
- The head-end system application server must be able to receive and send messages from and to the SOA Suite application server.

The types of servers and the tokens that need to be replaced for each are listed below. Further below are the specific configuration files that must be modified, as well as the locations in each file that must be modified. Note that a port is listed, but may not be necessary depending on the type of installation. Also note that the SOA Server will have to have the partition name defined that is used.

- **SOA Server:** This is the application server running the SOA Suite components, including Oracle Service Bus (OSB) and Oracle Business Process Execution Language (BPEL). The SOA server is referenced using the following tokens:
 - {SOA_HOST}: the server where the SOA server has been installed
 - {SOA_PORT_NUMBER}: the port used by the SOA server
 - {SOA_PARTITION_DG}: the partition used by the SOA server. There are different partitions for the different adapters used by Oracle Utilities Smart Grid Gateway.
- **XAI (OUAF) Server:** This is the application server running the Oracle Utilities Smart Grid Gateway (including the Oracle Utilities Application Framework, or OUAF) software, including the inbound/outbound message components. This server is referenced using the following tokens:
 - {WEB_WLHOST}: the server where Oracle Utilities Smart Grid Gateway and the message components have been installed
 - {WEB_WLPORT}: the port used by the Oracle Utilities Smart Grid Gateway application
 - {WEB_CONTEXT_ROOT}: the root directory at which the Oracle Utilities Smart Grid Gateway inbound web service
- **AMI Head-end Server:** This is the application server running the head-end system software. The AMI head-end server is referenced using the following tokens:
 - {Headend_MR_Server_DG}: the URL for either the actual head-end system's MR_Server MultiSpeak implementation, or the URL to an emulator test harness being used (if applicable). For example, the Adapter Development Kit includes a soapUI configuration that can be used to emulate a head-end system for testing purposes.
 - {Headend_CD_Server_DG}: the URL for either the actual head-end system's CD_Server MultiSpeak implementation, or the URL to an emulator test harness being used (if applicable). For example, the generic adapter includes a soapUI configuration that can be used to emulate a head-end system for testing purposes.
 - {Headend_OD_Server_DG}: the URL for either the actual head-end system's MR_Server MultiSpeak implementation, or the URL to an emulator test harness being used (if applicable). For example, the generic adapter includes a soapUI configuration that can be used to emulate a head-end system for testing purposes.

In addition, credentials for the WebLogic server must be specified in the build.properties file in the deploy folder:

- {WebLogic_UserName}: the user ID used to connect to the WebLogic server
- {WebLogic_Password}: the password for the {WebLogic_UserName} used to connect to the WebLogic server

Customizing BPEL Processes

This section provides an overview of how the sample BPEL processes provided with the Oracle Utilities Smart Grid Gateway Adapter Development Kit can be customized to meet specific business requirements, such as using custom XSL transformations and adding/editing the steps involved in the process.

Using Custom XSL Files

This process references XSL files to transform the messages from the Oracle Utilities Smart Grid Gateway standard format into the format used by the “generic” head-end system (based on the Multispeak protocol) when sending messages to the head-end system, and from the head-end system format into the Oracle Utilities Smart Grid Gateway standard format when sending messages back to Oracle Utilities Smart Grid Gateway. These XSL file references can be changed to custom XSL files that transform the messages into and from the format used by your head-end system. Refer to Oracle BPEL and Oracle JDeveloper documentation for more information about referencing XSL files within a BPEL process.

Making Changes to the Process

In addition to referencing custom XSL files for transformation, you can also add additional steps to the process to meet the specific business requirements of your implementation, or make other changes to the existing steps. Refer to Oracle BPEL and Oracle JDeveloper documentation for more information about adding and/or changing steps within BPEL process.

Note: Any changes made to this process for a particular AMI vendor and head-end system needs to be modeled based on the head-end system/AMI vendor’s business processes, including configuring the required request/response transactions required for a specific command (such a remote connect).

Commands

This section describes the general structure and flow of each SOA composite in the adapter development kit for the two-way commands. Most follow this basic model:

Common

The Common composite is a repository for files and logic that is used by other composites. For instance, the Proxies and default implementations of Process Callouts are defined in the Common composite.

Composite Properties

None.

Composite WSDLs

Callout Services

Process Callouts are customization points for integrators with identical inputs and outputs based on head-end formats. The Common composite contains default implementations in which incoming data is reflected back in an identical state. Each of the following is a Mediator component and uses an "echo"-type definition.

Process Callouts are usually associated with boolean composite properties which control whether they will be executed. They are activated by default so users can easily inject their customizations, but setting the properties to false can be a performance optimization. When set to false, the associated Process Callout will not be made and execution will continue normally.

Service	Description
OA_CalloutService	Used when the asynchronous reply in DeviceStatusCheck arrives.
MR_CalloutService	Used during Commission/Decommission and OnDemandRead operations.

Service	Description
CB_CalloutService	Used by the asynchronous callback processes of OnDemandRead and Connect/Disconnect.
CD_CalloutService	Used by Connect/Disconnect.
OD_CalloutService	Used in DeviceStatusCheck.

Proxies

Placing all the proxy web services in the Common composite creates a place to conveniently set endpoints. Each is a Mediator component which passes the data to the head-end system without modification

Proxy Web Service	Description
OD_ServerProxy	Used to transmit a DeviceStatusCheck request to the head-end system.
CD_ServerProxy	Used to transmit a Connect/Disconnect request to the head-end system.
MR_ServerProxy	Used to transmit an OnDemandRead request to the head-end system.

Other

AuxiliaryRoutinesService: A container defining helpful, commonly used functions:

- **FindExpTime:** Many MultiSpeak functions contain an expTime element, which is used to deliver the length of time to wait for the command to complete before failing. (The included test harness does not support timeouts.) If the input to the command composite does not contain this timeout, the process will read from its properties the years, months, days, hours, minutes, and seconds to wait for a result. This web service utilizes a Java method to combine these inputs into the proper XML field used in the MultiSpeak API. The properties are also used to control the timeout wait period of asynchronous callbacks within a command's BPEL process.
- **FindTimeout:** When the expTime element and units are supplied as input, it is usually still necessary to compute the timeout used in asynchronous callbacks. This method accepts the MultiSpeak fields and replies in the "POY0M0DT0H0M0S" format understood by BPEL.

Commission / Decommission

The CommissionDecommission composite takes care of registering and de-registering a device with the head-end system.

Composite Properties

Property Name	Default Value	Description
isExecutingCommissionReceived-Callout	true	Controls whether the Request Arrived callout executes.
isExecutingCommissionCompleted-Callout	true	Controls whether the Request Completed callout executes.
isExecutingDecommissionReceived-Callout	true	Controls whether the Request Arrived callout executes.

Property Name	Default Value	Description
isExecutingDecommissionCompleted-Callout	true	Controls whether the Request Completed callout executes.

Composite WSDLs

Composite	Description
CommissionDecommission Service	Entry point for the CommissionDecommission command. The operations are synchronous, so no additional WSDLs are needed.
MR_ServerCallout	Reference describing the process callout.
MR_ServerProxy	Reference describing the proxy used to invoke the head-end system.

Process Flow

1. SGG/OUAF invokes MeterAddNotification/MeterRemoveNotification operation using CommissionDecommissionService.
2. Test whether MeterAddNotification or MeterRemoveNotification is invoked. In both cases, the following steps are common for both the operations.
3. Composite properties are loaded and local variables are initialized.
4. Both the Header and Body inputs are transformed to MultiSpeak format.
5. If required, execute a process callout in MR_ServerCallout. Assign updated data to head-end request.
6. Invoke MeterAddNotification/MeterRemoveNotification via the MR_ServerProxy to the head-end system.
7. If required, execute a process callout in MR_ServerCallout. Assign updated data to head-end response.
8. Transform Header and Body head-end responses to SGG/OUAF format.
9. Reply to SGG/OUAF with synchronous results.

Connect / Disconnect

The ConnectDisconnect composite is responsible for starting and stopping the recording of usage data for a meter.

Composite Properties

Property Name	Default Value	Description
CB_CDCallbackEndpoint	http://[SERVER_NAME]/soa-infra/services/DG/ConnectDisconnect/CB_ServerService	The default endpoint to which MultiSpeak should send the asynchronous CB_Server callback.
isExecutingCDRReceivedCallout	true	Controls whether the Request Received callout executes.
isExecutingCDCCompletedCallout	true	Controls whether the Request Received Completed callout executes.

Property Name	Default Value	Description
isExecutingCDStatesChangedArrivedCallout	true	Controls whether the CD States Changed Notification arrival callout executes.
CallbackTimeoutYears	0	The number of years to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutMonths	0	The number of months to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutDays	0	The number of days to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutHours	0	The number of hours to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutMinutes	0	The number of minutes to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutSeconds	45	The number of seconds to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.

Composite WSDLs

Composite	Description
ConnectDisconnectService	Entry point for the ConnectDisconnect operation. After a synchronous reply, further updates will be sent to the specified location asynchronously using DG-ConnectDisconnectStateChgNotification.
CB_ServerService	MultiSpeak WSDL hosted to receive asynchronous CDStatesChangedNotification callbacks from the head end system.
CB_ServerCallout	Reference describing the process callout used when the asynchronous callback from the head end system arrives.
CD_ServerCallout	Reference describing the process callout.
CD_ServerProxy	Reference describing the proxy used to invoke the head end system.
AuxiliaryRoutines	Reference to common helper routines in the Common composite.
DG-ConnectDisconnectStateChgNotification	A reference to an inbound web service capable of processing asynchronous results from a Connect/Disconnect request.

Process Flow

1. SGG/OUAF invokes InitiateConnectDisconnect operation using ConnectDisconnectService.
2. Composite properties are loaded and local variables are initialized.
3. Test whether the input includes a expiration time
 - If Yes: Use AuxiliaryRoutines to compute timeout.
 - If No: Use composite properties and AuxiliaryRoutines to compute expiration time.
4. Both the Header and Body inputs are transformed to MultiSpeak format.
5. If required, execute a process callout in CD_ServerCallout. Assign updated data to head end request.
6. Add a callback URL to the head end request. This is the endpoint the head end will use to send the results.
7. Invoke InitiateConnectDisconnect via the CD_ServerProxy to the head end system.
8. If required, execute a process callout in CD_ServerCallout. Assign updated data to head end response.
9. Transform Header and Body head end responses to SGG/OUAF format.
10. Reply to SGG/OUAF with synchronous results.
11. Check for ErrorObject in the head end response.
12. If error object not found:

Await asynchronous response from head-end system for the period of expiration time calculated during start of this flow:

 - Receive CDStatesChangeNotification from CB_ServiceService.
 - Generate reply with no errors for CDStatesChangeNotification
 - Synchronously reply to the head end.
 - If required, execute a process callout in CB_ServerCallout. Assign updated data to the incoming request.
 - Transform Header and Body of incoming request to OUAF inbound web service format described in DG-ConnectDisconnectStateChgNotification.
 - If request contains responseURL
 - Invoke the inbound web service on given responseURL with the transformed incoming request.
 - Else
 - Invoke the inbound web service on definedURL with the transformed incoming request.

Device Status Check

DeviceStatusCheck is used to determine the health of a meter and to test that the meter can be reached on the network.

Composite Properties

Property Name	Default Value	Description
OD_ServerCallbackEndpoint	http://127.0.0.1:8001/soa-infra/services/DG/DeviceStatusCheck/OA_ServerService	The default endpoint to which MultiSpeak should send the asynchronous OA_Server callback.
isExecutingInitODRequest-ReceivedCallout	true	Controls whether the Request Arrived callout executes.
isExecutingInitODEventRequest-Completed	true	Controls whether the Request Completed callout executes.
isExecutingODEventNotification-Arrived	true	Controls whether the ODEventNotification arrival callout executes.
timeout.callback.years	0	The number of years to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
timeout.callback.months	0	The number of months to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
timeout.callback.days	0	The number of days to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
timeout.callback.hours	0	The number of hours to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.

Property Name	Default Value	Description
timeout.callback.minutes	0	The number of minutes to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
timeout.callback.seconds	45	The number of seconds to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.

Composite WSDLs

Composite	Description
OD_ServerService	Entry point for DeviceStatusCheck. After a synchronous reply, further updates will be sent to the specified location asynchronously using DG-OutageDetectionEventNotification.
OA_ServerService	MultiSpeak WSDL hosted to received asynchronous ODEventNotification callbacks from the head end system.
OD_ServerProxy	Reference describing the proxy used to invoke the head end system to initiate a Device Status Check.
OA_ServerCallout	Reference describing the process callout used when the asynchronous callback from the head end system arrives.
OD_ServerCallout	Reference describing the process callout used when initiating a Device Status Check.
AuxiliaryRoutines	Reference to common helper routines in the Common composite.
DG-OutageDetectionEventNotificationXAI	A reference to an inbound web service capable of processing asynchronous results from a Device Status Check request.

Process Flow

1. SGG/OUAF Initiates the Outage Detection service using OD_ServerService
2. Composite properties are loaded. Local variables are initialized. These mostly include boolean settings describing the state (such as whether or not the synchronous reply from the head-end system returned)
3. Test whether the input includes a expiration time (expTime element).
 - If Yes: Use AuxiliaryRoutines to compute timeout
 - If No: Use composite properties and AuxiliaryRoutines to compute expiration time

4. Both the Header and Body inputs are transformed to MultiSpeak format. This can be done either through direct mapping or through XSLT. In this instance, XSLT is used to transform the header and the body separately.
5. If the composite property indicates the process callout should occur, execute the “request arrived” process callout in OD_CalloutService. Assign updated data to head end request.
6. Add a callback URL to the head end request. This is the endpoint the head end will use to send the outage detection results. Some head end systems use other approaches, such as pre-configuring the URL for callbacks or allowing polling to find the results. In this case, the URL is configured in a composite property and corresponds to an implementation of the OA_Server WSDL. When the head end system has results, it will deliver them to this URL using the ODEventNotification method.
7. Invoke InitiateOutageDetectionEventRequest via the OD_ServerProxy to the head end system.
8. Split processing to handle simultaneous activities. The Flow activity does this in BPEL and it makes sense here because one process will handle a synchronous response and return it to the caller. The other process will sleep, or “dehydrate,” until the asynchronous ODEventNotification arrives or until the timeout value is reached.
 - Handle synchronous response to SGG/OUAF
 - If the composite property indicates the process callout should occur, execute the “request completed” process callout in OD_CalloutService. Assign updated data to head end response.
 - Transform Header and Body head end responses to SGG/OUAF format.
 - Reply to SGG/OUAF with synchronous results.
 - Set boolean variable indicating that the synchronous reply has been returned.
 - Await asynchronous response from head-end system.
 - Receive ODEventNotification from OA_ServerService. If the timeout period elapses, raise an error and stop waiting.
 - Synchronously reply to the head end with no errors
 - If the composite property indicates the process callout should occur, execute the “data arrived” process callout in OA_CalloutService. Assign updated data to the incoming request.
 - Transform Header and Body to inbound web service format described in DG-OutageDetectionEventNotification.
 - Invoke the inbound web service with the new data.
9. Fault Handlers look for any remote Fault returned from the head-end system. The MultiSpeak API does not define named faults, but they are still possible to encounter. For example, a security error or network error could be raised.
 - If the synchronous reply has been sent back to the caller, Terminate the flow. This indicates an error has occurred and more research in Enterprise Manager is warranted.
 - If the synchronous reply has not been sent, stop further processing and compose a reply which contains the fault information.

On Demand Read

OnDemandRead interrogates a meter for the usage at the current point in time.

Composite Properties

Property Name	Default Value	Description
CB_ServerCallbackEndpoint	http://[SERVER_NAME]/soa-infra/services/DG/OnDemandRead/CB_Server	The default endpoint to which MultiSpeak should send the asynchronous CB_Server callba
IsExecutingOnDemandReadRequestReceived	true	Controls whether the Request Received callout executes

Property Name	Default Value	Description
IsExecutingOnDemandReadRequestReceivedResponse	true	Controls whether the Request Received Completed callout executes
IsExecutingReadingChangedNotification	true	Controls whether the Reading Changed Notification arrival callout executes
CallbackTimeoutYears	0	The number of years to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutMonths	0	The number of months to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutDays	0	The number of days to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutHours	0	The number of hours to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutMinutes	0	The number of minutes to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.
CallbackTimeoutSeconds	45	The number of seconds to await a response from the MultiSpeak server. This property only takes effect when the expTime element is not supplied in the input to the service.

Composite WSDLs

Composite	Description
OnDemandReadService	Entry point for the OnDemandRead operation. After a synchronous reply, further updates will be sent to the specified location asynchronously using DG-ReadingChangedNotification.
CB_ServerService	MultiSpeak WSDL hosted to receive asynchronous ReadingChangedNotification callbacks from the head end system.
MR_ServerProxy	Reference describing the proxy used to invoke the head end system to initiate a On Demand Read.
MR_ServerCallout	Reference describing the process callout used when initiating a On Demand Read.
CB_ServerCallout	Reference describing the process callout used when the asynchronous callback from the head end system arrives.
AuxiliaryRoutines	Reference to common helper routines in the Common composite.
DG-ReadingChangedNotificationXAI	A reference to an inbound web service capable of processing asynchronous results from a On Demand Read request.

Process Flow

1. SGG/OUAF invokes InitiateMeterReadingsByMeterID operation using OnDemandReadService.
2. Composite properties are loaded. Local variables are initialized.
3. Test whether the input includes a expiration time
 - If Yes: Use AuxiliaryRoutines to compute timeout
 - If No: Use composite properties and AuxiliaryRoutines to compute expiration time
4. Both the Header and Body inputs are transformed to MultiSpeak format.
5. If required, execute a process callout in MR_ServerCallout. Assign updated data to head end request.
6. Add a callback URL to the head end request. This is the endpoint the head end will use to send the results.
7. Invoke InitiateMeterReadingsByMeterID via the MR_ServerProxy to the head end system.
8. If required, execute a process callout in MR_ServerCallout. Assign updated data to head end response.
9. Transform Header and Body head end responses to SGG/OUAF format
10. Reply to SGG/OUAF with synchronous results
11. Check for ErrorObject in the head end response.
12. If error object not found
 - Await asynchronous response from head end for the period of expiration time calculated during start of this flow
 - Receive ReadingChangedNotification from CB_ServiceService.
 - Generate reply with no errors for ReadingChangedNotification.
 - Synchronously reply to the head end.
 - If required, execute a process callout in CB_ServerCallout. Assign updated data to the incoming request.
 - Transform Header and Body of incoming request to OUAF inbound web service format described in DG-ReadingChangedNotificationXAI.
 - If request contains responseURL
 - Invoke the inbound web service on given responseURL with the transformed incoming request.
 - Else

- Invoke the inbound web service on definedURL with the transformed incoming request.

Working with Enterprise Manager

Oracle Enterprise Manager (OEM) is useful for troubleshooting and diagnosing issues communicating with the head end system. In particular, security and other communications issues can be discerned.

To locate the instance of a service that is showing a problem, open the **Dashboard** view of the service. Each run instance is time-indexed. The **State** column in the first table contains the most important information for each instance. Completed messages show up with a green check icon. Terminated instances are indicated with a grey stop icon. Instances that are still running are marked as such. Runtime exceptions are in the bottom window.

When you click on the instance ID, a new window opens showing the entire process flow. This view is particularly useful in debugging.

Note the **State** column showing the status of each instance within the flow. SOA processes are made up of several calls to SOA components and web services. The **Instance** column shows a rough ordering of the operations. A typical approach to troubleshooting would find the “lowest” instance of an error or termination. This would be the error that is deepest within the process and is usually the source of the problem. In the above case, the deepest error is in the very first composite for the process. More information can be found by clicking into the link within the **Instance** column.

The level of detail is dependent on the auditing level set on the server. In this case, the error is in the response from the head end system.

OEM also contains a centralized location to control security. On a **Dashboard** screen for a composite, the **Policies** tab shows the OWSM policies attached to the composite. Typically, a log policy is placed on any inbound or outbound communication. Also, all services or references are delivered with attached basic http security policies.

MultiSpeak Implementation

This section lists the subset of MultiSpeak schemas and WSDLs utilized by the Adapter Development Kit.

MultiSpeak Head End System Service Definitions

- CB_Messages.wsdl
- CB_Server.wsdl
- CD_Messages.wsdl
- CD_PortTypes.wsdl
- CD_Server.wsdl
- MR_Messages.wsdl
- MR_PortTypes.wsdl
- MR_Server.wsdl
- OA_Messages.wsdl
- OA_Server.wsdl
- OA_ServerCollisions.wsdl
- OD_Messages.wsdl
- OD_PortTypes.wsdl
- OD_Server.wsdl

MultiSpeak Head End XML Schemas

- cpsm.xsd
- gml.xsd
- xlink.xsd
- mspcommon.xsd
- CB_Server.xsd
- CD_Server.xsd

- MR_Server.xsd
- OA_Server.xsd
- OD_Server.xsd

Configuring an Adapter Development Kit Head-End System

This section outlines the configuration required for the Oracle Utilities Smart Grid Gateway to communicate with the smart meters.

Inbound Web Services

Inbound web services define the details of how messages are received from an external system. This includes incoming usage and device events, as well as messages sent from the head-end system in response to a command request.

The following inbound web services must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating inbound web services.

Inbound Web Service Name	Description
D1-BulkRequestHeader	Bulk Request Header
D1-BulkRequestUpdate	Bulk Request Update
D1-BulkResponse	Bulk Response
D1-DeviceEventSeeder	Device Event Seeder
D1-DeviceStatusCheck	Device Status Check
D1-InitialLoadIMD	IMD Seeder
D1-PayloadErrorNotif	Payload Error Notification
D1-PayloadStatistics	Payload Statistics
D1-PayloadSummary	Payload Summary
DG-ConDisconStChgNotification	Initiate Connect Disconnect Response
DG-OutageDetectionEventNotification	Initiate Outage Detection Response
DG-ReadingChangedNotification	Reading Changed Notification

Note: The following apply to all of the above inbound web services:

Message Options

- **Trace:** No
- **Debug:** No
- **Active:** Yes

Operations

- **Operation Name:** Same as web service name
- **Schema Type:** Business Object
- **Schema Name:** Applicable business object code
- **Transaction Type:** Add

Message Senders

Message senders define the details of how messages are sent to an external system, such as messages containing device command requests.

The following message senders must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating message senders.

Message Sender	Description
DG-COMM	Generic Adapter Commission
DG-DCOMM	Generic Adapter Decommission
DG-INTOOUTDET	Initiate Outage Detection Request
DGXAIssender	Used for Meter Decommission

Note: The following apply to all of the above message senders:

Main Tab:

- **Invocation Type:** Real-time
- **Message Class:** RTHTTPSNDR (Sender routes message via HTTP real-time)
- **MSG Encoding:** UTF-8 message encoding

Context Tab:

- **HTTP Header:** SOAPAction: <OPERATION>
- **HTTP Login User:** <USER_ID>
- **HTTP Login Password:** <PASSWORD>
- **HTTP Method:** POST
- **HTTP URL 1:** http://<EM_SERVER>:<EM_SERVER_PORT>/soa-infra/services/Generic/<SERVICE>

where:

- <OPERATION>: the operation performed by the message sender (see Operation column in the table above)
- <USER_ID>: the user ID used to log into WebLogic Enterprise Manager
- <PASSWORD>: the password used to log into WebLogic Enterprise Manager
- <EM_SERVER_IP>: the machine name or IP address of server where the WebLogic Enterprise Manager is installed
- <EM_SERVER_PORT>: the port where the WebLogic Enterprise Manager is installed
- <SERVICE>: the service invoked by the message sender (see Service column in the table above)

Outbound Message Types

Outbound message types define specific types of messages sent to an external system, such as messages containing device command requests.

The following outbound message types must be configured in your system. If these are not present in your configuration, add them. Refer to the Oracle Utilities Application Framework documentation for more information about creating outbound message types.

Outbound Message Type	Description
DG-COMM	Generic Adapter Commission
DG-DCOMM	Generic Adapter Decommission

Note: The following apply to all of the above outbound message types:

- **Business Object:** D1-OutboundMessage (Outbound Message)
- **Priority:** Priority 50

External System

External systems represent external applications with which the Smart Grid Gateway will exchange messages or data. In the case of the Smart Grid Gateway adapters, external systems represent the head-end systems with which the adapters communicate.

An external system that represents the head-end system must be present in your system. If this is not present in your configuration, add it, along with the following Outbound Message Types. Refer to the Oracle Utilities Application Framework documentation for more information about creating external systems.

External System — Generic:

- **External System:** Generic
- **Description:** Generic
- **Outbound Message Types:**

Outbound Message Type	Description	Message Sender
DG-COMM	Generic Adapter Commission	DG-COMM
DG-DCOMM	Generic Adapter Decommission	DG-DCOMM

Note: The following apply to all of the above outbound message types:

- **Processing Method:** Real-time
- **Message XSL:** DG-Request.xsl
- **Response XSL:** DG-Response.xsl

Service Provider

Service providers represent external entities that serve various roles relative to the application, including head-end systems, billing systems to which the application sends bill determinant data, market participants in a deregulated environment, outage management systems that receive meter event data from the application, or other parties that require or provide information to the system. The head-end systems that collect and send measurement data and meter events to the application are defined as service providers.

A service provider that represents the head-end system must be present in your system. If this is not present in your configuration, add it. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about creating service providers.

Service Provider - Generic:

- **Service Provider:** Generic
- **Description:** Generic
- **External Reference ID:** Generic
- **External System:** Generic
- **Our Name/ID in Their System:**
- **AMI Device ID Type:** Internal Meter Number
- **AMI Measuring Component ID Type:** Channel ID

Processing Methods

Processing methods define the format or means by which a service provider receives and/or sends data from and/or to the application, including bill determinants, usage data, or device events. Processing methods are also used to define how to create information internal to the application such as initial measurement data and device events. Processing methods can also be used to define how command requests are sent to the head-end system.

The following types of processing methods must be configured for the head-end system service provider. Refer to the Oracle Utilities Service and Measurement Data Foundation documentation for more information about configuring processing methods.

Initial Measurement Creation

Initial measurement creation processing methods define the business objects used to create initial measurements. The IMD Seeder inbound web service uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from the head-end system.

Device Event Mapping

Device event mapping processing methods define how head-end-specific device events are mapped to standard device event names. The Device Event Seeder inbound web service uses this processing method to determine which type of device event business object to instantiate when receiving device events from the head-end system.

UOM Translation

UOM translation processing methods define how head-end-specific unit of measure (UOM) codes are mapped to standard UOM codes. This processing method is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Commands

Command processing methods define how command requests are sent to a head-end system. More specifically, they define the type of outbound communication business object to create for each type of command, and the outbound message type to send to the head-end system.

The following types of command processing methods can be configured for the head-end system service provider, based on the requirements of each implementation using the “How to Create OB COMM/Send OB Message” processing method business object (D1–HowToCreateActivityOBComm).

Command	Processing Role	Default Business Object	Default Outbound Message Type
Device Commission	Device Registration	DG-MeterAddNotification	Commission
Device Decommission	Device Removal	DG-MeterRemoveNotification	Decommission
Device Status Check	Device Status Check	DG-InitiateOutageDetection	Get Status
On-Demand Read (Scalar)	On-Demand Read (Scalar)	DG-InitiateMeterByMeterId	Initiate Meter Read by Meter ID
Remote Connect	Remote Connect	DG-InitiateConnectDisconnect	Connect Device
Remote Disconnect	Remote Disconnect	DG-InitiateConnectDisconnect	Disconnect Device

Configuring Endpoint URIs

Part of configuring your adapter is configuring your BPEL composites to work with your head-end system by defining the appropriate Endpoint URIs for each of the commands.

The default approach to defining Endpoints URIs is redeployment or reinstallation of the BPEL composites. For example, by default, changing an adapter from using the test harness to a production environment using the actual head end system requires editing the appropriate installation menu options and redeploying the BPEL composites. The Endpoints URIs defined during installation and deployment for each adapter are listed in the **Smart Grid Gateway Installation and Configuration Worksheets** section of the *Oracle Utilities Smart Grid Gateway Installation Guide*.

You can also use an “Endpoint Override” Domain Value Map (DVM) to override Endpoints URIs defined during deployment and installation. This DVM allows defining specific keys that provide an alternate URL that will override the original installed value. Endpoint Override DVMs can be edited using the Oracle SOA Composer.

The Adapter Development Kit endpoint override DVM (DG–EndpointOverrides.dvm) uses a specific set of keys, each used for one or more commands. The table below lists the DVM keys available for the Landis+Gyr adapter and the command used with each:

DVM Key	Commands
MR_Server	Device Commissioning Device Decommissioning On-Demand Read (Scalar) On-Demand Read (Interval)
CD_Server	Remote Connect Remote Disconnect
OD_Server	Device Status Check

To define an override Endpoint URI for an adapter built from the Adapter Development Kit, use the following procedure:

1. Open the SOA Composer for your BPEL configuration.

The URL for the SOA Composer is `http://server:port/soa/composer`.

2. Select the DG–EndpointOverrides.dvm in the left panel.
 - In Fusion Middleware v12.2.1, this is located under **Shared** in the **Deployment View**, or under **Domain Value Maps** in the **Types View**.
 - In Fusion Middleware v12.2.2, this is located under **Metadata** in the **Deployment View**.

The DVM will open in the right panel. The **Description** field lists the available keys for the DVM (only the first key is shown, but you can scroll through the contents to view the list. The panel also displays a list of previously defined keys.

3. Click the **Create Session** button (above the left panel) to begin an editing session.
4. Click the **Add Domain Values** icon (“+”) to add a new key.

The **Add Domain Values** dialog opens.

5. Enter the appropriate values in the **Add Domain Values** dialog as follows:
 - **key**: The DVM key for the Endpoint URI you wish to define (see the table above).
 - **EndpointURI**: The override Endpoint URI.
6. Click **OK**.

The new DVM value will appear in the list of keys.

7. Click the **Save** icon to save the DVM values.
8. Click the **Publish** button to activate all the changes in the editing session.

Enter an optional note for the session in the **Publish Session** dialog.

Changes take effect immediately upon publishing the session.

Click **Discard** to discard your changes.

Click **Exit** to exit your current session. Note that your session will still be open if you exit. Use **Discard** to end your session without making changes.

Configuring Adapter Development Kit Extendable Lookups

Note: This section applies to to **both** middleware and native implementations of the Smart Grid Gateway Adapter Development Kit,

This section outlines some of the extendable lookups that must be configured for use with a customized adapter. Refer to the Oracle Utilities Application Framework documentation for more information about working with extendable lookups.

Device Event Mapping

The Device Event Mapping extendable lookup is used to determine which type of device event business object to instantiate when receiving device events from the head-end system.

Each value defined for the Device Event Mapping extendable lookup should include the following:

- **Head-End System Event Name:** The event name used by the head-end system.
- **Description:** A description of the device event
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Standard Event Name:** The standard event name for device events of this type, from the “Standard Event Name” extendable lookup.

Head-End UOM Code to Standard UOM Mapping

Usage received from the head-end system may use utility-specific unit of measures (UOMs). These custom UOMs must be mapped to standard UOM codes. The head-end system UOM Code to Standard UOM Mapping extendable lookup is used to determine how to map head-end system UOM codes to standard UOM codes when receiving usage from the head-end system.

Each value defined for the head-end system UOM Code to Standard UOM Mapping extendable lookup should include the following:

- **Head-End Unit of Measure:** The unit of measure code used by the head-end system
- **Unit of Measure:** The unit of measure defined in the system.
- **Description:** A description of the unit of measure code.
- **Status:** The status of the lookup value (can be Active or Inactive)

Interval Status Code to Condition Mapping

Interval usage received from the head-end system can include interval status codes that indicate the status or condition of the interval value. These interval status codes must be mapped to standard condition codes in the system. The Generic Interval Status Code to Condition Mapping extendable lookup is used to determine how to map head-end system interval status codes to standard status codes when receiving usage from the head-end system.

Each value defined for the Generic Interval Status Code to Condition Mapping extendable lookup should include the following:

- **Interval Status:** The head-end system interval status code
- **Description:** A description of the interval status code.
- **Status:** The status of the lookup value (can be Active or Inactive)
- **Condition:** The condition code to which the interval status code is to be mapped, from the Measurement Condition extendable lookup.

Other Extendable Lookups

Business Object Name	Description
DG-CDReasonCodeLookup	ADK - Connect Disconnect Reason Code
DG-GenericTimeUnits	ADK - Time Units

Business Object Name	Description
DG-LoadActionCodeLookup	ADK - Load Action Code
DG-OutageEventTypeLookup	ADK - Outage Event Type
DG-ServiceTypeMappingLookup	ADK - Service Type Mapping

Using the Adapter Development Kit Test Harness

Oracle Utilities Smart Grid Gateway Adapter Development Kit includes a test harness that can be configured to simulate a general head-end system for testing the two-way commands. The test harness includes a BPEL composite, web services for standard meter functions, and an XML file that can be used to contain information for one or more meters. This section describes the test harness and its components.

Locating the WSDL for the Test Harness

Follow these procedures to locate the Adapter Development Kit test harness WSDL:

How to Use Enterprise Manager to Locate the WSDL

1. Open Enterprise Manager and use the navigation pane to open the dashboard of the test harness composite:
2. The top bar of the dashboard contains several buttons and icons. One of these is a “world” icon with a puzzle piece over it. Click this icon to display a list of the WSDLs and endpoint URIs for the composite:
3. Click the UtilService WSDL URL link to see the WSDL in the browser, or right click and save it to your machine

Depending on your requirements, it may be necessary to download the associated schema found in the wsdl:types section. The URL can be pasted into a browser tab and downloaded in the same manner as the WSDL. The main schema has imported schemas that may also be required.

How to Use a Direct URL to locate the WSDL

The WSDL can be accessed without Enterprise Manager by understanding the paths used on the SOA server. In general, they have the following form:

```
http://{server name}:{port number}/soa-infra/services/{partition}/
{Composite}/{Web Service}?WSDL
```

So by default, the test harness WSDL can be found at

```
http://{server name}:{port number}/soa-infra/services/DG_Test/DGTestHarness/
UtilService?WSDL
```

Web Services

This section describes the web services included in the Adapter Development Kit test harness BPEL composite.

General Services

This section describes the general services of the Adapter Development Kit test harness composite.

LoadMeterIndex

This web service loads the data store from the internal file. By default if the store is already in memory, it will *not* reload. This behavior can be overridden with the forceReload parameter.

Input: LoadMeterIndexInput

Part: payload

Element: LoadMeterIndexRequest

Parameter	Description
forceReload	A switch telling the system whether to reload the meter index from the configuration file. Default value is false.

Output: LoadMeterIndexOutput

Part: payload

Element: LoadMeterIndexResult

Parameter	Description
loaded	A boolean value for whether or not the index was reloaded from the configuration file

Fault: UtilityFault (see [UtilityFault](#) on page 907 for more details).

ViewAuditTrail

This web service returns the audit log for the entire session.

Input: ViewAuditTrailInput

Part: payload

Element: ViewAuditTrailRequest

Parameters: This is an empty request. There are no parameters.

Output: ViewAuditTrailOutput

Part: payload

Element: ViewAuditTrailResult

This element is an entry consisting of a timestamp and an Operation. Each entry may have an associated meter object showing what changed.

Fault: UtilityFault (see [UtilityFault](#) on page 907 for more details).

UtilityFault

Fault with similar mapping to SGG/OUAF faults:

Typically, the faultCode, faultString, faultActor, and detail/text elements will be populated.

Locate Meter Services

This section describes the locate meter web services of the Adapter Development Kit test harness composite.

FindMeters

This web service queries the data store for one or more meters. The difference between GetMeter and FindMeters is GetMeter can return at most one meter and it must match the provided ID exactly. GetMeter will throw an error if the ID is not found. FindMeters can return more than one meter (when using the regex) and will not throw an error when the ID does not match any of the meters in the index.

Input: FindMetersInput

Part: payload

Element: FindMetersRequest

Parameter	Description
id	The meter ID for which to search
isRegex	The provided id can be a regex value when this parameter is true. Hint: to search for all meters in the system, use "." for the ID.

Output: FindMetersOutput

Part: payload

Element: FindMetersResult

Zero or more meter objects can be returned from the search

Fault: See [UtilityFault](#) on page 907. Unlike other methods, FindMeters does not throw an exception if the meter is not found.

IsMeterDefined

This web service queries whether a particular meter is defined in the data store.

Input: IsMeterDefinedInput

Part: payload

Element: IsMeterDefinedRequest

Parameter	Description
id	The meter ID for which to search

Output: IsMeterDefinedOutput

Part: payload

Element: IsMeterDefinedResult

Whether or not the provided ID is part of the index.

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

GetMeter

This web service returns all the attributes of a single meter from the in-memory data store. The difference between GetMeter and FindMeters is GetMeter can return at most one meter and it must match the provided ID exactly. GetMeter will throw an error if the ID is not found. FindMeters can return more than one meter (when using the regex) and will not throw an error when the ID does not match any of the meters in the index.

Input: GetMeterInput

Part: payload

Element: GetMeterRequest

Parameter	Description
id	The meter ID for which to search

Output: GetMeterOutput

Part: payload

Element: GetMeterResult

The meter object requested by the ID.

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

Meter Administration Services

This section describes the meter administration services of the Adapter Development Kit test harness composite.

AddMeters

This web service adds a set of meters to the in-memory data store. This will not permanently add it to the control file.

Input: AddMetersInput

Part: payload

Element: AddMetersRequest

Parameter	Description
id	The identification code for the meter.
utility	An informational string.
serviceType	One of the valid ServiceType values (see schema). "Electric" is the only option at this time.
isCommissioned	Whether or not the meter is in a commissioned state.
loadActionCode	One of the possible LoadActionCode values used in Connect and Disconnect (see schema).
outageEventType	One of the possible OutageEventType values used in Device Status Check (see schema).
executionStatus	One of the possible ExecutionStates (see schema). These values control how the meter will respond to commands.
updateIfExists	Whether or not to update the meter with the provided values if it already exists in the index.
Comment	An informational string describing the purpose of the meter.
Channels	A listing of unit of measures supported by this meter.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.

Output: AddMetersOutput

Part: payload

Element: AddMetersResult

Whether or not each meter was added to the index.

Fault: See [UtilityFault](#) on page 907.

RemoveMeter

This web service removes a meter from the in-memory data store. This will not permanently remove it from the control file.

Input: RemoveMeterInput

Part: payload

Element: RemoveMeterRequest

Parameter	Description
id	The ID for the meter to be removed.

Output: RemoveMeterOutput

Part: payload

Element: RemoveMeterResult

Whether or not the meter was removed from the index.

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

AddMeterChannel

This web service adds a new channel to a single meter.

Input: AddMeterChannelInput

Part: payload

Element: AddMeterChannelRequest

Parameter	Description
id	The identification code for the meter.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.
description	A longer description of the unit of measure.

Output: AddMeterChannelOutput

Part: payload

Element: AddMeterChannelResult

Whether or not the channel was added to the index.

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

RemoveMeterChannel

This web service removes a Channel from a meter.

Input: RemoveMeterChannelInput

Part: payload

Element: RemoveMeterChannelRequest

Parameter	Description
id	The ID for the meter to be removed.
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.

These three parameters are combined to locate a unique channel

Output: RemoveMeterChannelOutput

Part: payload

Element: RemoveMeterChannelResult

Whether or not the channel was removed from the meter.

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

ReadScalarMeter

This web service generates a scalar reading for each channel of a given meter.

Input: ReadScalarMeterInput

Part: payload

Element: ReadScalarMeterRequest

Parameter	Description
id	The ID for the meter to be read.

Output: ReadScalarMeterOutput

Part: payload

Element: ReadScalarMeterResult

Zero or more scalar readings for the given meter.

Parameter	Description
uomCode	A code describing the unit of measure for the channel.
uomName	A short string containing the name of the unit of measure.
decimals	The number of digits to the right of the decimal that should be generated when reading the meter.

Parameter	Description
description	A longer description of the unit of measure.
value	A random number representing the scalar reading.

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

Meter Attribute Administration Services

This section describes the meter administration services of the Adapter Development Kit test harness composite.

GetOutageEventType

This web service queries the outage event type for a given meter. The OutageEventType is used by DeviceStatusCheck.

Input: GetOutageEventTypeInput

Part: payload

Element: GetOutageEventTypeRequest

Parameter	Description
id	The ID for the meter for which the OutageEventType should be retrieved.

Output: GetOutageEventTypeOutput

Part: payload

Element: GetOutageEventTypeResult

The value of the OutageEventType attribute for the requested meter.

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

SetOutageEventType

This web service updates the outage event type for a given meter.

Input: SetOutageEventTypeInput

Part: payload

Element: SetOutageEventTypeRequest

Parameter	Description
id	The ID for the meter for which the OutageEventType should be set.
value	The new value of OutageEventType to set on the meter.

Output: SetOutageEventTypeOutput

Part: payload

Element: SetOutageEventTypeResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

GetLoadActionCode

This web service queries the load action code for a given meter. This is the Connect/Disconnect behavior.

Input: GetLoadActionCodeInput

Part: payload

Element: GetLoadActionCodeRequest

Parameter	Description
id	The ID for the meter for which the LoadActionCode should be retrieved.

Output: GetLoadActionCodeOutput

Part: payload

Element: GetLoadActionCodeResult

The value of the LoadActionCode attribute for the requested meter.

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

SetLoadActionCode

This web service updates the load action code for a given meter.

Input: SetLoadActionCodeInput

Part: payload

Element: SetLoadActionCodeRequest

Parameter	Description
id	The ID for the meter for which the LoadActionCode should be set.
value	The new value of LoadActionCode to set on the meter.

Output: SetLoadActionCodeOutput

Part: payload

Element: SetLoadActionCodeResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

IsCommissioned

This web service queries the commissioning status for a given meter. This is the Commission/Decommission behavior.

Input: IsCommissionedInput

Part: payload

Element: IsCommissionedRequest

Parameter	Description
id	The ID for the meter for which the Commissioned status should be retrieved.

Output: IsCommissionedOutput

Part: payload

Element: IsCommissionedResult

The value of the Commissioned status attribute for the requested meter.

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

SetCommission

This web service updates the commissioning status for a given meter.

Input: SetCommissionedInput

Part: payload

Element: SetCommissionedRequest

Parameter	Description
id	The ID for the meter for which the Commissioned status should be set.
value	The new value of Commissioned status to set on the meter.

Output: SetCommissionedOutput

Part: payload

Element: SetCommissionedResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

GetExecutionStatus

This web service queries the status of the property controlling the overall execution of the command.

Input: GetExecutionStatusInput

Part: payload

Element: GetExecutionStatusRequest

Parameter	Description
id	The ID for the meter for which the ExecutionStatus should be retrieved.

Output: GetExecutionStatusOutput

Part: payload

Element: GetExecutionStatusResult

The value of the ExecutionStatus attribute for the requested meter.

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

SetExecutionStatus

This web service updates the property controlling the overall completion of the command.

Input: SetExecutionStatusInput

Part: payload

Element: SetExecutionStatusRequest

Parameter	Description
id	The ID for the meter for which the ExecutionStatus should be set.
value	The new value of ExecutionStatus to set on the meter.

Output: SetExecutionStatusOutput

Part: payload

Element: SetExecutionStatusResult

The boolean response indicates the success or failure of the update (not the current field status).

Fault: See [UtilityFault](#) on page 907. Thrown when meter id is not found.

Sample Meters File

The Adapter Development Kit includes an XML file and schema that can be used for configuring one or more meters for use with the test harness. The file, metersdb.xml, is located in the Test/DGTestHarness directory and can be edited with an appropriate XML editor such as XML Spy. This section describes the attributes in the metersdb.xml file.

The meterdb.xml file contains one or more **Meter** elements that have the following attributes:

Meter Attribute	Definition
id	The meter identifier. This value should match the amiDeviceID setting in the Oracle Utilities Application Framework.
utility	This is informational only.
serviceType	This is informational only.
ServiceType	An enumeration that is described in the schema.
isCommissioned	A boolean value that describes whether or not the meter is commissioned or decommissioned. The associated MultiSpeak commands are MeterAddNotification and MeterRemoveNotification.
loadActionCode	This value is for the Connect and Disconnect commands and has enumeration values described in the schema. The value is returned in the CDStatesChangedNotification MultiSpeak command.
outageEventType	This value is used by DeviceStatusCheck and gives the status returned by the ODEventNotification call. Its enumeration values are described in the schema.

Meter Attribute	Definition
executionStatus	<p>This value does not reflect a MultiSpeak command, but is instead intended to give a state of the operation. There are four valid values:</p> <p>Success: When a meter has this status the operation will complete without error.</p> <p>ResponseTimeout: When a meter has this status an asynchronous reply will never arrive (not relevant for Commission/Decommission commands).</p> <p>SyncOperationFailure: When a meter has this status the initial communication to the simulated head-end system will produce an error.</p> <p>AsyncOperationFailure: When a meter has this status, the asynchronous callback from the head-end system will arrive, but will indicate an error (not relevant for Commission/Decommission commands).</p>

A meter can also contain the following elements:

- **Comment:** A field which is for informational use only and is meant to indicate the purpose of the meter.
- **Channels:** Used in reading the meter for On Demand Read commands. A channel contains the following attributes:

Channel Attribute	Definition
uomCode	The units of measure code that should be returned when the meter is read.
uomName	The units of measure name that should be returned when the meter is read.
description	A longer form. When the meter is read, a random number is generated for this value.
decimals	A value to indicate how many places to the right of the decimal that random number should have.

The Adapter Development Kit Native Format

Note: The Adapter Development Kit Native Format can be used with **both** middleware and native Smart Grid Gateway Adapter implementations.

The Adapter Development Kit supports loading usage and event data exported from the AMI head-end system in the “native” initial measurement and device event data formats (the format of the initial measurement and device event seeder business objects). Processing of the ADK native format is supported by the following OSB projects:

- **SGG-DG-SEEDER-BASE**
- **SGG-DG-SEEDER-CM**

Refer to [Initial Measurements and Device Events](#) on page 858 and [OSB Project Summary](#) on page 877 for more information about these OSB projects.

Format Details

The ADK native format is an XML format that contains zero or more initial measurements and/or device events, as follows:

- The collection of initial measurements and/or device events are encapsulated within in an <SGGIMDsEvents> element.

- Each initial measurement or device event is defined in the format of the initial measurement and device event seeder business objects, encapsulated by the following elements:
 - **Initial Measurements:** <D1-InitialLoadIMD>
 - **Device Events:** <D1-DeviceEventSeeder>
- The format can support any number of initial measurements and/or device events.
- Initial measurements can be either scalar or interval measurements.

See [Adapter Development Kit Native Format Example](#) on page 917 for an example of this format. See [Adapter Development Kit Native Format Schema](#) on page 918 for the native format XML schema.

Adapter Development Kit Native Format Example

The following is an example of the ADK native format. This example contains 2 initial measurements (1 scalar and 1 interval) and 2 device events (PowerOutage and PowerRestored).

```

Smart Grid Gateway Adapter Native Implementations

This section describes Smart Grid Gateway native implementations. Native implementations can be used with **either** on-premises implementations of Oracle Utilities Smart Grid Gateway, or with Oracle Utilities cloud services such as Oracle Utilities Meter Solution Cloud Service or Oracle Utilities Customer Cloud Service.

Supported Head End Systems

Oracle Utilities Meter Solution products support integration with a number of vendor-specific head end systems via Oracle Smart Grid Gateway Adapters. The table below lists the supported versions of head end system for each Adapter available with Oracle Utilities Meter Solution products.

Adapter	Head End System Version
Adapter for Itron OpenWay	7.0 Itron OpenWay Operations Center SR 5.3, 5.4
Adapter for Landis+Gyr	Gridstream Command Center 7.5, 8.1, 8.4
Adapter for Sensus RNI	Sensus RNI 4.10, 4.12
Adapter for Silver Spring Networks (Itron AMM)	UtilityIQ Version 4.10, 4.12, 4.14, 5.0, 5.1
MV-90 Adapter for Itron	N/A SGG supports the .mv9 binary, mainframe data format.

Payload Processing

In native implementations, Oracle Smart Grid Gateway adapters process usage and device event payloads via batch processing. Files are sent from a head end system to a file system (for on-premises implementations) or an Oracle Cloud Object Storage location (for cloud services), where they are processed via batch processes.

Note: The total length of the file name for payload files, including the name, delimiter, and extension, should be no greater than 96 characters.

This process requires set up and configuration of the following:

- **Key Rings and Key Pairs:** Records used to link an Oracle Cloud Object Storage location to records in Oracle Utilities cloud services. Used with cloud services only.
- **Object Storage Locations:** One or more Oracle Object Storage buckets where payload files are sent from the head end system for processing. Used with cloud services only.
- **File Storage Configuration Extendable Lookup Values:** An extendable lookup value that defines the file location used for payload processing and allows it to be referenced by batch processes
- **Head End Systems:** A record that defines how specific types of payload processing are handled, such the business object to use to create initial measurements and device events
- **Adapter Extendable Lookups:** Lookup value that define details used by data mapping and processing
- **SGG Payload Processing Configuration Extendable Lookup Values:** An extendable lookup value that defines payload processing details for a specific head end system
- **Payload Processing Batch Controls:** A batch control used for payload process (based on a template batch control provided with the base package)

See the following sections below for more details about each of these.

Note: The Itron OpenWay Adapter uses an alternative method for processing usage and device event payloads. See [Itron OpenWay Payload Processing](#) for more information.

Creating Key Rings and Pairs

Note: Key Rings and Pairs are used with cloud services **only**.

When using Smart Grid Gateway adapters with cloud services, connection between the Oracle Utilities cloud service and Oracle Object Storage requires an API signature key. See **API Key Management** in the *Oracle Utilities Cloud Services Object Storage Setup Guide* for more information.

API key rings and key pairs are maintained in the **Key Ring** portal. This portal contains the following zones:

- **Key Ring:** Displays basic information about the key ring
- **Key Pairs:** Displays a list of key pairs for the current key ring

Key rings are defined by the following:

- **Key Ring:** A unique code for the key ring
- **Key Ring Class:** Signature (default)
- **Status:** The current status of the key ring. Note: Key pairs can only be generated for Active key rings. Once a key ring has been deactivated, you can no longer create key pairs for that ring.
- **Description:** A name for the key ring (this will be referenced in the File Location extendable lookup)

Once the key ring is created, you need to generate and activate the key pair. Click **Generate Key** to generate a key pair for the key ring.

Key Pairs are defined by the following:

- **Sequence:** The sequence of the key pair (the order in which the key pair was created)
- **Creation Date/Time:** The date/time when the key pair was created
- **Key Status:** The current status of the key pair. Key pairs are inactive when first created.
- **Public Key:** Click **View** to open a dialog box containing the public key.
- **Action:** Click **Activate** to activate an inactive key pair.

Once the key ring and key pair have been created, the key should be pasted into the **User API Key** in **Oracle Identification and Access Management (IAM)**. See the **User API Keys** section in the **Security and Access Management** section of the **Managing Object Storage** chapter in the *Oracle Cloud Infrastructure Services* documentation. To copy the public key click **View** in the **Actions** column in the **Key Pairs** zone, and select and copy the text in the **View Public Key** dialog box.

The last step is to activate the key. Click **Activate** in the **Actions** column in the **Key Pairs** zone. A dialog box opens displaying the following message: “Warning(s): Activating a key assumes that you have already registered the public key with the appropriate third parties. Press Cancel to abort.” Note: Be sure to copy the public key to **Oracle Identification and Access Management** before activating it. Click **OK** to activate the key. The **Key Status** column will change to “Active”.

Creating Object Storage Locations

Note: Object Storage Locations are used with cloud services **only**.

When using Smart Grid Gateway adapters with cloud services, you need to create one or more buckets in Oracle Object Storage where payload files will be sent for processing. Refer to the *Oracle Utilities Cloud Services Object Storage Setup Guide* and the *Oracle Cloud Infrastructure* documentation for more information about creating buckets in Oracle Object Storage.

After creating the buckets in Oracle Object Storage, make a note of the following, as this information is needed in later configuration steps:

- Namespace
- User Oracle Cloud ID (User OCID)
- Tenancy Oracle Cloud ID (Tenancy OCID)
- Compartment Oracle Cloud ID (Compartment OCID)

Suggested Buckets for Payload Processing

This section outlined suggested sets of Object Storage buckets for each of the Smart Grid Gateway adapters.

General Guidelines

As a general rule, each adapter should have separate buckets for each of the following:

- Usage payloads
- Usage archive
- Usage errors
- Device Event payloads
- Device Event archive

- Device Event errors

If an adapter uses payloads in more than one format (such as in CSV and XML formats), you should also consider creating separate buckets for each file format type.

Note: If possible, archive buckets should be created in an “Archive” storage tier.

Adapter Development Kit

The table below lists suggested Object Storage buckets for the Adapter Development Kit:

Bucket Name	Storage Tier	Smart Grid Gateway Description
adk-csv	Standard	SGG ADK Adapter - CSV input
adk-csv-arch	Archive	SGG ADK Adapter - CSV archive
adk-csv-error	Standard	SGG ADK Adapter - CSV errors
adk-seeder	Standard	SGG ADK Adapter - IMD Seeder input
adk-seeder-arch	Archive	SGG ADK Adapter - IMD Seeder archive
adk-seeder-error	Standard	SGG ADK Adapter - IMD Seeder errors
adk-xml	Standard	SGG ADK Adapter - XML input
adk-xml-arch	Archive	SGG ADK Adapter - XML archive
adk-xml-error	Standard	SGG ADK Adapter - XML errors

Adapter for Itron OpenWay

The table below lists suggested Object Storage buckets for the Adapter for Itron OpenWay:

Bucket Name	Storage Tier	Smart Grid Gateway Description
itronexception	Standard	SGG Itron OW Adapter - event input
itronexception-arch	Archive	SGG Itron OW Adapter - event archive
itronexception-error	Standard	SGG Itron OW Adapter - event errors
itronxml	Standard	SGG Itron OW Adapter - XML input
itronxml-arch	Archive	SGG Itron OW Adapter - XML archive
itronxml-error	Standard	SGG Itron OW Adapter - XML errors

MV90 Adapter for Itron

The table below lists suggested Object Storage buckets for the MV90 Adapter for Itron

Bucket Name	Storage Tier	Smart Grid Gateway Description
mv90-usage	Standard	SGG MV90 Adapter - usage input

Bucket Name	Storage Tier	Smart Grid Gateway Description
mv90-usage-arch	Archive	SGG MV90 Adapter - usage archive
mv90-usage-error	Standard	SGG MV90 Adapter - usage errors

Adapter for Landis+Gyr

The table below lists suggested Object Storage buckets for the Adapter for Landis+Gyr:

Bucket Name	Storage Tier	Smart Grid Gateway Description
lg-cim-event	Standard	SGG Landis+Gyr Adapter - CIM input
lg-cim-event-arch	Archive	SGG Landis+Gyr Adapter - CIM archive
lg-cim-event-error	Standard	SGG Landis+Gyr Adapter - CIM errors
lg-event	Standard	SGG Landis+Gyr Adapter - event input
lg-event-arch	Archive	SGG Landis+Gyr Adapter - events archive
lg-event-error	Standard	SGG Landis+Gyr Adapter - event errors
lg-usage	Standard	SGG Landis+Gyr Adapter - usage input
lg-usage-arch	Archive	SGG Landis+Gyr Adapter - usage archive
lg-usage-error	Standard	SGG Landis+Gyr Adapter - usage errors

Adapter for Sensus

The table below lists suggested Object Storage buckets for the Adapter for Sensus:

Bucket Name	Storage Tier	Smart Grid Gateway Description
sensus-event	Standard	SGG Sensus Adapter - event input
sensus-event-arch	Archive	SGG Sensus Adapter - events archive
sensus-event-error	Standard	SGG Sensus Adapter - event errors
sensus-usage	Standard	SGG Sensus Adapter - usage input
sensus-usage-arch	Archive	SGG Sensus Adapter - usage archive
sensus-usage-error	Standard	SGG Sensus Adapter - usage errors

Adapter for Silver Spring Networks

The table below lists suggested Object Storage buckets for the Adapter for Silver Spring Networks:

Bucket Name	Storage Tier	Smart Grid Gateway Description
ssn-csv	Standard	SGG SSN Adapter - CSV input

Bucket Name	Storage Tier	Smart Grid Gateway Description
ssn-csv-arch	Archive	SGG SSN Adapter - CSV archive
ssn-csv-error	Standard	SGG SSN Adapter - CSV errors
ssn-ssnxml	Standard	SGG SSN Adapter - XML input
ssn-ssnxml-arch	Archive	SGG SSN Adapter - XML archive
ssn-ssnxml-error	Standard	SGG SSN Adapter - XML errors

Creating File Storage Extendable Lookup Values

Payload processing requires defining details of file storage locations. These are file system or Object Storage locations where payload files are posted for processing. File storage configuration information is captured as values for the File Storage Configuration (F1-FileStorage) extendable lookup. These records will be referenced by the batch controls that will process the payloads.

Values for this extendable lookup are defined by the following:

- **Value:** A unique code for the extendable lookup value. This value will be referenced as a batch control parameter value.
- **Description:** A description of the extendable lookup value
- **Status:** The current status of the value. Select “Active”.
- **File Storage Details:** This section defines details for the file storage location, including:
 - **File Adapter:** The type of file adapter for the location. Options include:
 - **Native File Storage:** Used for on-premises implementations. Additional details for this type of adapter include:
 - **File Path:** A valid file path to the file location on the file system where payload files will be found
 - **Oracle Cloud Object Storage:** Used with Oracle Utilities cloud services. Additional details for this type of adapter include:
 - **User:** The user Oracle Cloud ID (ODIC) for the object storage location
 - **Tenancy:** The tenancy Oracle Cloud ID (ODIC) for the object storage location
 - **Compartment:** The compartment Oracle Cloud ID (ODIC) for the object storage location
 - **Namespace:** The namespace for the object storage location
 - **Key Ring:** The Key Ring you created earlier
 - **Region:** The region of the object storage tenancy for the connection (Values for this field are defined in the F1_REGION_FLG lookup.
 - **Bucket Name Prefix:** Prefix used by Object Storage Bucket configuration

Refer to **External File Storage** in the *Oracle Utilities Application Framework Administrative User Guide* and the *Oracle Utilities Cloud Services Object Storage Setup Guide* for more information about using Oracle Object Storage with cloud service implementations.

Creating Head End Systems

The next step is to create a record for the head end system. This record defines processing methods for the head end system.

Processing Methods for Payload Processing

The following processing methods should be configured to support payload processing:

- **Device Event Mapping:** defines how head end-specific device events are mapped to standard device event names. The Device Event Seeder business object uses this processing method to determine which type of device event business object to instantiate when receiving device events from a head-end system.
- **Initial Measurement Creation:** defines the business objects used to create initial measurements. The IMD Seeder business object uses this processing method to determine which type of initial measurement business object to instantiate when receiving usage from a head end system.
- **UOM Translation:** defines how head end-specific unit of measure (UOM) codes are mapped to standard UOM codes.

If usage payload include time of use periods or service quantity identifiers, you should also configure **SQI Translation** and **TOU Translation** processing methods.

See [Head End Systems](#) and [Understanding Processing Methods](#) in the *Administrative User Guide* for more information about creating and configuring a head end system and its processing methods.

Configuring Adapter Extendable Lookups

Smart Grid Gateway adapters use extendable lookups to define data mapping and processing rules specific to each adapter. These include:

- **Device Event Mapping:** used to map head end specific device event codes to standard event names
- **UOM Code to Standard UOM Mapping:** used to map head end specific units of measure (UOM) to standard UOM codes
- **Status Code Mapping:** used to map head end specific interval status codes to standard Condition codes.

Some adapters have additional extendable lookups used to define categories, statuses, and other data. See the following topics for information about adapter-specific extendable lookups:

- [Configuring Itron OpenWay Extendable Lookups](#)
- [Configuring Landis+Gyr Extendable Lookups](#)
- [Configuring MV90 Extendable Lookups](#)
- [Configuring Sensus Extendable Lookups](#)
- [Configuring Silver Spring Networks Extendable Lookups](#)

Creating SGG Payload Processing Extendable Lookup Values

You also have to create an extendable lookup value to define how usage and event payloads will be processed.

Payload processing configuration information is captured in the SGG Payload Processing Configuration (D1-SGGPayloadProcess) extendable lookup.

Values for this extendable lookup are defined by the following:

- **Value:** A unique code for the extendable lookup value. This value will be referenced as a batch control parameter value.
- **Description:** A description of the lookup value
- **Status:** The current status of the value. Set this to “Active”.
- **Processing Details:** This section defines details for payload processing, including
 - **Payload Handler Class Name:** The Java class name for the processing handler to be used. See [Payload Handler Classes and Parameters](#) below for more information.
 - **Head-End System:** The head end system for which the configuration will apply. Select from the drop-down list.
 - **Populate Raw:** A checkbox that indicates if the payload data is populated as raw data.
 - **Payload Processing Result Type:** The type of payload to which the configuration applies. Options include:
 - Device Events
 - Initial Measurements
 - Initial Measurements and Device Events

- **IMD Seeder BO (Interval):** The seeder business object used to create interval initial measurements. The base package includes the “IMD Seeder” (D1-IMDSeeder) business object for this. Applicable only if the Payload Processing Result Type is “Initial Measurements” or “Initial Measurements and Device Events”.
- **IMD Seeder BO (Scalar):** The seeder business object used to create scalar initial measurements. The base package includes the “IMD Seeder” (D1-IMDSeeder) business object for this. Applicable only if the Payload Processing Result Type is “Initial Measurements” or “Initial Measurements and Device Events”.
- **Device Event Seeder BO:** The seeder business object used to create device events. The base package includes the “Device Event Seeder” (D1-DeviceEventSeeder) business object for this. Applicable only if the Payload Processing Result Type is “Device Events” or “Initial Measurements and Device Events”.
- **Filter IMD:** A checkbox that indicates if initial measurements should be filtered. Applicable only if the Payload Processing Result Type is “Initial Measurements” or “Initial Measurements and Device Events”. See **Filtering Payloads** below for more information.
- **Filter Device Events:** A checkbox that indicates if device events should be filtered. Applicable only if the Payload Processing Result Type is “Device Events” or “Initial Measurements and Device Events”. See **Filtering Payloads** below for more information.
- **Dynamic Parameters:** A list of parameter names and values that support additional processing rules, based on the specified Payload Handler Class. See [Payload Handler Classes and Parameters](#) below for specific parameters supported by each adapter.
- **User Exit Interceptors:** Defines custom Groovy Library Scripts to be executed via user exit calls when parsing and transforming incoming usage and device data in custom and non-standard formats. User exit interceptors are defined as follows:

Payload Processing User Exit Type	Groovy Library Script	Groovy Library Method
On Get Parser	Parsing script	getParser
On Get Transformer	Transforming script	getTransformer
On Result List	Handler script	getHandler

See [Adapter Development Kit Custom Payload Processing](#) for more information about the On Get Parser and On Get Transformer User Exit Interceptors. See [Mapping Additional Fields](#) for information about the On Result List User Exit Interceptor.

Note: On Get Parser and On Get Transformer User Exit Interceptors are applicable only when the **Payload Handler Class Name** is set to `com.splwg.d1.domain.sgg.dg.processing.PayloadHandlerViaUserExits`.

Payload Handler Classes and Parameters

This section provides valid Payload Handler Class Names and associated dynamic parameters for supported head end systems and payload types.

Adapter Development Kit

As delivered, the Adapter Development Kit supports payload processing of usage and event data exported from an AMI head end system in the “native” initial measurement and device event data formats (the format of the initial measurement and device event seeder business objects). See [The Adapter Development Kit Native Format](#) for more information.

Payload Type: ADK CSV

- **Payload Handler Class:** `com.splwg.d1.domain.sgg.dg.processing.CSVPayloadHandler`

Payload Type: ADK XML

- **Payload Handler Class:** `com.splwg.d1.domain.sgg.dg.processing.XMLPayloadHandler`

Payload Type: ADK Seeder

- **Payload Handler Class:** com.splwg.d1.domain.sgg.dg.processing.SeederPayloadHandler

Processing Custom and Non-Standard Formats

The Adapter Development Kit can be configured to support payload processing of data from AMI head end systems in custom and non-standard formats. Processing payloads of this type requires a specific **Payload Handler Class** (see below), and creation of Groovy Library Scripts to parse and transform data into the “native” format. See **Adapter Development Kit Custom Payload Processing** and **Payload Processing User Exit Interceptor Scripts** for more information.

- **Payload Handler Class:** com.splwg.d1.domain.sgg.dg.processing.PayloadHandlerViaUserExits

The Adapter Development Kit also supports payload processing of data in the Common Information Model (CIM) format. See [Adapter Development Kit Common Information Model \(CIM\) Payload Processing](#) for more information.

Adapter for Itron OpenWay

Payload Type: Itron OpenWay XML

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d8.processing.ItronXMLPayloadHandler
- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
intervalValueDecPlaces	Optional value. Specifies the number of digits after the decimal place for the quantity value. If this parameter is missing, the processing logic defaults the number of digits after the decimal place to 6.
filterRegisterSource	Optional value. Determines if source register data should be filtered. Valid values are ‘true’ and ‘false’ (default)

Payload Type: Itron OpenWay Exception

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d8.processing.ExceptionPayloadHandler

MV90 Adapter for Itron

Payload Type: MV90

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d5.processing.MV90PayloadHandler
- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
usePhysicalChannel	Optional value. Determines whether the physical channel ID is passed to the IMD seeder to create the measuring component identifier number. If this is set to false, the MV90 LOGCHAN field is used.
fieldForDvcIdN	Optional value. Specifies which field is used as the value for the device ID. Valid values include: <ul style="list-style-type: none"> • DC_RECID • DC_CUSTID • DC_METERID (default)

Dynamic Parameter Name	Description and Valid Values
MV90ScalarChannelSuffix	Optional value. Holds a suffix value to be added to the measuring component identifier number when a scalarIMD is created for register reads. Default value is “_S”
processMV90ScalarData	Optional value. Determines if register reads are processed. Valid values are ‘true’ and ‘false’ (default).
sendStatusAsIs	Optional value. Determines if the status codes will be passed as they came from the head end. If this set to false or not provided, then the default existing behavior when a status code is parsed and status types passed to the IMD seeder in which bits are turned on. Valid values are ‘true’ and ‘false’ (default).
MV90DateFormat	Optional value. Holds the date format used to parse provided date-time fields. The code supports the limited list of values for the format. If this parameter is missing or if the value supplied to it does not match the values from this list then the format used will be MDDYYhhmm, the default value. Valid values include: <ul style="list-style-type: none"> • MMDDYYhhmm (default) • MMYDDhhmm • DDMMYYhhmm • DDYYMMhhmm • YYMMDDhhmm • YYDDMMhhmm
MV90IntervalValueDecPlaces	Optional value. Specifies the number of digits after the decimal place for the quantity value. If this parameter is missing, the processing logic defaults the number of digits after the decimal place to 6.
MV90StrtmtrAndStopmtrToDecimal	Optional value. Determines if the MV90 STRTMTR (Start Reading Meter) and STOPMTR (Stop Reading Meter) will be converted to a decimal. The processing logic will treat these fields as decimal use the setting to determine how many decimal points are required.
usePulseMultiplierAndOffset	Optional value. If set to "true", specifies the pulse values are multiplied by the pulse mutlipler. Valid values include: <ul style="list-style-type: none"> • true • false (default) <p> Note: This setting only applies to MV90 files that have a Pulse datatype.</p>

Adapter for Landis+Gyr

Payload Type: L+G Usage

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d3.processing.LGUsagePayloadHandler

- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
dateTimeInUTC	Indicates whether the Landis+Gyr system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device. Valid values are 'true' and 'false' (default)

Payload Type: L+G Event

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d3.processing.LGEventPayloadHandler
- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
dateTimeInUTC	Indicates whether the Landis+Gyr system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device. Valid values are 'true' and 'false' (default)

Payload Type: L+G CIM Event

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d3.processing.LGCIMEventPayloadHandler
- **Dynamic Parameters:** N/A

Adapter for Sensus

Payload Type: Sensus RNI Usage

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d6.processing.SensusUsagePayloadHandler
- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
dateTimeInUTC	Indicates whether the Sensus RNI system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device. Valid values are 'true' and 'false' (default).
useExternalTOU	Applies to Scalar usage only. Indicates whether or not an externally referenced TOU period should be used when processing measurement data. When set to true the TOU period Sensus provides will be passed to the IMD Seeder as an external TOU "preVEE/externalTOU". When not provided or set to false then the TOU period Sensus provides will be passed to the IMD Seeder as the external MC identifier number "preVEE/mcIdN". Valid values are 'true' and 'false' (default).

Dynamic Parameter Name	Description and Valid Values
sendStatusAsIs	Determines if the status codes will be passed as they received from the head end. When set to true status codes will be sent as they are received from the head end. When not provided or set to false the status codes from the head will be processed through a bit mask to produce multiple individual statuses. Valid values are 'true' and 'false' (default).
sendIntervalDateTimes	When set to true the "preVEE/msrms/mL/dt" element of the IMD seeder for interval records will be populated with the interval date/time and the element "preVEE/enDt" will be populated with the interval date/time of the last interval. When not provided or set to false the "preVEE/msrms/mL/dt" element of the IMD seeder for interval records will not be populated and the element "preVEE/enDt" will be populated with: start date + spi * number of intervals. Valid values are 'true' and 'false' (default).
scalarExpanding	Optional Value. Defines the number of register reads to process in scalar payloads. When defined, Sensus payload processing uses this setting to ensure that all the scalar reads included in a payload will be processed. Default value is 2.

Payload Type: Sensus RNI Event

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d6.processing.SensusEventPayloadHandler
- **Dynamic Parameters:**

Dynamic Parameter Name	Description and Valid Values
dateTimeInUTC	Indicates whether the Sensus RNI system is sending date/time information in UTC (true) or local time of the device (false). If not provided the default behavior will be local time of the device. Valid values are 'true' and 'false' (default)

Adapter for Silver Spring Networks

Payload Type: Silver Spring Networks CSV

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d7.processing.SSNCSVPayloadHandler

Payload Type: Silver Spring Networks XML

- **Payload Handler Class:** com.splwg.d1.domain.sgg.d7.processing.SSNXMLPayloadHandler

Common Parameters

The following parameters can be used by all of the supported head end system adapters.

Dynamic Parameter Name	Description and Valid Values
suppressPayloadStatistics	Optional parameter. Determines if the PayloadStatistics business object will not be created while processing payload. If this set to false or not provided, then the default existing behavior when a PayloadStatistics business object is created at the start of the payload processing. Valid values are 'true' and 'false' (default).
suppressPayloadErrorNotification	Optional parameter. Determines if the PayloadErrorNotification business object will not be created when an error occurs while processing payload. If this set to false or not provided, then the default existing behavior when a PayloadErrorNotification business object is created for every error occurred during the payload processing. If this set to false, the error description will be written into the application log file. Valid values are 'true' and 'false' (default).
suppressPayloadSummary	Optional parameter. Determines if the PayloadSummary business object will not be created while processing payload. If this set to false or not provided, then the default existing behavior when a PayloadSummary business object is created at the end of the payload processing. Valid values are 'true' and 'false' (default).
commitSizeInKB	<p>Optional Parameter. Specifies the total amount of memory (in KB) allocated for Device Event and IMD seeders before they are committed. Seeders are kept in memory until their size exceeds the value defined for this parameter or the end of payload is reached.</p> <p>Default value is 100.</p> <p>Note: This parameter (either the default value or a specified value) is ignored when the chunkSize parameter is set.</p>
chunkSize	<p>Optional parameter. Specifies the size in bytes of a portion (chunk) of the payload that will be processed in a single batch "thread".</p> <p>If parameter is set, the commitSizeInKB parameter is ignored.</p> <p>This parameter is supported by the following payload formats:</p> <ul style="list-style-type: none"> • Landis+Gyr Usage • Landis+Gyr Events • MV90 Usage • Sensus RNI Usage • Sensus RNI Events • Silver Spring Networks Usage (CSV) • Adapter Development Kit Usage sample format (CSV) • Adapter Development Kit via User Exits (if an instance returned from the <code>getParser</code> method implements the <code>com.splwg.d1.domain.sgg.dg.processing.ChunkProcessor</code> interface).

Filtering Payloads

When **Filter IMD** is selected, only measurements whose <externalUOM> matches one of the values defined in the head end system's UOM Code to Standard UOM Mapping extendable lookup are passed into the system for processing.

When **Filter Device Events** is selected, only device events whose <externalEventName> matches one of the values defined in the head end system's Device Event Mapping extendable lookup are passed into the system for processing.

Upload Statistics Activities

Upload statistics activities are activities that contain statistics related to the processing of usage and device events sent from a head end system.

There are three types of upload statistics activities:

- **Payload Statistics:** Contains statistics related to a specific payload (file) containing one or more initial measurements or device events.
- **Payload Error Notification:** Contains details concerning processing errors encountered in an individual payload (file) containing one or more initial measurements or device events.
- **Payload Summary:** Contains processing summary statistics for an individual payload (file) containing one or more initial measurements or device events. Payload Summary used to update related payload statistics upon the completion of payload processing.

Upload statistics activities are created during processing of payload files as follows:

- When processing begins for a payload, a **Payload Statistics** activity is created to record the process.
- If an error occurs during processing, a **Payload Error Notification** activity is created.
- When payload processing is complete, a **Payload Summary** activity is created, which in turn, updates the Payload Statistics activity with details concerning the processing of the payload, including (the start and end time of the processing, the total processing time, the number of initial measurements or device events processed, and the number of initial measurement or device event errors (if any).

Suppressing Upload Statistics Activities

Creation of upload statistics activities can be suppressed through the use of the following dynamic parameters in the SGG Payload Processing Configuration Extendable Lookup:

- `suppressPayloadStatistics`
- `suppressPayloadSummary`
- `suppressPayloadErrorNotification` (**Note:** If this set to false, the error description will be written into the application log file.)

See **Common Parameters** in [Payload Handler Classes and Parameters](#) for more information about these parameters.

Creating Payload Processing Batch Controls

The last step is to create payload processing monitor batch controls based on the Payload Processing Monitor Template (D1-PLPRM) template. You can create separate batch controls for each head end system or for specific payload types, or any combination of both. For example, you might create a separate batch control for Itron OpenWay usage payloads and device event payloads. Creating specific batch controls allows more control when setting up batch process scheduling for payload processing. For instance, you may want to run usage payload processing every hour, but device payload processing every two hours.

To create a payload processing monitor batch control, search for the "Payload Processing Monitor Template" (D1-PLPRM) batch control, click **Duplicate**, enter a unique code for the duplicate batch control and click **OK**.

This new batch control can be used to process payloads received from head end systems.

Payload Processing Batch Control Parameters

Payload processing batch processing is controlled by the following parameters:

Parameter Name	Description	Detailed Description	Required?
includeFiles	Include Files	The pattern for types of files to pick up during polling. The parameter supports the "glob" syntax for using wildcard characters.	True
fileLocation	File Location	The Object Storage bucket to poll files from. This should be the Value of the File Location Extendable Lookup value for the appropriate bucket (usage or event).	True
processingConfiguration	Processing Configuration	The Value of the SGG Payload Processing Configuration Extendable Lookup value	True
errorLocation	Error Location	The Object Storage bucket where defected portions of payload and related rejection details are stored. This should be the Value of the File Location Extendable Lookup value for the appropriate "error" bucket.	True
postProcessingAction	Post Processing Action	Defines what happens to a file after it has been processed: delete (default), archive or rename. If "archive" is selected, an archive bucket should be provided.	False
archiveLocation	Archive Location	The Object Storage bucket where processed files are moved to. Required if the Post Processing Action is "archive". This should be the Value of the File Location Extendable Lookup value for the appropriate "archive" bucket.	False
processedFileExtension	Processed File Extension	The text to be appended to the file name after the file has been processed. Default is "PROCESSED".	False
maxRaiseSize	Maximum Raise Size	This parameter defines the maximum number of files that the batch program would submit for processing on each polling cycle. Default is No Maximum.	False
DIST-THD-POOL	Thread Pool	Thread pool name to use if the DEFAULT thread pool is not desired.	False

Note: Refer to [Creating Object Storage Locations](#) for lists of suggested Object Storage buckets for each adapter.

Mapping Additional Fields

Measurements and device event files received from head end systems can include additional fields containing data to be imported into Oracle Utilities Smart Grid Gateway. These additional fields must be mapped to elements within the measurements and device events processed by Smart Grid Gateway.

This mapping can be performed through use of a custom Groovy script, via the "On Result List" User Exit Interceptor specified in the SGG Payload Processing Configuration Extendable lookup.

Payload Processing Overview

This section provides an overview of the payload processing logic when mapping data in incoming measurements or device events.

Oracle Utilities Meter Data Framework Steps

1. The file upload process program starts reading the file.
2. The upload process creates an instance of the Payload Handler class specified on the SGG Payload Processing Configuration extendable lookup. This class handles the interaction with the User Exit Interceptor script.
3. The upload process invokes the “On Result List” User Exit Interceptor. This executes a “handler” Groovy Library Script that returns an instance of a class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadProcessingCMHandler` interface.

This “CM payload handler” is initialized with a stream opened for the incoming file and a business object instance of SGG Payload Processing Configuration extendable lookup.
4. The upload process parses data from the incoming document into the “Plain XML” format and transforms the Plain XML data into a set of Initial Measurements (IMDs) or/and Device Events in the “native” XML format and returns each as child nodes added to the Result List parent node.
5. The upload process invokes the CM payload handler, passing the Result List parent node.
6. The CM payload handler transforms data the Result List parent node based on the logic in the Handler script. See **CM Payload Handler Steps**, below.
7. The upload process creates business object instances for all child nodes of the Result List.
8. The process steps (4-9) are repeated until the process returns NULL on step 4 (when there are no further records to process).

CM Payload Handler Steps

1. The CM payload handler reads the given measurement or device event inside the Result List node.
2. The CM payload handler transforms specific data elements inside the measurement or device event (such as replacing a `<externalUOM>` element with the standard `<UOM>` element) based on the logic in the handler script, and updates the Result List accordingly.

CM Handler Payload Processing User Exit Interceptor Scripts

Mapping data is performed via a Groovy Library Script that is invoked via a user exit during payload processing. The script used in this process is referred to as a “handler” script.

Handler Script

The “handler” script is responsible for transforming and mapping data elements within measurements and device events.

This script should include the `gethandler` method that returns an instance of a class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadProcessingCMHandler` interface.

To view details of the `PayloadProcessingCMHandler` interface in the Application Viewer, select the Java Docs Viewer, select the `com.splwg.dl.domain.sgg.dg.processing` Java package, and select `PayloadProcessingCMHandler` from the list of interfaces.

The “handler” script should be defined for the “On Result List” Payload Processing User Exit Type in the User Exit Interceptors section on the SGG Payload Processing Configuration extendable lookup. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.

Configuration Steps

Configuration of Smart Grid Gateway adapters to support mapping of non-standard data involves the following steps:

1. Create a “handler script” that transforms and maps specific data elements inside the measurement or device event (such as replacing a `<externalUOM>` element with the standard `<UOM>` element). See [CM Handler Payload Processing User Exit Interceptor Scripts](#) for more information.

2. Create an SGG Payload Processing Configuration extendable lookup value. The **Payload Handler Class Name** should reference one of the usage or event “PayloadHandler” classes listed in the [Payload Handler Classes and Parameters](#) section. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information about creating these extendable lookup values..
3. Specify the script for the “On Result List” **Payload Processing User Exit Type** in the **User Exit Interceptors** section on the SGG Payload Processing Configuration extendable lookup. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.
4. Create other objects and data used with payload processing, including:
 - Key Rings and Pairs (See [Creating Key Rings and Pairs](#))
 - Object Storage Locations (See [Creating Object Storage Locations](#))
 - File Storage Extendable Lookup values (See [Creating File Storage Extendable Lookup Values](#))
 - Head End System (See [Creating Head End Systems](#))
 - Payload Processing Batch Controls (See [Creating Payload Processing Batch Controls](#))

Sample Implementation

The following sample illustrates how additional fields can be mapped into the XML format sent to Smart Grid Gateway. In this case, the unit of measure for incoming measurement data is defined by an <externalUOM>, which must be mapped to the standard <UOM> element.

Sample Script

The below Groovy Script will loop through a list of “D1-IMDSeeder” nodes and check the “externalUom” for a value (GD_KWH in this example), and if equal then the <UOM> element will be created with the <externalUOM> values and the <externalUOM> element will be removed.

Script Type: Groovy Library Script

Step 10: Groovy Imports

```
import org.w3c.dom.Document;
import org.w3c.dom.Element;
import org.w3c.dom.NodeList;
import org.w3c.dom.Node;
import com.splwg.dl.domain.sgg.processing.PayloadProcessingCMHandler;
import com.splwg.shared.logging.Logger;
import com.splwg.shared.logging.LoggerFactory;
import com.splwg.base.support.scripting.XMLUtils;
```

Step 20: Groovy Library Interface

```
PayloadProcessingCMHandler getHandler()
```

Step 30: Groovy Members

```
public PayloadProcessingCMHandler getHandler() {
    return new CMhandler();
}

public class CMhandler implements PayloadProcessingCMHandler{

    org.w3c.dom.Document onList(org.w3c.dom.Document resultList, org.w3c.dom.Document pla

    NodeList imdList=resultList.getDocumentElement().getElementsByTagName("D1-
    IMDSeeder");
    for(int i=0;i<imdList.getLength();i++){
        Element imdEl = (Element) imdList.item(i);
```

```

//check if msrs element exists
NodeList msrsList = imdEl.getElementsByTagName("msrs");
if (msrsList.length > 0) {
    //get preVEE
    NodeList preVEENodeList = imdEl.getElementsByTagName("preVEE");
    Element preVEENode = (Element) preVEENodeList.item(0);
    //get externaluom
    NodeList uomList = preVEENode.getElementsByTagName("externalUOM");

    Element uomElm = uomList.length>0 ? uomList.item(0) : null;
    String uom = uomElm!=null ? uomElm.getTextContent() : "";
    //get mcIdN
    NodeList mcIdNList = preVEENode.getElementsByTagName("dvcIdN");
    if ( uom.compareTo("GD_KWH")==0 && mcIdNList.length>0 ) {
        Element externalUOMElm = resultList.createElement("uom");
        externalUOMElm.setTextContent(uom);
        //replace uom with externalUOM
        preVEENode.replaceChild(externalUOMElm, uomElm);
    }
}
}
return resultList;
}
}

```

Sample File

Below is a sample Landis+Gyr usage file. Note that this file has a "Units" value of "GD_KWH".

```

Itron OpenWay Payload Processing

By default, payload processing for the Itron OpenWay adapter works differently than it does for other adapters, but it can be configured to work like other adapters in which payloads are saved to a staging area in Oracle Object Storage and then processed via batch processing. For large volumes, saving to the staging area provides better performance because it allows the web service to simply drop off the payload, and the collection of saved payloads can then be processed in multiple batch processing threads.

Configuration of Itron payload processing requires the same set up and configuration as other adapters. Some specifics regarding configuration for Itron processing include the following:

- **Object Storage Locations:** Itron OpenWay payload processing uses object storage locations (including Key Rings, Key Pairs and File Storage Configuration extendable lookup values) to capture usage and event payloads or exceptions received from the head end system.
- **Head End Systems and Extendable Lookups:** Itron payload processing uses head end system and extendable lookup configuration in the same manner as other adapters.
- **SGG Payload Processing Configuration Extendable Lookup Values:** These values define payload processing details for the Itron head end system (which is referenced on the payload processing batch control).
- **Payload Processing Batch Controls:** A batch control used for payload process (based on a template batch control provided with the base package)
- **Master Configuration:** Configuration settings for Itron OpenWay payload processing, including specifying the use of a payload staging area in Object Storage. See [Itron OpenWay Master Configuration](#) for more information about configuring the system to process Itron OpenWay payloads and exceptions.

Deferring Batch Processing

We recommend configuring a monitor process on the Pending status of the Initial Load initial measurement business objects so that the VEE and measurement creation processes can be deferred to batch processing.

Deferring processing has the following additional benefits:

1. It can ensure chronological processing for scalar reads which provides more efficient processing. Processing scalar reads out of order can result in additional work as reconciliation initial measurements will be created and processed to true up the consumption calculations.
2. It can ensure measuring components are processed in order based on their relationships. For example, if a scalar channel is configured as the check channel for an interval channel, the scalar channel will be processed first so that its data is available for sum checks and any interval gap filling required.

Configuration

Configuring deferred processing involves adding the “IMD Monitor – Physical Devices” Batch Control as the Monitor Process on the Pending status to the following business objects:

- D1-InitialLoadIMDInterval
- D1-InitialLoadIMDScalar

When initial measurement processing is deferred it will be necessary to schedule the “IMD Monitor – Physical Devices” Batch Control to run more frequently. It should be scheduled such that it runs with a higher thread count immediately after the Itron Scheduled Reads cycle has completed and with fewer threads throughout the rest of day to pick up any other initial measurements that might be received (such as those received via On Demand Read commands).

Default Processing — Not Recommended

By default, payload processing for the Itron OpenWay adapter works differently than it does for other adapters. Instead of using batch processing, Itron payloads are processed as they are received. Payloads and exceptions sent from the Itron OpenWay head end system are received via inbound web services that invoke business components that process the payloads and exceptions as they are received rather than posting them to object storage locations. See [Itron OpenWay Inbound Web Services](#) for more information about the inbound web services used to receive payloads and exceptions from the Itron OpenWay head end system. This approach is not recommended.

Adapter Development Kit Custom Payload Processing

This section describes how the Oracle Utilities Smart Grid Gateway Adapter Development Kit can be configured to process custom payload formats, including payloads from non-supported head end systems.

Introduction

As delivered, the Adapter Development Kit supports payload processing of usage and event data exported from an AMI head end system in the “native” initial measurement and device event data formats (the format of the initial measurement and device event seeder business objects).

The Adapter Development Kit can also be configured to support payload processing of data from AMI head end systems in custom and non-standard formats. This involves creation of Groovy Library Scripts to:

- Parse the payload into a “plain XML” format, and
- Transform the plain XML format into the “native” initial measurement and device event data formats

These scripts are executed as User Exit Interceptors configured on the SGG Payload Processing Configuration extendable lookup. See [Creating SGG Payload Processing Configuration Extendable Lookup Values](#).

Custom Payload Processing Overview

This section provides an overview of the payload processing logic when converting incoming data into the native format.

Oracle Utilities Meter Data Framework Steps

1. The file upload process program starts reading the file.
2. The upload process creates an instance of the Payload Handler class. This class handles the interaction with the User Exit Interceptor scripts.
3. The upload process invokes the “On Get Parser” User Exit Interceptor. This executes a “parser” Groovy Library Script that returns an instance of a class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadParser` interface.

This “payload parser” is initialized with a stream opened for the incoming file and a business object instance of SGG Payload Processing Configuration extendable lookup.

4. The upload process invokes the “On Get Transformer” User Exit Interceptor. This executes a “transformer” Groovy Library Script that returns an instance of a class that implements `com.splwg.dl.domain.sgg.dg.processing.PayloadTransformer` interface.
- This “payload transformer” is initialized with a string representing the origin of the payload and business object instance of SGG Payload Processing Configuration extendable lookup.
5. The upload process invokes the payload parser to parse data from the incoming document into the “Plain XML” format. See [Payload Parser Steps](#), below.
 6. The upload process invokes the payload transformer, passing the Plain XML data and a Result List parent node.
 7. The payload transformer transforms the Plain XML data into a set of Initial Measurements (IMDs) or/and Device Events in the “native” XML format and returns each as child nodes added to the Result List parent node. See [Payload Transformer Steps](#), below.
 8. The upload process creates business object instances for all child nodes of the Result List.
 9. The process steps (5-9) are repeated until the payload parser returns NULL on step 5 (when there are no further records to process).

Payload Parser Steps

1. The payload parser reads an input stream until it hits the logical end of portion of data (each usage or event record), which could be transformed into Plain XML.
2. The payload parser parses the data and converts into the Plain XML format.
3. The process is performed for each call from the upload process.

Payload Transformer Steps

1. The payload transformer reads the given Plain XML.
2. The payload transformer generates a set of XML nodes representing Initial Measurements (IMDs) or Device Events. Names for nodes are taken from the provided SGG Payload Processing Configuration.
3. The payload transformer adds the generated nodes to the given Result List node.

Payload Processing User Exit Interceptor Scripts

Conversion of data from custom and non-standard formats into the “native” format is performed via a pair of Groovy Library Scripts that are invoked via user exits during payload processing (see [Custom Payload Processing Overview](#)). The two scripts used in this process include a “parser” script, and a “transformer” script.

Parser Script

The “parser” script is responsible for parsing the incoming data and converting it into the Plain XML format. This script should include the `getParser` method that returns an instance of a class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadParser` interface.

To view details of the `PayloadParser` interface in the Application Viewer, select the **Java Docs Viewer**, select the `com.splwg.dl.domain.sgg.dg.processing` Java package, and select `PayloadParser` from the list of interfaces.

The “parser” script should be defined for the “On Get Parser” Payload Processing User Exit Type in the **User Exit Interceptors** section on the SGG Payload Processing Configuration extendable lookup. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.

The base package includes two sample parser scripts that can be used as examples when developing custom parser scripts. See [Sample Implementation](#).

Transformer Script

The “transformer” script is responsible for converting data the Plain XML format into the “native” format. This script should include the `getTransformer` method that returns an instance of a class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadTransformer` interface.

To view details of the *PayloadTransformer* interface in the Application Viewer, select the **Java Docs Viewer**, select the `com.splwg.dl.domain.sgg.dg.processing` Java package, and select *PayloadTransformer* from the list of interfaces.

The “transformer” script should be defined for the “On Get Transformer” Payload Processing User Exit Type in the **User Exit Interceptors** section on the SGG Payload Processing Configuration extendable lookup. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.

The base package includes two sample transformer scripts that can be used as examples when developing custom transformer scripts. See [Sample Implementation](#).

Configuration Steps

Configuration of the Adapter Development Kit to support conversion of non-standard formats into the “native” format involves the following steps:

1. Create a “parser script” that converts data from the incoming format into Plain XML format.
See [Payload Processing User Exit Interceptor Scripts](#) for more information.
2. Create a “transformer script” that converts data from the Plain XML format to the “native” format.
See [Payload Processing User Exit Interceptor Scripts](#) for more information.
3. Create an SGG Payload Processing Configuration extendable lookup value with a **Payload Handler Class Name** of “com.splwg.dl.domain.sgg.dg.processing.PayloadHandlerViaUserExits”.
See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.
4. Specify the parser script for the “On Get Parser” Payload Processing User Exit Type in the **User Exit Interceptors** section on the SGG Payload Processing Configuration extendable lookup.
See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.
5. Specify the transformer script for the “On Get Transformer” Payload Processing User Exit Type in the **User Exit Interceptors** section on the SGG Payload Processing Configuration extendable lookup.
See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.
6. Create other objects and data used with payload processing, including:
 - Key Rings and Pairs (See [Creating Key Rings and Pairs](#))
 - Object Storage Locations (See [Creating Object Storage Locations](#))
 - File Storage Extendable Lookup values (See [Creating File Storage Extendable Lookup Values](#))
 - Head End System (See [Creating Head End Systems](#))
 - Payload Processing Batch Controls (See [Creating Payload Processing Batch Controls](#))

Sample Implementation

The Smart Grid Gateway Adapter Development Kit includes sample parser and transformer scripts that demonstrate how custom payload processing works. These sample scripts include samples for processing data in comma separated values (CSV) format and in XML format.

Comma Separated Values Format

This page describes the comma separated values format sample implementation.

Sample File Format

In this sample, data is stored as a comma separated values file.

Note: Values in this example cannot contain a literal comma character. This restriction is added for the simplicity of file parser implementation. The parsing logic can be re-implemented to avoid this restriction. It will not affect the rest of functionality.

The sample CSV file contains the following record types:

Interval Usage: Used for interval usage measurements

Device Events: Used for device events

Trail record: Used to provide the read date/time and number of interval usage and device event records in the file

Interval Usage Format

#	Field Name	Type	Definition
1	Record Type ID	Constant value “U”	Record type identifier
2	Start Date/Time	Time in the Unix Time format.	Meter read’s start date/time
3	End Date/Time	Time in the Unix Time format.	Meter read’s end date/time
4	Device Id	Arbitrary Text	Device identifier
5	Interval Duration	Numeric Integer	The time interval between readings in seconds (seconds per interval).
6	UOM	Arbitrary Text	Describes the units of the data values
7	Data Entry(s)	Numeric Floating-Point and optional Arbitrary Text separated by “:”	Each record can contain unlimited number of data entry fields. Each data entry is a set of two fields – a reading value and an optional reading status flag. Fields are separated by “:” character. The separator is not present when the reading status flag is not provided.

Device Event Format

#	Field Name	Type	Definition
1	Record Type ID	Constant value “E”	Record type identifier
2	Event Date/Time	Time in the Unix Time format.	The date and time at which the event occurred
3	Device Id	Arbitrary Text	Device identifier
4	Event Name	Arbitrary Text	The primary identification name of the event

Trail Record Format

#	Field Name	Type	Definition
1	Record Type ID	Constant value “T”	Record type identifier
2	Creation Date/Time	Time in the Unix Time format.	Meter read’s start date/time
3	Total Records	Numeric Integer	Displays number of records in file

Sample File

```
U,1,86400,DEVICE_DG_0,900,KWH,1:S,2.5,-3.99:R,4:B
E,86400,DEVICE_DG_1,Power Outage
U,2,86400,DEVICE_DG_2,900,KWH,1:S,2,3:R,4:B,5,6,7:A
E,86402,DEVICE_DG_3,Tamper attempt suspected
U,3,86400,DEVICE_DG_4,900,KWH,1:S
T,86401,5
```

Sample Scripts

The sample implementation includes the following sample scripts designed for use with the above CSV format:

DG_SmplPrCSV: This sample script includes one method in the Library Interface – `getParser()`. The method returns an instance of the class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadParser` interface. The class contains the following logic:

1. Parses an incoming payload in the CSV Format.
2. Transforms incoming data to Usage or Event related structures based on incoming data type
3. Returns one by one that structures in the Plain XML format

DG_SmPrCSVCh: This script is provided as a sample to demonstrate how to parse the CSV format in chunks (created via the `chunkSize` parameter) by utilizing a helper. This sample script includes one method in the Library Interface – `getParser()`. The method returns an instance of the class that implements the `com.splwg.dl.domain.sgg.dg.processing.ChunkProcessor` and `com.splwg.dl.domain.sgg.dg.processing.GenericPayload` interfaces.

The `ChunkProcessor` interface distinguishes a chunking-aware processor from the rest of implementations. A custom parser implemented in groovy can implement this interface. The `GenericPayload` interface defines methods needed to get access to a payload via specific helpers. Via this interface, a custom parser gets access to an instance of `LineReaderChunked`.

If the `chunkSize` dynamic parameter is not set in an SGG Payload Processing configuration the entire payload will be processed. See [Common Parameters](#) for more information about the `chunkSize` parameter.

The class contains the following logic:

1. Reads a line from incoming payload by utilizing the `LineReaderChunked.readLineWithinChunk()` method
2. Parses a line in the incoming payload (in the CSV Format) that was read in the previous step.
3. Transforms incoming data to Usage or Event related structures based on incoming data type
4. Returns one by one that structures in the Plain XML format

DG_SmplTrCSV: This sample script includes one method in the Library Interface – `getTransformer()`. The method returns an instance of class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadTransformer` interface. The class contains the following logic:

1. Transforms incoming message in the Plain XML format into the “native” format (the IMD Seeder or Device Event Seeder XML nodes).

2. Adds new XML nodes as child nodes to the given Result List.

Use the **Script** portal to view these scripts in more detail.

Parsing

The parser script performs the following data mapping.

Interval Usage to Plain XML Mapping

The following table shows the mapping between fields in incoming interval data and child elements of Payload/Usage element in the Plain XML format:

Interval Usage Field	Plain XML Element
Record Type ID	RecordType
Start Date/Time	StartDateTime
End Date/Time	EndDateTime
Device Id	DeviceId
Interval Duration	IntervalDuration
UOM	UOM
Data Entry(s)	Intervals/ Interval/ Value [Status]
Record content from incoming file.	RawData

Device Event to Plain XML Mapping

The following table shows the mapping between fields in incoming interval data and child elements of Payload/Event element in the Plain XML format:

Device Event Field	Plain XML Element
Record Type ID	RecordType
Event Date/Time	DateTime
Device Id	DeviceId
Event Name	Name
Record content from incoming file.	RawData

XML Schema of Plain XML Format

The Plain XML consists of the Interval Usage and Device Event related elements at the same time.

```
<xs:schema attributeFormDefault="unqualified"
elementFormDefault="qualified"
targetNamespace="http://xmlns.oracle.com/GenericAdapter"
```

      <xs:element name="DeviceId" type="ga:NonEmptyString"/>
      <xs:element name="Name" type="ga:NonEmptyString"/>
    </xs:sequence>
  </xs:complexType>
  <xs:simpleType name="RecordTypeEventType">
    <xs:restriction base="xs:string">
      <xs:enumeration value="E"/>
    </xs:restriction>
  </xs:simpleType>
  <xs:simpleType name="NonEmptyString">
    <xs:restriction base="xs:string">
      <xs:minLength value="1"/>
    </xs:restriction>
  </xs:simpleType>
</xs:schema>

```

Note: Note: A part of incoming file that been used to generate current Plain XML structure will be placed into the Payload/RawData element.

Transformation

The transformer script performs the following mapping.

Plain XML to Seeder XML Mapping

The payload transformer creates the IMD or/and Device Event Seeder XML elements as following:

Usage Mapping: If name of Payload/* node is equal to 'Usage' (interval usage), the script creates an XML element with a name defined in the SGG Payload Processing Configuration field “IMD Seeder BO (Interval)” and the structure according to the following mapping table:

Plain XML Element	IMD Seeder Element	Notes
RecordType	N/A	
DeviceId	dvcIdN	
UOM	externalUOM	
IntervalDuration	spi	
StartDateTime	stDt	Convert to OUAF "dateTime" type
EndDateTime	enDt	Convert to OUAF "dateTime" type
Intervals/		
Interval/		
Value [Status]	msrs	Value
msrs/mL/q		
Status ->		
msrs/mL/sts/stsL/st		
N/A	imdType	Const value 'D1IL'
	externalId	Value stored in setOrigin method.
	serviceProviderExternalId	Value stored in setConfiguration method.
RawData	rawData	If the SGG Payload Processing Configuration has the Populate RAW checkbox checked.

Device Event Mapping: If name of Payload/* node is equal to 'Event' (device event data) create an XML element with a name defined in the SGG Payload Processing Configuration field “Device Event Seeder BO” and the structure according to the following mapping table:

Plain XML Element	Device Event Seeder Element	Note
RecordType	N/A	
DateTime	eventDateTime	Convert to OUAF "dateTime" type

Plain XML Element	Device Event Seeder Element	Note
DeviceId	externalUOM	
Name	externalEventName	
	externalSourceIdentifier	Value stored in setOrigin method.
	externalSenderId	Value stored in setConfiguration method.
RawData	rawEventInformation	If the SGG Payload Processing Configuration has the Populate RAW checkbox checked.

XML Format

This page describes the XML format sample implementation.

Sample File Format

The file format is described in the Online IMD Upload hint on the **Online IMD and Event Upload** screen. (Select **Menu**, select **Communication**, select **Load IMDs/Events (XML)**).

Sample File

```

</deviceList>

```

Sample Scripts

The sample implementation includes the following sample scripts designed for use with the above XML format:

DG_SmplPrXML: This sample script includes one method in the Library Interface – `getParser()`. The method returns an instance of the class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadParser` interface. The class contains the following logic:

1. Parses an incoming payload in XML format
2. Fetches information about current device
3. Breaks an incoming data into separate initial measurement data structures
4. Extends these structures with device information
5. Returns one by one these structures in the Plain XML format

DG_SmplTrXML: This sample script includes one method in the Library Interface – `getTransformer()`. The method returns an instance of class that implements the `com.splwg.dl.domain.sgg.dg.processing.PayloadTransformer` interface. The class contains the following logic:

1. Transforms incoming message in the Plain XML format into the IMD Seeder XML nodes
2. Adds new XML nodes as child nodes to the given Result List

Use the **Script** portal to view these scripts in more detail.

Parsing

The XML parser script maps data from the above XML format into the Plain XML format.

XML Schema of Plain XML Format

```

  <xs:restriction base="xs:string">
    <xs:minLength value="1"/>
  </xs:restriction>
</xs:simpleType>
</xs:schema>

```

Transformation

The transformer script performs the following mapping.

Plain XML to Seeder XML Mapping

The payload transformer script does the following:

1. Creates an XML element with a name defined in the SGG Payload Processing Configuration field “IMD Seeder BO (Interval)” and copies all elements from the Plain XML as child nodes of new element.
2. Inserts the “externalId” element populated with value stored in setOrigin method.
3. Inserts the “serviceProviderExternalId” element populated with value stored in setConfiguration method.
4. If the SGG Payload Processing Configuration has the **Populate RAW** checkbox checked, inserts the “rawData” element populated with the textual XML representation of Plain XML element.

Adapter Development Kit Common Information Model (CIM) Payload Processing

This section describes how the Oracle Utilities Smart Grid Gateway Adapter Development Kit can be configured to process payload formats in the Common Information Model (CIM) format.

CIM Payload Processing Introduction and Overview

The Adapter Development Kit supports payload processing of data in the Common Information Model (CIM) format. The CIM formats and standards supported by the Adapter Development Kit are based on the *International Standard* (IEC 61968-9, Edition 2.0), available [here](#). Reference to specific data elements from the CIM usage and event payload formats used in this section are based on this document. Refer to this document for detailed information about the CIM standard and payload formats.

Usage payloads are processed in the same manner as other formats and other adapters. Payload files are sent from a head end system to a file system (for on-premises implementations) or an Oracle Cloud Object Storage location (for cloud services), where they are processed via batch processes. See [Payload Processing](#) for more information about this process and the related configuration. Events can also be processed in this manner.

Event payload can also be processed through an Inbound Web Service, which sends the payload to a file location where it is processed via batch processing. See [Event Processing Inbound Web Service](#) for more information. This approach is most often used when receiving real-time events from a head end system.

This section outlines the specific configuration necessary to process CIM-based payloads.

Creating CIM Payload Processing Extendable Lookup Values

Payload processing of CIM usage and events requires configuration of values for the SGG Payload Processing Configuration extendable lookup. This section outlines the specific configuration for usage and event payload processing extendable lookups for CIM usage and events. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information about this extendable lookup including parameters not listed in this section.

Usage

Extendable lookup values for CIM usage payload processing should include the following parameters:

- **Payload Handler Class Name:** com.splwg.d1.domain.sgg.dg.processing.PayloadHandlerViaUserExits
- **Payload Processing Result Type:** Initial Measurements
- **IMD Seeder BO (Interval):** IMD Seeder (D1-IMDSeeder) (Applicable only If processing interval usage)
- **IMD Seeder BO (Scalar):** IMD Seeder (D1-IMDSeeder) (Applicable only If processing scalar usage)
- **Dynamic Parameters:** As appropriate for your implementation
- **User Exit Interceptors:**

Payload Processing User Exit Type	Groovy Library Script	Groovy Library Method
On Get Parser	DG_CimUPrXML (SGG ADK Generic CIM XML Parser)	getParser
On Get Transformer	DG_CimUTrXML (SGG ADK Generic CIM XML Transformer)	get Transformer

Device Events

Extendable lookup values for CIM event payload processing should include the following parameters:

- **Payload Handler Class Name:** com.splwg.d1.domain.sgg.dg.processing.PayloadHandlerViaUserExits
- **Payload Processing Result Type:** Device Events
- **Device Event Seeder BO:** Device Event Seeder (D1-DeviceEventSeeder)
- **Dynamic Parameters:** As appropriate for your implementation
- **User Exit Interceptors:**

Payload Processing User Exit Type	Groovy Library Script	Groovy Library Method
On Get Parser	DG_CimEvtPr (CIM Events Parser using XMLReader)	getParser
On Get Transformer	DG_CimEvtTr (CIM Events Transformer)	get Transformer

CIM Event Processing Inbound Web Service

Event processing can be handled via the EventMessage operation of the ADK CIM Events and Alarms (DG-CIMEvents) SOAP-based inbound web service. This approach is most often used when a head end system sends real-time events to Smart Grid Gateway.

When invoking this webservice, the event payload should be included in the web service call. Refer to the International Standard document for detailed information about the event data to be included in the web service call.

The ADK CIM Events and Alarms (DG-CIMEvents) service sends the payload to a file location where it is processed via batch processing.

The file location is defined in the **Arrived Data Save Locations** section of the ADK - Master Configuration, which includes the following parameters:

- **File Storage:** A File Storage Configuration (F1-FileStorage) extendable lookup value that defines the staging area to which the payloads will be saved. See **Creating File Storage Extendable Lookup Values** (LINK) for more information.
- **Output Bucket/Folder Name:** The bucket name (if saving to Oracle Object Storage), or a directory below the specified file storage location (if saving to a local file system).
- **Filename Generation Script:** The name of a service script used to compose the filename when saving the incoming payload. The Default Filename Generator (D1DEFFNGEN) script is used by default if not specified.
- **XSL Transformer Template:** The name of an XSL used to create the event payload from the incoming inbound message data. Select the "ADK - CIM EndDeviceEvents Output" (DG-CIMEndDvcEvtsOutput.xsl) XSL.
- **File Extension:** An extension used for the name of the outputted file. It can be specified with or without a leading dot (ex: ".txt" or ".xml").

CIM Payload Processing Data Mapping and Extendable Lookups

Unit of Measure Mapping

Unit of measure mapping is based on the ReadingType string in the CIM payload and uses the ADK - UOM Code to Standard UOM Mapping (DG-HeadendUOMLookup) extendable lookup. Refer to the [International Standard document](#) for detailed information about the ReadingType data element.

For example, a payload with a ReadingType string of "0.0.2.4.1.1.12.0.0.0.0.0.0.0.3.72.0" could be mapped to the "Kilowatt Hour" unit of measure as follows:

- **Head-End Unit of Measure:** 0.0.2.4.1.1.12.0.0.0.0.0.0.0.3.72.0
- **Unit of Measure:** Kilowatt Hour

Interval Size Mapping

Interval size (expressed as seconds per interval or SPI) mapping is based on the measuringPeriod value extracted from the ReadingType string and uses the ADK CIM Measuring Period Lookup (DG-CIMMeasuringPeriodLookup) extendable lookup. The measuringPeriod is the third element in the ReadingType string. Refer to the [International Standard document](#) for detailed information about the measuringPeriod and ReadingType elements.

For example, the measuringPeriod in a payload with a ReadingType string of "0.0.2.4.1.1.12.0.0.0.0.0.0.0.3.72.0" is "2" (the third value in the string). This could be mapped to an SPI of 900 (15 minutes) as follows:

- **Measuring Period:** 2
- **Interval Size:** 00:15:00

Condition Code Mapping

Condition code mapping is based on the ReadingQualityType string in the CIM payload (if present) and uses the the ADK - Interval Sts Code to Cond Map (DG-IntStsCodeToCondMapLookup) extendable lookup. Refer to the [International Standard document](#) for detailed information about the ReadingQualityType data element.

For example, a payload with a ReadingQualityType string of "3.8.8" could be mapped to the "System Estimate" condition code as follows:

- **Interval Status:** 3.8.8
- **Condition:** System Estimate

Event Type Mapping

Event type mapping is based on the EndDeviceEventType string in the CIM payload and uses the the ADK - Device Event Mapping (DG-DeviceEventMappingLookup) extendable lookup. Refer to the [International Standard document](#) for detailed information about the EndDeviceEventType data element.

For example, a payload with a EndDeviceEventType string of "3.12.0.257" could be mapped to the "Tamper Detected" standard event name as follows:

- **Head-End System Event Name:** 3.12.0.257
- **Standard Event Name:** Tamper Detected

CIM Payload Processing Sample Payloads

This section provides sample CIM usage and event payloads. Refer to the [International Standard document](#) for detailed information about the data elements in these examples.

Usage

The following example represents a meter reading containing four KWH interval values and four KW scalar readings.

```

          </end:NameTypeAuthority>
        </end:NameType>
      </end:Names>
    </end:Assets>
    <end:EndDeviceEventType ref="3.12.0.257"/>
  </end:EndDeviceEvent>
</end:EndDeviceEvents>
```

Smart Meter Commands

This section provides information about implementing smart meter commands with native implementations and Oracle Utilities cloud services, including Oracle Utilities Meter Solution Cloud Service.

Device Communication Overview

The basic communication for all business processing is essentially the same. A communication request is sent from the Oracle Utilities application to the head-end system. This request would be for a connect/disconnect, commission/decommission, measurement data, an on-demand read, or another type of request that the head-end system supports. The head-end system receives the message, acts on the request, and returns a reply.

See [Communications](#) in the *Business User Guide*, and [About Communications](#) in the *Administrative User Guide* for basic information about command activities and communications.

Native Implementation Command Processing

When using native implementation of Smart Grid Gateway adapters, including with Oracle Utilities cloud services, command processing works slightly differently than it does in middleware (on-premises) implementations.

The table below provides a brief description of the communication process, and lists example objects used by the Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay. Note that the process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process.

Step	Process	Example Data
1.	A user initiates a remote connect command for a device. A remote connect activity business object is instantiated for the command.	Activity Business Object: Remote Connect (D1-RemoteConnect)

Step	Process	Example Data
2.	<p>The remote connect command activity business object creates an outbound communication.</p> <p>The specific type of outbound communication business object created is determined by the head end system (based on the processing role defined in an Enter algorithm of the “Connection Ready” status of the command activity business object’s lifecycle).</p>	<p>Outbound Communication Business Object: Itron - Reconnect Meter (Remote Connect)</p> <p>(D8-ReconnectMeterDR)</p>
3.	<p>The outbound communication creates an outbound message.</p> <p>The specific type of outbound message created is determined by the head end system (based on the processing role defined in an Enter algorithm of the “Awaiting Response” status of the outbound communication business object’s lifecycle).</p>	<p>Outbound Message Type Business Object: Outbound Message for Itron connect command</p> <p>(D8-ItronRemoteConnectOutbndMsg)</p>
4.	<p>The outbound message is sent to the head end system via an External System, Message Sender, and Outbound Message Type.</p> <p>The head end system sends a synchronous response to acknowledge receipt of the request.</p>	<p>External System: Itron OpenWayHead End System</p> <p>Message Sender: Itron – Remote Connect (D8-Reconnect)</p> <p>Outbound Message Type: Itron – Remote Connect (D8-RemoteConnect)</p>
5.	<p>As the status of the command request is updated, the head end system sends periodic messages.</p> <p>These messages are received by an Inbound Web Service which creates instances of an inbound communication business object.</p> <p>The specific type of inbound communication business object created is determined by the Inbound Web Service.</p>	<p>Inbound Communication Business Object: Itron – StatusChanged</p> <p>(D8-StatusChanged)</p>
6.	<p>When the command request has been completed, it sends a status changed inbound communication with a “Completed” status.</p> <p>This transitions the outbound communication business object to its “Completed” state.</p>	<p>Inbound Communication Business Object: Itron – StatusChanged</p> <p>(D8-StatusChanged)</p>
7.	<p>The remote connect command activity business object creates a “results” outbound communication.</p> <p>The specific type of outbound communication business object created is determined by the head end system (based on the processing role defined in an Enter algorithm of the “Connection Ready” status of the command activity business object’s lifecycle).</p>	<p>Outbound Communication Business Object: Itron - Reconnect Meter Results</p> <p>(D8-ReconnectMeterResultDR)</p>

Step	Process	Example Data
8.	<p>The outbound communication creates an outbound message.</p> <p>The specific type of outbound message created is determined by the head end system (based on the processing role defined in an Enter algorithm of the “Awaiting Response” status of the outbound communication business object’s lifecycle).</p>	<p>Outbound Message Type Business Object: Outbound Message for Itron connect result command</p> <p>(D8-ItronRemoteCntRsltOutMsg)</p>
9.	<p>An Enter Algorithm on the “Evaluate Response” status of the outbound message business object’s lifecycle evaluates the response.</p>	<p>Enter Algorithm: Evaluate Get Reconnect Results Response</p> <p>(D8-EVGRCMRST)</p>
10.	<p>The “result” outbound communication creates a completion event to update the status of the device to indicate it has been connected.</p> <p>The specific type of completion event business object created is specified in an Enter algorithm on the “Create Completion Event” Status of the outbound communication business object’s lifecycle.</p>	<p>Algorithm: Create Connect Completion Event from Result</p> <p>(D8-CRCNCER)</p> <p>Completion Event Business Object: Connect Device</p> <p>(D1-ConnectDevice)</p>
11.	<p>The outbound communication updates the “Connect/Disconnect Completion Flag” and the original activity business object.</p> <p>This update is performed by an Enter algorithm on the “Completed” Status of the outbound communication business object’s lifecycle.</p>	

In the case of commands that also request usage readings, such as On Demand Read or Scheduled Read, usage readings are sent separately via DataArrived messages separately to the DataSubscriberService Inbound Web Service, where they can be routed to Object storage for payload processing.

Smart Meter Command Flows

This section provides information about the smart meter command flows used by supported Smart Grid Gateway adapters.

Itron OpenWay Command Flows

The table below lists the communication flows used with each Itron OpenWay command, including:

- **Command:** The specific smart meter command
- **Outbound Communication:** The outbound communication business object created by the command. This sends the command request to the head end system.
 - **Result Outbound Communication** The outbound communication business object used to request the result of a command request
- **Inbound Communication:** The inbound communication created by the response from the head end system
- **Completion Event:** The completion event(s) triggered by the command, if any. Completion events are used to update data in the system as a result of a smart meter command. For example, if a command changes the status of a device, the completion event is responsible for making that change.

Command	Outbound Communication	Inbound Communication	Completion Event
Device Commissioning	Itron - Add Meter Definition (Commission) (D8-AddMeterDefinitionsDR)		Device Commissioning Completion Event
Device Decommissioning	Itron - Deregister Meter (Decommission) (D8-DeregisterMeterDR)		Device Decommissioning Completion Event
Remote Connect	Itron - Reconnect Meter (Remote Connect) (D8-ReconnectMeterDR) Result: Itron - Reconnect Meter Result (D8-ReconnectMeterResultDR)	Itron - StatusChanged (D8-StatusChanged)	Connect Device Completion Event
Remote Disconnect	Itron - Meter Remote Disconnect (D8-DisconnectMeterDR) Result: Itron - Disconnect Meter Result (D8-DisconnectMeterResultDR)	Itron - StatusChanged (D8-StatusChanged)	Disconnect Device Completion Event
On-Demand Read (Scalar)	Itron - Contingency Read (Scalar) (D8-ReadScalarDR) Result: Itron - On Demand Read Result (D8-ReadOnDemandReadResultDR)	Itron - StatusChanged (D8-StatusChanged)	Create IMD Completion Event
On-Demand Read (Interval)	Itron - Contingency Read (Interval) (D8-ReadIntervalDR) Result: Itron - On Demand Read Result (D8-ReadOnDemandReadResultDR)	Itron - StatusChanged (D8-StatusChanged)	Create IMD Completion Event
Scheduled Read (Scalar)	Itron - Interrogate By Group (D8-InterrogateByGroupDR) Result: Itron - Interrogate by Group Results (D8-InterrogateByGroupResultDR)	Itron - StatusChanged (D8-StatusChanged)	Create IMD Completion Event
Scheduled Read (Interval)	Itron - Interrogate By Group (D8-InterrogateByGroupDR) Result: Itron - Interrogate by Group Results (D8-InterrogateByGroupResultDR)	Itron - StatusChanged (D8-StatusChanged)	Create IMD Completion Event
Device Status Check	Itron - Ping By Endpoints (Status Check) (D8-PingByEndpointsDR)	Itron - StatusChanged (D8-StatusChanged)	

Command	Outbound Communication	Inbound Communication	Completion Event
	Result: Itron - Ping By Endpoints Result (D8- PingByEndpointsResultDR)		
Multi-Device Status Check	Itron – Ping By Endpoints Multi-Device (D8-PingByEndpointsMultiDvcDR)	Itron – StatusChanged (D8-StatusChanged)	
	Result: Itron – Ping By Endpoints Multi Dvc Result (D8- PingByEndpointsMDResultDR)		
Load Check	Itron – Detect Load Side Voltage (D8-DetectLoadSideVltgeByMtrDR)	Itron – StatusChanged (D8-StatusChanged)	
	Result: Itron – Detect Load Side Voltage Result (D8- DetLoadSideVoltageMtrRsltDR)		
Read Disconnect State	Itron - Read Disconnect State (D8-ReadDisconStateByMtrDR)	Itron – StatusChanged (D8-StatusChanged)	
	Result: Itron - ReadDisconnectStateByMeter Result (D8-ReadDisconStByMtrResultDR)		

Landis+Gyr Command Flows

The table below lists the communication flows used with each Landis+Gyr command, including:

- **Command:** The specific smart meter command
- **Outbound Communication:** The outbound communication business object created by the command. This sends the command request to the head end system.
- **Inbound Communication:** The inbound communication created by the response from the head end system
- **Completion Event:** The completion event(s) triggered by the command, if any. Completion events are used to update data in the system as a result of a smart meter command. For example, if a command changes the status of a device, the completion event is responsible for making that change.

Command	Outbound Communication	Inbound Communication	Completion Event
Device Commissioning	L+G Add Meter to Inventory(MultiSpeak) (D3-AddMeterToInventryMultiSpDR)		Device Commissioning Completion Event
Device Decommissioning	L+G Meter Remove Notification (MultiSpeak) (D3-MtrRmvNotifMultiSpeakDR)		Device Decommissioning Completion Event
Meter Retire	L+G Meter Retire Notification (D3-MeterRetireNotificationDR)		
Meter Exchange	L+G Meter Exchange Notification (D3-MeterExNotificatnMultiSpDR)		

Command	Outbound Communication	Inbound Communication	Completion Event
Remote Connect	L+G Initiate Connect Disconnect DR (D3-InitiateConnectDisconnectDR)	Con/Discon State Change Notif- Direct Route (D3-ConnectDisconStateChgNtfDR)	Connect Device Completion Event
Remote Disconnect	L+G Initiate Connect Disconnect DR (D3-InitiateConnectDisconnectDR)	Con/Discon State Change Notif- Direct Route (D3-ConnectDisconStateChgNtfDR)	Disconnect Device Completion Event
Demand Reset	L+G Schedule Demand Reset (Multispeak) (D3-ScheduleDemandResetDR)	Reading Changed Notification Direct Route (D3-ReadingChgNotificationDR)	
On-Demand Read (MultiSpeak)	L+G MultiSpeak Initiate Meter Read By Meter Num Direct Route (D3-InitiateMRByMtrNbrDR)	Reading Changed Notification Direct Route (D3-ReadingChgNotificationDR)	Create IMD Completion Event
On-Demand Read (Interval) [CIM]	CIM Meter On Demand Read Direct Route (Interval) (D3-CIMGetLPDataDR)	CIM AsyncReply MeterReads Direct Route (D3- CIMAsyncReplyMeterReadingDR)	Create IMD Completion Event
On-Demand Read (Scalar) [CIM]	CIM Meter On Demand Read Direct Route (Scalar) (D3-CIMMeterOnDemandReadDR)	CIM AsyncReply MeterReads Direct Route (D3- CIMAsyncReplyMeterReadingDR)	Create IMD Completion Event
Device Status Check	CIM Ping Direct Route (D3-CIMPingDR)	CIM AsyncReply MeterReads Direct Route (D3- CIMAsyncReplyMeterReadingDR)	

Unit of Measure Filtering for On-Demand Reads

Readings returned via On-Demand Read commands are filtered on the combination of Unit of Measure/Time of Use/Service Quantity Identifiers (UOM/TOU/SQI) configured for the device and measuring component. When filtering is enabled, only readings that match a configured UOM/TOU/SQI combination are processed. All others are filtered out.

Filtering is enabled by default via the “Opt Out Of Filtering” parameter (set to "false" by default) on the D3-CRRCCEDR (Create IMD Completion Event -Direct Route) algorithm on the Create Completion Events status of the D3-ReadingChgNotificationDR (L+G Reading Changed Notification Direct Route) business object.

The D3-VALDVCFDR (Check if Device has any Filtering errors Direct Route) algorithm on the Validate status of the D3-ReadingChgNotificationDR business object is used to check for errors related to filtering. The value of the “Opt Out Of Filtering” parameter on this algorithm must match the value of the same parameter on the D3-CRRCCEDR algorithm. The “Opt Out Of Filtering” parameter should both be set to either "false" (the default) or "true" (if filtering is to be disabled).

CIM Commands

For CIM-based on-demand read commands, filtering is enabled by default via the “Opt Out Of Filtering” parameter (set to "false" by default) on the D3-CRCIMCE (Create CIM Completion Event Direct Route) algorithm on the Create

Completion Events status of the D3-CIMAsyncReplyMeterReadingDR (CIM AsyncReply MeterReads Direct Route) business object.

The D3-VALCCIMCE (Check if Device has Filtering errors CIM Completion Event Direct Route) algorithm on the Validate status of the D3-CIMAsyncReplyMeterReadingDR (CIM AsyncReply MeterReads Direct Route) business object is used to check for errors related to filtering. The value of the “Opt Out Of Filtering” parameter on this algorithm must match the value of the parameter on the D3-CRCIMCE algorithm. The parameters should both be set to either "false" (the default) or "true" (if filtering is to be disabled).

Sensus Command Flows

The table below lists the communication flows used with each Sensus command, including:

- **Command:** The specific smart meter command
- **Outbound Communication:** The outbound communication business object created by the command. This sends the command request to the head end system.
- **Inbound Communication:** The inbound communication created by the response from the head end system
- **Completion Event:** The completion event(s) triggered by the command, if any. Completion events are used to update data in the system as a result of a smart meter command. For example, if a command changes the status of a device, the completion event is responsible for making that change.

Command	Outbound Communication	Inbound Communication	Completion Event
Device Commissioning	Sensus -Meter Add Notification Direct Route (D6-MeterAddNotificationDR)		Device Commissioning Completion Event
Device Decommissioning	Sensus -Meter Remove Notification Direct Route (D6-MeterRemoveNotificationDR)		Device Decommissioning Completion Event
Remote Connect	Sensus - Initiate Conn Discon - DR (D6-InitiateConnectDisconnectDR)	Sensus Conn/Discon State Chg Direct Route (D6-ConnectDisconStateChgNtfDR)	Connect Device Completion Event
Remote Disconnect	Sensus - Initiate Conn Discon - DR (D6-InitiateConnectDisconnectDR)	Sensus Conn/Discon State Chg Direct Route (D6-ConnectDisconStateChgNtfDR)	Disconnect Device Completion Event
On-Demand Read (MultiSpeak)	Sensus - Initiate Meter Read By Meter ID (D6-InitiateMeterByMeterIdDR)	Sensus - Reading Changed Notification (D6-ReadingChgNotificationDR)	Create IMD Completion Event
Device Status Check	Sensus Initiate Outage Detection DR (D6-InitiateOutageDetectionDR)	Sensus Outage Detect Event Notif Direct Route (D6-ODEventNotificationDR)	

Unit of Measure Filtering for On-Demand Reads

Readings returned via On-Demand Read commands are filtered on the combination of Unit of Measure/Time of Use/Service Quantity Identifiers (UOM/TOU/SQI) configured for the device and measuring component. When filtering is enabled, only readings that match a configured UOM/TOU/SQI combination are processed. All others are filtered out.

Filtering is enabled by default via the “Opt Out Of Filtering” parameter (set to "false" by default) on the D6-CCOMPEVDR (Create IMD Completion Event Direct Route) algorithm on the Create Completion Events status of the D6-ReadingChgNotificationDR (Sensus - Reading Changed Notification DR) business object.

The D6-VALDVCFDR (Check if Device has any Filtering errors Direct Route) algorithm on the Validate status of the D6-ReadingChgNotificationDR business object is used to check for errors related to filtering. The value of the "Opt Out Of Filtering" and "Xpath to External UOM" parameters on this algorithm must match the values of the same parameters on the D6-CCOMPEVDR algorithm. The "Opt Out Of Filtering" parameters should both be set to either "false" (the default) or "true" (if filtering is to be disabled).

Silver Spring Networks Command Flows

The table below lists the communication flows used with each Silver Spring Networks command, including:

- **Command:** The specific smart meter command
- **Outbound Communication:** The outbound communication business object created by the command. This sends the command request to the head end system.
 - **Get Status Outbound Communication:** The outbound communication business object used to request the status of a command request
 - **Result Outbound Communication:** The outbound communication business object used to request the result of a command request
- **Outbound Messages:** The outbound message business objects for one or more outbound messages created by the outbound communication. These should be configured on the Silver Spring Networks external system.
- **Completion Event:** The completion event(s) triggered by the command, if any. Completion events are used to update data in the system as a result of a smart meter command. For example, if a command changes the status of a device, the completion event is responsible for making that change.

Command	Outbound Communication	Outbound Messages	Completion Event
Device Commissioning (see Note below)	SSN - Replace Location (D7-ReplaceLocationDR)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg) Replace Location: SSN - Replace Location (Comm) OB Message (D7-ReplaceLocationOBMsg)	Device Commissioning Completion Event
Device Decommissioning	SSN - Replace Device At Location (Decomm) (D7-ReplDeviceAtLocForDecommDR)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg) Replace Device at Location: SSN - Replace Device At Loc O/B Message: (D7-ReplaceDeviceAtLocOBMsg)	Device Decommissioning Completion Event
Remote Connect	SSN - Add Remote Provisioning Job - Polling (D7-AddRemoteProvJobDRP)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg) Connect Disconnect: SSN - Connect Disconnect OB Message (D7-ConnectDisconnectOBMsg)	Connect Device Completion Event

Command	Outbound Communication	Outbound Messages	Completion Event
Remote Disconnect	Get Status: SSN - Get Job Status for Polling (D7-GetJobStatusDRP)	SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)	Disconnect Device C Event
	Result: SSN - Connect Disconnect Results (D7-ConnectDisconnectResultDR)	SSN - GetConnectDisconnectResult OB Message (D7-GetCntDiscntResultOBMsg)	
	SSN - Add Remote Provisioning Job - Polling (D7-AddRemoteProvJobDRP)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg)	
		Connect Disconnect: SSN - Connect Disconnect OB Message (D7-ConnectDisconnectOBMsg)	
On-Demand Read (Scalar)	Get Status: SSN - Get Job Status for Polling (D7-GetJobStatusDRP)	SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)	Create IMD Comple
	Result: SSN - Connect Disconnect Results (D7-ConnectDisconnectResultDR)	SSN - GetConnectDisconnectResult OB Message (D7-GetCntDiscntResultOBMsg)	
	SSN - Add Mtr Read Job (Scalar) - Polling (D7-AddMeterReadJobScalarDRP)	Find Device: SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg)	
		Add Meter Read Job Scalar: SSN - Add Meter Read Job Scalar OB Msg Type (D7-AddMeterReadJobScalarOBMsg)	
	Get Status: SSN - Get Job Status for Polling (D7-GetJobStatusDRP)	SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)	
	Result: SSN - Meter Read Results (Scalar) (D7-MeterReadResultsScalar)	SSN - GetMeterReadResults(Scalar) By JobId (D7-GetSclrMtrRdRstByJobIdOBMsg)	

Command	Outbound Communication	Outbound Messages	Completion Event
On-Demand Read (Interval)	<p>SSN - Add Mtr Read Job (Interval) - Polling (D7-AddMeterReadJobIntervalDRP)</p> <p>Get Status: SSN - Get Job Status for Polling (D7-GetJobStatusDRP)</p> <p>Result: SSN - Meter Read Results (Interval) (D7-MeterReadResultsInterval)</p>	<p>Find Device:</p> <p>SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg)</p> <p>Add Meter Read Job Interval: SSN - AddMeterReadJob Interval OB Msg Type (D7-AddMeterReadJobIntervalOBMsg)</p> <p>SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)</p> <p>SSN - GetMeterReadResults(Interval) By JobId (D7-GetIntMtrRdRsltByJobIdOBMsg)</p>	Create IMD Comple
Device Status Check	<p>SSN - Add Ping Job - Polling (D7-AddPingJobDRP)</p> <p>Get Status: SSN - Get Job Status for Polling (D7-GetJobStatusDRP)</p> <p>Result: SSN - Ping Results (D7-PingResultsDR)</p>	<p>Find Device:</p> <p>SSN - Find Device Outbound Message (D7-FindDeviceOutboundMsg)</p> <p>Add Ping Job:</p> <p>SSN - Add Ping Job OB Message (D7-AddPingJobOBMsg)</p> <p>SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)</p> <p>SSN - Get Ping Results O/B Message (D7-GetPingResultsOBMsg)</p>	

Note: Service points must be provisioned in the Silver Spring Networks (Itron AMM) system before the Device Commissioning command can be used.

Configuring Communication Types for Job Status Polling

The following outbound communication business objects (from the table above) all have corresponding communication types that must be configured before outbound communications based on those business objects can be created. The table below lists the communication type business objects used with each.

Outbound Communication Business Object	Communication Type Business Object
SSN - Add Remote Provisioning Job - Polling (D7-AddRemoteProvJobDRP)	SSN - Add Remote Prov Job Polling DR Type (D7-AddRemoteProvDRPType)

Outbound Communication Business Object	Communication Type Business Object
SSN - Add Mtr Read Job (Scalar) - Polling (D7-AddMeterReadJobScalarDRP)	SSN - Add Meter Read Job (Scalar) Polling DR Type (D7-AddMeterReadJobScalrDRPType)
SSN - Add Mtr Read Job (Interval) - Polling (D7-AddMeterReadJobIntervalDRP)	SSN - Add Meter Read Job (Interval) Polling DR Type (D7-AddMeterReadJobIntDRPType)
SSN - Add Ping Job - Polling (D7-AddPingJobDRP)	SSN - Add Ping Job Polling DR Type (D7-AddPingJobDRPType)
Get Job Status for Polling (D7-GetJobStatusDRP)	SSN - Get Job Status Polling DR Type (D7-GetJobStatusDRPType)

Refer to [Communication Types](#) for more information about communication types.

Get Job Status Polling Parameters and Polling Modes

The **Get Job Status Polling** parameters on these communication types are used to define how polling works with outbound communications of the corresponding type. These include **Retry Frequency** parameters (the minimum amount of time (expressed as hours:minutes:seconds) the system will wait between polling iterations for jobs created by communications of this type) and **Maximum Retries** parameters (the maximum number of times the system will try to poll for the status of jobs created by communications of this type), which must be configured in order to use these outbound communications.

There are two modes of polling:

- **Initial** polling occurs immediately and within the same transaction as any previous portion of the command. This setting is useful when the head end is expected to quickly complete the job (within a few seconds). To use Initial polling, define values for the **Initial Polling Retry Frequency** and **Initial Polling Maximum Retries** parameters.
- **Out of Process** polling occurs within its own transaction triggered either separately by a user or by a batch process. This mode is useful when the head end system is likely to take more than a few seconds to complete the job. The **Polling Retry Frequency** and **Polling Maximum Retries** parameters are used with Out of Process polling. If these parameters are not configured on the communication type, the values defined in the **SSN - Get Job Status Configuration** section of the Silver Spring Networks Version Master Configuration are used in their place.

Refer to the **Get Job Status Polling** embedded help on the above communication types for more information about polling modes and parameters.

Polling and Batch Processing

When a communication enters the "Polling Ready" state, it polls the head end system via a Get Status Outbound Communication. If the initial polling parameters have been exceeded (or the initial polling parameters were not defined), the communication transitions to the "Polling in Progress" state. Communications in this state can be transitioned using the Outbound Communication Polling - Monitor (D7-OCPL) batch process (or the **Poll Job Status** button in the **Outbound Communication** zone in the **Communication** portal.)

If using the Outbound Communication Polling - Monitor (D7-OCPL) batch process, the system should be configured to run the process frequently (every few minutes).

Polling and the creation of Get Job Status outbound communications requires the following "Get Job Status" processing method be defined for the Silver Spring Networks head end system:

- **Processing Role:** Get Job Status
- **Default Business Object:** SSN - Get Job Status for Polling (D7-GetJobStatusDRP)

See [Silver Spring Networks Processing Methods](#) for more information about processing methods used with Silver Spring Networks.

Unit of Measure Filtering for On-Demand Reads

Readings returned via On-Demand Read commands are filtered on the combination of Unit of Measure/Time of Use/Service Quantity Identifiers (UOM/TOU/SQI) configured for the device and measuring component. When filtering is enabled, only readings that match a configured UOM/TOU/SQI combination are processed. All others are filtered out.

Filtering is enabled by default via the “Opt Out Of Filtering” parameter (set to "false" by default) on the D7-CCOMPEVSR (SSN - Create Completion Event Scalar) algorithm on the Create Completion Events status of the D7-MeterReadResultsScalar (SSN - Meter Read Results (Scalar)) business object (for scalar on-demand read commands) and/or on the D7-CCEVTINDR (SSN - Create Completion Event Interval) algorithm on the Create Completion Events status of the D7-MeterReadResultsInterval (SSN - Meter Read Results (Interval)) business object (for interval on-demand read commands).

When filtering is enabled, the “Filter if invalid external MC identifier” parameter on the D7-CCOMPEVSR and D7-CCEVTINDR algorithms controls what should happen if a measuring component cannot be found using the MC Identifier Number sent from the head end system. When set to 'Yes' and no measuring component is found, the initial measurement will be filtered. When set to 'No' and no measuring component is found, the system will attempt to find the measuring component using the UOM and TOU. The value of the “Filter if invalid external MC identifier” on the D7-CCOMPEVSR and D7-CCEVTINDR algorithms must match the value of the “Error if invalid external MC identifier” parameter on the D1-DER-SPRMC algorithm on the IMD Seeder (D1-IMDSeeder) business object. The parameters should both be set to either ‘yes’ or ‘no’.

Deprecated Outbound Communications

The outbound communication business objects listed in the table above replace the following outbound communication business objects, which will be deprecated in a future release.

Command	Deprecated Outbound Communication Business Object
Remote Connect/Remote Disconnect	SSN - Connect or Disconnect (D7-ConnectDisconnectDR)
On-Demand Read (Scalar)	SSN - Add Meter Read Job (Scalar) (D7-AddMeterReadJobScalarDR)
On-Demand Read (Interval)	SSN - Add Meter Read Job (Interval) (D7-AddMeterReadJobIntervalDR)
Device Status Check	SSN - Add Ping Job (D7-AddPingJobDR)

Filtering On-Demand Read Payloads

By default, the On-Demand Read command is initiated for a specific meter (device) and returns readings (measurement data) for each register or channel (measuring component) on the meter. However, in some circumstances, an implementation may not want measurements returned for every channel. For instance, they may only want or need billing-related data, or only a subset of the data recorded by the meter.

Measurement payloads received via On-Demand Read commands can be filtered based on unit of measure (UOM) by adding custom logic to the XLS files used to send and receive On-Demand Read command.

This filtering can be implemented by editing the appropriate XSL to include a variable containing a list of "approved UOMs" list and logic that filters the payload based on the "approved list" variable.

Examples

The lines noted by “<!-- List of approved UOMS -->” and “<!-- UOM Filtering here -->” in the following excerpts from Landis+Gyr XSL files illustrate how the files can be edited to apply UOM filtering.

Head End System XSL Files

The table below lists the XSL files that can be used to filter payloads using this approach for each head end system.

XSL files can be edited using the **Managed Content** portal.

Head End System	XSL	Where Used
Landis+Gyr	D3-CIMMeterReadingRequest.xsl	Inbound Web Service (CIM Service Callback)
Landis+Gyr	D3-ReadingChgNotifRequest.xsl	Inbound Web Service (Reading Changed Notification (Callback))
Sensus	D6-ReadingChgNotifRequest.xsl	Inbound Web Service (Sensus MultiSpeak CB_Server Interface)
Silver Spring Networks	D7-GetMtrRdRsByJobIDResp.xsl	External System Message XSL (provided by implementation)

Sending Outbound Communications

Sending outbound communications to a head end system involves configuring the following entities:

- **Outbound Message Types:** Define how outbound messages of a specific type are handled. Outbound message types are based on a specific outbound message business object that defines the data structure of the message. See [Defining Outbound Message Types](#) in the *Administrative User Guide* and [Creating Outbound Message Types](#) below for more information.
- **Message Senders:** Define details for sending messages to external systems. See [Message Senders](#) in the *Administrative User Guide* for more information.
- **External System:** Defines a set of outbound message types that can be sent to the head end system. See [External Systems](#) in the *Administrative User Guide* for more information.

- **Head End System:** Defines processing rules for the head end system, such as the specific activities and communications created for smart meter commands. See [Head End Systems](#) and [Processing Methods](#) in the *Administrative User Guide* and [Configuration Processing Methods](#) below for more information.

Creating Outbound Message Types

Outbound message types must be configured for each command you plan to use in your implementation. The base package includes a set of outbound message types that can be used. The tables below lists the outbound message types provided for each Smart Grid Gateway adapter.

Itron OpenWay Outbound Message Types

This table lists the outbound message types used with the Itron OpenWay adapter, along with the business objects used with each.

Command	Outbound Message Type / Business Object	“Result” Outbound Message Type / Business Object
Device Commissioning	Itron - Add Meter Definitions O/B Msg Type (D8-AMDOBM)	N/A
	Itron - Commissioning Outbound Message (D8-ItronCommissionOutboundMsg)	
Device Decommissioning	Itron - Deregister Meter O/B Msg Type (D8-DREGOBM)	N/A
	Itron - Decommissioning Outbound Message (D8-ItronDecommissionOutbndMsg)	
Remote Connect	Itron - Reconnect Meter O/B Msg Type (D8-RCNOBM)	Itron - Get Reconnect Meter Result O/B Msg Type (D8-GRCNOBM)
	Itron - Remote Connect Outbound Message (D8-ItronRemoteConnectOutbndMsg)	Itron - Get Remote Connect Results Outbound Message (D8-ItronRemoteCntRsltOutMsg)
Remote Disconnect	Itron - Disconnect Meter O/B Msg Type (D8-DISCOMOBM)	Iron - Get Disconnect Meter Result O/B Msg Type (D8-GDMROBM)
	Itron - Disconnect Outbound Message (D8-ItronRemoteDisconnectOutMsg)	Itron - Get Disconnect Result Outbound Message (D8-ItronRemoteDcntRsltOutMsg)
On-Demand Read (Scalar)	Itron - Contingency Read O/B Msg Type (D8-CRDOBM)	Itron - Get Contingency Read Results O/B Msg Type (D8-GCRDOBM)
	Itron - Contingency Read Outbound Message (D8-ItronOnDemandReadOutbndMsg)	Itron - Get Contingency Read Result Outbound Message (D8-ItronOnDemandReadRsltOBMsg)
On-Demand Read (Interval)	Itron - Contingency Read O/B Msg Type (D8-CRDOBM)	Itron - Get Contingency Read Results O/B Msg Type (D8-GCRDOBM)
	Itron - Contingency Read Outbound Message (D8-ItronOnDemandReadOutbndMsg)	Itron - Get Contingency Read Result Outbound Message (D8-ItronOnDemandReadRsltOBMsg)
Scheduled Read (Scalar)	Itron - Scheduled Read O/B Msg Type (D8-SROBM)	Itron - Get Scheduled Read Result O/B Msg Type (D8-GSRROBM)
	Itron - Schedule Read Outbound Message (D8-ItronInterrogateByGrpOBMsg)	Itron - Get Schedule Read Result Outbound Message (D8-ItronInterrogateByGrpRsltOB)

Command	Outbound Message Type / Business Object	“Result” Outbound Message Type / Business Object
Scheduled Read (Interval)	Itron - Scheduled Read O/B Msg Type (D8-SROBM)	Itron - Get Scheduled Read Result O/B Msg Type (D8-GSRROBM)
	Itron - Schedule Read Outbound Message (D8-ItronInterrogateByGrpOBMsg)	Itron - Get Schedule Read Result Outbound Message (D8-ItronInterrogateByGrpRsltOB)
Device Status Check	Itron - Ping By Endpoints O/B Msg Type (D8-DSCOBM)	Itron - Get Ping By Endpoints Result O/B Msg Type (D8-GDSCROBM)
	Itron - Device Status Check Outbound Message (D8-ItronDvcStatusChkOutbndMsg)	Itron - Get Device Status Check Result Outbound Message (D8-ItronDvcStatusChkRsltOBMsg)
Multi-Device Status Check	Itron - Multi Ping By Endpoints O/B Msg Type (D8-MDSCOBM)	Itron - Get Multi Ping By Endpoints Result O/B Msg Type (D8-GMDSCOBM)
	Itron - Multi Device Status Check Outbound Message (D8-ItronDvcStChkMtDvcOutbndMsg)	Itron - Get Multi Device Status Check Result Outbound Message (D8-ItronDvcStChkMtDvcRsltOBMsg)
Load Check	Itron - Detect Load Side Voltage O/B Msg Type (D8-DLSVOBM)	Itron - Get Detect Load Side Voltage Results O/B Msg Type (D8-GDLSVOBM)
	Itron - Detect Load Side Voltage Outbound Message	Itron - Get Detect Load Side Voltage Result Outbound Message
	(D8-ItronDetectLoadSideVolOBMsg)	(D8-ItronDetLSVoltMtrRsltOutMsg)

Landis+Gyr Outbound Message Types

This table lists the outbound message types used with the Landis+Gyr adapter, along with the business objects used with each.

Command	Outbound Message Type / Business Object
Device Commissioning	Add Meter to Inventory (L+G) (D3-AMIOMTYP)
	LG - Add Meter To Inventory OB Message (D3-AddMeterToInventoryOBMsg)
Device Decommissioning	Notify Remove Meter (L+G) (D3-MRENOMTYP)
	LG - Meter Remove Notification OB Message (D3-MeterRemoveNotifOBMsg)
Meter Retire	Notify Retire Meter (L+G) (D3-MRNOMTYP)
	LG - Meter Retire Notification OB Message (D3-MeterRetireNotifOBMsg)
Meter Exchange	Notify Exchange Meter (L+G) (D3-MENOBMTYP)
	LG - Meter Exchange Notification OB Message (D3-MeterExchNotificatnOBMsg)
Remote Connect	Initiate Connect Disconnect by Meter Number (L+G) (D3-INCODIOBM)
	LG Initiate Connect Disconnect OB Message (D3-InitConnectDisconnectOBMsg)

Command	Outbound Message Type / Business Object
Remote Disconnect	Initiate Connect Disconnect by Meter Number (L+G) (D3-INCODIOBM) LG Initiate Connect Disconnect OB Message (D3-InitConnectDisconnectOBMsg)
Demand Reset	Schedule Demand Reset (L+G) (D3-SDROMTYP) LG - Schedule Demand Reset OB Message (D3-ScheduleDemandResetOBMsg)
On-Demand Read (MultiSpeak)	Initiate Read by Meter Number (L+G) (D3-INMRMNOBM) L+G MultiSpeak InitiateMeterReadByMeterNumber OB Message (D3-InitMtrReadByMtrNumOBMsg)
On-Demand Read (Interval) [CIM]	Initiate On-Demand Read (CIM L+G) (D3-CIMODR) CIM AMIRequest GetMeterReads OB Message (D3-CIMAMIRequestGetMtrRdOBMsg)
On-Demand Read (Scalar) [CIM]	Initiate On-Demand Read (CIM L+G) (D3-CIMODR) CIM AMIRequest GetMeterReads OB Message (D3-CIMAMIRequestGetMtrRdOBMsg)
Device Status Check	Initiate Device Status Check (CIM L+G) (D3-CIMDSC) CIM AMIRequest GetMeterReads OB Message (D3-CIMAMIRequestGetMtrRdOBMsg)

Sensus Outbound Message Types

This table lists the outbound message types used with the Sensus adapter, along with the business objects used with each.

Command	Outbound Message Type / Business Object
Device Commissioning	Notify Add Meter (Sensus) (D6-SMANOMTYP) Sensus - Meter Add Notification OB Message (D6-MeterAddNotificationOBMsg)
Device Decommissioning	Notify Remove Meter (Sensus) (D6-SMRNOMTY) Sensus -Meter Remove Notification OB Msg (D6-MeterRemoveNotificatnOBMsg)
Remote Connect	Initiate Connect Disconnect by Meter Number (Sensus) (D6-INCODIOBM) Sensus Initiate Connect Discon OB Message (D6-InitConnectDisconnectOBMsg)

Command	Outbound Message Type / Business Object
Remote Disconnect	Initiate Connect Disconnect by Meter Number (Sensus) (D6-INCODIOBM) Sensus Initiate Connect Discon OB Message (D6-InitConnectDisconnectOBMsg)
On-Demand Read (MultiSpeak)	Initiate Read by Meter Id (Sensus) (D6-SIMROMTY) Sensus - Initiate Meter Read By MtrID OBMsg (D6-InitMtrRdMtrIdOBMsg)
Device Status Check	Initiate Outage Detection (Sensus) (D6-SIODTOMTY) Sensus InitiateOutageDetection OB Message (D6-InitOutageDetectionOBMsg)

Silver Spring Networks Outbound Message Types

This table lists the outbound message types used with the Silver Spring Networks adapter, along with the business objects used with each.

Command	Outbound Message Type / Business Object	“Result” Outbound Message Type / Business Object
Device Commissioning	Replace Location (Commission SSN) (D7-RLOCOBMTY) SSN - Replace Location (Comm) Outbound Message (D7-ReplaceLocationOBMsg)	N/A
Device Decommissioning	Replace Device (Decommission SSN) (D7-RDVCOBMTY) SSN - Replace Device At Loc O/B Message (D7-ReplaceDeviceAtLocOBMsg)	N/A
Remote Connect	Connect Disconnect Device (SSN) (D7-CDCOBMTYP) SSN - Connect Disconnect OB Message (D7-ConnectDisconnectOBMsg)	Get Connect Disconnect Result (SSN) (D7-GCDROBMTY) SSN - GetConnectDisconnectResult OB Message (D7-GetCntDiscentResultOBMsg)
Remote Disconnect	Connect Disconnect Device (SSN) (D7-CDCOBMTYP) SSN - Connect Disconnect OB Message (D7-ConnectDisconnectOBMsg)	Get Connect Disconnect Result (SSN) (D7-GCDROBMTY) SSN - GetConnectDisconnectResult OB Message (D7-GetCntDiscentResultOBMsg)
On-Demand Read (Scalar)	Add Scalar Read Job (SSN) (D7-AMRJSCOBT) SSN - Add Meter Read Job Scalar OB Message (D7-AddMeterReadJobScalarOBMsg)	Get Scalar Read Results by Job Id (SSN) (D7-GMRRBJOMT) SSN - GetMeterReadResults(Scalar) OB Message (D7-GetSclrMtrRdRstByJobIdOBMsg)

Command	Outbound Message Type / Business Object	“Result” Outbound Message Type / Business Object
On-Demand Read (Interval)	Add Interval Read Job (SSN) (D7-AMRJINOBT) SSN - AddMeterReadJob Interval OB Message (D7-AddMtrReadJobIntervalOBMsg)	Get Interval Read Results by Job Id (SSN) (D7-GIMRRJOMT) SSN - GetMeterReadResults(Interval) OB Message (D7-GetIntMtrRdRsltByJobIdOBMsg)
Device Status Check	Add Meter Ping Job (SSN) (D7-APJOBM) SSN - Add Ping Job OB Message (D7-AddPingJobOBMsg)	Get Device Ping Job Results (SSN) (D7-GPJROM) SSN - Get Ping Results O/B Message (D7-GetPingResultsOBMsg)

Creating Message Senders

You must create message senders for each outbound communication that will be sent to the head end system as part of the command communication process.

Note: When creating message senders as part of the command communication process used with Smart Grid Gateway adapters, the **HTTP URL** must point to the appropriate server and head end system version. If an implementation has more than one version of a given head end system, each can have its own server and URL.

Note: When creating message senders as part of the command communication process used with native implementations, the **Message Class** MUST be set to **SOAPSNDR** (Sender for real-time HTTP / SOAP messages).

See [Message Senders](#) in the *Administrative User Guide* for more information about creating message senders.

Creating an External System

You must create an external system that represents the head end system and defines a set of outbound message types that can be sent to the head end system.

External System Outbound Message Types

You must configure an outbound message type on the external system for each type of message you will send to the head end system. An external system’s outbound message types are defined by the following:

- **Outbound Message Type:** The outbound message type created for the message (see [Creating Outbound Message Types](#))
- **Processing Method:** The method by which the message will be sent. This should be set to “Real-time” Smart Grid Gateway outbound communications.
- **Message Sender:** The message sender created for the message (see [Creating Message Senders](#))
- **Message XSL / Response XSL:** XSL files used to transform your message and the response to the message into the appropriate format used by the head end system (Message XSL) and Smart Grid Gateway (Response XSL). Each Smart Grid Gateway adapter includes XSL files for each type of outbound communication.

See [External Systems](#) in the *Administrative User Guide* for more information about creating external systems.

Itron OpenWay XSL Files

The table below lists the XSL provided for use with outbound message types based on the outbound message business objects provided with the Itron OpenWay adapter.

Outbound Message Business Object	Message XSL	Response XSL
Outbound Message for Itron Commission (D8-ItronCommissionOutboundMsg)	D8-CommissionRequest.xsl	D8-CommissionResponse.xsl

Outbound Message Business Object	Message XSL	Response XSL
Outbound Message for Itron Decommission (D8-ItronDecommissionOutbndMsg)	D8-DecommissionRequest.xml	D8-DecommissionResponse.xml
Outbound Message for Itron connect command (D8-ItronRemoteConnectOutbndMsg)	D8-ReconnectRequest.xml	D8-ReconnectResponse.xml
Outbound Message for Itron connect result command (D8-ItronRemoteCntRsltOutMsg)	D8-GetReconnectRsRequest.xml	D8-GetReconnectRsResponse.xml
Outbound Message for Itron disconnect command (D8-ItronRemoteDisconnectOutMsg)	D8-DisconnectRequest.xml	D8-DisconnectResponse.xml
Outbound Message for Itron disconnect result command (D8-ItronRemoteDcntRsltOutMsg)	D8-GetDisconnectRsRequest.xml	D8-GetDisconnectRsResponse.xml
Outbound Message for Itron Contingency Read command (D8-ItronOnDemandReadOutbndMsg)	D8-ContRdByEndptsRequest.xml	D8-ContRdByEndptsResponse.xml
O/B Msg for Itron Contingency Read Result (D8-ItronOnDemandReadRsltOBMsg)	D8-GetContRdByEndptsRsReq.xml	D8-GetContRdByEndptsRsResp.xml
Outbound Message for Itron Schedule Read command (D8-ItronInterrogateByGrpOBMsg)	D8-InterrogateByGroupReq.xml	D8-InterrogateByGroupResp.xml
Outbound Message for Itron Schedule Read Result command (D8-ItronInterrogateByGrpRsltOB)	D8-GetIntByGroupRsRequest.xml	D8-GetIntByGroupRsResponse.xml
Outbound Message for Itron Device status check (D8-ItronDvcStatusChkOutbndMsg)	D8-PingByEndpointsRequest.xml	D8-PingByEndpointsResponse.xml
O/B Msg for Itron DeviceStatusCheck Result (D8-ItronDvcStatusChkRstlOBMsg)	D8-GetPingByEndptsRsReq.xml	D8-GetPingByEndptsRsResp.xml
Outbound Message for Itron Multi device status check (D8-ItronDvcStChkMtDvcOutbndMsg)	D8-PingByEndpointsRequest.xml	D8-PingByEndpointsResponse.xml

Outbound Message Business Object	Message XSL	Response XSL
O/B Message for Itron MultiDeviceStatusCheck Result (D8-ItronDvcStChkMtDvcRsltOBMsg)	D8-GetPingByEndptsRsReq.xml	D8-GetPingByEndptsRsResp.xml
Outbound Message for Itron Detect Load Side Voltage (D8-ItronDetectLoadSideVolOBMsg)	D8-DetLSVByMeterRequest.xml	D8-DetLSVByMeterResponse.xml
Outbound Message for LoadCheckResult Cmd (D8-ItronDetLSVoltMtrRsltOutMsg)	D8-GetDetLSVByMeterRsReq.xml	D8-GetDetLSVByMeterRsResp.xml
Outbound Message for Itron Read Disconnect State D8-ItronReadDisconStateOutMsg	D8-RdDiscStByMtrsRequest.xml	D8-RdDiscStByMtrsResponse.xml
Outbound Message for ReadDisconStateMeter Cmd D8-ItronRdDiscStByMtrRsltOutMsg	D8-GetRdDiscStByMtrsRsReq.xml	D8-GetRdDiscStByMtrsRsResp.xml

Landis+Gyr XSL Files

The table below lists the XSL provided for use with outbound message types based on the outbound message business objects provided with the Landis+Gyr adapter.

Outbound Message Business Object	Message XSL	Response XSL
LG - Add Meter To Inventory OB Message D3-AddMeterToInventoryOBMsg	D3-AddMtrToInvRequest.xml	D3-AddMtrToInvResponse.xml
LG - Meter Remove Notification OB Message D3-MeterRemoveNotifOBMsg	D3-MtrRemoveNotfRequest.xml	D3-MtrRemoveNotfResponse.xml
LG - Meter Retire Notification OB Message D3-MeterRetireNotifOBMsg	D3-MtrRetireNotfRequest.xml	D3-MtrRetireNotfResponse.xml
LG -Meter Exchange Notification OB Message D3-MeterExchNotificatnOBMsg	D3-MtrExcNotifRequest.xml	D3-MtrExcNotifResponse.xml
L+G Initiate Connect Disconnect OB Message D3-InitConnectDisconnectOBMsg	D3-InitiateConnDisconReq.xml	D3-InitiateConnDisconResp.xml
LG - Schedule Demand Reset OB Message D3-ScheduleDemandResetOBMsg	D3-ScheduleDemandRstReq.xml	D3-ScheduleDemandRstResp.xml

Outbound Message Business Object	Message XSL	Response XSL
L+G MultiSpeak InitiateMeterReadByMeterNumber OB Message D3-InitMtrReadByMtrNumOBMsg	D3-InitMtrRdMtrNumRequest.xml	D3-InitMtrRdMtrNumResponse.x
CIM AMIRequest GetMeterReads OB Message D3-CIMAMIRequestGetMtrRdOBMsg	D3-CIMGetMtrReadsRequest.xml	D3-CIMGetMtrReadsResponse.x

Sensus XSL Files

The table below lists the XSL provided for use with outbound message types based on the outbound message business objects provided with the Sensus adapter.

Outbound Message Business Object	Message XSL	Response XSL
Sensus - Meter Add Notification OB Message D6-MeterAddNotificationOBMsg	D6-MtrAddRemoveNotifReq.xml	D6-MeterAddNotifResponse.xml
Sensus -Meter Remove Notification OB Msg (D6-MeterRemoveNotificatnOBMsg)	D6-MtrAddRemoveNotifReq.xml	D6-MeterAddNotifResponse.xml
Sensus Initiate Connect Discon OB Message (D6-InitConnectDisconnectOBMsg)	D6-InitiateConnDisconReq.xml	D6-InitiateConnDisconResp.xml
Sensus Initiate Connect Discon OB Message (D6-InitConnectDisconnectOBMsg)	D6-InitiateConnDisconReq.xml	D6-InitiateConnDisconResp.xml
Sensus MultiSpeak InitiateMeterReadByMeterNumber OB Message (D6-InitMtrRdMtrIdOBMsg)	D6-InitMtrRdMtrIdRequest.xml	D6-InitMtrRdMtrIdResponse.xml
Sensus InitiateOutageDetection OB Message (D6-InitOutageDetectionOBMsg)	D6-InitOutDetectRequest.xml	D6-InitOutDetectResponse.xml

Silver Spring Networks XSL Files

The table below lists the XSL provided for use with outbound message types based on the outbound message business objects provided with the Silver Spring Networks adapter.

Outbound Message Business Object	Message XSL	Response XSL
SSN - Find Device Outbound Message D7-FindDeviceOutboundMsg	D7-FindDeviceRequest.xml	D7-FindDeviceResponse.xml

Outbound Message Business Object	Message XSL	Response XSL
SSN - Get Job Status Outbound Message D7-GetJobStatusOutboundMsgType	D7-GetJobStatusRequest.xml	D7-GetJobStatusResponse.xml
SSN - Replace Location (D7-ReplaceLocationDR)	D7-ReplaceLocationRequest.xml	D7-ReplaceLocationResponse.xml
SSN - Replace Device At Location (Decomm) (D7-ReplDeviceAtLocForDecommDR)	D7-RepDvcAtLocRequest.xml	D7-RepDvcAtLocResponse.xml
SSN - Connect or Disconnect (D7-ConnectDisconnectDR)	D7-AddRemProvJobRequest.xml	D7-AddRemProvJobResponse.xml
SSN - Connect Disconnect Results (D7-ConnectDisconnectResultDR)	D7-GetRemProvRsByJobIDReq.xml	D7-GetRemProvRsByJobIDResp.xml
SSN - Add Meter Read Job Scalar OB Msg D7-AddMeterReadJobScalarOBMsg	D7-AddMtrRdJobScRequest.xml	D7-AddMtrRdJobScResponse.xml
SSN - GetMeterReadResults(Scalar) By JobId D7-GetSclrMtrRdRstByJobIdOBMsg	D7-GetMtrRdRsByJobIDReq.xml	D7-GetMtrRdRsByJobIDResp.xml
SSN - AddMeterReadJob Interval OB Msg D7-GetIntMtrRdRsltByJobIdOBMsg	D7-AddMtrRdJobIntRequest.xml	D7-AddMtrRdJobIntResponse.xml
SSN - GetMeterReadResults(Interval) By JobId D7-GetIMtrRdRsltJobIdOBMsgTyp	D7-GetMtrRdRsByJobIDReq.xml	D7-GetMtrRdRsByJobIDResp.xml
SSN - Add Ping Job (D7-AddPingJobDR)	D7-AddPingJobRequest.xml	D7-AddPingJobResponse.xml
SSN - Ping Results (D7-PingResultsDR)	D7-GetMtrRdRsByJobIDReq.xml	D7-GetMtrRdRsByJobIDResp.xml

Configuring Processing Methods

In order to send smart meter commands to a head end system, appropriate processing methods must be configured on the head end system record. The tables below list the details appropriate to configuring processing methods for each command.

This table includes the following:

- **Command:** The command you wish to configure. When a command is initiated for a device, the system creates a command activity.
- **Processing Role:** The Processing Role appropriate for the command to be configured.
- **Business Object:** The outbound communication business object to be created by the command activity. Note that most commands have separate business objects for the initial command request and the result request.

- **Outbound Message Business Object** The business object that should be used when creating outbound message types for each command. Note that most commands use separate business objects for the initial outbound message type and the result outbound message type.

Itron OpenWay Processing Methods

This table lists the details appropriate to configuring processing methods for each command supported for the Itron OpenWay head end system.

Command	Processing Role	Business Object	Outbound Message Business Object
Device Commissioning	Device Registration	Itron - Add Meter Definition (D8-AddMeterDefinitionsDR)	Outbound Message for Itron Commissioning command D8-ItronCommissionOutboundMsg
Device Decommissioning	Device Deregistration	Itron - Deregister Meter (D8-DeregisterMeterDR)	Outbound Message for Itron Decommissioning command D8-ItronDecommissionOutboundMsg
Remote Connect	Remote Connect	Itron - Reconnect Meter (Remote Connect) D8-ReconnectMeterDR)	Outbound Message for Itron connect command D8-ItronRemoteConnectOutboundMsg
	Get Remote Connect Result	Itron - Reconnect Meter Result (D8-ReconnectMeterResult)	Outbound Message for Itron connect result command (D8-ItronRemoteCntRsltOutMsg)
Remote Disconnect	Remote Disconnect	Itron - Disconnect Meter (D8-DisconnectMeterDR)	Outbound Message for Itron disconnect command D8-ItronRemoteDisconnectOutboundMsg
	Get Remote Disconnect Result	Itron - Disconnect Meter Result (D8-DisconnectMeterResult)	Outbound Message for Itron disconnect result command (D8-ItronRemoteDcntRsltOutMsg)
On-Demand Read (Scalar)	On-Demand Read (Scalar)	Itron - Contingency Read (Scalar) (D8-ReadScalarDR)	Outbound Message for Itron Contingency Read command D8-ItronOnDemandReadOutboundMsg
	Get On-Demand Read Result	Itron - On Demand Read Result (D8-ReadOnDemandReadResultDR)	O/B Msg for Itron Contingency Read Result (D8-ItronOnDemandReadRsltOBMsg)
On-Demand Read (Interval)	On-Demand Read (Interval)	Itron - Contingency Read (Interval) (D8-ReadIntervalDR)	Outbound Message for Itron Contingency Read command (D8-ItronOnDemandReadOutboundMsg)
	Get On-Demand Read Result	Itron - On Demand Read Result (D8-ReadOnDemandReadResultDR)	O/B Msg for Itron Contingency Read Result (D8-ItronOnDemandReadRsltOBMsg)
Scheduled Read (Scalar)	Send Schedule Read Request	Itron - Interrogate by Group (Scalar) (D8-InterrogateByGroupDR)	Outbound Message for Itron Schedule Read command (D8-ItronInterrogateByGrpOBMsg)

Command	Processing Role	Business Object	Outbound Message Business Object
Scheduled Read (Interval)	Get Schedule Read Result	Itron - Interrogate by Group Results (D8- InterrogateByGroupResultDR)	Outbound Message for Itron Schedule Read command (D8-ItronInterrogateByGrpRsltOB)
	Send Schedule Read Request	Itron - Interrogate by Group (Interval) (D8-InterrogateByGroupDR)	Outbound Message for Itron Schedule Read command (D8-ItronInterrogateByGrpOBMsg)
Device Status Check	Get Schedule Read Result	Itron - Interrogate by Group Results (D8- InterrogateByGroupResultDR)	Outbound Message for Itron Schedule Read command (D8-ItronInterrogateByGrpRsltOB)
	Device Status Check	Itron - Ping by Endpoints (Status Check) (D8-PingByEndpointsDR)	Outbound Message for Itron Device status check (D8-ItronDvcStatusChkOutbndMsg)
Multi-Device Status Check	Get Device Status Check Result	Itron - Ping By Endpoints Result (D8- PingByEndpointsResultDR)	O/B Msg for Itron DeviceStatusCheck Result (D8-ItronDvcStatusChkRsltOBMsg)
	Multi-Device Status Check	Itron - Ping By Endpoints Multi-Device (D8-PingByEndpointsMultiDvcDR)	Outbound Message for Itron Multi device check (D8-ItronDvcStChkMtDvcOutbndMsg)
Load Check	Get Multi-Device Status Check Result	Itron – Ping By Endpoints Multi Dvc Result (D8- PingByEndpointsMDResultDR)	O/B Message for Itron MultiDeviceStatus Result (D8-ItronDvcStChkMtDvcRsltOBMsg)
	Load Check	Itron - Detect Load Side Voltage (D8-DetectLoadSideVoltageByMtrDR)	Outbound Message for Itron Detect Load Voltage (D8-ItronDetectLoadSideVolOBMsg)
	Get Load Check Results	Itron – Detect Load Side Voltage Result (D8- DetLoadSideVoltageMtrRsltDR)	Outbound Message for LoadCheckResult (D8-ItronDetLSVoltMtrRsltOutMsg)

Landis+Gyr Processing Methods

This table lists the details appropriate to configuring processing methods for each command supported for the Landis +Gyr head end system.

Command	Processing Role	Business Object	Outbound Message Business Object
Device Commissioning	Device Registration	L+G Add Meter to Inventory(MultiSpeak) (D3-AddMeterToInventoryMultiSpDR)	LG - Add Meter To Inventory OB Message D3-AddMeterToInventoryOBMsg
Device Decommissioning	Device Removal	L+G Meter Remove Notification (MultiSpeak) (D3-MtrRmvNotifMultiSpeakDR)	LG - Meter Remove Notification OB Message (D3-MeterRemoveNotifOBMsg)

Command	Processing Role	Business Object	Outbound Message Business Object
Meter Retire	Device Deregistration	L+G Meter Retire Notification (D3-MeterRetireNotificationDR)	LG - Meter Retire Notification OB Messa (D3-MeterRetireNotifOBMsg)
Meter Exchange	Device Installation	L+G Meter Exchange Notification (D3-MeterExNotificatnMultiSpDR)	LG -Meter Exchange Notification OB Me (D3-MeterExchNotificatnOBMsg)
Remote Connect	Remote Connect	L+G Initiate Connect Disconnect DR (D3-InitiateConnectDisconnectDR)	L+G Initiate Connect Disconnect OB Mes (D3-InitConnectDisconnectOBMsg)
Remote Disconnect	Remote Disconnect	L+G Initiate Connect Disconnect DR (D3-InitiateConnectDisconnectDR)	L+G Initiate Connect Disconnect OB Mes (D3-InitConnectDisconnectOBMsg)
Demand Reset	Demand Reset	L+G Schedule Demand Reset (Multispeak) (D3-ScheduleDemandResetDR)	LG - Schedule Demand Reset OB Messag (D3-ScheduleDemandResetOBMsg)
On-Demand Read (MultiSpeak)	On-Demand Read (Scalar)	L+G MultiSpeak Initiate Meter Read By Meter Num Direct Route (D3-InitiateMRByMtrNbrDR)	L+G MultiSpeak InitiateMeterReadByMeterNumber OB M (D3-InitMtrReadByMtrNumOBMsg)
On-Demand Read (Interval) [CIM]	On-Demand Read (Interval)	CIM Meter On Demand Read Direct Route (Interval) (D3-CIMGetLPDataDR)	CIM AMIRequest GetMeterReads OB M (D3-CIMAMIRequestGetMtrRdOBMsg)
On-Demand Read (Scalar) [CIM]	On-Demand Read (Scalar)	CIM Meter On Demand Read Direct Route (Scalar) (D3-CIMMeterOnDemandReadDR)	CIM AMIRequest GetMeterReads OB M (D3-CIMAMIRequestGetMtrRdOBMsg)
Device Status Check	Device Status Check	CIM Ping Direct Route (D3-CIMPingDR)	CIM AMIRequest GetMeterReads OB M (D3-CIMAMIRequestGetMtrRdOBMsg)

Sensus Processing Methods

This table lists the details appropriate to configuring processing methods for each command supported for the Sensus head end system.

Command	Processing Role	Business Object	Outbound Message Business Object
Device Commissioning	Device Registration	Sensus -Meter Add Notification Direct Route (D6-MeterAddNotificationDR)	Sensus - Meter Add Notification OB Mess D6-MeterAddNotificationOBMsg
Device Decommissioning	Device Removal	Sensus -Meter Remove Notification Direct Route (D6-MeterRemoveNotificationDR)	Sensus -Meter Remove Notification OB M (D6-MeterRemoveNotificatnOBMsg)
Remote Connect	Remote Connect	Sensus - Initiate Conn Discon - DR (D6-InitiateConnectDisconnectDR)	Sensus Initiate Connect Discon OB Messa (D6-InitConnectDisconnectOBMsg)

Command	Processing Role	Business Object	Outbound Message Business Object
Remote Disconnect	Remote Disconnect	Sensus - Initiate Conn Discon - DR (D6-InitiateConnectDisconnectDR)	Sensus Initiate Connect Discon OB Messa (D6-InitConnectDisconnectOBMsg)
On-Demand Read (MultiSpeak)	On-Demand Read (Scalar)	Sensus - Initiate Meter Read By Meter ID (D6-InitiateMeterByMeterIdDR)	Sensus MultiSpeak InitiateMeterReadByMeterNumber OB M (D6-InitMtrRdMtrIdOBMsg)
Device Status Check	Device Status Check	Sensus Initiate Outage Detection DR (D6-InitiateOutageDetectionDR)	Sensus InitiateOutageDetection OB Messa (D6-InitOutageDetectionOBMsg)

Silver Spring Networks Processing Methods

This table lists the details appropriate to configuring processing methods for each command supported for the Silver Spring Networks head end system.

Command	Processing Role	Business Object	Outbound Message Business Object
Device Commissioning	Device Registration	SSN - Replace Location (D7- ReplaceLocationDR)	SSN - Replace Location (Comm) OB Mes (D7-ReplaceLocationOBMsg)
Device Decommissioning	Device Removal	SSN - Replace Device At Location (Decomm) (D7- ReplDeviceAtLocForDecommDR)	SSN - Replace Device At Loc O/B Messa ReplaceDeviceAtLocOBMsg)
Remote Connect	Remote Connect	SSN - Add Remote Provisioning Job - Polling (D7-AddRemoteProvJobDRP)	SSN - Connect Disconnect OB Message (ConnectDisconnectOBMsg)
	Get Remote Connect Result	SSN - Connect Disconnect Results (D7- ConnectDisconnectResultDR)	SSN - GetConnectDisconnectResult OB M (D7-GetCntDiscntResultOBMsg)
Remote Disconnect	Remote Disconnect	SSN - Add Remote Provisioning Job - Polling (D7-AddRemoteProvJobDRP)	SSN - Connect Disconnect OB Message (ConnectDisconnectOBMsg)
	Get Remote Disconnect Result	SSN - Connect Disconnect Results (D7- ConnectDisconnectResultDR)	SSN - GetConnectDisconnectResult OB M (D7-GetCntDiscntResultOBMsg)
On-Demand Read (Scalar)	On-Demand Read (Scalar)	SSN - Add Mtr Read Job (Scalar) - Polling (D7-AddMeterReadJobScalarDRP)	SSN - Add Meter Read Job Scalar OB Ms D7-AddMeterReadJobScalarOBMsg)
	Get On-Demand Read Result (Scalar)	SSN - Meter Read Results (Scalar) (D7-MeterReadResultsScalar)	SSN - GetMeterReadResults(Scalar) By J (D7-GetSMtrRdRsltJobIdOBMsgTyp)
On-Demand Read (Interval)	On-Demand Read (Interval)	SSN - Add Mtr Read Job (Interval) - Polling (D7-AddMeterReadJobIntervalDRP)	SSN - AddMeterReadJob Interval OB Ms (D7-AddMtrReadJobIntervalOBMsg)
	Get On-Demand Read Result (Interval)	SSN - Meter Read Results (Interval) (D7-MeterReadResultsInterval)	SSN - GetMeterReadResults(Interval) By (D7-GetIMtrRdRsltJobIdOBMsgTyp)

Command	Processing Role	Business Object	Outbound Message Business Object
Device Status Check	Device Status Check	SSN - Add Ping Job - Polling (D7-AddPingJobDRP)	SSN - Add Ping Job OB Message (D7-AddPingJobOBMsg)
	Get Device Status Check Result	SSN - Ping Results (D7-PingResultsDR)	SSN - Get Ping Results O/B Message (D7-GetPingResultsOBMsg)
Get Job Status	Get Job Status	SSN - Get Job Status for Polling (D7-GetJobStatusDRP)	SSN - Get Job Status Outbound Message (D7-GetJobStatusOutboundMsg)

Receiving Inbound Communications

Receiving inbound communications from a head end system involves configuring the following:

- **Inbound Web Services:** These services are used to receive inbound communications from external systems. See [Inbound Web Services](#) in the *Administrative User Guide* for more information.
- **Master Configurations:** Defines configuration settings for individual adapters.

Inbound Web Services

Inbound web services are used to receive inbound communications from external systems. The tables below list the inbound web services provided with each Smart Grid Gateway adapter.

Itron OpenWay Inbound Web Services

The table below lists the inbound web service provided with the Itron OpenWay adapter.

Name	Description
D8-RequestStatusChangedService	<p>Itron RequestStatusChangedService: Use to receive “status changed” messages from the Itron OpenWay head end system.</p> <p>This service creates instances of the “Itron – StatusChanged” (D8-StatusChanged) inbound communication business object for each message.</p>
D8-DataSubscriberService	<p>Itron DataSubscriberService: Used to receive usage and device event payloads from the Itron OpenWay head end system.</p> <p>This service invokes the “Itron – DataArrived Request” (D8_DATAARR) service script, which invokes the ItronDataArrivedStreamProcessor business component to process the usage or device event payload based on the configuration of the Itron Master Configuration, the SGG Payload Processing Configuration extendable lookup, and the File Storage extendable lookup.</p>
D8-EventSubscriberService	<p>Itron EventSubscriberService: Used to receive device event payloads from the Itron OpenWay head end system.</p> <p>This service invokes the “Itron – EventsArrived Request” (D8_EVENTSARR) service script, which invokes the ItronEventsArrivedStreamProcessor business component to process the device event payload based on the configuration of the Itron Master Configuration, the SGG Payload Processing Configuration extendable lookup, and the File Storage extendable lookup.</p>

Name	Description
D8-ExceptionSubscriberService	<p>Itron ExceptionSubscriberService: Used to receive exceptions from the Itron OpenWay head end system.</p> <p>This service invokes the “Itron – ExceptionsArrived Request” (D8_EXCPARR) service script, which invokes the ItronExceptionsArrivedStreamProcessor business component to process the exception based on the configuration of the Itron Master Configuration, the SGG Payload Processing Configuration extendable lookup, and the File Storage extendable lookup.</p>

Landis+Gyr Inbound Web Services

The table below lists the inbound web services provided with the Landis+Gyr adapter.

Name	Schema Name	Request / Response XSL
CD State Changed Notification (Callback) (D3-CB_CD)	D3-ConnectDisconStateChgNtfDR	D3-ConDisconStateChgNtfReq.xsl D3-ConDisconStateChgNtfResp.xsl
Reading Changed Notification (Callback) (D3-CB_MR)	D3-ReadingChgNotificationDR	D3-ReadingChgNotifRequest.xsl D3-ReadingChgNotifResponse.xsl
CIM Service Callback (D3-CIMCallback)	D3-CIMAsyncReplyMeterReadingDR	D3-CIMMeterReadingRequest.xsl D3-CIMMeterReadingResponse.xsl
Schedule Demand Response (Multispeak) (D3-ScheduleDemandResetResponse)	D3-ReadingChgNotificationDR	D3-ReadingChgNotifRequest.xsl D3-ReadingChgNotifResponse.xsl

Sensus Inbound Web Services

The table below lists the inbound web services provided with the Sensus adapter.

Name	Schema Name	Request / Response XSL
Reading Changed Notification (Callback) (D6-CB_MR)	D6-ReadingChgNotificationDR	D6-ReadingChgNotifRequest.xsl D6-ReadingChgNotifResponse.xsl
Sensus MultiSpeak CB_Server Interface (D6-CB_Server)	D6-ConnectDisconStateChgNtfDR	D6-ConDisconStateChgNtfReq.xsl D6-ConDisconStateChgNtfResp.xsl
	D6-ReadingChgNotificationDR	D6-ReadingChgNotifRequest.xsl D6-ReadingChgNotifResponse.xsl

Name	Schema Name	Request / Response XSL
Sensus MultiSpeak OA_Server Interface (D6-OA_Server)	D6-ODEventNotificationDR	D6-ODEventNotifRequest.xml D6-ODEventNotifResponse.xml
Unsolicited Event Response D6-UnsolicitedEventNotification	D6-UnsolicitedEvtNotification	

Adapter Development Kit - Creating Custom Commands

This section describes how the Oracle Utilities Smart Grid Gateway Adapter Development Kit can be configured to support custom smart meter commands, including those from non-supported head end systems.

This includes:

- An overview of the data and objects used by smart meter commands
- A description and example of synchronous commands
- A description and example of asynchronous commands

Overview

This section provides an overview of how smart meter commands work and the types of objects used in executing commands when implementing Smart Grid Gateway adapters using native implementations and with Oracle Utilities cloud services.

As noted in [Device Communication Overview](#), command processing works slightly differently than it does in middleware implementations. That section provides an introduction to command processing in Smart Grid Gateway adapters, and the **Native Implementation Command Processing** section provides a step-by-step description of the various data and objects created as part of command processing.

The remainder of this section provides additional details regarding the three primary types of data and objects used with smart meter command processing:

- Command Activities
- Outbound Communications
- Inbound Communications

Command Activities

Smart meter commands are managed by activities. Activities orchestrate one or more communications and execute any completion events associated with the command.

Key Algorithms

This section outlines some of the important algorithms executed as part of the command activity's lifecycle.

Some algorithms are directly shared by multiple business objects and multiple lifecycle states. In other cases, unique algorithms will perform the same role across business objects. The following section refers to the algorithms generically.

Lifecycle State	Algorithms
Validate	<p>The Validate state is an opportunity to check whether the command should execute.</p> <ul style="list-style-type: none"> • Check Device Command Eligibility: Checks whether the command request is eligible for the device by calling the Determine Eligible Commands Business Service (D1-DetermineEligibleCommands). The command request is considered eligible if it exists in the eligible commands list returned by the business service. • Validate Head End's Capability to Perform Activity: This algorithm checks to ensure that the head end system has the capability to support the command requested. It accomplishes this by invoking the Determine Service Providers and Methods Business Service. • Check for Existing Active Request: This algorithm looks for non-Final Activities with the same Device and of the same type. This prevents duplicate requests from being sent to the head end system.
Validation Error	<p>If the Activity fails validation, it transitions to the Validation Error state. From this state the activity can be retried and create To Do entriesto notify users of the error.</p> <ul style="list-style-type: none"> • Retry BO In Error: Reprocesses the BO by transitioning it to its original state. • Create To Do Entry for BO in Error: This algorithm attempts to create a To Do entry using the To Do type and role specified by the algorithm parameters. • Generic To Do Completion for BOs: This algorithm completes all To Do entries with Drill Keys = Current Business Object's prime keys except for To Do Types with Characteristic Type and Value as specified by algorithm parameters. This prevents the existence of multiple To Do entries for the same command and device.
Waiting For Effective Date	<p>Prior to sending the request to the head end system, the activity enters this state.</p> <ul style="list-style-type: none"> • Wait Time Out - Transition to Rejection: This algorithm rejects the business object if the expiration date time has been reached. • Wait for Effective Date: When the required date is reached, this algorithm transitions the business object to the next configured state. • Send Response to External Requester: This algorithm sends an acknowledging received response outbound message to the requester if the business object is configured to do so.
Connection Ready	<p>The Connection Ready state shows that the activity can be executed and creates the proper outbound communication business object. This state can be re-entered when there are multiple outbound communications that are required by the head end system's API.</p> <ul style="list-style-type: none"> • Create Outbound Communication: This algorithm creates an outbound communication instance if the value of the completion flag specified by an algorithm parameter is false. • Create Results Outbound based on Completion Flag: This algorithm triggers a secondary communication to the head end system based on the value of an algorithm parameter. Typically, this indicates the successful completion of an initial outbound communication.

Lifecycle State	Algorithms
Communication In Progress	<p>This lifecycle state indicates that an outbound communication is in-progress.</p> <ul style="list-style-type: none"> • Wait Time Out - Transition to Exception: If the business object has been in the In Progress state too long, this algorithm transitions the business object to an exception state. • Check Children Communications: If all of the outbound communication business object instances related to this activity have completed, the algorithm transitions the business object to the next state.
Communication Error	<p>An error-handling lifecycle state to which the business object transitions when the communication encounters a problem. The algorithms are similar to those in the Validation Error state.</p> <ul style="list-style-type: none"> • Wait Time Out - Transition to Rejection: If the business object has been in the In Progress state too long, this algorithm transitions the business object to a rejection state. • Retry BO In Error: This algorithm reprocesses the business object by transitioning it to its original state. • Create To Do Entry for BO in Error: This algorithm attempts to create a To Do entry using the To Do type and role specified by the algorithm parameters. • Generic To Do Completion for BOs: This algorithm completes all To Do entries with Drill Keys = Current Business Object's prime keys except for To Do Types with Characteristic Type and Value as specified by algorithm parameters. This prevents the existence of multiple To Do entries for the same command and device
Retry	<p>The lifecycle state responsible for discarding existing outbound communications and transitioning the activity back to Connection Ready.</p>
Execute Completion Events	<p>This lifecycle state collates the information acquired by the communications and creates some result. For example, in a DeviceStatusCheck, the overall results are set.</p> <ul style="list-style-type: none"> • Execute Completion Events: Fires the completion events associated with the activity.
Completion Event Error	<p>This is another error-handling state similar to the Validation Error and the Communication Error states. The algorithms are the same as in those states.</p>
Completed	<p>This is the final state representing a successful activity. Finishing tasks are performed and external requesters are notified.</p>
Discarded	<p>Similarly to the Completed state, the Discarded state finishes the activity and indicates an overall failure. External requesters are notified of the failure and other finishing tasks are performed.</p>

Outbound Communications

Outbound Communications represent the business logic of sending a request and receiving a reply. Outbound communication business objects are based on the D1-COMMOUT maintenance object. The outbound communication is not the actual message, but creates the outbound message. Outbound communication business objects used with native implementations are suffixed with “-DR” for “direct route” to indicate the request go straight to the head end system.

Schema

This section provides details concerning outbound communication business object schemas.

Outbound communication schemas typically have a “sendDetail” element corresponding to the data being sent to the head end system, or more precisely, the XSL handler for the outbound message. The synchronous response is transformed by the XSL handler and placed into the “responseDetail” element.

Key Algorithms

This section outlines some of the important algorithms executed as part of the outbound communication’s lifecycle.

Some algorithms are directly shared by multiple business objects and multiple lifecycle states. In other cases, unique algorithms will perform the same role across business objects. The following section refers to the algorithms generically.

Lifecycle State	Algorithms
Validate	<p>Similar to the activity, the Validate state houses algorithms that will execute prior to sending the message.</p> <ul style="list-style-type: none"> Validate Communication Type: This algorithm ensures the communicationType field is populated on the message.
Validation Error	<p>If the Validate state encounters an error, the business object transitions to this state. The algorithms are similar to those in the activity business object.</p>
Awaiting Response	<p>The Awaiting Response state sends an outbound message and awaits the response.</p> <ul style="list-style-type: none"> Populate Send Detail: Each outbound communication has a specific algorithm to populate all the schema elements that are required to create the outbound message. Create Outbound Message: This algorithm creates a specific outbound message based on the Processing Role. The response is stored in the responseDetails element. Timeout: This algorithm detects whether a communication has been waiting for an asynchronous response too long.
Retry	<p>The lifecycle state responsible for transitioning the outbound communication back to Awaiting Response.</p>
Response Error	<p>The business object enters the Response Error state when an error has occurred in sending the request. It contains algorithms for creating To Do entries and for retrying similar to the activity’s Communication Error state.</p>
Completed	<p>This is the final state representing a successful outbound communication. Finishing tasks such as setting flags for use by subsequent communications and notifying the parent activity of completion are performed.</p>
Discarded	<p>Includes an algorithm that transfers the parent activity to Failed.</p>

Inbound Communications

Inbound communication business objects are based on the D1-COMMIN maintenance objects. Inbound Communication objects have a much less defined schema since they are driven by the needs of the head end system’s API and those of the business process. As with outbound communications, the schema does not represent the exact message, but is the post-processed XSL result.

Key Algorithms

This section outlines some of the important algorithms executed as part of the inbound communication's lifecycle.

Some algorithms are directly shared by multiple business objects and multiple lifecycle states. In other cases, unique algorithms will perform the same role across business objects. The following section refers to the algorithms generically.

Lifecycle State	Algorithms
Validate	<p>Similar to the activity, the Validate state houses algorithms that will execute as the message is created.</p> <ul style="list-style-type: none"> • Validate Communication Type: This algorithm ensures the communicationType field is populated on the message. • Find Parent Outbound Communication for Async Inbound: This algorithm is responsible for linking the incoming message with the original outbound communication using, for example, a transaction ID. This algorithm is what causes an inbound communication to be linked with a larger process.
Validation Error	<p>If the Validate state encounters an error, the business object transitions to this state. The algorithms are similar to those in the activity business object.</p>
Evaluate Response	<p>The Evaluate Response state processes the inbound communication in the context of an "asynchronous response." The algorithms should perform any required update tasks such as setting flags on the parent outbound communication.</p>
Completed	<p>This successful end state for inbound communications should transition the parent outbound communication to the next state. This typically completes the outbound communication and may trigger the activity to create a subsequent outbound communication.</p>
Discarded	<p>The parent outbound communication should transition to a failure state. This will also place the activity into the Communication Error state where it will await corrections or a Retry attempt.</p>

Synchronous Commands

Synchronous commands, also known as "request-reply" commands, are single HTTP transactions with an initial request followed by a response. The request will contain whatever information is necessary to complete the command, such as meter identifiers or dates. The reply will contain any results generated by the command. It could be a simple acknowledgement or a complex data structure. In general, it will return quickly as HTTP transactions will fail if the response does not arrive quickly enough.

Example: Itron Commissioning Process

This section provides an example of a synchronous command, the commission device command supported by the Itron OpenWay adapter.

The Itron OpenWay 3.9 command for registering a meter (commissioning a device) in the system is AddMeterDefinitions in the `www.itron.com.ami.2008.10.provisioning.wsdl` definition. The Smart Grid Gateway Adapter for Itron OpenWay typically sends a meter serial number and some other configuration data. The response indicates whether or not an error was encountered.

The image below illustrates the process flow used by this command.

Itron AddMeterDefinitions

Below is a summary of the important features of the Smart Grid Gateway implementation of this command. Many of the concepts can be applied when creating a custom synchronous command.

Command Activity — Device Commissioning

Business Object: D1-DeviceCommissioning

Lifecycle and Algorithms

The table below outlines some of the important algorithms used by the Device Commissioning command activity.

Lifecycle State	Algorithms
Validate	<p>The important features here are not the specific algorithms, but rather the ability to perform validation logic at a process level.</p> <ul style="list-style-type: none"> • D1-VALDVCNAC – Validate Device Not Already Commissioned: This algorithm checks whether the device is already commissioned • D1-VHPCOMMS – Validate Head-End's Capability to Commission Device: This algorithm checks to ensure that the head-end system has the capability to support the command requested. Some commands may not be supported by every head end system. • D1-CACTCOMM – Check for Existing Active Commissioning Command Request: This algorithm prevents multiple, simultaneous commands from being issued by SGG. • D1-CHKFDCOMM – Check for Concurrent Decommissioning Command Request: This algorithm prevents a commissioning request from executing when there is a current decommissioning request.
Commission Ready	<p>Several algorithms in this state are designed to create outbound communications to the head end system based on various conditions.</p> <ul style="list-style-type: none"> • D1-AMIOBCOMM – AMI Device Identifier Outbound Communication Creation: This algorithm creates an outbound message, a communication to the head end system.
Communication In Progress	<ul style="list-style-type: none"> • D1-CHKCHILD – Check Children Communications: This algorithm checks all of the outbound communications related to the activity and, if complete, will transition the activity.
Execute Completion Events	<ul style="list-style-type: none"> • D1-EXCMPEVTS – Execute Completion Events: This algorithm provides a mechanism for running completion events upon successful completion of the commissioning operation.

Outbound Communication — Itron - Add Meter Definition (Commission)

Business Object: D8-AddMeterDefinitionsDR

Schema

The portions of the schema that contain the payload of the web service request and response communications are the `sendDetail` element (constructed using the D8-AddMeterDefinitionsDRDA data area) and the `responseDetail` element (constructed using the D8-AddMeterDefRespDRDA data area). The XSLs used to create or decipher XML conforming to the Itron structure use these elements as a basis.

Lifecycle and Algorithms

The table below outlines some of the important algorithms used by the Add Meter Definition outbound communication.

Lifecycle State	Algorithms
Validate	<ul style="list-style-type: none"> D1-VALCOMTP – Validate Communication Type: This algorithm ensures the communication type is populated on the communication.
Awaiting Response	<ul style="list-style-type: none"> D8-PAMDSDDR – Itron - Populate Add Meter Definitions Send Detail - Direct Route: This algorithm constructs the <code>sendDetails</code> element used in the outbound request. D8-COUTMCMDR – Create Outbound Message for Commissioning / Decommissioning Direct Route: This algorithm determines the correct outbound message to create based upon the input processing role. The reply from the head end system will be stored in the <code>responseDetails</code> element and log entries will be created for the creation of the outbound message and the result (whether it is a success or a failure).
Response Error	<p>The business object will transition to this state if the reply indicates a failure.</p> <ul style="list-style-type: none"> D8-RAMBOE – Itron - Retry Add Meter BO in Error: This algorithm provides a means to retry the communication in the event of an error. D8-CTDEBOEO – Itron - Create To Do Entry for BO in Error for Outbound: This algorithm creates a To Do entry in order to inform a user to take corrective action. D1-ALLOWTPA – Set Allow Transition Parent Activity Flag To True For Synchronous Outbound Communication: This algorithm conditionally allows the parent activity to transition to complete.
Create Completion Event	<ul style="list-style-type: none"> D8-CRCDCOMPE – Itron - Create Commission Device Completion Event: This algorithm creates a completion event to show the device as commissioned.
Completed	<ul style="list-style-type: none"> D8-UCCFTPA – Itron - Update Commission Completion Flag: This algorithm notifies the parent command activity that the communication has completed.

Message Sender XSLs

Outbound messages created by Add Meter Definition outbound communication use the following XSL files:

- **Request XSL:** D8-CommissionRequest.xml
- **Response XSL:** D8-CommissionResponse.xml

Refer to [Creating Message Senders](#) on page 993 for more information about creating message senders.

Itron Commissioning XSL Transformations

The Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay supports multiple versions of the Itron OpenWay API. To achieve this support, several of the request XSLs check a version number embedded in the source

schema. Similarly, the responses XSLs are designed to handle different source XML and map the values to the common SGG format.

The Itron commissioning process uses the following XSL transformations.

D8-CommissionRequest.xsl

```

Asynchronous Commands

An asynchronous command is actually a collection of two or more synchronous commands. This type of command is useful when more than a few seconds will elapse before results can be collected and returned. A typical use case will begin with a Smart Grid Gateway request to start a job on the head end system. The initial request will contain enough data to initiate the process, such as a meter identifier or a date range. The response usually contains an identifier for the process started on the head end system. At some later time, a request will be initiated by the head end

system. The request will contain the same process identifier so it can be linked to the original request. Some head end systems use this secondary request to indicate the status of the process. Other head end systems send the results of the process in the secondary request. Typically, the response message for either type of secondary request is a functional acknowledgement.

Example: Itron On-Demand Read Process

This section provides an example of an asynchronous command, the On-Demand Read command supported by the Itron OpenWay adapter.

The Itron `www.itron.com.ami.2008.10.data.wsdl` definition contains a series of commands for an On-Demand Read process. The Smart Grid Gateway adapter for Itron OpenWay initiates the process by invoking the `ContingencyReadByEndpoints` method. The reply contains a “request token ID” that identifies the entire flow and will be shared by subsequent communications. On the Itron side, a job for collecting usage and events is configured. To inform the caller (SGG) that the job is starting, Itron sends a `StatusChanged` request (defined in `www.itron.com.ami.2008.10.common.wsdl`) containing “State = Initialized”. Itron sends another `StatusChanged` request to notify SGG that the process of gathering the usage is underway. As the usage is collected, Itron submits one or more `DataArrived` requests to SGG. When Itron has finished making internal requests for usage, it sends a final `StatusChanged` request to SGG. That completion notification informs SGG that it should submit `GetContingencyReadByEndpointsResult`, the reply to which contains information about errors encountered during the process.

The image below illustrates the process flow used by this command.

Below is a summary of the important features of the Smart Grid Gateway implementation of this command. Many of the concepts can be applied when creating a custom synchronous command.

Command Activity — On-Demand Read (Interval)

Business Object: D1-OnDemandReadInterval

Lifecycle and Algorithms

The table below outlines some of the important algorithms used by the On-Demand Read (Interval) command activity.

Lifecycle State	Algorithms
Validate	<p>The important features here are not the specific algorithms, but rather the ability to perform validation logic at a process level.</p> <ul style="list-style-type: none"> • D1-VALDEVMC – Validate that Device has appropriate Measuring Component: This algorithm ensures the device has at least one measuring component whose Measuring Component Type is registered as interval type • D1-VALIDCMD – Validate Headend's capability to perform On Demand Read (Interval): This algorithm checks whether the head end system has the capability to support an on-demand read request. If the command is supported, an outbound communication business object is returned. • D1-CHKMST – Check for existing Measurements: This algorithm checks whether complete measurements for the specified time period exist in the database already.
Connection Ready	<ul style="list-style-type: none"> • D1-CODRIOB – Create Outbound communication for OnDemandRead Interval: This algorithm creates an outbound communication business object based on the Processing Role and algorithm parameters. The algorithm will look up the outbound communication business object defined for the Processing Role parameter and create an instance of that business object. In the case of this business object, the parameter is D1IN and it should create an instance of the D8-ReadIntervalDR business object. <p>Once the Outbound Communication record is created, the Activity business object moves from the Connection Ready state to the Communication In Progress state. When the outbound communication is complete, it moves the Activity to next default state, which is Connection Ready (the activity moves from Communication In Progress <i>back</i> to Connection Ready). The outbound communication will also set the “isOnDemandReadComplete” flag value in the activity business object, in this case, indicating the outbound communication for a particular processing role was created. If the condition is true, the processing moves on to next algorithm.</p> <ul style="list-style-type: none"> • D1-CODRSRTOB – Create On Demand Read Results Outbound based on Completion Flag: This algorithm is the second algorithm in this state responsible for sending outbound communications. If the completion flag passed as a parameter is true, it will create the second outbound communication. In this example, it should create an instance of D8-ReadOnDemandReadResultDR to send a second request to Itron for the results of the Contingency Read operation.
Waiting for Measurement	<ul style="list-style-type: none"> • D1-RIINTM – Retrieve Interval Initial Measurements: This algorithm retrieves the most recent Initial Measurement Data for each interval measuring component for the period of the measurement requested.

Outbound Communication — Itron - Contingency Read (Interval)

Business Object: D8-ReadIntervalDR

Schema

The portions of the schema that contain the payload of the web service request and response communications are the `sendDetail` element (constructed using the D8-ContingencyReadRequestDR data area) and the `responseDetail` element (constructed using the D8-ContingencyReadResponDtIDA data area). The XSLs used to create or decipher XML conforming to the Itron structure use these elements as a basis.

Lifecycle and Algorithms

The table below outlines some of the important algorithms used by the Contingency Read outbound communication.

Lifecycle State	Algorithms
Validate	<ul style="list-style-type: none"> D1-VALCOMTP – Validate Communication Type: This algorithm ensures the communication type is populated on the communication.
Awaiting Response	<ul style="list-style-type: none"> D8-PSDMRSCDR – Itron - Populate Send Detail for ContingencyReadByEndpoints Direct Route: This algorithm populates the <code>sendDetail</code> element with the needed items for the web service input. D8-COUTMINDR – Itron - Create Outbound Message Contingency Read (Interval): This algorithm determines the correct outbound message to create based upon the input processing role. The reply from the head end system will be stored in the <code>responseDetails</code> element and log entries will be created for the creation of the outbound message and the result (whether it is a success or a failure).
Response Error	<ul style="list-style-type: none"> D8-RBORINTER – Itron - Retry Read Interval BO in Error: This algorithm provides a means to retry the communication in the event of an error.
Completed	<ul style="list-style-type: none"> D1-UCFLAGTPA – Update On-Demand Read Completion Flag And Transition Parent Activity: If requirements are met, this algorithm sets the completion flag on the parent activity to “true” and transitions it to the next state.

Inbound Communication — Itron - StatusChanged

Business Object: D8-StatusChanged

This business object handles the inbound StatusUpdate requests. It contains the request token ID created by the initial request. When it receives schema values of “State = Completed” and Result of either Canceled or Success, it triggers the next command in the Activity. For On-DemandRead, the next command is GetContingencyReadByEndpointsResult.

Schema

Unlike other communications containing `sendDetail` or `responseDetail` elements, this business object contains an input element with child elements that map to the those within the StatusChanged XSD definition.

Lifecycle and Algorithms

The table below outlines some of the important algorithms used by the Status Changed Read inbound communication.

Lifecycle State	Algorithms
Validate	<ul style="list-style-type: none"> D8-IDNPOCAA – Find Parent Outbound Communication For Async Inbound: This algorithm finds the initial outbound communication associated with the current inbound communication using the request token id.
Evaluate Response	<ul style="list-style-type: none"> D8-EVALSTCHG – Itron - Evaluate Response for StatusChanged: This algorithm performs a task based on the values of the arriving StatusChanged request. If the Status is Completed and the Result is Success or Failure, the parent outbound communication is completed. This alerts the activity to initiate the next outbound communication.

Outbound Communication — Itron - On Demand Read Result

Business Object: D8-ReadOnDemandReadResultDR

This is the second of two outbound requests within the Itron Contingency Read API. The outbound request submits the request token ID. The response contains error information collected by the Itron server during the execution of the Contingency Read process.

Schema

The portions of the schema that contain the payload of the web service request and response communications are the `sendDetail` element (constructed using the D8-ReadODRRResultRequestDR data area) and the `responseDetail` element (constructed using the D8-ReadODRRResultResponseDR data area). The XSLs used to create or decipher XML conforming to the Itron structure use these elements as a basis.

Lifecycle and Algorithms

The table below outlines some of the important algorithms used by the On-Demand Read Result outbound communication.

Lifecycle State	Algorithms
Awaiting Response	<ul style="list-style-type: none"> D8-PSDODRRDR – Itron - Populate OnDemand Read Result Send Details: This algorithm populate the <code>sendDetail</code> element for the outbound message. Primarily, this consists of the request token ID. D8-CODRROBDR – Create Outbound Message for On Demand Read Result: This algorithm determines the correct outbound message to create based upon the input Processing Role. The reply from the head end system will be stored in the <code>responseDetails</code> element and log entries will be created for the creation of the outbound message and the result (whether it is a success or a failure).
Evaluate Response	<ul style="list-style-type: none"> D8-EVODRRSLT – Create Outbound Message for On Demand Read Result: This algorithm evaluates the response from Itron and determines whether the command was successful or was a failure. D8-VDVCMCDR – Validate if Device has appropriate Measuring Component: This algorithm performs a check to ensure that the reading has a proper measuring component.

Service Script: Itron - DataArrived Request

This Groovy—based service script handles the incoming DataArrived requests. It saves the payload to file storage locations (including Cloud Object Storage buckets in the case of cloud implementations) based on configuration.

Schema

The schema maps closely to the Itron DataArrived message. It includes the D8-DataArrived data area.

Steps

Step 10 Edit Data – Invoke Main Groovy Method

This step shows how to trigger a Groovy script from other OUAF objects. It is similar to a main method in other programming languages. In this case, it is called by an Inbound Web Service method.

Step 20 – Groovy Imports

This step imports other classes needed by the script.

Step 30 – Groovy Members

1. Look up the Master Configuration object
2. Use the Master Configuration to find the File Storage details
 - a. Find the File Adapter type
 - b. Compute a filename using a configured generation script
 - c. Compute a fill URL using the bucket, filename, and other details
3. Use the FileStorageAdapter business service to save the file to the targeted location.

Message Sender XSLs

Outbound messages created by on-demand read outbound communications use the following XSL files:

ContingencyReadByEndpoints

- **Request XSL:** D8-ContingencyReadByEndpointsRequest.xml
- **Response XSL:** D8-ContingencyReadByEndpointsResponse.xml

GetContingencyReadByEndpointsResult

- **Request XSL:** D8-GetContingencyReadByEndpointsResultRequest.xml
- **Response XSL:** D8-GetContingencyReadByEndpointsResultResponse.xml

Refer to [Creating Message Senders](#) on page 993 for more information about creating message senders.

Inbound Web Services

The Itron on-demand read process uses the following inbound web services.

D8-RequestStatusChangedService

- **Operation Name:** StatusChanged
- **Schema Name:** Itron — Status Changed BO
- **Request XSL:** D8-RequestStatusChangedServiceRequest.xml
- **Response XSL:** D8-RequestStatusChangedServiceResponse.xml

D8-DataSubscriberService

- **Operation Name:** DataArrived
- **Schema Name:** Itron — DataArrived Request Script
- **Request XSL:** D8-DataSubscriberServiceRequest.xml
- **Response XSL:** D8-DataSubscriberServiceResponse.xml

Itron On-Demand Read XSL Transformations

The Oracle Utilities Smart Grid Gateway Adapter for Itron OpenWay supports multiple versions of the Itron OpenWay API. To achieve this support, several of the request XSLs check a version number embedded in the source schema. Similarly, the responses XSLs are designed to handle different source XML and map the values to the common SGG format.

The Itron on-demand read process uses the following XSL transformations.

D8-ContRdByEndptsRequest.xml

```
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"

Adapter Development Kit - Common Information Model Commands

This section describes how the Oracle Utilities Smart Grid Gateway Adapter Development Kit can be configured to process smart meter commands in the Common Information Model (CIM) format.

CIM Commands Introduction and Overview

The Adapter Development Kit supports smart meter commands in the Common Information Model (CIM) format. The CIM formats and standards supported by the Adapter Development Kit are based on the International Standard (IEC 61968-9, Edition 2.0), available [here](#). Reference to specific data elements from the CIM command messages used in this section are based on this document. Refer to this document for detailed information about the CIM commands.

Adapter Development Kit CIM Command Flows

The table below lists the communication flows used with Common Information Model (CIM) commands, including:

- **Command:** The specific smart meter command
- **Outbound Communication:** The outbound communication business object created by the command. This sends the command request to the head end system.
- **Inbound Communication:** The inbound communication created by the response from the head end system
- **Completion Event:** The completion event(s) triggered by the command, if any. Completion events are used to update data in the system as a result of a smart meter command. For example, if a command changes the status of a device, the completion event is responsible for making that change.

Command	Outbound Communication	Inbound Communication	Completion Event
Device Status Check	ADK CIM Ping Direct Route (DG-CIMPingDR)	ADK CIM Ping Response Direct Route (DG-CIMPingResponseDR)	
On-Demand Read (Interval) [CIM]	ADK CIM On-Demand Read Direct Route (Interval) (DG-CIMGetMtrReadIntervalDR)	ADK CIM On-Demand Read Response Direct Route (DG-CIMMtrReadResponseDR)	Create IMD Completion Event
On-Demand Read (Scalar) [CIM]	ADK CIM On-Demand Read Direct Route (Scalar) (DG-CIMGetMtrReadScalarDR)	ADK CIM On-Demand Read Response Direct Route (DG-CIMMtrReadResponseDR)	Create IMD Completion Event

Configuring Command Types

The following communication business objects (from the table above) all have corresponding communication types that must be configured before communications based on those business objects can be created. The table below lists the communication type business objects used with each.

Communication Business Object	Communication Type Business Object
ADK CIM Ping Direct Route (DG-CIMPingDR)	ADK - CIM Ping DR Type (DG-CIMPingDRType)

Communication Business Object	Communication Type Business Object
ADK CIM Ping Response Direct Route (DG-CIMPingResponseDR)	ADK - CIM Ping Async Response DR Type (DG-CIMPingResponseDRType)
ADK CIM On-Demand Read Direct Route (Interval) (DG-CIMGetMtrReadIntervalDR)	ADK - CIM On-Demand Read (Interval) DR Type (DG-CIMGetMtrReadIntervalType)
ADK CIM On-Demand Read Direct Route (Scalar) (DG-CIMGetMtrReadScalarDR)	ADK - CIM On-Demand Read (Scalar) DR Type (DG-CIMGetMtrReadScalarType)
ADK CIM On-Demand Read Response Direct Route (DG-CIMMtrReadResponseDR)	ADK - CIM AsyncReply MeterReads DR Type (DG-CIMMtrReadResponseDRType)

Refer to [Communication Types](#) for more information about communication types.

CIM Command Extendable Lookups

Processing of CIM commands requires configuration of values for a number of extendable lookups. This topic outlines the extendable lookups used with processing CIM commands.

Payload Processing Extendable Lookups

Processing of measurement data returned via on-demand read commands requires configuration of values for the following extendable lookups:

- **Unit of Measure Mapping:** Unit of measure mapping is based on the ReadingType string in the CIM payload and uses the ADK - UOM Code to Standard UOM Mapping (DG-HeadendUOMLookup) extendable lookup.
- **Interval Size Mapping:** Interval size (expressed as seconds per interval or SPI) mapping is based on the measuringPeriod value extracted from the ReadingType string and uses the ADK CIM Measuring Period Lookup (DG-CIMMeasuringPeriodLookup) extendable lookup.
- **Condition Code Mapping:** Condition code mapping is based on the ReadingQualityType string in the CIM payload (if present) and uses the the ADK - Interval Sts Code to Cond Map (DG-IntStsCodeToCondMapLookup) extendable lookup.

See [CIM Payload Processing Data Mapping and Extendable Lookups](#) for more information about these extendable lookups.

ADK CIM Header Verb Lookup

The ADK CIM Header Verb Lookup (DG-CIMHeaderVerbLookup) extendable lookup defines values for message type verbs used in CIM messages. Refer to Annex A in the [International Standard document](#) (LINK) for detailed information about verbs. This extendable lookup is pre-populated with values from the International Standard document.

ADK CIM Reply Code Lookup

The ADK CIM Reply Code Lookup (DG-CIMReplyCodeLookup) extendable lookup contains the enumeration of the values in the Reply / Error / Code element in replies from the head end system. The values are defined in Annex B in the [International Standard document](#) (LINK). Values comprise two numbers separated by a dot. Example: ReplyCode = <ReplyCode Category> “.” <ReplyCode Index>

This extendable lookup is pre-populated with values from **Table B.10 – Common enumerations** in the International Standard document.

ADK CIM Reply Result Lookup

The ADK CIM Reply Result Lookup (DG-CIMResponseReplyRsltLookup) extendable lookup contains the enumeration of the values for the Reply.Result value returned from the head end system. This extendable lookup is pre-populated with values from the International Standard document (Refer to Annex B).

ADK CIM Data Source Extendable Lookup

The ADK CIM Data Source Extendable Lookup (DG-DataSourceLookup) extendable lookup is used to map descriptions to data sources defined in the head end system. Each value defined for the CIM Data Source extendable lookup should include the following:

- **Data Source:** The CIM code for the data source
- **Description:** A description of the data source
- **Status:** The status of the lookup value (can be Active or Inactive)

This extendable lookup is pre-populated with two values : AMI and Database.

Sending CIM Command Outbound Communications

This topic describes the configuration required to process (CIM) outbound communications.

Adapter Development Kit CIM Outbound Message Types

Outbound message types must be configured for each command you plan to use in your implementation. The base package includes a set of outbound message types that can be used.

This table lists the outbound message types used with Adapter Development Kit CIM commands, along with the business objects used with each.

Command	Outbound Message Type / Business Object
Device Status Check	ADK - CIM Get MeterReadings (DG-CIMGMR) / ADK CIM GetMeterReads OB Message (DG-CIMGetMtrRdOBMsg)
On-Demand Read (Interval)	ADK - CIM Get MeterReadings (DG-CIMGMR) / ADK CIM GetMeterReads OB Message (DG-CIMGetMtrRdOBMsg)
On-Demand Read (Scalar)	ADK - CIM Get MeterReadings (DG-CIMGMR) / ADK CIM GetMeterReads OB Message (DG-CIMGetMtrRdOBMsg)

See [Outbound Messages](#) in the *Administrative User Guide* for more information about creating message senders.

Adapter Development Kit CIM Message Senders

You must create message senders for each outbound communication that will be sent to the head end system as part of the command communication process.

Note: When creating message senders as part of the command communication process used with native implementations, the Message Class MUST be set to SOAPSNDR (Sender for real-time HTTP / SOAP messages).

See [Message Senders](#) in the *Administrative User Guide* for more information about creating message senders.

Adapter Development Kit CIM External System

You must create an external system that represents the head end system and defines a set of outbound message types that can be sent to the head end system.

Adapter Development Kit CIM XSL Files

The table below lists the XSL provided for use with outbound message types based on the outbound message business objects provided for use with Adapter Development Kit CIM commands.

Outbound Message Type	Outbound Message Business Object	Message XSL	Response XSL
ADK - CIM Get MeterReadings (DG-CIMGMR)	ADK CIM GetMeterReads OB Message (DG-CIMGetMtrRdOBMsg)	DG-CIMGetMtrReadsRequest.xsl	DG-CIMGetMtrReadsResponse.xsl

Adapter Development Kit CIM Processing Methods

In order to send smart meter commands to a head end system, appropriate processing methods must be configured on the head end system record.

This table lists the details appropriate to configuring processing methods for each command used with the Adapter Development Kit.

Command	Processing Role	Business Object	Outbound Message Business Object
Device Status Check	Device Status Check	ADK CIM Ping Direct Route (DG-CIMPingDR)	ADK CIM GetMeterReads OB Message (DG-CIMGetMtrRdOBMsg)
On-Demand Read (Scalar)	On-Demand Read (Scalar)	ADK CIM On-Demand Read Direct Route (Scalar) (DG-CIMGetMtrReadScalarDR)	ADK CIM GetMeterReads OB Message (DG-CIMGetMtrRdOBMsg)
On-Demand Read (Interval)	On-Demand Read (Interval)	ADK CIM On-Demand Read Direct Route (Interval) (DG-CIMGetMtrReadIntervalDR)	ADK CIM GetMeterReads OB Message (DG-CIMGetMtrRdOBMsg)

See [Configuring Processing Methods](#) for more information.

Receiving CIM Command Inbound Communications

Inbound web services are used to receive inbound communications from external systems.

The table below lists the inbound web service provided for use with Adapter Development Kit CIM commands.

Name	Description
DG-CIMPingResponse	This Inbound Web Service receives incoming asynchronous callback requests for Device Status Check. This web service accepts requests for the Response method defined in http://iec.ch/TC57/2011/abstract Generic.wsdl.
DG-CIMODRRResponse	This Inbound Web Service receives incoming asynchronous callback requests for On-Demand Reads. This web service accepts requests for the Response method defined in http://iec.ch/TC57/2011/abstract Generic.wsdl.

See [Inbound Web Services](#) for more information.

Cloud Service Test Harness

The Smart Grid Gateway Cloud Service Test Harness is used to simulate a head end system for testing smart meter commands in a cloud implementation.

The test harness is "stateless", meaning it does not store meters or their current status. The harness is designed to return a successful result to all command requests by default. Devices must be created in a specific manner to return an error.

How the Test Harness Works

The test harness includes SOAP web service implementations for each command supported by the various Smart Grid Gateway adapters. The Test Harness's container is managed by Oracle cloud services and internal routing definitions allow web service requests to locate the proper container without requiring users to update ports or other configurations. There is no user-accessible configuration required for the test harness itself.

Creating Devices for use with the Test Harness

The test harness works with any sort of device capable to sending smart meter commands. By default, all commands are successful.

Devices must be created in a specific manner in order for errors to be returned from the test harness. Specifically, commands for devices whose identifiers (badge number, serial number, internal meter number, pallet number, external ID, MDM external ID, and asset ID) end in "ERR" will return an error. This means that when setting up devices for testing via the test harness, you must create separate devices for successful and unsuccessful (error) results.

The simplest approach when creating "error" devices is to use the same identifier value for all identifiers, but at a minimum, "ERR" MUST be the final part of the identifier value for the **AMI Device ID Type** and **AMI Pre-Commissioning Device ID Type** configured on the head end system.

Defining Head End Systems, Processing Methods, Outbound Message Types, and Message Senders for use with the Test Harness

This section provides guidelines for creating data and records used with smart meter commands when using the test harness.

Head End System

When configuring a head end system for use with the test harness, note the identifier types specified in the **AMI Device ID Type** and **AMI Pre-Commissioning Device ID Type** fields. When creating devices intended to return an error, the identifier values for the identifier type(s) specified for these fields MUST end in "ERR" to return an error from the test harness.

Outbound Message Types

When creating outbound message types for use with the test harness, use the appropriate outbound business object based on the specific command. See [Smart Meter Command Flows](#) for details.

Message Senders

When creating message senders for use with the test harness, use the following settings:

Main tab:

- **Invocation Type:** Real-Time
- **Message Class:** SOAPSNDNR
- **Active:** <checked>
- **Msg Encoding:** UTF-8 message encoding

Context tab:

- **HTTP Header:** soapAction: <soapaction>

where <soapaction> is the URI (Soap Action) for the command as shown under [Adapter-Specific Test Harness Commands](#) below.

Note the format used here is:

SoapAction: {URI}

That's using a **colon, followed by a space** between the SoapAction and the value. You **cannot** use an equals (=) sign. For example:

```
SoapAction: http://www.multispeak.org/Version_4.1_Release/
MeterAddNotification
```

- **HTTP Login User:** A user which has been assigned to the SGGHarnessUser role in Oracle Identity Cloud Service (IDCS). See **Setting Up a User with Access to the Smart Grid Gateway Test Harness** in the *Oracle Utilities Cloud Services Administration Guide* for more information.
- **HTTP Login Password:** The password for the user above.
- **HTTP Method:** POST
- **HTTP URL 1:** <endpoint_URL>

where <endpoint_URL> is the HTTP URL or the command as shown under **Adapter-Specific Test Harness Commands** below, formatted as follows:

```
@SGG_TEST@<adapter_name>/<webservice>
```

where:

- @SGG_TEST@ is a token that combines the protocol, host, port, tenant, domain, and application
- <adapter_name> is one “lg”, “itron”, “ssn”, or “sensus”, as appropriate
- <webservice> is a name specific to each adapter (e.g. OD_Server, MR_CB, DeviceManager, and so on. See [Adapter-Specific Test Harness Commands](#))

Note: When creating message senders for use with the test harness, do **NOT** specify a **Sender Security Type** on the **Context** tab.

External Systems

When creating outbound message types on external systems and for use with the test harness, be sure to specify the appropriate Message XSL and Response XSL files based on the outbound message business object. See [Creating an External System](#) for lists of these files.

Processing Methods

Command processing methods for a head end system used with the test harness should reference an Outbound Message Type, either the **Default Outbound Message Type** or an **Outbound Message Type** for a specific **Device Type**.

Adapter-Specific Test Harness Commands

This section provides specific details for invoking commands for specific adapters.

Each adapter comprises multiple web services that enable commands. The commands available for each web service for each adapter are provided below.

HTTP Header Format

The format used for the HTTP Header is as follows:

SoapAction: {URI}

That's using a **colon, followed by a space** between the SoapAction and the value. You **cannot** use an equals (=) sign. For example:

```
SoapAction: http://www.multispeak.org/Version_4.1_Release/MeterAddNotification
```

Itron OpenWay Commands

Control Service

The table below lists details for commands available via the Itron OpenWay Control Service web service.

Command	Web Method	HTTP Header	HTTP URL
Connect	ReconnectMeter	SoapAction: http:// www.itron.com/ ami/2008/10/control/ ControlService/ ReconnectMeter	@SGG_TEST@/itron/ www.itron.com.ami.2008.10 control
Connect (Result)	GetReconnectMeterResult	SoapAction: http:// www.itron.com/ ami/2008/10/control/ ControlService/ GetReconnectMeterResult	@SGG_TEST@/itron/ www.itron.com.ami.2008.10 control
Disconnect	DisconnectMeter	SoapAction: http:// www.itron.com/ ami/2008/10/control/ ControlService/ DisconnectMeter	@SGG_TEST@/itron/ www.itron.com.ami.2008.10 control
Disconnect (Result)	GetDisconnectMeterResult	SoapAction: http:// www.itron.com/ ami/2008/10/control/ ControlService/ GetDisconnectMeterResult	@SGG_TEST@/itron/ www.itron.com.ami.2008.10 control
Load Check	DetectLoadSideVoltageByMeter	SoapAction: http:// www.itron.com/ ami/2008/10/control/ ControlService/ DetectLoadSideVoltageByMeter	@SGG_TEST@/itron/ www.itron.com.ami.2008.10 control
Load Check (Result)	GetDetectLoadSideVoltageByMeterResult	SoapAction: http:// www.itron.com/ ami/2008/10/control/ ControlService/ GetDetectLoadSideVoltageByMeterResult	@SGG_TEST@/itron/ www.itron.com.ami.2008.10 control

Control Diagnostic

The table below lists details for commands available via the Itron OpenWay Control Diagnostic web service.

Command	Web Method	HTTP Header	HTTP URL
Device Status Check	PingByEndpoints	SoapAction: http:// www.itron.com/ ami/2012/03/ control/diagnostic/ DiagnosticService/ PingByEndpoints	@SGG_TEST@/itron/ www.itron.com.ami.2012.03 control.diagnostic

Command	Web Method	HTTP Header	HTTP URL
Device Status Check (Result)	GetPingByEndpointsResult	SoapAction: http://www.itron.com/ami/2012/03/control/diagnostic/DiagnosticService/GetPingByEndpointsResult	@SGG_TEST@itron//www.itron.com.ami.2012.03 control.diagn
Read Disconnect State	ReadDisconnectStateByMeters	SoapAction: http://www.itron.com/ami/2012/03/control/diagnostic/DiagnosticService/ReadDisconnectStateByMeters	@SGG_TEST@itron//www.itron.com.ami.2012.03 control.diagn
Read Disconnect State (Result)	GetReadDisconnectStateByMetersResult	SoapAction: http://www.itron.com/ami/2012/03/control/diagnostic/DiagnosticService/GetReadDisconnectStateByMetersResult	@SGG_TEST@itron//www.itron.com.ami.2012.03 control.diagn

Data Service

The table below lists details for commands available via the Itron OpenWay Data Service web service.

Command	Web Method	HTTP Header	HTTP URL
On-Demand Read	ContingencyReadByEndpoint	SoapAction: http://www.itron.com/ami/2008/10/data/DataService/ContingencyReadByEndpoints	@SGG_TEST@itron//www.itron.com.ami.2008.10 data
On-Demand Read (Result)	GetContingencyReadByEndpointsResult	SoapAction: http://www.itron.com/ami/2008/10/data/DataService/GetContingencyReadByEndpointsResult	@SGG_TEST@itron//www.itron.com.ami.2008.10 data
Scheduled Read	InterrogateByGroup	SoapAction: http://www.itron.com/ami/2008/10/data/DataService/InterrogateByGroup	@SGG_TEST@itron//www.itron.com.ami.2008.10 data
Scheduled Read (Result)	GetInterrogateByGroupResult	SoapAction: http://www.itron.com/ami/2008/10/data/DataService/GetInterrogateByGroupResult	@SGG_TEST@itron//www.itron.com.ami.2008.10 data

Provisioning Service

The table below lists details for commands available via the Itron OpenWay Provisioning Service web service.

Command	Web Method	HTTP Header	HTTP URL
Commission	AddMeterDefinitions	SoapAction: http:// www.itron.com/ ami/2009/08/provisioning/ ProvisioningService/ AddMeterDefinitions	@SGG_TEST@/itron/ www.itron.com.ami.2009.08.provisioning
Decommission	DeregisterMeters	SoapAction: http:// www.itron.com/ ami/2009/08/provisioning/ ProvisioningService/ DeregisterMeters	@SGG_TEST@/itron/ www.itron.com.ami.2009.08.provisioning

Landis+Gyr Commands

MR_CB

The table below lists details for commands available via the Landis+Gyr MR_CB web service.

Command	Web Method	HTTP Header	HTTP URL
Commission	MeterAddNotification	SoapAction: http:// www.multispeak.org/ Version_3.0/ MeterRemoveNotification	@SGG_TEST@/Ig/MR_ CB
Decommission	MeterRemoveNotification	SoapAction: http:// www.multispeak.org/ Version_3.0/ MeterAddNotification	@SGG_TEST@/Ig/MR_ CB
Meter Retire	MeterRetireNotification	SoapAction: http:// www.multispeak.org/ Version_3.0/ MeterRetireNotification	@SGG_TEST@/Ig/MR_ CB
On-Demand Read	InitiateMeterReadByMeterNumber	SoapAction: http:// www.multispeak.org/ Version_3.0/ InitiateMeterReadByMeterNumber	@SGG_TEST@/Ig/MR_ CB
Scheduled Demand Reset	ScheduleDemandReset	SoapAction: http:// www.multispeak.org/ Version_3.0/ ScheduleDemandReset	@SGG_TEST@/Ig/MR_ CB

CD_MR

The table below lists details for commands available via the Landis+Gyr CD_MR web service.

Command	Web Method	HTTP Header	HTTP URL
Meter Exchange	MeterExchangeNotification	SoapAction: http:// www.multispeak.org/ Version_3.0/ MeterExchangeNotification	@SGG_TEST@/Ag/CB_ MR

CD_CB

The table below lists details for commands available via the Landis+Gyr CD_CB web service.

Command	Web Method	HTTP Header	HTTP URL
Connect/Disconnect	InitiateConnectDisconnect	SoapAction: http:// www.multispeak.org/ Version_3.0/ InitiateConnectDisconnect	@SGG_TEST@/Ag/CD_ CB

Metering

The table below lists details for commands available via the Landis+Gyr Metering web service.

Command	Web Method	HTTP Header	HTTP URL
Add Meter to Inventory	AddMeterToInventory	SoapAction: turtletech.com/ TS2/AddMeterToInventory	@SGG_TEST@/Ag/ Metering

CIM

The table below lists details for commands available via the Landis+Gyr CIM web service.

Command	Web Method	HTTP Header	HTTP URL
On Demand Read (Interval & Scalar)	AMIRrequest	SoapAction: urn:LandisGyr.G3 @SGG_TEST@/Ag/CIMService	@SGG_TEST@/Ag/ CIMService
Device Status Check			

Note: The Landis+Gyr ScheduleDemandReset API does not offer a way to pass a callback URL in. In actual use, L+G allows the callback to be configured in their system. To handle the scenario in the Test Harness, add an additional HTTP header named **SGG-Callback-Endpoint** to the callback URL in the Message Sender. The value of the header should be the address of the D3-CB_MR Inbound Web Service, for example: SGG-Callback-Endpoint: "https://144.25.14.142:8086/iddev2/prod/ccs/soap/api/iws/D3-CB_MR". The URL value is located near the bottom of the WSDL on the Inbound Web Service record.

Sensus Commands

MR_Server

The table below lists details for commands available via the Sensus MR_Server web service.

Command	Web Method	HTTP Header	HTTP URL
Commission	MeterAddNotification	SoapAction: http:// www.multispeak.org/ Version_4.1_Release/ MeterAddNotification	@SGG_TEST@/sensus/ MR_Server
Decommission	MeterRemoveNotification	SoapAction: http:// www.multispeak.org/ Version_4.1_Release/ MeterRemoveNotification	@SGG_TEST@/sensus/ MR_Server
On-Demand Read	InitiateMeterReadingsByMeterID	SoapAction: http:// www.multispeak.org/ Version_4.1_Release/ InitiateMeterReadingsByMeterID	@SGG_TEST@/sensus/ MR_Server

CD_Server

The table below lists details for commands available via the Sensus CD_Server web service.

Command	Web Method	HTTP Header	HTTP URL
Connect/Disconnect	InitiateConnectDisconnect	SoapAction: http:// www.multispeak.org/ Version_4.1_Release/ InitiateConnectDisconnect	@SGG_TEST@/sensus/ CD_Server

OD_Server

The table below lists details for commands available via the Sensus OD_Server web service.

Command	Web Method	HTTP Header	HTTP URL
Device Status Check	InitiateOutageDetectionEventRequest	SoapAction: http:// www.multispeak.org/ Version_4.1_Release/ InitiateOutageDetectionEventRequest	@SGG_TEST@/sensus/ OD_Server

Silver Spring Networks Commands

Note: The Silver Spring Networks adapter works differently from the other adapters. This adapter does not use SoapAction identifiers on the operations, so the HTTP Header can be left off of the Message Sender configuration.

DataAggregation

The table below lists details for commands available via the Silver Spring Networks DataAggregation web service.

Command	Web Method	HTTP URL
	GetMeterFieldStatus	@SGG_TEST@/ssn/ DataAggregation

DeviceManager

The table below lists details for commands available via the Silver Spring Networks DeviceManager web service.

Command	Web Method	HTTP URL
All	FindDevice	@SGG_TEST@/ssn/DeviceManager
Commission	ReplaceLocation	@SGG_TEST@/ssn/DeviceManager
Decommission	ReplaceDeviceAtLocation	@SGG_TEST@/ssn/DeviceManager

JobManager

The table below lists details for commands available via the Silver Spring Networks JobManager web service.

Command	Web Method	HTTP URL
Connect/Disconnect	addRemoteProvisioningJob	@SGG_TEST@/ssn/JobManager
On-Demand Read	addMeterReadJob	@SGG_TEST@/ssn/JobManager
Device Status Check	addPingJob	@SGG_TEST@/ssn/JobManager
On-Demand Read, Device Status Check	getJobStatus	@SGG_TEST@/ssn/JobManager
Connect/Disconnect	getJobStatusForDevice	@SGG_TEST@/ssn/JobManager

DeviceResults

The table below lists details for commands available via the Silver Spring Networks DeviceResults web service.

Command	Web Method	HTTP URL
Connect/Disconnect	getRemoteProvisioningResultsByJobID	@SGG_TEST@/ssn/DeviceResults
On-Demand Read	getMeterReadResultsByJobID	@SGG_TEST@/ssn/DeviceResults
Device Status Check	getPingresultsByJobID	@SGG_TEST@/ssn/DeviceResults

Web Service Authentication

This section describes configuration settings for web service authentication for each Smart Grid Gateway Adapter.

Each adapter section below includes guidelines for defining credentials to outbound web service requests and instructions for delivering credentials when calling back into the application via inbound web services.

For the purposes of this document, “Inbound” refers to requests originating from outside Smart Grid Gateway and are targeted at Smart Grid Gateway web services. “Outbound” requests originate within Smart Grid Gateway and are targeted at web services hosted on other servers.

Itron OpenWay Web Service Authentication

Inbound Requests

Incoming requests should utilize standard basic HTTPS authentication.

Outbound Requests

The Itron system can be configured to expect a WSSE security element in the SOAP header for authentication. That element will contain certain features such as a nonce, in addition to the credentials. This can be configured in Smart

Grid Gateway by setting the Message Sender's **Sender Security Type** value to "ITRON" (as shown in the following screen capture).

The screenshot shows the 'Message Sender' configuration page with the 'Context' tab selected. The 'Message Sender' field contains 'SGG'. Below is a table of context values:

	Context Type	Context Value
+ [trash]	* HTTP Login User	* sgg
+ [trash]	* HTTP Login Password	* ...
+ [trash]	* Sender Security Type	* ITRON
+ [trash]	* HTTP URL 1	* http://ugbu-phx-352.sphxprshared1.gbucdsint02phx.oraclevcn.com:8086
+ [trash]	* HTTP Method	* POST
+ [trash]	* HTTP Header	* SoapHeader: http://www.itron.com/ami/2008/10/control/ControlServ

Landis+Gyr Web Service Authentication

The L+G Adapter communicates using the MultiSpeak 3.0 standard as well as the Common Information Model (CIM) standard. The MultiSpeak standard includes a SOAP Header element, MultiSpeakMsgHeader with "UserId" and "Pwd" security attributes. The Message Sender configuration is used to insert credentials into the header element. Incoming requests will be scanned for header credentials when an instruction to do so is found in the URL.

Similarly, the CIM standard defines credential locations within the SOAP Header and Body, depending on the version.

MultiSpeak 3.0

Inbound Requests

Include "/multispeak30" prior to the inbound web service name in the URL to signal the application that it should locate credentials in the MultiSpeakMsgHeader SOAP Header element.

Example: https://144.25.13.161:8086/tnt22a/test03/ccs/soap/api/iws/multispeak30/D3-CB_MR

Outbound Requests

On the **Context** tab of the **Message Sender** portal, add a **Sender Security Type** row with a value of "MS_V30" (as shown in the following screen capture). The values of the **HTTP Login User** and **HTTP Login Password** will be added as attributes of MultiSpeakMsgHeader in the outgoing SOAP header.

The screenshot shows the 'Message Sender' configuration page with the 'Context' tab selected. The 'Message Sender' field contains 'SGG'. Below is a table of context values:

	Context Type	Context Value
+ [trash]	* HTTP Login User	* sgg
+ [trash]	* HTTP Login Password	* ...
+ [trash]	* Sender Security Type	* MS_V30
+ [trash]	* HTTP URL 1	* http://www.multispeak.org/Version_3.0/InitiateMeterReadByMeterNu
+ [trash]	* HTTP Header	* SoapAction: http://www.multispeak.org/Version_3.0/InitiateMeterRea
+ [trash]	* HTTP Method	* POST

CIM 1.2

Inbound Requests

Include “/cim12” prior to the inbound web service name in the URL to signal the application that it should include SOAP Body credentials ({Specific Message Type}/Header/User/UserId and {Specific Message Type}/Header/Property/Name[text() = 'Password']).

Example: <https://144.25.13.161:8086/tnt22a/test03/ccs/soap/api/iws/cim12/D3-CIMCallback>

Outbound Requests

CIM 1.2 outbound requests should utilize either standard basic HTTPS authentication or send credentials in the SOAP Header element as in CIM 2.0.

CIM 2.0

Inbound Requests

Include “/cim20” prior to the inbound web service name in the URL to signal the application that it should include credentials in the SOAP Header in the form of elements:

- {http://www.landisgyr.com/iec61968/2010/03}UserName
- {http://www.landisgyr.com/iec61968/2010/03}Password

Example: <https://144.25.13.161:8086/tnt22a/test03/ccs/soap/api/iws/cim20/D3-CIMCallback>

Outbound Requests

On the **Context** tab of the **Message Sender** portal, add a **Sender Security Type** row with a value of “CIM” (as shown in the following screen capture). The values of the **HTTP Login User** and **HTTP Login Password** will be added to the outgoing SOAP Header as elements:

- {http://www.landisgyr.com/iec61968/2010/03}UserName
- {http://www.landisgyr.com/iec61968/2010/03}Password

The screenshot shows the 'Message Sender' portal with the 'Context' tab selected. The 'Message Sender' field contains 'SGG' and the 'Owner' field is empty. Below is a table of context items:

	Context Type	Context Value
+ [trash]	* HTTP Login User	* sgg
+ [trash]	* HTTP Login Password	* ***
+ [trash]	* Sender Security Type	* CIM
+ [trash]	* HTTP URL 1	* http://ugbu-phx-352.snphxprshared1.gbucdsint02phx.oraclevcn.com:8086
+ [trash]	* HTTP Header	* SoapAction: urn:LandisGyr.GSIS.CimService.CIMService.AMIRequest
+ [trash]	* HTTP Method	* POST

Sensus Web Service Authentication

MultiSpeak 4.1 Release

Inbound Requests

Include “/multispeak41” prior to the inbound web service name in the URL to signal the application that it should locate credentials in the MultiSpeakMsgHeader SOAP Header element.

Ex: https://144.25.13.161:8086/tnt22a/test03/ccs/soap/api/iws/multispeak41/D6-CB_Server

Outbound Requests

On the **Context** tab of the **Message Sender** portal, add a **Sender Security Type** row with a value of “MS_V41R” (as shown in the following screen capture). The values of the **HTTP Login User** and **HTTP Login Password** will be added as attributes of MultiSpeakMsgHeader in the outgoing SOAP header.

Master Configurations

Master configurations define configuration settings for individual adapters. The sections below provide details for the master configuration provided for each Smart Grid Gateway adapter.

Itron OpenWay Master Configuration

The “Itron – Master Config” master configuration defines details used by the Itron OpenWay commands and payload processing, including the following:

- **Itron Version:** Used to specify the version of the Itron OpenWay head end system being used.
- **Command Status Changed URL Configuration:** Used to define URL configuration for asynchronous callback requests.
 - **Status Changed Service URL Script:** Used to define a service script which composes the URL for asynchronous callbacks. The script should include an /output/applicationUrl field containing the results. When determining the URL, the system initially checks if a script has been configured on this field, and if so, that script is used. If this field is blank (which is the default), the Determine Application URL (D1-DetStChSU) script is used to compose the URL.
 - **Default Status Changed Service URL:** The base portion of a URL sent to the head end system which provides a location to which it should send an asynchronous callback request. This base URL is appended by command-specific URL components defined as algorithm parameters on "Populate Send Details." algorithms on outbound communication business objects.
 - **Commands:** Command-specific base URLs for asynchronous callback requests
- **Arrived Data Save Locations:** Used to define how payloads and exceptions are routed and processed by the Itron DataSubscriberService, Itron EventSubscriberService, and Itron ExceptionSubscriberService inbound web services.
 - **DataArrived Output Configuration:** Defines how payloads are routed and processed by the Itron DataSubscriberService inbound web service.
 - **Save to Staging:** A flag that indicates if payloads routed and processed by the Itron DataSubscriberService inbound web service should be saved to a staging area in Oracle Object Storage. This should be set to "Yes" to enable the use of a staging area in Object Storage.
 - **File Storage:** The staging location where payloads are routed for later processing. This should be a File Location Extendable Lookup value.
 - **Output Bucket/Folder Name:** The specific object storage bucket or folder within the file storage location where payloads are routed.
 - **Filename Generation Script:** The name of a service script used to compose the filename when saving incoming payloads to the staging area. By default, the D8-DEFFNGEN script is used.
 - **EventsArrived Output Configuration:** Defines how event payloads are routed and processed by the Itron EventSubscriberService inbound web service.
 - **Save to Staging:** A flag that indicates if event payloads routed and processed by the Itron EventSubscriberService inbound web service should be saved to a staging area in Oracle Object Storage. This should be set to "Yes" to enable the use of a staging area in Object Storage.
 - **File Storage:** The staging location where event payloads are routed for later processing. This should be a File Location Extendable Lookup value.
 - **Output Bucket/Folder Name:** The specific object storage bucket or folder within the file storage location where event payloads are routed.
 - **Filename Generation Script:** The name of a service script used to compose the filename when saving incoming event payloads to the staging area. By default, the D8-DEFFNGEN script is used.
 - **ExceptionsArrived Output Configuration:** Defines how exceptions are routed and processed by the Itron ExceptionSubscriberService inbound web service
 - **Save to Staging:** A flag that indicates if exceptions routed and processed by the Itron ExceptionSubscriberService inbound web service should be saved to a staging area in Oracle Object Storage. This should be set to "Yes" to enable the use of a staging area in Object Storage.

- **File Storage:** The staging location where exceptions are routed for later processing. This should be a File Location Extendable Lookup value.
- **Output Bucket/Folder Name:** The specific object storage bucket or folder within the file storage location where exceptions are routed.
- **Filename Generation Script:** The name of a service script used to compose the filename when saving exceptions to the staging area. By default, the D8-DEFFNGEN script is used.

Landis+Gyr Master Configuration

The “L+G – Master Config” master configuration defines details used by the Landis+Gyr commands and payload processing, including the following:

- **Command Status Changed URL Configuration:** Used to define URL configuration for asynchronous callback requests
 - **Status Changed Service URL Script:** Used to define a service script which composes the URL for asynchronous callbacks. The script should include an /output/applicationUrl field containing the results. When determining the URL, the system initially checks if a script has been configured on this field, and if so, that script is used. If this field is blank (which is the default), the Determine Application URL (D1-DetStChSU) script is used to compose the URL.
 - **Default Status Changed Service URL:** The base portion of a URL sent to the head end system which provides a location to which it should send an asynchronous callback request. This base URL is appended by command-specific URL components defined as algorithm parameters on "Populate Send Details." algorithms on outbound communication business objects.
 - **Commands:** Command-specific base URLs for asynchronous callback requests
- **AMI Events Configuration:** Used to define settings for the CIM AMIEvent interface
 - **Save to Staging Area:** Flag that indicate whether to save incoming data to a staging area, such as Oracle Object Storage, or process it directly
 - **Processing Configuration Value:** An SGG Payload Processing Configuration extendable lookup used when immediately processing the AMIEvent payloads

Sensus Master Configuration

The “Sensus Master Configuration” master configuration defines details used by the Sensus commands and outage events, including the following:

- **Command Status Changed URL Configuration:** Used to define URL configuration for asynchronous callback requests
 - **Status Changed Service URL Script:** Used to define a service script which composes the URL for asynchronous callbacks. The script should include an /output/applicationUrl field containing the results. When determining the URL, the system initially checks if a script has been configured on this field, and if so, that script is used. If this field is blank (which is the default), the Determine Application URL (D1-DetStChSU) script is used to compose the URL.
 - **Default Status Changed Service URL:** The base portion of a URL sent to the head end system which provides a location to which it should send an asynchronous callback request. This base URL is appended by command-specific URL components defined as algorithm parameters on "Populate Send Details." algorithms on outbound communication business objects.
 - **Commands:** Command-specific base URLs for asynchronous callback requests
- **Outage Events Head End System:** Used to define the head end system expected to which outage events are sent via the ODEventNotification interface

Silver Spring Networks Version Master Configuration

The “SSN – Version Master Config” master configuration specifies the version of the Silver Spring Networks head end system with which the system is communicating:

- **SSN Version:** Used to define the version of the Silver Spring Networks head end system. Options include:

- SSN v4.10 (WSDL 2.1)
- SSN v4.14 (WSDL 2.5.1)
- SSN v4.4 (WSDL v1.4)
- SSN v4.7 (WSDL v1.6)
- SSN v5.0-5.1 (WSDL v2.7)
- SSN v5.1 (WSDL v2.8)
- **SSN - Get Job Status Configuration:** Used to specify the **Retry Limit** and **Wait Duration (in Seconds)** for the Get Job Status requests sent by outbound communications.

Native Implementation Configuration Checklists

This section provides an overview of the steps involved in configuring Native implementations of Oracle Utilities Smart Grid Gateway adapters, including [Payload Processing](#) and [Smart Meter Command Processing](#).

Payload Processing Checklist

1. Create Keys and Key Rings (Cloud Only). See [Creating Key Rings and Pairs](#) for more information.
 2. Configure Object Storage Locations (Cloud Only). See [Creating Object Storage Locations](#) for more information.
 3. Configure File Storage Extendable Lookup Values. See [Creating File Storage Extendable Lookup Values](#) for more information.
 4. Configure a Head End System to represent the Head End System. See [Creating Head End Systems](#) for more information.
 5. Configure Processing Methods for the Head End System appropriate for payload processing, including.
 - Initial Measurement Creation
 - Device Event Mapping
 - UOM Translation
-  **Note:** These processing methods rely on extendable lookups. See [Configuring Adapter Extendable Lookups](#) for more information.
6. Configure SGG Payload Processing Extendable Lookup Values. See [Creating SGG Payload Processing Extendable Lookup Values](#) for more information.
 7. Configure the adapter's Master Configuration (if appropriate). See [Master Configurations](#) for more information.
 8. Configure Other Extendable Lookup Values. See [Configuring Adapter Extendable Lookups](#) for more information.
 9. Configure Batch Controls. See [Creating Payload Processing Batch Controls](#) for more information.

Smart Meter Command Processing Checklist

1. Configure Activity Types for each command you wish to support in your implementation. Smart meter commands are activities in the system. For each command you plan to support, confirm that you have a corresponding Activity Type configured.
 2. Configure Communication Types appropriate for each command you wish to support in your implementation. Each communication sent to the head end system as part of a command request requires a communication type. See the following sections for more information about the specific communications used with each command:
 - [Itron OpenWay Command Flows](#)
 - [Landis+Gyr Command Flows](#)
 - [Sensus Command Flows](#)
 - [Silver Spring Networks Command Flows](#)
-  **Note:** Note: Most Adapters use outbound communications only.
3. Configure Message Senders for each command you wish to support in your implementation. See [Sending Outbound Communications](#) and [Creating Message Senders](#) for more information.

4. Configure Outbound Message Types each command you wish to support in your implementation. See [Sending Outbound Communications](#) and [Creating Outbound Message Types](#) for more information.
5. Configure an External System to represent the Head End System.
 - a. Configure Message Senders/Outbound Message Types for each command you wish to support in your implementation See [Sending Outbound Communications](#) and [Creating an External System](#) for more information.
6. Configure a Head End System to represent the Head End System. Head End Systems reference the corresponding External System. See [Creating Head End Systems](#) for more information.
7. Configure Processing Methods for the Head End System appropriate for each command you wish to support in your implementation. See [Configuring Processing Methods](#) for more information.
8. Configure Inbound Web Services as appropriate for the Head End System See [Receiving Inbound Communications](#) and [Inbound Web Services](#) for more information.
9. Configure the adapter's Master Configuration (if appropriate) See [Master Configurations](#) for more information.
10. Configure Extendable Lookups See [Configuring Adapter Extendable Lookups](#) for more information.

Configuration Details Reference

Refer to Knowledge Base article [2785031.1](#) on [My Oracle Support](#) for a spreadsheet containing configuration details for the following Adapters:

- Itron OpenWay
- Silver Spring Networks
- Landis+Gyr
- MV90 (Payload Processing Only)

This spreadsheet contains lists of configuration objects used by each adapter, including:

- Activity Types
- Communication Types
- Message Senders
- Head End System
- Outbound Message Type
- External System
- Master Configurations (as applicable)
- Extendable Lookups
- Batch Controls

Defining Service Order Management Options

Understanding Service Order Management

At a high level, service order management handles requests for service as follows:

Receive / Create Service Order Request

A service order request is created and/or received. This can be as a result of a customer requesting a change to their service such as enabling or disabling service when moving into or out of a residence, but can also be the result of other business processes, such as a request to cut service due to non-payment.

Regardless of the origin of the request, a service order request is created in a customer information system (CIS) such as Oracle Utilities Customer Care and Billing), which in turn is sent to Service Order Management.

Create Service Order Activity

When Service Order Management receives the service order request, it creates a service order activity. This activity will manage and orchestrate any/all other activities needed to fulfill the original service request.

Evaluate Service Point and/or Meter

The service order activity then evaluates the current state of the service point, meter, or item, and determines the appropriate action(s) to take to fulfill the service request.

Create Activities as Needed / Appropriate

Based on the evaluation of the service point/meter/item, the service order activity creates one or more activities as needed.

- Service order field activities involve sending workers into the field to perform service. This can include meter installation, meter replacement, and other activities.
- Command activities are smart meter commands used to remotely change the state of the meter. This can include connect, disconnect, checking the device status (ping), or requesting an on-demand reading.

Following each of activities, the orchestration activity re-evaluates the state of the service point/ meter/item to determine the next appropriate action(s) required to fulfill the original service request.

For example, when enabling service at a service point with a smart scalar meter, a typical scenario might involve the following:

1. Service Order Field Activity - Install Meter
2. Command Activity: Commission Device
3. Command Activity: Remote Connect
4. Command Activity: On Demand Read - Scalar

Update Requesting System

When the service order activity determines that everything necessary to satisfy the service order request is ready, the service order activity will inform the requester and complete the original request.

Send Notification to Subscribing Systems

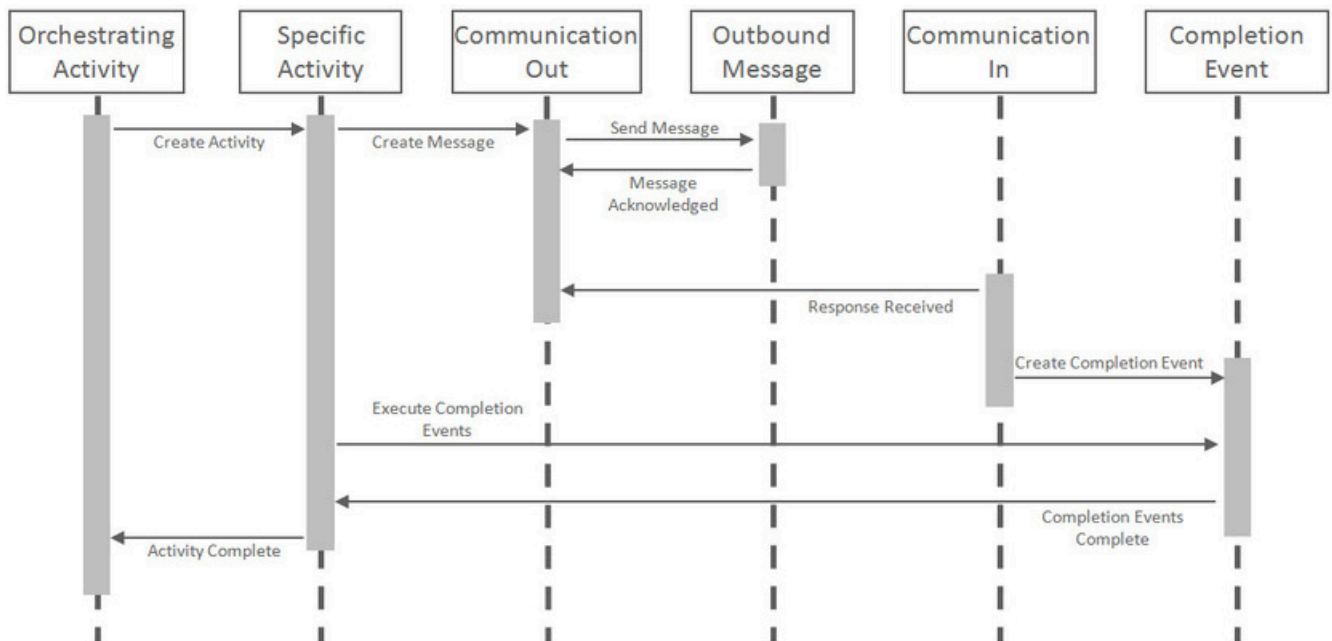

The service order activity can also be configured to send notifications to other subscribing systems regarding the status of the service point/meter/item.

Service Order Activities

Understanding Service Order Activities

This section describes service order activities and how they manage the service order process.

Service order activities coordinate a large number of child transactions that represent the communication to and from an external application. The below diagram depicts a service order activity:

Each object in the sequence diagram has a distinct set of duties within the context of the communication:

- **Orchestrating Activity:** controls the overall intent of the communication. For example it may "Enable Service" which would include initiating one-to-many specific activities to install the meter and begin the flow of the metered commodity to the service point.
- **Specific Activity:** can be initiated from an orchestrating activity or directly. These activities represent a single task to be carried out such as installing a meter or a remote disconnect smart meter command.
- **Communication Out:** orchestrates the communication to the external application and provides robust handling for any errors that might occur during that communication.
- **Outbound Message:** represents the message payload sent to the external system and the synchronous response.
- **Communication In:** orchestrates the handling of an asynchronous or unsolicited response from an external system.
- **Completion Event:** carries out the results of the communication. For example, in the case of a remote connect it would create the appropriate on off history entry for the device's installation event.

The base package provides the following types of service order activities:

- **Enable Service:** Used to enable service at a service point.
- **Disable Service:** Used to disable service at a service point.
- **Cut for Non-Payment:** Used to cut off service at a service point due to non-payment of past due amounts.
- **Reconnect Service for Payment:** Used to restore service at a service point after receipt of past due payment.
- **Exchange Meter:** Used to orchestrate the exchange of meters at service point, such as in the event that a customer upgrades their meter.
- **Back to Back Service:** Used to orchestrate a change of service when the customer at a service point changes (such as when owners/tenants change).

Service Order Activity Processing

To understand how service order activities manage the service order process, it's important understand the lifecycle of orchestration activity business objects.

Service Order Orchestration Activity Lifecycle

All service order orchestration activity business objects share a common parent business object that defines their lifecycles. This is the Service Point Activity Orchestration business object (D1-SPActivityOrchestration). The table below outlines the lifecycle for this business object.

State	Description
Pending	<p>The initial state for orchestration activities.</p> <p>An Enter algorithm sends an acknowledgement to the requesting system.</p> <p>The activity is transitioned to the next state via a monitor process.</p>
Validate	<p>Enter algorithms perform the following:</p> <ul style="list-style-type: none"> Validate Activity Type Validate Service Point <p>Check for a non-final duplicate service order request activity for the same service point.</p>
Validation Error	<p>If the business object fails any of the validations in the Pending state, it enters this state.</p> <p>Activities in this state can be corrected and retried.</p>
Discarded	<p>Activities discarded in other states enter this state.</p> <p>Enter algorithms perform the following:</p> <ul style="list-style-type: none"> Validate that non-final child activities can be discarded without the need for a cancel activity Cancel non-final child activities Send a failure notification to the requesting system
Waiting for Effective Date	<p>If an orchestration activity has a future effective date, it remains in this state until the effective date is reached.</p> <p>A Monitor algorithm transitions the activity to the next state when the activity's effective date time is reached (process date time \geq effective date time).</p>
Are SP and Device Ready?	<p>Each type of orchestration activity business object has a unique set of Enter algorithms that perform operations as appropriate for the type of service order request.</p> <p>See Service Order Activity Algorithm Types on page 1051 for more information about these algorithms.</p>
Activity in Progress	<p>Orchestration activities remain in this state while their child activities are processed.</p> <p>A Monitor algorithm transitions the activity to the "Are the SP and Device Ready?" state if there are no non-final child activities related to the current activity.</p> <p>A Monitor algorithm validates that the orchestration activity has not been in its current state for too long, based on the Expiration Days parameter on the orchestration activity's type and the Expiration Date/Time on the orchestration activity</p> <p>An Exit algorithm resets the Expiration Date/Time on the orchestration activity such that each time the activity exits this state its Expiration Date/Time is updated.</p>
Activity Error	<p>If one or more child activities enters an Error state, the orchestration activity enters this state.</p> <p>Activities in this state can be corrected and retried.</p>

State	Description
Retry	<p>When an orchestration activity is retried after correction of an error condition, it enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Check to determine if there are child field activities in progress that have outbound communications awaiting a response.</p> <p>Transition any non-final child activity to the "Reject" state (the state defined as "Reject" on the child activity business object lifecycle. This is most often the "Discarded" state).</p>
Completed	<p>Orchestration activities enter this state when all child activities have successfully completed.</p> <p>An Enter algorithm send a success notification to the requesting system.</p>

Use the Business Object and Algorithm portals to view additional details about this business object and its lifecycle algorithms.

Cancel / Update Orchestration Lifecycle

The Cancel Orchestration (D1-CancelOrchestration) and Update Orchestration (D1-UpdateOrchestration) business objects have a similar lifecycle, with the following exceptions:

- There is no "Waiting for Effective Date" state.
- In place of the "Are SP and Device Ready?" state, they have "Cancel Specific Activity" / "Update Specific Activity" states. Enter algorithms on these states attempt to cancel or update a specific child activity.
- In the place of "Activity In Progress" and "Activity Error" states, they have "Communication in Progress" and "Communication in Error" states.

Use the Business Object and Algorithm portals to view additional details about this business object and its lifecycle algorithms.

Throttling Commands Issued from Service Order Activities

Service order management can be configured to limit, or "throttle", the number of smart meter command activities initiated by a service order activity that are executed within a specified time range. For example, in a situation in which a utility initiates dozens (or hundreds) of cut for non-payment service activities on a single day, this feature allows the execution of the related remote disconnect commands to be spread out over a number of hours rather than executing all of those commands in the first hour of the day.

Note: Throttling is only supported for Cut Service for Non-Payment service order activities and Remote Disconnect smart meter command activities.

Configuring throttling of command processing is done via parameters on the service order activity type and the related smart meter command activity type.

Service Order Activity Type

The following **Business Hours** parameters on the Cut Service for Non-Payment activity type are used to define the business days and hours during which remote disconnect commands can be executed:

- **Ensure Business Hours:** Indicates if commands should be processed during specified business hours as defined by the **Work Calendar**, **Start Hour**, and **End Hour** parameters.
- **Work Calendar:** The work calendar used to determine work days on which commands can be processed.
- **Start Hour:** The start hour of the day during which commands can be processed.
- **End Hour:** The end hour of the day during which commands can be processed.

Refer to the **Business Hours** embedded help on the Cut Service for Non-Payment activity type for more details.

Smart Meter Command Activity Type

The **Throttle Parameters** on the Remote Disconnect activity type are used to define if throttling is enabled, and if so, the number of commands that can be processed during specific time ranges during each business day. These parameters include:

- **Throttle Option:** Specifies if throttling is allowed. If set to "Allowed", one or more time ranges must be defined in the **Schedule** list.
- **Schedule:** Defines one or more time ranges (defined by the **From** and **To** columns) and the number of records that can be processed during each (defined by the **Number of Requests** column).

Batch Processing

Processing of commands configured for throttling is performed using the Command Request Wait Monitor with Throttle Option batch control (D1-CRWTO).

This batch control monitors command activities in the "Wait For Effective Date/Time" state, and if the Throttle Option parameter (enableThrottle) is set to "Y", it will only process up to the number of records specified in the current time range defined in the **Schedule** section on the command activity type. For example, if there are 50 Remote Disconnect commands in the "Wait For Effective Date/Time" state and this batch control (with **Throttle Option** set to "Y") is run during a time range for which the **Number of Requests** is set to 30, only 30 of the commands will be transitioned to the Connection Ready state.

This batch control can be used for all commands, with the **Throttle Option** parameter set as appropriate based on the type of command activities. As of this release, throttling is only available with Remote Disconnect smart meter command activities.

Notes:

- This batch control can be used only with command activity business objects whose "Wait For Effective Date/Time" state does NOT have a monitor process defined.
- If this batch control is run more than once during a specific time range, it will process up to the number of records specified for that time range during each run. In the previous example, if the batch control were to be run twice during the same time range, the first run would process 30 records, and the second would process the remaining 20 records.

See the **Detailed Description** of this batch control for more information.

Service Order Activity Algorithm Types

When an orchestration activity enters the "Are SP and Device Ready?" state, a set of Enter algorithms are used to evaluate the state of the service point / meter / item to determine which actions are required to complete the service request. These algorithms are based on the following algorithm types.

Customer-Device Compatibility Check (D1-DVCOMCHK)

Algorithms of this type execute the "Customer-Device Compatibility Algorithm" defined on the orchestration activity's activity type. Algorithms of this type uses the following parameters:

- **Activity BO To Create If Compatibility Detected:** Specifies the activity business object to instantiate if the algorithm detects an in compatibility between the customer/service point and device.

Note: The base package does not include algorithm types for the "Activity Type - Customer Device Compatibility" algorithm entity.

Connect Only If Previously Connected (D1-CONPRECON)

Algorithms of this type check if the "Connect New Device" flag has a value. If the flag is not populated, the algorithm sets the value of the flag based on the connection status of the device prior to the meter exchange (used only with Meter Exchange requests).

For additional information, refer to the D1-CONPRECON Algorithm Type.

Create Meter Exchange Field Activity (D1-CREMTREXC)

Algorithms of this type create a service order field activity based on details provided in the algorithm's parameters. Algorithms of this type uses the following parameters:

- **Activity and Specific Field Task to Create:** Specifies the type of activity business object and field task type to create for meter exchange service order field activities, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create.
specificFieldTask	Specifies the Field Task Type when creating a service order field activity. This value comes from the Field Task Type extendable lookup.

For example, to create a service order field activity based on the D1-FieldActivity business object and the Exchange Meter field task type, these mnemonics would be configured as follows:

```
activityBOToCreate=D1-FieldActivity specificFieldTask=D1-ExchangeMeter
```

For additional information, refer to the D1-CREMTREXC Algorithm Type.

Decommission Removed Meter (D1-DCRMMTR)

Algorithms of this type create a decommissioning command for a removed meter (used only with Meter Exchange requests). Algorithms of this type uses the following parameters:

- **Decommission Activity BO to be created:** Specifies the type of activity business object to create when decommissioning a meter. The specific activity is created, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create.

For example, to create a smart meter command activity based on the D1-DeviceDecommission business object, this parameter would be configured as follows:

```
activityBOToCreate=D1-DeviceDecommission
```

For additional information, refer to the D1-DCRMMTR Algorithm Type.

Create Specific Activity (D1-CRSPACT)

Algorithms of this type determine if a specific activity needs to be created based on the state of the service point. Algorithms of this type use the following parameters to specify the conditions and activity to be created:

- **Field Activity BO:** Specifies the field activity business object to instantiate if the algorithm creates a field task type (see next parameter).
- **SP State and Activity BO to Create:** Specifies the type of activity business object to create based on the state of the service point. This parameter can be repeated up to 20 times. Instances of the parameter are evaluated one at a time and the first condition matching the state of the service point is used. Parameters should be ordered from the most restrictive condition to the least restrictive. This parameters uses the following mnemonics to indicate the state (any combination of the following) of the service point:

Mnemonic	Description
servicePointConnected	Specifies if the service point is currently connected Valid values are "true" and "false".
disconnectLocation	Specifies the "Disconnect Location" for the service point. Valid values are "D1SR" (source) and "D1DV" (device).
deviceInstalledAtSP	Specifies if there is a device currently installed at the service point. Valid values are "true" and "false".
installationEventStatusOverride	Specifies the value of the "Installation Status" option type of the Install Event's Status ("Pending", "Conn-PreComm", "ManualOff", etc.)

Based on the unique combination of these mnemonics, a specific activity is created, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create (used most often to specify a command business object)
specificFieldTask	Specifies the field task type when creating a service order field activity. This value comes from the Field Task Type extendable lookup. Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the field activity business object to create.
spTypeCategory	Specifies a service point type category. Valid values include "D1MT" (meter), "D1IT" (item), "D1MI" (multi-item), from the SP_CATEGORY_FLG lookup. Specifying this mnemonic indicates that a service order field activity should be created only if the service point's category match the one specified by this mnemonic.
executeOverrideAlgorithm	Specifies whether or not to execute the algorithm specified for the Override Device/Task Algorithm on the service order orchestration activity type. This allows the activity business object to create to be dynamically determined based on an algorithm instead of the "activityBOToCreate" or "specificFieldTask" mnemonics. Valid values are "true" and "false".

For example, the following parameter configuration would create a "Connect Service Point and Install Meter" service order field activity given the following conditions:

- Service Point Connected: False
- Disconnect Location: Source
- Device Installed at Service Point: False
- Service Point Category: Meter

```
servicePointConnected=false disconnectLocation=D1SR deviceInstalledAtSP=false specificFieldTaskType=ConnSPAtSrceAndInstMtr spTypeCategory=D1MT
```

Note: Additional values for the **SP State and Activity BO to Create** parameter can be defined using the **Field Task By Service Point Condition** zone on the [Activity Type](#) portal.

For additional information, refer to the D1-CRSPACT Algorithm Type.

Update Device (D1-UPDDVC)

Algorithms of this type determine if an activity needs to be created to update the device based on the state of the service point and device installed at the service point. Algorithms of this type use the following parameters to specify the conditions and activity to be created.

- **Error if SP Not Connected or no Device Installed (Default is Yes):** Indicates if the algorithm should return an error if the service point is not connected or if a device is not currently installed. Valid values are "Yes" and "Con" (continue)
- **SP State and Activity BO to Create:** Specifies the type of activity business object to create based on the state of the service point. This parameter can be repeated up to 20 times. Instances of the parameter are evaluated one at a time and the first condition matching the state of the service point is used. Parameters should be ordered from the most restrictive condition to the least restrictive. This parameters uses the following mnemonic to indicate the state (any combination of the following) of the service point:

Mnemonic	Description
installationEventStatusOverride	Specifies the value of the "Installation Status" option type of the Install Event's Status ("Pending", "Conn-PreComm", "ManualOff", etc.)

Based on the value of this mnemonic, a specific activity is created, as defined by the following mnemonics:

Mnemonic	Description
activityBOToCreate	Specifies the activity business object to create (used most often to specify a command business object)
specificFieldTask	Specifies the Field Task Type when creating a service order field activity. This value comes from the Field Task Type extendable lookup. Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the field activity business object to create.
spTypeCategory	Specifies a service point type category. Valid values in include "D1MT" (meter), "D1IT" (item), "D1MI" (multi-item), from the SP_CATEGORY_FLG lookup. Specifying this mnemonic indicates that a service order field activity should be created only if the service point's category match the one specified by this mnemonic.

Mnemonic	Description
alternativeFieldTask	<p>Specifies an alternative Field Task Type to use when creating a service order field activity in the event that the device does not support the command indicated by the "activityBOToCreate" mnemonic.</p> <p>Note: If this mnemonic is specified, the "Field Activity BO" parameter should specify the field activity business object to create.</p> <p>A value of 'skip' will continue the evaluation of the algorithm's next parameter</p>

For example, the following parameter configuration would create a "Turn On Meter" service order field activity given the following conditions:

- Installation Status: Manual Off
- Service Point Category: Meter

```
installEventStatusOverride=ManualOff specificFieldTask=D1-TurnOnMeter spTypeCategory=D1MT
```

Note: Additional values for the **SP State and Activity BO to Create** parameter can be defined using the **Field Task By Device Condition** zone on the [Activity Type](#) portal.

Other parameters used by algorithms of this type include:

- **Field Activity BO:** Specifies the field activity business object to instantiate if the algorithm creates a field task type (see above parameter).
- **XPath of Activity Element controlling Activity creation:** Defines an element within the activity business object schema that can be used to control whether or not this algorithm should create an activity. For example, to specify that the value of the "Connect New Device" flag be used to determine whether or not the algorithm should create an activity, this parameter could be set to "connectNewDevice".
- **Element value indication that Activity creation should not proceed:** Specifies a value for the element defined in the "XPath of Activity Element controlling Activity creation" parameter that would indicate that the algorithm should not create an activity. Valid values are based on the element defined for the "XPath of Activity Element controlling Activity creation" parameter. For example, to specify that an activity should not be created if the "Connect New Device" flag is set to "Do Not Connect / Turn On", this parameter should be set to "D1NC" (from the D1_CONNECT_NEW_DEVICE_FLG lookup).

For additional information, refer to the D1-UPDDVC Algorithm Type.

Remote Turn Off Turn On (D1-REMONOFF)

Algorithms of this type remotely turn a device off and on for a Back to Back service request. Algorithms of this type use the following parameters:

- **Device Incompatibility Detected Activity BO:** Specifies the activity business object the algorithm will look for. If the algorithm finds an activity of this business object, the algorithm terminates.
- **Remote Connect BO:** Specifies the activity business object to instantiate when creating a remote connect command.
- **Remote Disconnect BO:** Specifies the activity business object to instantiate when creating a remote disconnect command.
- **Installation Event Status Override for Connect:** The override status to which the Installation Event Status is set after performing a remote connect command.
- **Installation Event Status Override for Disconnect:** The override status to which the Installation Event Status is set after performing a remote disconnect command.

For additional information, refer to the D1-REMONOFF Algorithm Type.

Check for Measurement (D1-CHKMSMT)

Algorithms of this type determine if measurements exist on activity's service point as of the service date/time. If no measurement is found, algorithms of this type create an activity to either obtain or wait for a measurement. The specific type of activity is based on the type and configuration of the device and service point. Algorithms of this type use the following parameters:

- **Activity BO To Wait For Measurement:** Specifies the activity business object to instantiate when the algorithm logic indicates it should wait for a measurement for the service point.
- **Activity BO For Field Read:** Specifies the field activity business object to instantiate when the algorithm logic indicates it should request a meter reading from the field.
- **Specific Field Task:** Specifies the field task type when creating a service order field activity for a meter reading from the field.
- **Activity BO To Wait For Scheduled Read:** Specifies the activity business object to instantiate when the algorithm logic indicates it should wait for a scheduled read for the service point.
- **Activity BO For On Demand Read - Scalar:** Specifies the activity business object to instantiate when the algorithm logic indicates it should issue an on-demand read (scalar) smart meter command.
- **Start Range for Normal Measurement Condition:** The start of the range of conditions that indicate "normal" measurements when the algorithm is searching for measurements for the service point.
- **End Range for Normal Measurement Condition:** The end of the range of conditions that indicate "normal" measurements when the algorithm is searching for measurements for the service point.
- **Minimum Range for bottom Measurement condition:** The minimum measurement condition used when searching for measurements for the service point. Used only when no measurements are found in the "normal" range defined by the "Start/End Range Normal Measurement Condition" parameters.

The following parameters on the orchestration activity type are also used by algorithms of this type when searching for measurements for the service point:

- **Look for Measurement within the Day:** Limits the search to the reference date (the service date).
- **Minimum and Maximum Offset Number of Days:** Numbers of days added to /subtracted from the reference date to expand the search period.

For additional information, refer to the D1-CHKMSMT Algorithm Type.

Algorithm Types and Orchestration Activity Business Objects

Each of the orchestration activity business objects uses a different set of these algorithm types. The table below lists which of these algorithm types are defined for each of the service order orchestration activity business objects.

	Enable Service	Disable Service	Cut for Non-Payment	Reconnect for Payment	Meter Exchange	Back-to-Back
Customer-Device Compatibility Check	X					X
Connect Only If Previously Connected					X	
Create Specific Activity	X					
Create Meter Exchange Field Activity					X	

	Enable Service	Disable Service	Cut for Non-Payment	Reconnect for Payment	Meter Exchange	Back-to-Back
Update Device	X	X	X	X	X	X
Remote Turn Off Turn On						X
Decommission Removed Meter					X	
Check For Measurement:	X	X	X			X

Cancel / Update Orchestration - Algorithm Types

Enter algorithms on the "Cancel Specific Activity" and "Update Specific Activity" states attempt to cancel or update a specific child activity. These algorithms are based on the following algorithm types.

- **Cancel Specific Activity:** Algorithms of this type cancel the specific activity (either a service order field activity or a smart meter command) that is associated to the Cancel or Update orchestration activity, based on the current status of the specific activity.
- **Update Specific Activity:** Algorithms of this type update the specific activity (either a service order field activity or a smart meter command) that is associated to the Cancel or Update orchestration activity, based on the current status of the specific activity.

Algorithm Type	Algorithm(s)
Cancel Specific Activity (D1-CANSPACT)	Cancel Specific Activity (D1-CANSPACT)
Update Specific Activity (D1-UPDSPAC)	Update Specific Activity (D1-UPDSPAC)

Use the Algorithm Type and Algorithm portals to view additional details about these algorithms.

Understanding Service Order Activity Types

Service order activity types must be configured for each type of service order activity.

Service order activity types are assigned to the following Activity Type Categories:

Service Order Activity	Activity Type Category
Back-to-Back Service	Request Orchestration
Cancel Orchestration	Orchestration Maintenance
Cut Service for Non-Payment	Request Orchestration
Disable Service	Request Orchestration
Enable Service	Request Orchestration
Exchange Meter	Request Orchestration
Reconnect Service for Payment	Request Orchestration
Update Orchestration	Orchestration Maintenance

Refer to [Understanding Activity Types](#) on page 707 for more information about activity types.

Service Order Activity Types and Divisions

Service order activity types can specify a Division, to represent the specific operating company associated with activities of that type. If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", users can only access service order activities or service order field activities with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

See [Understanding Divisions](#) for more information about divisions.

Configuring Service Order Activity Types

You use the **SOM Activity Type** portal is to view and maintain service order activity types.

Refer to [Understanding Activity Types](#) for more information.

You can access the portal by selecting **Admin, Communication, SOM Activity Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured service order activity types as well as service order activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Field Task By Device Condition:** This zone is used to configure field tasks such as Turn On Device or Turn Off Device, based on the device condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Update Device \(D1-UPDDVC\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes" , only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

- **Field Task By Service Point Condition:** This zone is used to configure field tasks such as "Install Device" or "Connect SP", based the service point condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Create Specific Activity \(D1-CRSPACT\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

Service Order Management Configuration

The following table outlines the activity types that must be configured for the service order activity types supported by Service Order Management:

Service Order Activity	Activity Type (Business Object)
Enable Service	Enable Service (D1-EnableServiceType)

Service Order Activity	Activity Type (Business Object)
Disable Service	Disable Service (D1–DisableServiceType)
Cut Service for Non-Payment	Cut Service for Non-Payment (D1–CutServiceForNonPaymentType)
Reconnect Service for Payment	Reconnect for Payment (D1–ReconnectForPaymentType)
Meter Exchange	Exchange Meter (D1–ExchangeMeterType)
Back-to-Back Service	Back-to-Back Service (D1–BackToBackServiceType)
Cancel Orchestration	Cancel Orchestration (D1–CancelOrchestrationType)
Update Orchestration	Update Orchestration (D1–UpdateOrchestrationType)

The demonstration database contains examples of each of these service order activity types.

Service Order Field Activities

Understanding Service Order Field Activities

This section describes service order field activities and how they communicate with field work management systems.

Service order field activities are activities that involve sending workers into the field to perform service. This can include meter installation, meter replacement, and other activities.

Service order field activities send messages to a field work system, which in turn assigns them to crews to be completed in the field.

Field Activity Information

All service order field activities are based on the Field Activity (D1-FieldActivity) business object, and include the following user-accessible information:

- **Status:** The current status of the service order field activity.
- **Service Date/Time:** The date and time the service order field activity was created.
- **Service Point:** The service point associated with the service order field activity.
- **Field Task Type:** The field task type for the service order field activity. This defines the type of task and other processing details regarding how Service Order Management processes the service order field activity. See [Field Task Types](#) for more details about field task types.
- **Recipient:** The field work system service provider to which the service order field activity is sent for scheduling and assignment.
- **Device ID:** The device related to the service order field activity (if applicable).
- **Request Information:** Details of the service order request, including requester and external system information.
- **Contact Details (or Customer Information):** Contact details for the customer associated with the service order request.
- **Address Information:** The address of the service point associated with the service order field activity.

The field activity business object also contains other information that is populated by algorithms and scripts as the service order field activity is processed by the system.

How Do Service Order Field Activities Work?

At a high level, service order field activities work as follows:

Create Field Activity

A service order orchestration activity creates a service order field activity based on the current state of the service point/meter/item.

Retrieve Required Data

The service order field activity uses a set of pre-processing algorithms to derive and populate data needed by the activity, such as the device, service point, address, effective date, and others.

Request Appointment (Optional)

If the service order field activity task type specifies that field tasks of this type require an appointment, the service order field activity checks for available appointment slots in the field work system and sends a notification to the appointment handling system.

Create Outbound Communication

The service order field activity creates an outbound communication to send the service order field activity to the field work system. The outbound communication gathers the information required by the field work system before being sent. This information is retrieved by a set of processing scripts defined on the field task type.

Receive Inbound Communication

When the service order field activity has been completed, the field work system sends an inbound communication back to Service Order Management.

Inbound communications can contain Field Activity Remarks (entered by field resources when they perform and complete their field work. If the Field Activity Remarks reference completion events, they are executed.

The inbound communications create completion events as defined on the field task type. If the service order field activity was successfully completed, it creates the "Completion Events When Successful" completion events. If the service order field activity was canceled, it creates the "Completion Events When Canceled" completion events.

Execute Completion Events

After receiving the inbound communication, a service order field activity algorithm transitions any active completion events into their executed state.

Complete Processing

The service order field activity completes its processing by doing the following:

- Updating the parent orchestration activity
- Sending a success response to the requester
- Transitioning the parent orchestration activity to the next state in its lifecycle
- Sending a service order field activity completion outbound communication to subscribing systems.

Service Order Field Activity Processing

This section outlines how service order field activities are processed.

Pre-Processing, Validation, and Post-Processing Algorithms

When service order field activities are first instantiated, a set of pre-processing algorithms populate and derive information needed for the activity, such as the activity type, service point, device, address, effective date, and other information.

Validation algorithms validate this information when first retrieved and when updated.

When service order field activities are completed, a post-processing algorithm populates the activity end date/time.

Service Order Field Activity Lifecycle

As a service order field activity moves through its lifecycle, it triggers various business processes based on the type of service order field activity. The table below outlines the lifecycle for the Field Activity (D1-FieldActivity) business object.

State	Description
Pending	<p>The initial state for service order field activities.</p> <p>An Enter algorithm sends an acknowledgement to the requesting system.</p> <p>The activity is transitioned to the next state via a monitor process.</p>
Validate	<p>Enter algorithms perform the following:</p> <ul style="list-style-type: none"> Validate Activity Type (and transition to error if invalid) Derive and validate service order field activity recipient Validate duplicate and conflict service order field activities Derive and validate service order field activity service point Derive and validate service order field activity device Validate address constituents Check for any existing cut service restrictions <p>The activity is transitioned to the next state via a monitor process.</p>
Validation Error	<p>If the business object fails any of the validations in the Pending state, it enters this state.</p> <p>Enter algorithms perform the following:</p> <ul style="list-style-type: none"> Create a To Do based on specified To Do Type and To Do Role Set the "Allow Child to Transition Parent Activity" flag to "yes". This allows the service order field activity to transition the parent orchestration activity if needed. <p>Activities in this state can be corrected and retried.</p>
Waiting to Request	<p>If a service order field activity has a future effective date, it remains in this state until the effective date is reached.</p> <p>A Monitor algorithm transitions the activity to the next state when the activity's effective date time is reached (process date time >= effective date time).</p> <p>An Enter algorithm sets the "Allow Child to Transition Parent Activity Based On Effective Date" flag to "yes". This allows the service order field activity to transition the parent orchestration activity if needed.</p>

State	Description
Waiting for Appointment	<p>If the service order field activity passes its validations and the effective date has been reached, the activity enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Evaluate if an appointment is required for field tasks of this type. If not, the activity transitions to the "Communication in Progress" state.</p> <p>Create a To Do if an appointment is necessary but the system is not able to send an appointment request.</p> <p>Set the "Allow Child to Transition Parent Activity" flag to "yes". This allows the service order field activity to transition the parent orchestration activity if needed.</p> <p>Send a notification to the appointment handling system.</p> <p>Monitor algorithms perform the following:</p> <p>Verify if an appointment has been supplied.</p> <p>Send a notification to the appointment handling system.</p> <p>The activity is transitioned to the next state via a monitor process.</p> <p>See Waiting for Appointment for more information about this state.</p>
Communication in Progress	<p>Service order field activities enter this state following the "Waiting for Appointment" or "Retry" states.</p> <p>Enter algorithms perform the following:</p> <p>Create an outbound communication for the service order field activity (see Communication in Progress for more information).</p> <p>Set the "Allow Child to Transition Parent Activity" flag to "yes". This allows the service order field activity to transition the parent orchestration activity if needed.</p> <p>Monitor algorithms perform the following:</p> <p>Check for existing child communications.</p> <p>Check that the activity hasn't timed out.</p>

State	Description
Discarded	<p>Activities discarded in other states enter this state.</p> <p>Enter algorithms perform the following:</p> <ul style="list-style-type: none"> Cancel outstanding outbound communications. Cancel outstanding completion events. Populate the cancel reason. Send a failure notification to the requesting system. Transition the parent activity to the "Activity Error" state (see Service Order Orchestration Activity Lifecycle for more information). Check if a Cancel Orchestration activity is required.
Communication Error	<p>If an outbound or inbound communication an Error state, the service order field activity enters this state.</p> <p>Monitor algorithms perform the following:</p> <ul style="list-style-type: none"> Check that the activity hasn't timed out. <p>Enter algorithms perform the following:</p> <ul style="list-style-type: none"> Create a To Do based on specified To Do Type and To Do Role. Set the "Allow Child to Transition Parent Activity" flag to "yes". This allows the service order field activity to transition the parent orchestration activity if needed. Activities in this state can be corrected and retried.
Retry	<p>When a service order field activity is retried after correction of an error condition, it enters this state.</p> <p>Enter algorithms perform the following:</p> <ul style="list-style-type: none"> Check to determine if there are associated outbound communications in progress. Cancel any outstanding outbound communications.

State	Description
Execute Completion Events	<p>After an inbound communication is received, it enters this state.</p> <p>Enter algorithms perform the following:</p> <p>Executes completion events defined on the field task type (these completion events were initially created by the inbound communication).</p> <p>Evaluates the "Field Activity Completed" flag on the service order field activity. If this is set to "No", the service order field activity is transitioned to the "Canceled In Field" state.</p> <p>The activity is transitioned to the next state via a monitor process.</p> <p>See Execute Completion Events for more information about this state.</p>
Completion Event Error	<p>If an error occurs during completion event processing, the service order field activity enters this state.</p> <p>Monitor algorithms perform the following:</p> <p>Check that the activity hasn't timed out.</p> <p>Enter algorithms perform the following:</p> <p>Create a To Do based on specified To Do Type and To Do Role.</p> <p>Set the "Allow Child to Transition Parent Activity" flag to "yes". This allows the service order field activity to transition the parent orchestration activity if needed.</p> <p>Activities in this state can be corrected and retried.</p>
Completed	<p>Service order field activities enter this state when all completion events have successfully completed.</p> <p>Enter algorithms perform the following:</p> <p>Update the parent orchestration activity.</p> <p>Send a success response to the requester.</p> <p>Transition the parent orchestration activity to the next state in its lifecycle.</p> <p>Send a service order field activity completion outbound communication to subscribing systems.</p>

State	Description
Canceled in Field	<p>If the "Field Activity Completed" flag on the field activity is set to "No", the service order field activity enter this state.</p> <p>Enter algorithms perform the following:</p> <p>Send a failed response to the requester.</p> <p>Transition the parent orchestration activity to the "Activity Error" state.</p> <p>Create a To Do to notify users that the service order field activity has been canceled.</p>

Waiting for Appointment

When a service order field activity enters the "Wait for Appointment" state, it first determines if an appointment is necessary for the service order field activity. If not, the activity moves on to the "Communication in Progress" state (see below).

If an appointment request cannot be sent for some reason, the service order field activity creates a To Do item to alert a user to attempt to manually request an appointment. Otherwise, the service order field activity sends an outbound message to the field work system requesting an appointment. based on the appropriate processing role defined on the."Send Notification to Appointment Handling System - Enter" algorithm.

Processing Role	Outbound Communication Business Object
Appointment Response (default)	Send Appointment Response Outbound Message (D1-SendApptRespOutboundMsg)
Used if: An appointment is required and needs to be scheduled Appointment has been set	Note: An outbound message must be created based on this business object.

The response from the field work system can be received by creating an Inbound Web Service that references the "Book selected appointment to Field Activity" (D1-BookAppt) service script.

While in this state, monitor algorithms verify if an appointment has been supplied and send notifications to the field work system.

Communication in Progress

Service order field activity communications are records of messages sent between Service Order Management and an external field work system. Communications can flow both outbound and inbound.

See [Service Order Field Activity Communication](#) on page 1066 for more information about service order field activity communication.

Manually Completing Service Order Field Activities

Service order field activities in the "Communication in Progress" state can be manually completed or canceled by clicking **Complete** in the **Record Actions** section of the **Activity** zone. This opens the **Field Activity Manual Completion** page where the user can enter appropriate details to manually complete the field activity (such as completion information, service point information, device information, and so on). When submitted, this page creates an inbound communication and transitions the field activity to the next state as appropriate.

Note: Implementations can define custom service scripts for each field task type in the **Manual FA Completion Controls** section on the Field Task Type extendable lookup to customize the sections displayed on the **Field Activity Manual Completion** page.

Execute Completion Events

After receiving the inbound communication, the service order field activity enters the "Execute Completion Events" state.

The inbound communication will have previously created completion events for the service order field activity, based on those defined on the field task type or those referenced by field activity remarks. These creation events begin in the "Pending" state.

An Enter algorithm transitions completion events associated with the service order field activity into their "Executed" state.

Service Order Field Activity Communication

This section outlines how service order field activities communicate with field work systems.

When a service order field activity enters the "Communication in Progress" state, it sends an outbound communication to the field work system, and waits for an inbound communication response.

See **Understanding the Service Order Field Activity Communication Process** below for more information about the role of communications in the service order field activity communication process.

Outbound Communications

Outbound Communications represent messages sent from Service Order Management to an external field work system. Outbound communications use the following types of objects:

Outbound Communication Business Objects

An outbound communication business object exists for each type of message to be sent to an external system. For service order field activities, the following base package outbound communication objects can be used.

Type of Outbound Communication	Outbound Communication Business Object
Initial service order field activity outbound communication	Field Activity Outbound Communication (D1-FieldActivityOBComm)
Modify outbound communication Used to send an update to a service order field activity previously sent to the field work system.	Field Activity Outbound Communication (D1-ActivityModifyOBComm)

Outbound Message Types

A outbound message type must also be created for each type of message to be sent to an external system. Again, this is based on the types of messages the system is designed to accept. For service order field activities, the following outbound message types are needed:

Type of Outbound Communication	Outbound Message Type
Initial Service Order Field Activity Message	Field Activity Outbound Message
Modify Existing Service Order Field Activity	Modify Field Activity Outbound Message

Refer to the Oracle Utilities Application Framework documentation for more information about outbound message types.

External Systems

You must also create an External System for each external system to which Service Order Management will send messages. Each external system defines a set of outbound message types that will be sent to that system. Each external system outbound message type also specifies the following:

- The processing method used to send the message (Batch, XAI, or Real-time)
- Message Sender (if Processing Method is set to Real-time or XAI)
- Batch Control (if Processing Method is set to Batch)
- Message XSL, W3C Schema, and Response XSL (as applicable)

To continue the example above, you might create the following external system:

External Application		
Outbound Message Type	Processing Method	Batch Control
Field Activity Outbound Message	Batch	Sync Request Monitor (F1-SYNRQ)
Modify Field Activity Outbound Message	Batch	Sync Request Monitor (F1-SYNRQ)

Refer to the Oracle Utilities Application Framework documentation for more information about external systems.

Inbound Communications

Inbound Communications represent messages sent from an external field work system to Service Order Management. Inbound communications are typically sent in response to a service order field activity. Inbound communications use the following types of objects:

Inbound Communication Business Objects

An inbound communication business object must be created for each type of message to be received from an external system. For service order field activities, the following base package inbound communication object can be used.

Inbound Communication Business Object
Field Activity Inbound Communication (D1-FieldActivityIBComm)

Inbound Web Service

You must also create an Inbound Web Service for each type of message to be received from an external system. Inbound web services define the details of how messages are received from an external system, including the inbound communication business object (or business service or service script) to be invoked when the response message is received. As in the case of inbound communication business objects, the set of inbound web services you need to create is based on the types of messages the system is designed to send. To continue the example above, you might create the following inbound web services:

Inbound Web Service	Schema (Inbound Communication Business Object)
Field Activity Inbound Communication	Field Activity Inbound Communication D1-FieldActivityIBComm

Refer to the Oracle Utilities Application Framework documentation for more information about Inbound Web Services.

Field Activity Remarks

Inbound communications can contain activity remarks, which represent notes entered by the field worker as they perform and complete their field work. These can be solely informational, or can reference completion events via the "Remark Processing" section of the Field Activity Remark Type extendable lookup. This allows information sent with the inbound communication to initiate business processing if necessary.

Completion events specified on this extendable lookup are created by the inbound communication, and then executed when the service order field activity enters the "Execute Completion Events" state.

Understanding the Service Order Field Activity Communication Process

This section provides an overview of the communication process that takes place when a service order field activity is initiated. For each step in the process, the table below provides a brief description of the processing that takes place, and lists the specific base package objects used by Service Order Management

Note that the process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process.

Step	Process	Base Package Objects
1.	An orchestration activity creates a service order field activity as part of its processing. A service order field activity business object is instantiated for the command.	Field Activity Business Object: Field Activity (D1-FieldActivity)
2.	When the service order field activity enters the Communication in Progress state, it creates an outbound communication.	Outbound Communication Business Object: Field Activity Outbound Communication (D1-FieldActivityOBComm)
3.	A Enter algorithm on the "Awaiting Response" state of the outbound communication retrieves information needed by the outbound message to be sent to the field work system based on processing scripts specified on the field task type.	Enter Algorithm: Populate Send Detail for Field Activity (D1-POPSNDDTL)

Step	Process	Base Package Objects
4.	A Enter algorithm on the "Awaiting Response" state of the outbound communication creates an outbound message.	Enter Algorithm: Create Outbound Message (D1-COUTMSG) Note: An outbound message type for this message is not included in the base package.
5.	The outbound message is sent to middleware components via an External System and Batch Control. Middleware components utilize Business Process Execution Language (BPEL).	External System: MWM Batch Control: Sync Request Monitor (F1-SYNRQ)
6.	The middleware converts the outbound message from SOM format into the format used by the field work system, and sends the message to the field work system.	
7.	When the field work system sends a response, the middleware receives the response message from the field work system, and converts it from the format used by the field work system to SOM format and invokes an Inbound Web Service.	Inbound Web Service: D1-FieldActivityIBComm
8.	The Inbound Web Service picks up the message, and creates a corresponding inbound communication. The specific type of inbound communication business object created is determined by the Inbound Web Service.	Inbound Web Service: D1-FieldActivityIBComm Inbound Communication Business Object: Field Activity Inbound Communication (D1-FieldActivityIBComm)
9.	The inbound communication identifies the parent outbound communication.	Outbound Communication Business Object: Field Activity Outbound Communication (D1-FieldActivityOBComm)
10.	The inbound communication creates the completion events defined on the field activity field task type (Successful or Canceled, as appropriate) in the "Pending" state. If the inbound communication contains field activity remarks, it also executes any field activity remark completion events.	Inbound Communication Business Object: Field Activity Inbound Communication D1-FieldActivityIBComm

Step	Process	Base Package Objects
11.	<p>The inbound communication updates the outbound communication.</p> <p>This update is performed by an Enter algorithm on the "Completed" Status of the inbound communication business object's lifecycle.</p>	<p>Inbound Communication Business Object: Field Activity Inbound Communication</p> <p>D1-FieldActivityIBComm</p> <p>Outbound Communication Business Object: Field Activity Outbound Communication</p> <p>(D1-FieldActivityOBComm)</p>
12.	<p>The outbound communication updates the "Completion Flag" and the original service order field activity business object.</p> <p>This update is performed by an Enter algorithm on the "Completed" Status of the outbound communication business object's lifecycle.</p>	<p>Outbound Communication BO: Initiate Connect Disconnect (D3-InitiateConnectDisconnect)</p> <p>Field Activity Business Object: Field Activity (D1-FieldActivity)</p>

Unrelated Pickup Orders

When field work crews are out performing field work, it's possible that they will encounter other work unrelated to their current task that needs to be done. This type of work can be as simple as trimming a tree whose branches are too close to power lines, or the replacement of a meter for a different customer or service point. These types of task are referred to as "unrelated pickup activities." Crews can either work the field activity or leave it to be assigned to another crew at a later date.

When the crew creates an unrelated pickup activity in the field work system, it is sent to Service Order Management, and a corresponding service order field activity is created in the system.

Unrelated pickup activities can be created via one of the following Inbound Web Services:

- Field Activity Asynchronous Req Inbound (D1-FARequestAsynchronous)
- Field Activity Synchronous Req Inbound (D1-FARequestSynchronous)

Once created, they are processed like any other service order field activity. If the pickup activity was completed in the field before being sent to Service Order Management, it will quickly move through its lifecycle (as now further action is needed) until it reaches the "Completed" state.

Retrieving Service Point Information

If the unrelated pickup activity is customer-related it will require service point information to be created. This information can be queried by the field work crew via the "Field Work Service Point Query" (D1-FieldWorkSPQuery) Inbound web service.

This service uses set of service point criteria to allow the field crew to search for a service based upon either service point or device information. The service returns a list of service points that is configurable in length. If the number of results is larger than the configured maximum length the service indicates that additional records exist and the crew can request another set of results allowing them to identify the proper service point to associate to the activity.

There are times when an unrelated pick-up activity is identified but the field crew is out-of-coverage (i.e. no network connection) and they will not be able to immediately verify service point information. In this type of situation, the crew can input the service point criteria fields and create the activity, which, when imported into Service Order Management, will attempt to identify the service point based upon the information provided. If the service point can be uniquely identified everything should operate as normal. If the service point cannot be uniquely identified then the service order field activity is set to the error state.

Understanding Service Order Field Activity Types

A single service order field activity type must be configured to support communication with external field work systems such as Oracle Utilities Module Workforce Management. Service order activity types are assigned to the “Field Activity” Activity Type Category.

Refer to [Understanding Activity Types](#) on page 707 for more information about activity types.

Service Order Field Activity Types and Divisions

Service order field activity types can specify a Division, to represent the specific operating company associated with activities of that type. If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", users can only access service order activities or service order field activities with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

See [Understanding Divisions](#) for more information about divisions.

Configuring Service Order Field Activity Types

You use the **SOM Activity Type** portal to view and maintain service order field activity types.

Refer to [Understanding Activity Types](#) for more information.

You can access the portal by selecting **Admin, Communication, SOM Activity Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", this zone displays only unsecured service order field activity types as well as service order field activity types with a Division (or Divisions) associated with the user on the **User Miscellaneous Information** zone on the **Miscellaneous** tab of the **User** portal.

The following zones may appear as part of the portal's **Main** tab page:

- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Activity Type List:** This zone works differently than the typical zone that list types in that it displays both those activity types that have been configured as well as those activity types that have yet to be configured. Broadcast a record to display the details of the selected record.
- **Activity Type:** This zone provides information about the selected Activity Type
- **Field Task By Device Condition:** This zone is used to configure field tasks such as Turn On Device or Turn Off Device, based on the device condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Update Device \(D1-UPDDVC\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

- **Field Task By Service Point Condition:** This zone is used to configure field tasks such as “Install Device” or “Connect SP”, based the service point condition. The configurations defined in this zone are used by the **SP State and Activity BO to Create** parameter for algorithms based on the [Create Specific Activity \(D1-CRSPACT\)](#) algorithm type. This allows the **SP State and Activity BO to Create** parameter to be defined more than the 20 times allowed on the algorithm. Note that configurations defined in this zone can also include **Service Point Type**.

Note: If the **Restrict Division** setting in the **Control by Division** section in the MDM Master Configuration is set to "Yes", only service point types available to the user (based on division), and only field task types considered valid for the service point type can be defined in this zone.

Service Order Management Configuration

The following table outlines the activity types that must be configured for the service order field activity type supported by Service Order Management:

Field Activity	Activity Type (Business Object)
Field Activity	Field Activity (D1-FieldActivityType)

The demonstration database contains examples of each of these service order activity types.

Configuring Service Order Field Activity Reschedule Reasons

The Reschedule Reason (D1-RescheduleReasonLookup) extendable lookup can be used to define reasons for rescheduling field activities. Reschedule reasons are captured on field activities, as well as their parent service order activity and an update orchestration activity.

Use the following steps to define service order field activity reschedule reasons:

1. Select **Admin, General, Extendable Lookup** to access the **Extendable Lookup Query** portal.
2. Enter "D1-RescheduleReasonLookup" in the **Business Object** field (or enter "Reschedule Reason" in the **Description** field) and click **Search**.
3. Click the "Reschedule Reason" link in the **Description** column of the search results.
4. Click **Add**, and enter the following details for the reschedule reason (fields not listed below are optional):
 - **Reschedule Reason:** A code used to designate the reschedule reason.
 - **Status:** The status of the reschedule reason.
 - **Description:** A description of the reschedule reason. This is what will appear in **Reschedule Reason** drop-down list on the service order field activity.
5. Click **Save**.

Field Task Types

Understanding Field Task Types

A service order field activity's field task type defines details about the type of task to be performed and how the system will process the activity.

Field Task Type Information

Field task types are values for the Field Task Type (D1-FieldTaskTypeLookup) extendable lookup. Each field task type value includes the following information:

- **Routing:** Indicates if field tasks of this type can only be performed at a service point. Valid values are "SP Required" and "Pass-Through".
- **Appointment Option:** Indicates if an appointment (via a mobile workforce application) is required or applicable to field tasks of this type. Valid values are "Not Applicable", "Optional", and "Required".
- **Completion Events When Successful:** One or more completion events that are executed upon successful completion of field tasks of this type.
- **Completion Events When Canceled:** One or more completion events that are executed upon cancellation of field tasks of this type.
- **Duplicate Task Type Information:** Defines processing rules for handling potential duplicate field tasks, including:
 - **Allow Duplicates:** Specifies whether or not duplicate field tasks are allowed.
 - **Duplicate Threshold:** A number of hours used to determine if a newly instantiated field task type should be considered a duplicate.

- **Field Task Types:** A list of one or more field task types that are considered to be duplicates of the field task type.
- **Conflict Task Type Information:** Defines processing rules for handling potentially conflicting field tasks, including:
 - **Allow Conflicts:** Specifies whether or not conflicting field tasks are allowed.
 - **Conflict Threshold:** A number of hours used to determine if a newly instantiated field task type should be considered a conflict.
 - **Field Task Types:** A list of one or more field task types that are considered to conflict with the field task type.
- **Processing Scripts:** Defines one or more processing scripts to extract supplemental information needed by the mobile workforce application to schedule field tasks of this type.
- **Manual FA Completion Controls:** Defines an optional Service Script used to customize the sections displayed on the **Field Activity Manual Completion** page when manually completing service order field activities.

Configuring Field Task Types

Field task types are configured using the extendable lookup portal.

You can access the extendable lookup portal from the **Admin > General > Extendable Lookup**.

Use the **Extendable Lookup Search** zone to search for and select the Field Task Type (D1-FieldTaskTypeLookup) extendable lookup.

The following zones may appear as part of the portal's **Main** tab page:

- **Extendable Lookup List:** This zone displays a list of values for the Field Task Type extendable lookup.
- **Extendable Lookup List:** This zone provides information about the selected value.

Service Order Management Configuration

The following table outlines the field task types that must be configured to support each of the service order activity types supported by Service Order Management:

Service Order Activity	Field Task Types
Enable Service — Meters	Connect SP at Source: D1-ConnectSPAtSource Connect SP at Meter: D1-ConnectSPAtMeter Connect SP at Source and Turn On: D1-ConnectSPAtSourceAndTurnOn Connect SP at Meter and Turn On: D1-ConnectSPAtMeterAndTurnOn Connect SP at Source and Install Meter: D1-ConnSPAtSrceAndInstMtr Connect SP at Meter and Install Meter: D1-ConnSPAtMtrAndInstMtr Install Meter: D1-InstallMeter Turn On Meter: D1-TurnOnMeter

Service Order Activity	Field Task Types
Enable Service — Items	Connect SP at Source: D1-ConnectSPAtSource Item - Connect SP at Device: D1-ConnectSPAtDevice Item - Connect SP at Source and Turn On: D1-ConnSPAtSrcceAndTurnOnDvc Item - Connect SP at Device and Turn On: D1-ConnectSPAtDvcAndTurnOn Connect SP at Source and Install Device: D1-ConnSPAtSrcceAndInstDvc Connect SP at Device and Install Device: D1-ConnSPAtDvcAndInstDvc Item - Install Device: D1-InstallDevice Turn On Item: D1-TurnOnItem
Disable Service — Meters	Turn Off Meter: D1-TurnOffMeter
Disable Service — Items	Turn Off Item: D1-TurnOffItem
Cut Service for Non-Payment — Meters	Cut for Non-Payment: D1-CutForNonPayment
Cut Service for Non-Payment — Items	Item - Cut for Non-Payment: D1-CutItemForNonPayment
Reconnect Service for Payment — Meters	Reconnect for Payment: D1-ReconnectForPayment
Reconnect Service for Payment — Items	Item - Reconnect for Payment: D1-ReconnectItemForPayment
Meter Exchange	Exchange Meter: D1-ExchangeMeter
Item Exchange	Exchange Device: D1-ExchangeDevice
Back-to-Back — Meters	Read Meter: D1-ReadMeter

Service Order Management External Applications

The external systems used with Service Order Management must be defined as External Applications using the "External Application" (D1-ExternalApplication) business object. Examples of external systems can include:

- A customer information system (such as Oracle Utilities Customer Care and Billing)
- A field work system
- An asset management system (such as Oracle Utilities Operational Device Management or Oracle Utilities Work and Asset Management)

Information defined for external system service providers used by Service Order Management include:

- **Our Name/ID in Their System:** This is the value that the field work system uses to identify our system.
- **Utility Device ID Type:** This is the Device ID Type that will be used when communicating with the external application and it will be the assumed Device ID Type for any device identifiers sent from the external application.
- **Utility Service Point ID Type:** This is the Service Point ID Type that will be used when communicating with the external application and it will be the assumed Service Point ID Type for any service point identifiers sent from the external application.

Refer to [Understanding External Applications](#) on page 1157 and [Configuring External Applications](#) on page 1157 for more information about external applications.

Processing Roles

The external application's processing roles define how data relevant to the field work system is sent and/or created.

Field work service providers can use the following processing roles:

- **Activity Notification:** Used to send notifications to subscribing and/or requesting systems about the status of orchestration and/or service order field activities.
- **Appointment Request:** Used to send a request for an appointment to the field work system.
- **Cancellation Activity:** Used to send notifications to requesting systems when canceling orchestration and/or service order field activities.
- **Collection Details:** Used to retrieve details about collections processing (used with "Cut Service for Non-Payment" and "Restore Service for Payment" orchestration activities).
- **Customer Contact:** Used to send a contact to a customer regarding a service request
- **Field Activity:** Used to send a service order field activity to the field work system.
- **Field Activity Completion:** Used to send a notification regarding completion of a service order field activity.
- **Interim Status Update:** Used to send updates regarding the status of orchestration and service order field activities to requesting systems.
- **Meter Exchange Mapping:** Used to define how to define different types of meter exchanges based specific roles and device configurations. This can provide context to field crews to help ensure they install the correct type of device and device configuration when exchanging a meter.
- **Response - Appointment:** Used to send a request for an appointment to the field work system.
- **Response - Fail:** Used to send a response to an external system when Service Order Management fails to respond.
- **Response - Missed Appointment:** Used to send a response to the field work system when notification of a missed appointment is received.
- **Response - Negative Acknowledgement:** Used to send a negative acknowledgement response to an external system in the event that a request is rejected.
- **Response - Received:** Used to send a response to an external system to acknowledge receipt of a request.
- **Response - Success:** Used to send a response to an external system when Service Order Management successfully processes a request.
- **Send Field Activity Remark:** Used to send a service order field activity remark to a subscribing system
- **Update Activity:** Used to send notifications to requesting systems when updating orchestration and/or service order field activities.

Defining Settlement Options

Settlement Configuration Overview

This section provides information about set up and configuration of administration data used by calculations and processes provided with Oracle Utilities Market Settlements Management.

Settlement Subscription Types

Understanding Settlement Subscription Types

Settlement subscription types are collections of properties defining a class of settlement subscriptions. Settlement subscription types also control valid values for various attributes of settlement subscriptions.

Settlement subscription types are defined by:

- **Transaction Business Object:** The business object used for settlement transactions based on settlement subscriptions of this type
- **Default Recipient:** The recipient that will be defaulted for settlement subscriptions of this type. A settlement subscription's recipient dictates the system to which results of settlement transactions are sent.

- **Transaction Retention Mode:** Defines how settlement transactions based on settlement subscriptions of this type are retained. "Keep All" indicates that all settlement transactions are retained when a replacement transaction is created (older transactions are sent to a status of "Superseded"). "Keep One Record per Period" indicates that only a single settlement transaction is retained for a time period (older transactions are deleted when the new one is completed).
- **Valid Settlement Calculation Groups:** A list of valid settlement calculation groups for settlement subscriptions of this type
- **Valid Recipients:** A list of valid recipients for settlement subscriptions of this type
- **Communication:** The outbound communication type used to create of outbound communications when sending the results of settlement transactions based on settlement subscriptions of this type

Refer to [Configuring Settlement Units](#) for more information about setting up settlement units and their respective dimension combinations, factors, and factor values.

For a deeper functional understanding, refer to the [About Settlement Subscriptions](#) or [About Settlement Calculation](#) sections of the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* .

Configuring Settlement Subscription Types

Refer to [Understanding Settlement Subscription Types](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement**, then **Settlement Subscription Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Subscription Type List:** This zone lists all usage subscription type records. Broadcast a record to display the details of the selected record.
- **Settlement Subscription Type:** This zone displays details for the selected usage subscription type.

The settlement subscription type defines a number of lists for valid objects that can be used in conjunction with the overall usage calculation process:

- Valid Settlement Calculation Groups
- Valid Recipients

Settlement subscription types also define the outbound communication type used when sending the results of settlement transactions based on settlement subscriptions of this type.

Settlement Transaction Exception Types

Understanding Settlement Transaction Exception Types

Settlement Transaction Exception Types define the groupings of exceptions for a settlement transaction based on their functional similarity. This provides a way to define Settlement Transaction Exceptions in a distinct enough way to understand the root issue that was generated from the usage calculation rule.

For a deeper functional understanding of Settlement Calculation, refer to the [About Settlement Calculations](#) section of the *Oracle Utilities Meter Solution Business User Guide* .

Configuring Settlement Transaction Exception Types

This portal is used to display and maintain a Settlement Transaction Exception Type.

Refer to [Understanding Settlement Transaction Exception Types](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement**, then **Settlement Transaction Exception Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Transaction Exception Type List:** displays all of the Settlement Transaction Exception Types so you can choose the one you want to display in more detail

- **Settlement Transaction Exception Type:** shows the specific configuration for the selected Settlement Transaction Exception Type

Settlement Units

Understanding Settlement Units

Settlement units define the “lowest common denominator set” of aggregation dimensions. For example, if aggregations are performed based on Rate Class, Strata, Procurement Group, and Supplier, the following dimensions would form the “lowest common denominator set” of these dimensions (since these are shared by different suppliers):

- Rate Class
- Strata
- Procurement Group

Settlement units define factor values based on unique combinations of dimension values. Different factor values can be defined for each unique combination of a settlement unit’s dimensions. For example, a Rate Class, Strata, and Procurement Group settlement unit could have different factor values for each unique combination of those dimensions. These multi-variable factor values can be retrieved by value derivation algorithms when performing aggregation, estimation, and forecasting calculations based on the same dimensions as defined for the settlement unit.

For example, an aggregation measuring component that aggregates data based on a specific combination of Rate Class, Strata, and Procurement Group could retrieve a “loss” factor value from a Rate Class, Strata, and Procurement Group settlement unit based on the same combination of dimensions. See [Applying Losses](#) for an example of how settlement units can be referenced in aggregation calculations.

Aggregation processing also uses settlement units to generate counts of accounts for forecasting based on combinations of these dimensions.

Settlement units are defined by:

- **Dimensions:** The attributes by which aggregated data should be analyzed
- **Dimension Combinations:** Unique combinations of the settlement unit’s dimensions (defined in the **Settlement Unit Dimension Combination** zone)
- **Valid Factors:** Valid multi-variable factors (defined in the **Settlement Unit Valid Factors** zone)

Refer to [Configuring Settlement Units](#) for more information about setting up settlement units and their respective dimension combinations, factors, and factor values.

Configuring Settlement Units

Refer to [Understanding Settlement Units](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement**, then **Settlement Unit**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Unit:** This zone displays details for the settlement unit, including configured dimensions.
- **Settlement Unit Dimension Combinations:** This zone displays combinations of the settlement unit’s dimensions, based on the dimensions configured in the **Settlement Unit** zone. Click **Add Dimension Combination** in the zone’s title bar to add a new combination.
- **Settlement Unit Valid Factors:** This zone displays valid multi-variable factors for the settlement unit. Click **Add Factor** in the zone’s title bar to add a new factor. Values for these factors are defined on the **Multi-Variable Factor** tab.

The following zones appear as part of the portal's **Dimension Combinations** tab page:

- **Settlement Unit Dimension Combinations:** This zone displays a list of dimension combinations for the settlement unit. Broadcast a record to display the details of the selected record. Click **Add Dimension Combination** in the zone's title bar to add a new combination.
- **Dimension Combination Values:** This zone displays factor values for each multi-variable factor defined for the selected dimension combination. You can use this zone to add and/or edit factor values.

The following zones appear as part of the portal's **Multi-Variable Factor** tab page:

- **Multi-Variable Factor List:** This zone displays a list of multi-variable factors for the settlement unit. Broadcast a record to display the details of the selected record.
- **Multi-Variable Factor Value List:** This zone displays factor values for each dimension combination for the selected multi-variable factor. You can use this zone to add and/or edit factor values.

Settlement Calculations

Settlement Calculation Groups

Understanding Settlement Calculation Groups

Settlement calculation groups are collections of settlement calculation rules that are used to perform settlement calculations, including calculating service point quantities, totaling consumption and usage for settlement units, application of losses, and allocation of unaccounted for energy (UFE). During the settlement transaction process, the system executes the settlement calculation rules defined in the settlement calculation group referenced on the settlement subscription. The rules within a settlement calculation group are defined in a specific sequence, allowing control over the order in which the rules are executed.

Settlement calculation groups are associated with specific settlement subscriptions and settlement subscription types (or both). When assigned to settlement subscriptions, settlement calculation groups contain the settlement calculation rules used to perform the appropriate calculations. Settlement calculation groups associated with settlement subscription types are those groups considered valid for settlement subscriptions of that type.

Settlement calculation groups can also be referenced by the [Execute Usage Calculation Group](#) calculation rule.

Understanding Bulk Settlement Calculation Groups

Bulk settlement calculation groups are calculation groups intended for use with high volume calculations, such as UFE allocation.

Some specific differences between bulk settlement calculation groups and standard settlement calculation groups include:

- Bulk settlement calculation groups reference only a single settlement calculation rule.
- Execution of bulk settlement calculation groups is performed by batch execution only, typically within a set of calculations performed during settlement transaction processing.
- Bulk settlement calculation groups use the “Settlement Bulk Calculation Group” business object (D1–SettlementBulkCalcGroup).
- Bulk settlement calculation groups have a **Calculation Group Class** of “Settlement Bulk Calculation”.

Configuring Settlement Calculation Groups

This portal is used to display and maintain a settlement calculation group.

Refer to [Understanding Settlement Calculation Groups](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement**, then **Settlement Calculation Group**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Calculation Group:** This zone displays basic information about a settlement calculation group.
- **Settlement Calculation Rules List:** This zone lists the settlement calculation rules belonging to the group. Not applicable to bulk calculation groups.
- **Referencing Settlement Calculation Rules List:** This zone lists the settlement calculation rules that reference the group. Not applicable to bulk calculation groups.
- **Referencing Settlement Subscription Type List:** This zone lists the settlement subscription types that reference the group.
- **Referencing Settlement Subscription List:** This zone lists the settlement subscriptions that reference the group.

Configuring Bulk Settlement Calculation Groups

The **Settlement Calculation Group** portal is used to display and maintain bulk settlement calculation groups.

Refer to [Understanding Bulk Settlement Calculation Groups](#) for more information about bulk settlement calculation groups and [Configuring Settlement Calculation Groups](#) for more information about creating and maintaining bulk settlement calculation groups.

The following apply when creating new bulk settlement calculation groups:

- Select “Settlement Bulk Calculation Group” from the **Settlement Calculation Group Business Object** drop-down list.
- Use a naming convention of some sort to identify bulk settlement calculation groups (the **Settlement Calculation Group** portal does not provide a way to search for groups based on **Calculation Group Class**). For instance, consider including “bulk” or “blk” in the **Description** of bulk settlement calculation groups.

Settlement Calculation Rules

Understanding Settlement Calculation Rules

Settlement calculation rules are standard and custom rules that perform settlement calculations, including calculating service point quantities, totaling consumption and usage for settlement units, application of losses, and allocation of unaccounted for energy (UFE). Settlement calculation rules are created for a specific settlement calculation group. For example, if you were configuring two settlement calculation groups and both included a specific usage calculation rule, you would need to create two instances of the settlement calculation rule, one for each group.

On almost every settlement calculation rule, the failure of the rule results in a settlement transaction exception and the [Usage Transaction Exception Type](#) for the failure can be configured on the rule. These usage transaction exception types can also be set to a specific Exception Severity:

- **Information:** Used to highlight minor issues, but not sufficient to cause the settlement transaction to be put into a failure state. Exceptions of this category can be used to report on the frequency of interesting, but not fatal issues.
- **Issues:** Used to report a problem that will prevent the settlement transaction from being sent. Multiple "issue exceptions" can be created during settlement transaction processing. If at least one issue exists after all rules have been applied, the settlement transaction is transitioned to a failure state requiring review and approval.
- **Terminate:** Used to report a severe issue that will cause the settlement calculation process to stop and the settlement transaction to be transitioned immediately to a failure state requiring review and approval. Only one terminate exception can be issued (as the first one causes calculation processing to stop for a settlement transaction). This should be used for cases where manual override / approval isn't accurate.

For a deeper functional understanding of settlement calculation, refer to the [About Settlement Calculation](#) section of the *Oracle Utilities Meter Data Management / Smart Grid Gateway Business User Guide* .

Configuring Settlement Calculation Rules

This portal is used to display and maintain a settlement calculation rule.

Refer to [Understanding Settlement Calculation Rules](#), [Understanding Settlement Calculation Groups](#), and [Understanding Usage Transaction Exception Types](#) on page 668 for more information.

You can access the portal by selecting **Admin**, then **Settlement**, then **Settlement Calculation Rule**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Calculation Rule:** This zone displays details for the selected settlement calculation rule, including parameters used when executing the rule
- **Eligibility Criteria List:** Lists the eligibility criteria defined for the rule, if applicable.

Calculation Settlement Calculation Rules

The following is a list of the calculation settlement calculation rules provided as part of the base product. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Settlement Calculation Rule Name	Applicable Data Type(s)	Purpose
Apply Math (Interval Data)	Interval	<p>This rule is used to perform calculations on interval data and stores the results in the settlement transaction's service quantities. A variety of options are available on this rule that include defining the calculation type, variables to use, as well as the equation to use (math functions and expressions).</p> <p>This rule provides aggregated usage for all selected interval measuring components (filter by TOU, SQI & UOM) associated to a settlement subscription.</p> <p>This rule can also multiply total usage by a factor using a custom formula.</p>
Array Math	Interval, arrays, and calculated quantities	This rule is used to perform settlement calculations on arrays and interval data and it stores the results in the settlement transaction's service quantities.
Market Award Allocation	Interval	This rule is used to perform settlement calculations to allocate load based on market awards, based on appropriate methods for dividing load out to wholesale contracts.
Measuring Component Set Calculation	Interval and calculated quantities	This rule is used to perform UFE calculations.

<p>Vector and Service Quantity Math</p>	<p>Interval</p>	<p>This rule is designed to facilitate configuration of complex vector calculations. It is based on a series of underlying services with vectors configured as input to the calculations.</p> <p>Typical uses:</p> <p>Perform math using interval data. For example, take the difference between two curves, find max values, find coincident peaks, multiply a curve by a value, apply TOU maps, etc.</p> <p>Define complex formulas using various interval curves, profile factor values or calculated service quantities (bill determinant values).</p> <p>Support math functions: sin, cos, square root, etc.</p> <p>Store derived curves in memory that can be used in subsequent calculations</p> <p>Please note, this rule is not as efficient as other rules.</p>
---	-----------------	---

Decision-Making Settlement Calculation Rules

There are settlement calculation rules delivered as part of the base product that help with decision-making when executing the settlement calculation process. For more information on how each rule executes and can be configured, follow the link provided on the rule.

Settlement Calculation Rule Name	Purpose
<p>Execute Usage Calculation Group</p>	<p>This rule performs a call to execute a separate settlement calculation group which includes execution of all settlement calculation rules within that group.</p>
<p>Exception Handler</p>	<p>This rule is used to terminate processing if exception count criteria specified in the rule is met.</p>

Advanced Aside: Using Factors For Variables

A situation common in some implementations involves converting one unit of measure (UOM) to another. However, the conversion factor used in conversions of this type can differ based on many different types of criteria, such as the location of the service point or other characteristics. This type of calculation can be implemented as a settlement calculation rule that accumulates consumption for one UOM and converts the consumption to a different UOM by applying a factor to it.

Factors used for this purpose have a Factor Class of "Number," and use some unique rules:

- Number factors reference a characteristic type (with pre-defined values).
- Number factors reference an algorithm that retrieves or derives the value of the characteristic type at runtime.

Factor values for a Number factor are effective-dated pairings of a characteristic value and a corresponding value. Because these pairings are effective-dated, the value returned from the factor can change over time for each characteristic value. At run time, the rule retrieves / derives the characteristic value for the factor's characteristic type and then finds the value associated with the respective characteristic value. Factors can be related to any real or dynamic attribute, so rules of this type are very flexible. For example:

- **Real Attribute:** you could create a rule that retrieves a specific value based on the location of a service point.
- **Dynamic Attribute:** you could create a rule that retrieves a percentage value based on the amount the customer conserved as compared to the same period in the prior year, returning one value if the amount conserved is between 5% and 10%, another value if the amount conserved is between 10% and 20%, and a third value if the amount conserved is greater than 20%. The amount conserved is dynamically calculated at execution time and is compared to the characteristic values defined for the factor, and returns the appropriate value. In this example, if the amount conserved was anything less than 5%, no percentage value would be returned.

Calculation Rules

Array Math

This rule is used to perform settlement calculations on arrays and interval data and it stores the results in the settlement transaction's service quantities. Arrays can be derived from either measuring component sets or calculated quantities. Interval data vectors can be derived from measuring component sets, individual measuring components, or calculated quantities. A variety of options are available on this rule that include defining variables to use for arrays and interval data vectors, the specific calculations to perform (leveraging math functions and expressions), and how to save the results.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-ARRAYMATH Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-ArrayMath

Market Award Allocation

This rule is used to perform settlement calculations to allocate load based on market awards, based on appropriate methods for dividing load out to wholesale contracts. This rule takes in a vector from the settlement transaction and divides the load to be allocated to various market awards for a configured market product set. The allocated amounts should be tied to the contract connected to the market award and then saved to the settlement transaction as a new array.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D2-AWARDALOC Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-MarketAwardAllocation

Measuring Component Set Calculation

This rule is used to perform settlement UFE calculations.

This rule executes a batch program (D1-MCSCA, defined as a parameter on the Execute MC Set Calculation-Apply Rule algorithm), which in turn executes the Perform MC Set Calculation algorithm to perform the calculation. The rule configuration includes definition of variables and the equation used for UFE calculations. Variables can be based on specified measuring component sets, aggregation measuring components, or calculated quantities.

This rule should be used ONLY with Bulk Settlement Calculation Groups.

Note:

Additional detail on the logic of this rule can be found in the Detailed Description of the D1-EXEMCSCAL Algorithm Type.

For help with the meaning of specific configuration fields, refer to the embedded help on the screen when adding or editing the rule.

Business Object

D2-MCSetCalculation

Settlement Item Types

Understanding Settlement Item Types

Settlement Item Types define specific types of end-customer settlement accounts.

Settlement item types define the following attributes:

- **Settlement Item Business Object:** The business object to use create settlement items of this type.
- **Settlement Billed Usage Business Object:** The business object to use to capture billed usage for a settlement account.
- **Valid Service Point Types:** Valid service point types for the settlement item type.

Note: Settlement item types are similar to usage subscription types used in Meter Data Management, and are based on the Usage Subscription Type maintenance object (D1-USTYPE).

Configuring Settlement Item Types

Refer to [Understanding Settlement Item Types](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement**, then **Settlement Item Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Item Type List:** This zone lists all settlement item types. Broadcast a record to display the details of the selected record.
- **Settlement Item Type:** This zone displays details for the selected settlement item type.

Settlement Item Quantity Types

Understanding Settlement Item Quantity Types

Settlement item quantity types define types of quantities that can be stored for a settlement item. These quantity types are often infrequently calculated descriptors of a given customer and how they relate, at an aggregate level, to either the customer base as a whole or their particular rate class.

Settlement item quantity types use the following parameters:

- **Service Type:** The service type (electric, gas, water, etc.) for settlement item quantities of this type.
- **Settlement Item Quantity Business Object:** The business object used for settlement item quantities of this type.
- **Settlement Item Quantity Identifiers:** Value identifiers related to the current settlement item quantity type (used to provide shorthand descriptions of the various types of values measured by settlement item quantities of this type).

Configuring Settlement Item Quantity Types

You use the **Settlement Item Quantity Type** portal to display and maintain settlement item quantity types.

Refer to [Understanding Settlement Item Quantity Types](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement**, then **Settlement Item Quantity Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Settlement Item Quantity Type List:** This zone lists all settlement item quantity type records. Broadcast a record to display the details of the selected record.
- **Settlement Item Quantity Type:** This zone displays details for the selected settlement item quantity type.

Market Contract Types

Understanding Market Contract Types

Market Contract Types define specific types of market contracts used in settlement processing.

Market contract types define the following:

- The market associated with market contracts of this type
- The pricing category for market contracts of this type
- Whether market contracts of this type have Unique Contract Buyers. When set to "Yes", market contracts of this type are validated to ensure that each buyer only has one valid contract at a point in time for the market contract type.

Configuring Market Contract Types

Refer to [Understanding Market Contract Types](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement Market**, then **Market Contract Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Contract Type List:** This zone lists all market contract type records. Broadcast a record to display the details of the selected record.
- **Market Contract Type:** This zone displays details for the selected market contract type.

Market Products

Market Product Sets

Understanding Market Product Sets

Market Product Sets define the highest level grouping for a set of products that will be processed together. Market Product Sets are used by the Market Award Allocation settlement calculation rule as a way to gather a set of products and their related awards for division of load into an array of interval curves / vectors.

Market product sets define the following:

- The market associated with the product set
- The service type (electric, gas, etc.) of the product set

Configuring Market Product Sets

Refer to [Understanding Market Product Sets](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement Market**, then **Market Product Set**. You are brought to a query portal with options for searching. Once your record has been selected you are brought to the maintenance portal to view and maintain the selected record.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Product Set:** This zone displays details for the selected market product set.

Market Product Types

Understanding Market Product Types

Market Product Types define types of products used in settlement processing.

There are two primary types of market product types, each based on a specific business object:

- **Market Product Type:** Used for market product types whose award allocation is based on the configuration of the Market Award Allocation settlement calculation rule.
- **Formula-Based Market Type:** Used for market product types with more complex award allocation. This business object provides the ability to configure complex conditional calculations that take in both interval and scalar variables.

Market product types are defined by the following:

- **Division:** The division associated with the market product type.
- **Number of Decimals:** The number of decimal values used for market award quantities based on market products of this type.
- **Product Business Object:** The market product business object used for market products of this type.
- **Award Business Object:** The market award business object used for market awards based on market products of this type.
- **Calculation Details:** Applicable to Formula-Based Product Types only. Details used in performing formula-based calculations for market products of this type. Details include:
 - **Calculation Pre-Processing:** One or more algorithms to be executed prior to performing calculations for products of this type. These can include validation algorithms used to ensure the data being used by the calculations is valid and algorithms that retrieve, calculate, and store values used later in the calculation.
 - **Calculation Inputs:** Input variables (including Fixed Variables, Award Adhoc Characteristics, Factor Numbers, and Calculated Quantities) and Input Vectors (Fixed Vector Variables, Calculated Quantities, and Factor Profiles) that will be used in the calculations performed for products of this type.
 - **Calculations:** One or more calculations (based on the Calculation Inputs) to be performed for products of this type. Calculations can be based on Simple or Conditional formulas.
 - **Calculation Post-Processing:** Details of how the results of the calculations are saved and used in later processing. Options include:
 - **Save Results to Calculated Quantity:** Defines how calculation results are saved as service quantities on the Settlement Transaction that initiated the market product calculation and, if applicable, assigned to market contracts.
 - **Save Results to Characteristics:** Defines how calculation results are saved as characteristic values on the Settlement Transaction that initiated the market product calculation.

Configuring Market Product Types

Refer to [Understanding Market Product Types](#) for more information.

You can access the portal by selecting **Admin**, then **Settlement Market**, then **Market Product Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Market Product Type List:** This zone lists all market product type records. Broadcast a record to display the details of the selected record.
- **Market Product Type:** This zone displays details for the selected market product type.

Settlement Module Configuration

Oracle Utilities Market Settlements Management shares its application environment with other Oracle Utilities meter solution products, including Oracle Utilities Meter Data Management and Oracle Utilities Smart Grid Gateway. The default installation of any of these products provides access to all menu items and functionality provided with these products.

To configure the system such that only menu items and functionality used by Oracle Utilities Market Settlements Management is available, application users should be assigned to the following set of user groups:

- Meter Stack Common Services
- Meter Stack Common Batch Services*
- Settlement Services
- Settlement Batch Services*

*These user groups should be restricted to only those users who will be executing batch processing.

Refer to [Defining Users](#) in the *Oracle Utilities Application Framework Administrative User's Guide* for more information about setting up users.

Additional Independent Modules

Aggregation

Standard Aggregation

Configuring an Out-of-the-box Aggregation

Aggregation calculations should be run on an as needed basis. This can include running the following batch processes:

- Scanning for new aggregation dimension (D1-ADS): This process is applicable if the system is configured to use aggregation dimension scanners to detect new aggregation dimensions (such as a service point referencing a new transformer for which an aggregator measuring component doesn't currently exist)
- Performing aggregation calculations (D2-AGG): this batch handles the summarization of measurement values in order to create aggregated measurements.

Note that aggregation calculations should precede usage transaction processing if aggregated values serves as input to the calculation of bill determinants.

Refer to the [About Aggregations](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more information on this functionality. Refer to [Understanding Measuring Component Types](#) for information on Measuring Component Types provided for aggregation.

Understanding an Example Out-of-the-box Aggregation

The Oracle Utilities Meter Data Management base package includes an aggregation that aggregates measurement quantities for constituent measuring components based on postal code and service type dimensions. The table below outlines the types of objects used in this aggregation, based on the steps outlined above), and the specific objects for each type.

Dependency Order	Object Type	Base Package Example
1	Aggregator Measuring Component Business Object	D2-Aggregator (Aggregator - Postal and Service Type)

2	Aggregator Measuring Component UI Maps	Display: D2-AggMCDisp (Service Type and Postal Aggregator-Display) Maintenance: D2-AggMCMaint (Service Type and Postal Aggregator-Maintenance)
3	Aggregator Business Object Info Algorithm	D2-AMC-INFO (Service Type and Postal Aggregator - Information)
4	Find Constituent Measuring Components Algorithm	D2-DET-CMC (Find Constituent Measuring Components Based on Service Type and Postal)
5	Measuring Component Type	D2-AggregatorType (Aggregator Type)
6	Query Zone for Consumption Statistics Portal	D2-AGGMCQRY (Aggregator Search)
7	Dimension Scanner Activity Business Object	D2-ActivityAggDimScanner (Aggregator Creator - Postal / Service Type)
8	Dimension Scanner Activity UI Maps	Display: D2-AggDimScannerActDisp (Aggregator DS Activity-Display) Maintenance: D2-AggDimScannerActMaint (Aggregator DS Activity-Maintenance)
9	Dimension Scanner Activity Business Object Info Algorithm	D2-ADS-INFO (Aggregator Dimension Scanner Information)
10	Enter Algorithm for Scan State	D2-CRE-AGGMC (Aggregator MC Creation for Post Code and Service Type)
11	Activity Type	D2-ActivityTypeAggDimScanner (Aggregator Dimension Scanner Activity Type)

Refer to the [About Aggregations](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Creating a New Custom Aggregation

This section describes the overall process for creating a new custom Aggregation.

Refer to the [About Aggregations](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Execute the following steps:

1. Create a business object for the aggregator measuring component. This will flatten the dimensional value(s) into searchable characteristics. Whether this business object is a parent or a child of another aggregator business object depends on when periodic aggregation should occur:
 - a. If you want the periodic aggregation to occur when another aggregation occurs, it can be a child business object (meaning that it inherits the lifecycle (and therefore the deferred monitor) of the parent)
 - b. If you want to schedule its periodic aggregation independently from other aggregation business objects, this must NOT be a child business object as it will require its own deferred monitor (and deferred monitors can only be defined on parent business objects)
2. Create UI maps for the aggregator business object as follows:
 - a. One to display the aggregator measuring component (Display)
 - b. One to allow user to change / add a new one (Maintenance)

Note: A newer alternative to creating UI Maps would be to use UI Hints directly within the Business Object.

3. Create an info plug-in for the aggregator business object that concatenates together its dimension types and values.
4. Create a "Find Constituent Measuring Components" algorithm and plug it on the aggregator business object. This will be passed the aggregator measuring component and the from and to date/times. It will insert the constituent measuring component IDs and the respective from / to date-time of each onto a temporary table.
5. Create a measuring component type instance and reference the new aggregator measuring component business object (as well as the types of constituent measuring component types that should be aggregated).
6. Create a query zone for Consumption Statistics search to allow users to find the aggregator measuring component.

Optional steps:

1. Create a business object for the dimension scanner activity. This should be a child business object of the base package dimension scanner business object.
2. Create UI maps for the activity business object, as follows:
 - a. One to display the dimension scanner activity (Display).
 - b. One to allow users to change/add a new one (Maintenance).

Note: A newer alternative to creating UI Maps would be to use UI Hints directly within the Business Object.

3. Create an info plug-in that will describe what it scans.
4. Create an Enter algorithm on the Scan state that finds distinct combinations of the dimensional values and creates new aggregator measuring components when new ones are detected.

Note: You can reuse the base package deferred monitor **Aggregation Dimension Scanner Monitor (D1-ADS)** batch control .

Dynamic Aggregation

Dynamic Aggregation Configuration Overview

Standard aggregation processing uses specific algorithms configured to work with a specified set of dimensions. For example, the base package Service Type and Postal aggregation uses specific algorithms for dimension scanning and finding constituent measuring components.

In contrast, dynamic aggregation uses dynamic queries for the dimension scanning, find constituents, and aggregation processes. These dynamic queries are based on configuration of administrative data, including:

- **Data Sources** define the source of data to be aggregated, such as measurement data from usage subscriptions linked to a service point, badged or unbadged items, or other sources of data.
- **Aggregation Measuring Component Types** define the most important properties of aggregation measuring components used to store aggregated data.
- **Aggregation Groups** define the ordering of a series of related aggregations and the schedule of aggregation.

- **Measuring Component Sets** define the dimensions and criteria by which aggregation will be performed.

Aggregation Master Configuration

The Aggregation Master Configuration defines common parameters used with aggregation processing, including:

- Batch Controls used by the dimension scan and aggregation process, for both scheduled and adhoc execution.
- Details for how the system compares interval and billing data for the same set of customers in order to use only one source or other.

Data Sources

Understanding Data Sources

Data Sources define the source of data to be aggregated, such as measurement data from usage subscriptions linked to a service point, badged or unbadged items, or measuring component sets. Data sources also define configurations used when generating dynamic queries used by aggregation processing.

Data Source Classes

Data sources are defined by classes, each of which is based on a specific business object, and determines the type of configuration used by aggregation processing. More specifically, the data types configured on the data source are used when generating dynamic queries used by aggregation processing.

The table below lists the data source classes and the business object and configuration options for each. Consult the embedded help for more information about the specific configuration options used by each data source class.

Data Source Class	Usage	Business Object	Configuration Options
Measurements from US Service Points	Used when aggregating data from measuring components linked to service points via a usage subscription.	D1-DataSourceMeasurements	Measuring Component Types
Badged Items	Used when aggregating data from badged items.	D1-BadgedItemsDataSource	Item Types
Billed Service Quantities	Used when aggregating data based on billed services quantities.	D1-DataSourceBilledSerQuantity	Usage Subscription Types
Measuring Component Sets	Used when aggregating data from measuring component sets. Data sources of this class are used with composite aggregation.	D1-DataSourceMCSet	Usage Subscription Types
Unbadged Items	Used when aggregating data from unbadged items.	D1-DataSourceUnbadgedItems	Item Types
Measurements from US Direct Links	Used when aggregating data from measuring components directly linked to a usage subscription.	D1-DataSourceMeasurementDirect	Measuring Component Types
Service Point Quantities	Used when aggregating data based on service point quantities.	D1-DataSourceSPQuantities	Service Point Quantity Types

Data Source Template SQL

Data sources also provide template structured query language (SQL) used when generating dynamic queries used by aggregation processing. This template SQL is used as the basis for dynamic queries, and is extended by additional SQL generated from the data source configuration as well as configuration defined for measuring component sets, measuring components, and measuring component types that reference the data source. Template SQL is provided via the Data Source SQL (D1-DataSourceSQLLookup) extendable lookup. Values for this extendable lookup are used as the **Option Value** for the following business object options on the data source business object.

- **Dimension Scanner SQL:** The template SQL used when dimension scanning. This SQL is extended by the criteria, dimensions, and individually managed items configured on the measuring component sets being processed.
- **Find Constituents SQL:** The template SQL used when finding constituents. This SQL is extended by attributes defined on the aggregator measuring components being processed.
- **Aggregation SQL:** The template SQL used when performing aggregation. This SQL is extended by the value identifiers defined on the measuring component type of the aggregator measuring components being processed.

Configuring Data Sources

This portal is used to display and maintain data sources.

Refer to [Understanding Data Sources](#) for more information.

You can access the portal by selecting **Admin**, then **Aggregation**, then **Data Source**.

The following zones may appear as part of the portal's **Main** tab page:

- **Data Source List:** This zone lists all data source records. Broadcast a record to display the details of the selected record.
- **Aggregation Data Source:** This zone provides information about the selected data source.

Configuring Data Source Template SQL

Template SQL used when generating dynamic queries used in aggregation processing is defined in the Data Source SQL (D1-DataSourceSQLLookup) extendable lookup. The base package data source business objects reference appropriate base package values from this extendable lookup.

For example, the **Aggregation SQL** option on the Measurements from US Service Points data source business object (D1-DataSourceMeasurements) references the “D1_MSRMT_FROM_US_SP_MCTYPE_SQL” value from the Data Source SQL extendable lookup.

If an implementation requires template SQL that differs from the base package, custom extendable lookup values can be created and referenced on the data source business object.

When creating custom template SQL, start from an existing extendable lookup value. Select the value that most closely matches your requirements and use the **Duplicate** function to create a copy, and edit the SQL as needed.

Use the following procedure to add a custom extendable lookup value to a data source business object.

1. Add a business object option of the appropriate type to the data source business object. For instance, if creating custom SQL for aggregation, add an **Aggregation SQL** option.
2. Enter a **Sequence** higher than the base package option.
3. Specify the custom extendable lookup value in the **Option Value** field.

Dynamic Aggregation Measuring Component Types

Understanding Dynamic Aggregation Measuring Component Types

Like other measuring component types, dynamic aggregation measuring component types define the most important properties of a measuring component. In this case, they define the properties of aggregator measuring components.

Measuring component types used by dynamic aggregation use many of the same attributes as other types of measuring components, but some attributes are used differently. Some attributes used specifically by dynamic aggregation include:

Measuring Component Business Object: This should be an aggregator measuring component business object, such as one of the following:

- Aggregator Interval (D1-AggregatorInterval)
- Aggregator Scalar (D1-AggregatorScalar)
- Aggregator Customer Quantities (D1-AggregatorCustomerQuantity)
- Aggregator Items Measuring Component (D1-AggregatorItems)

Measurement Business Object: Aggregated measurements can be based on either the Measurement (D1-Measurement) business object or the Aggregation Measurement (D1-AggregationMeasurement) business object (based on the Aggregation Measurement maintenance object).

Data Source: The source of the data that will be aggregated and the specific type of data that should be aggregated. Note that the **Service Type** of the data source, as determined by its associated objects (e.g. Measuring Component Type, Device Type, Service Point Type), must match the **Service Type** for this measuring component type.

Value Identifiers: These store the values of UOM, TOU, and SQI that identify the measurements to be aggregated. For each value identifier either the **Value Calculation Method** or **Value Derivation Algorithm** must be defined (not both). These define how measurement values are calculated or derived during aggregation processing.

Refer to [Understanding Measuring Component Types](#) on page 617 for more information about measuring component types.

Configuring Dynamic Aggregation Measuring Component Types

The **Measuring Component Type** portal is used to display and maintain dynamic aggregation measuring components.

Refer to [Understanding Dynamic Aggregation Measuring Component Types](#) for more information about dynamic aggregation measuring components.

You can access the **Measuring Component Type** portal from **Admin > Device > Measuring Component**.

Refer to [Configuring Measuring Component Types](#) on page 622 for more information about working with measuring component types.

Aggregation Groups

Understanding Aggregation Groups

Aggregation Groups define the ordering of a series of related aggregations based on a set of configured Measuring Component Sets. Aggregation groups define the following attributes for aggregations performed for its Measuring Component Sets:

- The **Time Zone** for aggregated data
- **Aggregation Scheduling** can be based on either a Defined Lag, or a Processing Timetable.
 - **Defined Lag** scheduling uses the following parameters:
 - **Aggregation Cut Off Time:** The end time for aggregation calculations performed for Aggregation Measuring Components for Measuring Component Sets associated with the Aggregation Group. This is used to ensure a consistent end time for aggregation periods. This is especially useful when aggregating other aggregations.
 - **Aggregation Lag:** The number of days between the date on which aggregation calculations are performed and the end date of the aggregation period. This defines the time period between the aggregation calculation date and the aggregation horizon that serves to allow all measurements to arrive. This together with the Aggregation Horizon is used to determine the start and end dates of an aggregation period. For example, with an Aggregation Horizon of 5 and an Aggregation Lag of 2, aggregation calculations performed on January 9 would be for an aggregation period of January 3 through January 7. The next day (January 10), the aggregation period would shift to January 4 through January 8.
 - **Aggregation Horizon:** The number of days in the aggregation period for Aggregation Measuring Components for Measuring Component Sets associated with the Aggregation Group. This reflects the time

period during which there's a potential change in measurement data for one or more of the measuring components associated with Aggregation Measuring Components. This together with the Aggregation Lag is used to determine the start and end dates of an aggregation period.

- **Processing Timetable** scheduling uses a Processing Timetable Type to drive aggregation schedule.

Aggregation groups can be used to perform aggregations for Analytical or Settlement purposes (defined by the Aggregation Category).

Aggregation Group Runs

Aggregation group runs represent individual aggregation executions for an individual aggregation group. Aggregation group runs are used to capture the relevant details for an aggregation and track the status of the execution of the aggregation for each of the Measuring Component Sets for the aggregation group.

Aggregation group runs for a specific aggregation group are listed in the **Aggregation Group Run** zone on the **Aggregation Group** portal. This zone displays the following for each aggregation group run:

- Run Number
- Run Type (Scheduled vs. Ad Hoc)
- Status (Pending, In Progress, Completed, or Error)
- Aggregation Horizon Start
- Aggregation Horizon End
- Details

Details for a specific aggregation group run can be viewed by broadcasting the run in the **Aggregation Group Run** zone. The following is displayed for the selected run in the **Aggregation Group Run Details** zone:

- Sequence
- Measuring Component Set
- Initiation Method
- Batch Run

Configuring Aggregation Groups

This portal is used to display and maintain aggregation groups.

Refer to [Understanding Aggregation Groups](#) for more information.

You can access the portal by selecting **Admin**, then **Aggregation**, **Aggregation Group**.

The following zones may appear as part of the portal's **Main** tab page:

- **Aggregation Group List:** This zone lists all aggregation group records. Broadcast a record to display the details of the selected record.
- **Aggregation Group:** This zone provides information about a selected aggregation group.
- **Aggregation Measuring Component Sets:** This zone lists measuring component sets associated with the selected aggregation group. Click **Resequence** to change the order of the measuring component sets in the aggregation group. Click **Add** to add a new measuring component set to the aggregation group.
- **Aggregation Group Run:** This zone lists individual aggregation runs performed for the selected aggregation group. Broadcast a record to display the details of the selected record. This zone displays up to 10 records. If there are more than 10 records, use the **Previous** and **Next** buttons to navigate between pages of records. Click **Add** to execute an ad hoc aggregation group run.
- **Aggregation Group Run Details:** This zone displays details for a selected aggregation group run.

Measuring Component Sets

Understanding Measuring Component Sets

Measuring component sets are used to define the dimensions and criteria by which aggregation will be performed.

A measuring component set's **Measuring Component Type** defines the Measuring Component and Measurement Type to be used in capturing aggregation results, as well as the aggregation functions that will be used on the source transnational data and the Data Source that will identify where that transnational data will be retrieved from.

Measuring component sets are associated with an **Aggregation Group**, which controls when and how aggregation is processed. This includes the sequence in which the aggregation group's measuring component sets are processed, as well as the method by which aggregation processing is initiated for each (this information can be found in the **General Processing** section).

A measuring component set's **Measuring Component Set Class** defines the way in which the measuring component set is used in the aggregation process. Measuring component set classes are based on the measuring component set's business object, and can include:

- **Aggregation Foundation** measuring component sets are used to aggregate transactional data, such as measurements from service points linked via usage subscriptions or billed service quantities.
- **Aggregation Composite** measuring component sets are used to aggregate data from a set of other aggregations (which can be based on either foundation or other composite measuring component sets).
- **Adhoc** measuring component sets are used to aggregate data based on an adhoc, user-defined set of measuring components.

See **Foundation and Composite Aggregation** in [Dynamic Aggregation Processing](#) for more information.

Dimensions, Criteria, and Individually Managed Items

The **Dimensions** and **Criteria** defined for the measuring component set are used by the dimension scanning process to identify individual aggregation measuring components that should be created. Measuring components are also created for each **Individually Managed Item** for which data matches the item's configuration.

- **Dimensions** identify the attributes by which data should be aggregated. Dimensions can include characteristics, identifiers, market participants, and values from specific tables and columns. For example, aggregating data by loss profile code, service point type and service provider would require defining dimensions for a Loss Profile Code characteristic, the Service Point Type column from the Service Point table, and the Service Provider column from the Device table.
- **Criteria** define the ways in which the dimensions are evaluated through a series of inclusions, exclusions, or both. For example, to aggregate data for the "AGG-E-COM" and "AGG-E-RES" service point types, but NOT for devices from the "ELEC" service provider, criteria could be defined to include both of service point type values and exclude the "ELEC" service provider.
- The criteria provided for **Individually Managed Items** is used to identify specific customers that should be aggregated in isolation from all other data that matches the **Dimensions** and **Criteria** defined for the measuring component set.

More specifically, the dimension scanning template SQL (derived from the data source) is extended by the **Dimensions, Criteria, and Individually Managed Items** configured on the measuring component set being processed.

Consult the embedded help for more information about the specific configuration options used by **Dimensions, Criteria, and Individually Managed Items**. The Source Type and Source Entity values are defined in the Aggregation Criteria Source Type (D1-CriteriaSourceTypeLookup) extendable lookup. Refer to [Configuring Aggregation Criteria Source Types](#) for more information about this extendable lookup.

The manner in which the criteria provided will be evaluated is defined in formulas configured in the **Criteria Processing** section. Consult the embedded help for more information about defining criteria processing formulas.

Configuring Measuring Component Sets

This portal is used to display and maintain measuring component sets.

Refer to [Understanding Measuring Component Sets](#) on page 1092 for more information.

You can access the portal by selecting **Admin**, then **Aggregation, Measuring Component Set**.

The following zones may appear as part of the portal's **Main** tab page:

- **Measuring Component Set:** This zone displays details of a selected measuring component set.
- **Dimensions:** This zone lists the dimensions used to identify the attributes by which the aggregation should be analyzed. Note: Data in this zone is edited by clicking the **Edit** button in the **Measuring Component Zone**.
- **Criteria:** This zone lists the criteria that limits the data to be aggregated through a series of inclusions, exclusions, or both. Note: Data in this zone is edited by clicking the **Edit** button in the **Measuring Component Zone**.
- **Individually Managed Items:** This zone lists the criteria used to identify specific customers that should be aggregated in isolation from all other data that matches the dimensions and criteria defined for the measuring component set. Note: Data in this zone is edited by clicking the **Edit** button in the **Measuring Component Zone**.
- **Measuring Component Set Participants:** This zone displays the measuring components that are in the Measuring Component Set Participant table for the measuring component set. For each measuring component, this zone displays the most recent and last measurement date/times.

Configuring Aggregation Criteria Source Types

The options in the **Source Type** and **Source Entity** drop-down lists used when configuring Dimensions, Criteria, and Individually Managed Items are defined in the Aggregation Criteria Source Type (D1-CriteriaSourceTypeLookup) extendable lookup. The measuring component set business objects reference this extendable lookup.

Each of the base package Source Type values (Characteristic, Identifier, Market Participant, and Table) are records in this extendable lookup. The Source Entity values for each of these are defined in the corresponding record.

For example, the “Table” Source Type defines the base package “Table” Source Entity values (Device, Device Event, Measuring Component, Service Point, Usage Subscription, and Usage), along with criteria path details for each (based on data source class).

If an implementation requires Source Type or Source Entity values that differ from the base package, custom extendable lookup values can be created.

When for creating custom values for this extendable lookup, start from an existing extendable lookup value. Select the value that most closely matches your requirements and use the **Duplicate** function to create a copy, and edit as needed.

Configuring Dynamic Aggregation Step-by-Step

This section outlines the steps involved when configuring dynamic aggregation.

Create Device and Service Point Administrative Data

Many of the objects used in dynamic aggregation reference other device- and service point-related administration data, such as measuring component types, service point types, usage subscription types, etc. Make sure this data is in place before configuring entities used with dynamic aggregation.

Create Data Sources

Create data sources for each source of data from which data will be aggregated. Note that implementations can have multiple data sources of each class with different data type configuration (Measuring Component Types, Item Types, Usage Subscription Types, etc.). For example, an implementation with 15 measuring component types might want to aggregate data differently based on subsets of measuring component types. In this case, each subset of measuring component types could be defined on a different data source.

If applicable, create custom Template SQL extendable lookup values and add them to Data Source business objects as appropriate.

Create Aggregation Measuring Component Types

Create the aggregation measuring component types that will be used to define the attributes of the measuring components that will be created during aggregation processing.

Aggregation measuring component types reference an appropriate Data Source. Continuing the example above, each subset of measuring component types (each defined on a separate data source) would require a separate aggregation measuring component type.

Create Aggregation Groups

Create the aggregation groups that will be used to control aggregation processing, including aggregation groups for both foundation and composite aggregation processing.

Note: When initially creating aggregation groups, define only the basic data for each (name, category, and optional time zone). Add measuring component sets to aggregation groups when creating the latter in the next step.

Create Measuring Component Sets

Create the measuring component sets that will define the “buckets” by which the aggregated data will be grouped.

Measuring component sets reference aggregation measuring component types and aggregation groups.

Create custom Source Type records (if applicable).

Revise Aggregation Groups (if needed)

After creating measuring component sets, adjust the sequence of each within its aggregation group as appropriate. For example, this would be necessary if measuring component sets are created and added to aggregation groups in an order that differs from their intended sequence.

Extending Dynamic Aggregation

The dynamic aggregation functionality provides extensive flexibility through configuration of data sources, measuring component types, and measuring component sets to handle complex aggregation requirements. However, some implementations may require functionality and configuration options beyond that provided in the base package. For instance, an implementation may need to aggregate data of a source and type not covered by the base package data sources or use different dimensions and criteria or queries for aggregation processing.

In circumstances like these, the dynamic aggregation functionality can be extended through use of the Oracle Utilities Application Framework’s Configuration Tools (see [Configuration Tools](#)) and other options. This section outlines some of the possible approaches to extending this functionality.

Data Source Business Objects: If an implementation requires aggregation of a data type of source beyond those provided with the base package data source business objects, custom business objects can be created to support this requirement. Key considerations when creating custom data source business objects include:

- Configuration options such as “Sourced Measuring Component Types” or “Sourced Usage Subscription Types”
- Values for the “Aggregation SQL”, “Dimension Scanner SQL”, and “Find Constituents SQL” business object options from the Data Source SQL extendable lookup.
- Algorithms for the “Generate SQL For Data Source” system event that leverage the configuration options defined for the data source

Data Source SQL Extendable Lookup Values: If an implementation requires template SQL that differs from the base package, custom values for the Data Source SQL extendable lookup can be created and referenced on the data source business object. When creating custom template SQL, start from an existing extendable lookup value. Select the value that most closely matches the requirements and use the **Duplicate** function to create a copy, and edit the SQL as needed.

Aggregation Measuring Component Type Business Objects: If an implementation requires capturing data for measuring component types not provided in the base package, the base package aggregation measuring component type business objects can be extended as appropriate. Key considerations when creating custom measuring component type business objects include:

- Algorithms for the “Generate SQL For MC Type” system event that leverages the Value Identifiers and other information defined for the measuring component type

Aggregation Measuring Component Business Objects: If an implementation requires capturing data for measuring components not provided in the base package, the base package aggregation measuring component business objects can be extended as appropriate. Key considerations when creating custom measuring component business objects include:

- Algorithms for the “Generate SQL For Aggregator MC” system event that leverages the Value Identifiers and other information defined for the measuring component type
- Algorithms for the “Find Constituents” system event that uses the “Generate SQL for Aggregator MC” algorithm, data source configuration, and other configuration to find constituent data for aggregation
- Algorithms for the business object’s “Active” state, including data aggregation and value derivation

Measuring Component Set Business Objects: If an implementation requires capturing data for measuring component sets not provided in the base package, the base package aggregation measuring component set business objects can be extended as appropriate. Key considerations when creating custom measuring component set business objects include:

- Algorithms for the “Generate SQL For MC Set” system event
- Algorithms for the business object’s lifecycle states, as appropriate

Aggregation Criteria Source Type Extendable Lookup Values: If an implementation requires Source Type or Source Entity values for measuring component sets that differ from the base package, custom extendable lookup values can be created. When creating custom values for this extendable lookup, start from an existing extendable lookup value. Select the value that most closely matches the requirements and use the **Duplicate** function to create a copy, and edit as needed.

Consumption Synchronization

Configuring Consumption Synchronization

Note: Refer to [Introduction to Consumption Sync](#) for additional functional information about how consumption synchronization works.

Keeping consumption synchronized between two measuring components that meter the same quantity but at different frequencies is a complicated task. As such the configuration for this process is diffuse and requires settings across several key areas of the system to be aligned. This section will help guide you through the process of configuring consumption synchronization.

The consumption synchronization process is really a collection of processes within Oracle Utilities Meter Data Management that all work together to ensure that quantities between related channels remain consistent:

- **Estimation VEE Rules:** several rules align consumption between related channels. These rules allow estimations to be refined based on higher quality measurements from a related channel. These rules are core to the consumption synchronization process. In simple scenarios where a few intervals are missing for an interval measuring component these rules are all that are necessary for synchronization with the related channel (note: it requires that the related channels data for that same time period has already been processed through to final measurements). For more information on these rules please visit the following sections:
 - Interval Adjustment from Scalar
 - Scalar Calculation from Interval
 - Scalar Proration
 - Sum Check
 - Final Measurement Validation

Note: Refer to [About IMD Estimations](#) for more information about these rules

- **Periodic Estimation:** both the interval and scalar variations of periodic estimation play an important role in consumption synchronization by ensuring that both channels of data are without gaps. In simple scenarios where one channel is missing data and the other is not periodic estimation is all that is require to produce synchronized

consumption. It is important to note that this process itself does not perform estimations but rather it is responsible for creating estimation initial measurements to trigger the estimation VEE rules.

- **Consumption Synchronization Activities:** these activities work to fix alignment issues that occur when data for the related channels are processed out of order or when there are complex outage scenarios. These activities are created when higher quality data is received for one channel and the related channel has measurements that are eligible to be recalculated and adjusted to align the total consumption for the period across the two channels. It is important to note that this process itself does not perform estimations but rather it is responsible for creating estimation initial measurements to trigger the estimation VEE rules.

Device Configuration Type

As a default the system will not generate consumption synch activities for related measuring components. Turning on consumption synchronization activities is done through a few key fields on the device configuration type:

- **Keep Consumption Reference MC in Sync:** defines if the related measuring components should be kept in sync. It can be configured to provide a one way synchronization from primary to secondary or a two way synchronization between primary and secondary.
- **Minimum Condition to Sync Primary MC:** when the secondary measuring component can initiate synchronization of the primary this provides an ability to limit those situations to when the incoming data is of a minimum quality.
- **Sum Check VEE Exception Type:** provides further ability to limit initiation of synchronization. When configured the synchronization activities will only be created when the initial measurement being processed encounters a VEE exception of the type configured. More specifically, a sum check VEE exception which will indicate that the two channels are out of synch by a minimum tolerance amount. This can be used to avoid synchronization either when there is no difference between the channels or when there is only a small difference between the channels.
- **Enable Extended Reconciliation:** defines if synchronization calculations should extend to cover the total contiguous period of consumption synchronization eligible final measurements across both channels in the relationship. When set to “Yes” consumption synchronization algorithms on initial measurements will execute a measuring component relationship level gap analysis and create a consumption synchronization for an entire gap that will impact both measuring components in the relationship.

Note: Additional detail about these fields can be found in the embedded help for the device configuration type.

Register Auto-Read Measuring Component Type

The configuration available for the register auto-read measuring component type has an indirect impact on the consumption synchronization process. This configuration is primarily intended to allow for a register to re-evaluate previously created estimations when new more accurate readings are received even when no related measuring components exist. Where this has impact to the consumption synchronization process is that when a new scalar reading is received after a period of estimation it will result in the time period for that new initial measurement being expanded into the past. This is because any estimates prior to this new higher quality initial measurement will be logically removed and the start reading for the initial measurement will in turn be the last non-estimated measurement prior to the initial measurement. This creates an initial measurement that spans the entire period for which estimations exist and as a result when a consumption synchronization activity is generated it will result in that same period of time being re-evaluated on the related measuring component.

This functionality is controlled by a few key fields on the register auto-read measuring component type:

- **Ignore Estimates as IMD Start Reading:** controls whether estimates directly previous to newly received incoming initial measurement should be logically removed when that newly received initial measurement data is non-estimated.
- **Flag Future Estimates as Do Not Use:** controls whether estimates that come directly after newly received incoming initial measurements should be logically removed when that newly received initial measurement data is non-estimated
- **Actuals or Corrections Initial Re-Estimation:** works in tandem with the above two fields. When either scenario results in measurements being logically removed this field, when turned on, will reset the last contiguous

measurement date/time for the measuring component making it eligible once more for periodic estimation. With the end result being that those estimated measurements that were removed would be recreated as new estimates.

Measuring Components

In order for consumption synchronization to work it must know that two measuring components are related in a way that indicates they are measuring the same consumption. This is achieved by configuring the "Consumption Reference Measuring Component" field on the measuring component.

Not only does this establish the relationship but it also establishes which measuring component is considered to be primary and which is considered to be secondary.

A measuring component is considered to be secondary when it holds the relationship to the Consumption Check Measuring Component (the primary measuring component).

For example, consider the following related measuring components.

- Scalar Measuring Component: ER-SM-007 / 1 / Electric kWh Daily
- Interval Measuring Component: ER-SM-007 / 2 / Electric kWh 60min

If the scalar measuring component is the primary measuring component, it does NOT specify a "Consumption Reference Measuring Component", and the interval measuring component specifies the scalar measuring component as the "Consumption Reference Measuring Component".

If the interval measuring component is the primary measuring component, it does NOT specify a "Consumption Reference Measuring Component", and the scalar measuring component specifies the interval measuring component as the "Consumption Reference Measuring Component".

It is important to note that pending initial measurements for the secondary measuring component are processed by the D1-IMD batch process after the initial measurements for the primary measuring component. This ensures that the primary measuring component's final measurements will be available to the secondary measuring component's initial measurements VEE process to provide better quality estimations and validations.

Initial Load and Manual Initial Measurement Algorithms

Key to the consumption synchronization process are the algorithms that reside on initial load and manual initial measurements for both scalar and interval measuring components. These algorithms contain logic to identify final measurements on a related channel that are consumption synchronization eligible (typically estimated).

These algorithms allow definition of:

- The consumption synchronization activity created
- The condition range that defines consumption synchronization eligible final measurements

Please refer to the algorithm type descriptions for more information:

Algorithm Type	Description	Where used
D1-UPD-DTMC	Update Latest Measurement Date/ Time on MC with Consumption Sync	D1-InitialLoadIMDInterval D1-ManualIMDInterval
D1-UDTSCMCRE	Update Latest Measurement Date/Time on Scalar MC with Consumption Sync	D1-InitialLoadIMDScalar D1-ManualIMDScalar

Consumption Synchronization Activities

The consumption synchronization activities are initiated by initial measurements and are responsible for generating the appropriate estimation initial measurements to re-evaluate any consumption synchronization eligible final measurements for the related measuring component being processed.

These activities can be associated to one or more initiating initial measurements and are able to handle a broad combination of time periods which are not required to be contiguous.

If any generated estimation initial measurement does not finalize processing will be halted and details about the failed estimation initial measurement will be provided.

The following table identifies the catalogue of consumption synchronization activities:

Activity Type	Description	Activity Business Object
Related MC Consumption Sync - Scalar	This activity is generated to re-evaluate consumption sync eligible final measurements on scalar measuring components. One estimation initial measurement will be created per measurement needing to be re-evaluated.	D1-RelMCREScalar
Related MC Consumption Sync - Interval	This activity is generated to re-evaluate consumption sync eligible final measurements on interval measuring components. One estimation initial measurement will be created per contiguous set of interval measurements needing to be re-evaluated. Note the generated initial measurements will include non-consumption sync eligible final measurements which will help to feed into the estimation process to provide more accurate results.	D1-RelMCREInterval
Gap Period Consumption Sync	This activity will re-evaluate both measuring components in the relationship for a wider time period than the initiating initial measurement. Specifically the time period will be the total contiguous period of consumption sync eligible final measurements across both channels in the relationship.	D1-GapPeriodConsumpnSync

Each consumption synchronization activity has an algorithm that performs the core logic of the consumption synchronization process.

These algorithms allow definition of:

- The condition range that defines consumption synchronization eligible final measurements

Please refer to the algorithm type descriptions for more information:

Algorithm Type	Description	Where used
D1-RE-SCMC	Scalar MC Consumption Sync	D1-RelMCREScalar
D1-RE-INTVMC	Interval MC Consumption Sync	D1-RelMCREInterval
D1-GAPCSYNC	Gap Period Consumption Sync	D1-GapPeriodConsumpnSync

Periodic Estimation

The algorithm that initiates periodic estimation which is plugged in to the Smart Meter device business object has a key configuration setting related to consumption synchronization:

- **MC Type to Process First:** determines whether interval or scalar measuring components should be estimated first. This should be set to process whichever measuring component type is considered to be primary first.

Please refer to the algorithm type description for more information:

Algorithm Type	Description	Where used
D1-PERESTM	Periodic Estimation	D1-SmartMeter

Related Batch Controls

There are a few batches involved with Consumption Synchronization:

- **Related MC Consumption Sync (D1-RMCRE):** this processes any pending consumption synchronization activities.
- **Related MC Consumption Sync - Retry Act (D1-RMCRR):** this retries any consumption synchronization activities that fail to the Issue Detected state.

Dashboards

Configuring the Meter Operational Dashboard

This section describes the process for configuring the Meter Operational Dashboard.

Refer to the [Using the Meter Operational Dashboard](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more information on this functionality.

This dashboard leverages a method of pre-staging data known as Statistics Snapshots. See [Understanding Statistics](#) for more information on Statistics Snapshots.

A method for tracking Performance Targets (also known as Service Level Agreements) is available within the Meter Operational Dashboard as well. To understand how to set up Performance Targets, refer to [Understanding Performance Targets](#). The Performance Targets you configure will then be leveraged on the **Batch Performance** and/or **Database** tabs of the Meter Operational Dashboard.

Configuring the **Meter Operational Dashboard** includes the following:

Master Configuration

You can access the Master Configuration portal by selecting **Admin**, then **General**, then **Master Configuration**.

Select the MDM Operational Dashboard Configuration.

Use the **Add** button beside the record to configure for the first time. If a record has already been added, then click the **Edit** button instead. Use the embedded help to guide you through the meaning of each configuration field.

General Admin Data

Create the following administrative data.

Service Type:

- **Service Type:** MISC
- **Description:** Miscellaneous

Unit of Measure:

- **Unit of Measure:** CT
- **Description:** Count
- **Service Type:** Miscellaneous
- **Decimal Positions:** 0
- **Allowed on Measuring Component:** Yes
- **Measures Peak Quantity:** No
- **Magnitude:** 1
- **Base Unit of Measure:** BLANK

Activity Types for Payload Statistics

Configure the following payload statistics activity types:

- Payload Statistics
- Payload Error Notification
- Payload Summary

See [Configuring Activity Types](#) for more information.

See [Processing Statistics](#) in the *Business User Guide* for more information about payload statistics processing.

Measuring Component Types for Payload Statistics

Configure the following measuring component types:

Initial Measurements

Field / Section	Value
Measuring Component Type	STATS-IMD
Description	IMD Upload Statistics Aggregator
Measuring Component Type Business Object	Activity Upload Statistic Aggregator Type
Measuring Component Business Object	Payload Statistics Aggregator - IMD
Measurement Business Object	Measurement

Statistic Controls and Statistics Snapshots

Statistic Controls are the source for recording the transactions which have gone into exception/discarded state or have a pending to-do associated with them. These records are then fetched by MDM Operational Dashboard’s respective zones for Statistic and Trend display.

Statistic Snapshots capture the transactions which have gone into exception/discarded state or have a pending to-do associated with them at a specific time.

Statistic Controls are configuration records that record the daily transactions of Incomplete IMD by Status, VEE Exceptions by Type, Usage Transaction by Status, and Usage Transaction by To-Do.

Statistic Snapshots are captured daily via the Statistics Control Monitor (F1-STATS) batch process.

Configure the following Statistics Control records:

Statistics Control	Description	Category	Status	Snapshot Frequency Hours	Retention Mode	Snapshot Business Object
INCOMPLETE-IMD-STATUS	Incomplete IMDs by Status	Operational	Active	1.00	Retain All Snapshots	Same as Description
INCOMPLETE-UT-STATUS	Incomplete Usage Transaction by Status	Operational	Active	1.00	Retain All Snapshots	Same as Description
INCOMPLETE-UT-TD-EXCP	Incomplete Usage To Dos by Exception	Operational	Active	1.00	Retain All Snapshots	Same as Description

Statistics Control	Description	Category	Status	Snapshot Frequency Hours	Retention Mode	Snapshot Business Object
INCOMPLETE-VEE-TD-EXCP	Incomplete VEE To Dos by Exception	Operational	Active	1.00	Retain All Snapshots	Same as Description

Payload Statistics Aggregator Measuring Components

Create a measuring component for each head end system for each measuring component type. For example, assume the following head end systems are being used:

- MV90: Usage
- Landis+Gyr: Usage and Device Events

In this example, you would create the following measuring components:

- MV90 (STATS-IMD Measuring Component Type)
- L+G (STATS-IMD Measuring Component Type)
- L+G (STATS-EVENT Measuring Component Type)

Field	MV90 Usage	L+G Usage	L+G Device Events
Measuring Component Type	IMD Upload Statistics Aggregator	IMD Upload Statistics Aggregator	Event Upload Statistics Aggregator
Status	Active	Active	Active
How To Use	Additive	Additive	Additive
Head End System	MV90	L+G	L+G

Batch Processing

The Meter Operational Dashboard is configured to be refreshed daily. To refresh the data used in the dashboard, the following batch processes should be processed in sequence after daily payload processing from the head end systems is complete.

- **D1-PSACC** (Payload Statistics Accumulation - Monitor): Used to initiate aggregation and accumulation of payload statistics in payload statistics activities. This executes the Perform Activity Aggregation (D1-PRFACTAGG) algorithm in the activity's "Active" state and transitions the activity to the "Accumulate Statistics" state which executes the Accumulate Statistics Algorithm (D1-ACCSTATS) algorithm.

Use the following parameters when running this batch process:

- Measuring Component Maintenance Object (maintenanceObject): D1-ACTIVITY
- Restrict by Batch Code (isRestrictedByBatchCode): true
- **D1-MC** (MC MO Periodic Monitor Process): Used to initiate aggregation of statistics for statistics aggregator measuring components. This transitions measuring components from the "Active" state to the "Aggregate" state, which executes the Aggregate IMD Statistics (D1-AGIMDSTAT) or Aggregation Event Statistics (D1-AGEVTSTAT) algorithms that aggregate measurement and/or device event statistics.

Use the following parameters when running this batch process:

- Maintenance Object (maintenanceObject): D1-MEASRCOMP
- **F1-STATS** (Statistics Control Monitor): Used to generate Statistic Snapshots based on Statistic Controls.

Use the following parameters when running this batch process:

- Maintenance Object (maintenanceObject): F1-STATS
- Restrict by Business Object (restrictToBusinessObject): F1-Statistics
- Restrict by Status Code (restrictToBOStatus): ACTIVE

The flowchart below illustrates the order which payload processing and these batch processes should be executed.

Populating the Dashboard Zones

The table below outlines the source of data for the various zones in the Meter Operational Dashboard.

Dashboard Zone	Source of Data
IMD Loading Trend	Usage Payload Statistics Aggregator Measuring Components (which aggregate data from payload statistics activities) (MV90 Usage and L+G Usage measuring components from the example above)
Device Event Loading Trend	Device Event Payload Statistics Aggregator Measuring Components (which aggregate data from payload statistics activities) (L+D Device Events measuring component from the example above)
Incomplete IMDs by Status Incomplete IMDs Trend	Incomplete IMDs by Status Statistics Control and Statistics Snapshots
VEE To Dos by Exception Type VEE To Dos Trend	Incomplete VEE To Dos by Exception Statistics Control and Statistics Snapshots
Usage Transaction by Status Usage Transactions Trend	Incomplete Usage Transactions by Status Statistics Control and Statistics Snapshots

Dashboard Zone	Source of Data
Incomplete Usage To Dos by Exception	Incomplete Usage To Dos by Exception Statistics Control and Statistics Snapshots
Usage Transactions To Dos Trend	

Configuring the Meter Health Check Dashboard

This section describes the process for configuring the **Meter Health Check** tab of the **Meter Operational Dashboard**.

Refer to **Using the Meter Health Check Tab** in the *Business User Guide* for more information on this functionality.

This dashboard leverages a method of pre-staging data known as Statistics Snapshots. See [Understanding Statistics](#) for more information on statistics snapshots.

Configuring the **Meter Health Check** tab includes the following:

Master Configuration

To access the **Master Configuration** portal select **Admin**, select **General**, and select **Master Configuration**.

Select the **Meter Health Check Configuration** master configuration.

You can also access this master configuration by clicking **Configure** on the **Meter Health Check** tab on the **Meter Operational Dashboard**.

Click the **Add** icon beside the record to configure for the first time. If a record has already been added, then click the **Edit** icon instead. Use the embedded help to guide you through the meaning of each configuration field.

This master configuration includes the following options:

- **IMD Trend Days:** specifies the horizon of collected data for IMD Processing and IMD Quality statistics snapshots. The number of days captured in each snapshot. Default 30 days.
- Chart Options:
 - **Processing:** Allows configuration of the colors used for IMD Records, Average Measurements, and Maximum Measurements data on the **IMD Processing Trend** graph.
 - **Quality:** Allows configuration of the colors used for VEE Exceptions, Average Measurements, and Maximum Measurements data on the **IMD Quality Trend** graph.

Configure Statistic Control and Statistic Snapshots

Statistic controls are the source for capturing the numbers of initial measurement records, VEE exceptions, and average and maximum measurements displayed on the **Meter Health Check** tab.

Statistic snapshots capture the numbers for each metric. Statistic controls are configuration records that define the specific types of metrics to capture.

Statistic snapshots are captured periodically via the F1-STATS (Statistics Control Monitor) batch program.

Configure the following Statistics Control records:

Table listing details for types of health check statistics controls.

Statistics Control	Description	Category	Status	Snapshot Frequency Hours	Retention Mode	Snapshot Business Object
Processing	IMD Processing Statistics - Hourly	Operational	Active	24:00	Retain All Snapshots	IMD Processing Snapshot - Hourly (D1-IMDProcessingHourly)
Quality	IMD Quality Statistics - Hourly	Operational	Active	24:00	Retain All Snapshots	IMD Quality Snapshot - Hourly (D1-IMDQualityHourly)

See [Capturing Statistics](#) for more information about statistics.

Configure Statistics Control Business Object

The Statistics Control (F1-Statistics) business object should be configured to specify the "Statistics Control Monitor" batch control in the **Monitor Process** drop-down list on the "Active" state.

To configure this business object, do the following:

1. Open the Statistics Control (F1-Statistics) business object in the **Business Object** portal.
2. Navigate to the **Lifecycle** tab, and expand the "Active" state.
3. Select "Statistics Control Monitor" from the **Monitor Process** drop-down list.
4. Click **Save**.

Batch Processing

The **Meter Health Check** tab is configured to be refreshed regularly (as frequently as daily). To refresh the data used in the dashboard, the F1-STATS batch process should be processed in sequence after other regularly schedule batch processing is complete to generate statistic snapshots based on statistic controls.

Use the following parameters when running this batch process:

- Maintenance Object (maintenanceObject): F1-STATS
- Restrict by Business Object (restrictToBusinessObject): F1-Statistics
- Restrict by Status Code (restrictToBOSstatus): ACTIVE

Configuring the Service Order Management Dashboards

This section describes the process for configuring the **Service Order Operational Dashboard** and the **Service Order Trends Dashboard**.

Refer to the [Using the Service Order Operational Dashboard](#) and [Using the Service Order Trends Dashboard](#) sections of the *Business User Guide* for more information on this functionality.

Configuring the **Service Order Operational Dashboard** and **Service Order Trends Dashboard** includes the following:

Configure Activity Type

Configure the following payload statistics activity type:

- Activity Statistics Aggregator Creator

Use the following procedure to create this activity type:

1. Select **Admin**, then **Communication**, then **Activity Type**. The **Activity Type** portal and **Activity Type List** zone open.
2. Click the **Add/Edit** icon for the "Activity Statistics Aggregator Creator" activity type in the **Activity Type List** zone.
3. Specify the following:
 - **Create Aggregators for Field Activity Statistics:** Yes
 - **Create Aggregators for Command Activity Statistics:** Yes
 - **Activity-Requesting Service Providers:** The external system(s) that sends service requests
 - **Exception Handling:** **To Do Type**, **To Do Role**, and other values as appropriate for your implementation.
4. Click **Save**.

See [Configuring Activity Types](#) for more information.

Configure Measuring Component Types

Configure the following measuring component types for each service type in your implementation:

- Activity Processing Accumulation Aggregator
- Activity Aging Snapshot Aggregator
- Activity Processing Snapshot Aggregator
- Activity Processing Derived Snapshot Aggregator

The tables below provide details for these measuring component types based on the "Electric" service type from the demonstration database.

Sub-Aggregator Measuring Component Types:

Field	Activity Processing Snapshot Aggregator	Activity Processing Derived Snapshot Aggregator
Measuring Component Type	ACT_PROC_SNAP_AGG	ACT_PROC_DER_SNAP_AGG

Create Activity Aggregator Measuring Components

Create an activity aggregator measuring component for each activity type you wish to capture for each measuring component type you created above. For example, if you wanted to capture statistics for request orchestration activity types (such as Enable Service, Disable Service, and so on) for the above measuring component types, you would create a total of 24 measuring components, as follows:

Measuring Component Type	Aggregation Dimensions — Activity Type	Aggregation Dimensions — Service Type
Activity Processing Accumulation Aggregator	Back to Back Orchestrator	Electric
Activity Aging Snapshot Aggregator	Back to Back Orchestrator	Electric
Activity Processing Snapshot Aggregator	Back to Back Orchestrator	Electric
Activity Processing Derived Snapshot Aggregator	Back to Back Orchestrator	Electric
Activity Processing Accumulation Aggregator	Cut for Non Payment Orchestrator	Electric
Activity Aging Snapshot Aggregator	Cut for Non Payment Orchestrator	Electric
Activity Processing Snapshot Aggregator	Cut for Non Payment Orchestrator	Electric
Activity Processing Derived Snapshot Aggregator	Cut for Non Payment Orchestrator	Electric

Measuring Component Type	Aggregation Dimensions — Activity Type	Aggregation Dimensions — Service Type
Activity Processing Accumulation Aggregator	Disable Service	Electric
Activity Aging Snapshot Aggregator	Disable Service	Electric
Activity Processing Snapshot Aggregator	Disable Service	Electric
Activity Processing Derived Snapshot Aggregator	Disable Service	Electric
Activity Processing Accumulation Aggregator	Enable Service	Electric
Activity Aging Snapshot Aggregator	Enable Service	Electric
Activity Processing Snapshot Aggregator	Enable Service	Electric
Activity Processing Derived Snapshot Aggregator	Enable Service	Electric
Activity Processing Accumulation Aggregator	Exchange Meter	Electric
Activity Aging Snapshot Aggregator	Exchange Meter	Electric
Activity Processing Snapshot Aggregator	Exchange Meter	Electric
Activity Processing Derived Snapshot Aggregator	Exchange Meter	Electric
Activity Processing Accumulation Aggregator	Reconnect Service for Payment Orchestrator	Electric
Activity Aging Snapshot Aggregator	Reconnect Service for Payment Orchestrator	Electric
Activity Processing Snapshot Aggregator	Reconnect Service for Payment Orchestrator	Electric
Activity Processing Derived Snapshot Aggregator	Reconnect Service for Payment Orchestrator	Electric

If you wanted to also capture statistics for smart meter commands or field task types, you would need to create activity aggregator measuring components for each individual command or field task type for each measuring component type.

If you are creating service order activities from multiple initiating systems (such as a customer information system and a network management system), you would need to create separate sets of activity aggregator measuring components for each initiating system.

Configure the Service Order Management Master Configuration

You can access the Master Configuration portal by selecting **Admin**, then **General**, then **Master Configuration**.

Select the Service Order Management Master Configuration.

Use the **Add** button beside the record to configure for the first time. If a record has already been added, then click the **Edit** button instead. Use the embedded help to guide you through the meaning of each configuration field.

Create an Activity for each Measuring Component Type

Create an activity for each measuring component type created above. Based on the example above (from the demonstration database) you would create an activity for each of the following measuring component types for each service type:

- Activity Processing Accumulation Aggregator
- Activity Aging Snapshot Aggregator
- Activity Processing Snapshot Aggregator
- Activity Processing Derived Snapshot Aggregator

For example, if you configured measuring component types for both "Electric" and "Water" service types, you would create eight activities (two of each of the types listed above).

Use the following procedure to create these activities:

1. Select **Menu**, then **Communication**, then **Activity**, then **Add**. The **Select Type** page opens.
2. Select "Activity Statistics Aggregator Creator" from the **Activity Type** drop-down list and click **OK**. The **Activity Statistics Aggregator Creator** page opens.
3. Select the appropriate measuring component type from the **Aggregator Measuring Component Type** drop-down list.
4. Select the appropriate service type ("E", "Water", and so on) from the **Service Type** drop-down list.
5. Click **Save**.

See [Maintaining Activities](#) in the *Business User Guide* for more information about creating and maintaining activities.

Aggregation and Batch Processing

The Service Order Management dashboards are based on aggregated data, and are configured to be refreshed daily. To refresh the data used in the dashboard, the following aggregation and batch processes should be processed in sequence each day.

Dimension Scanning

- **D1-ADS** (Aggregation Dimension Scanner Monitor): Used to transition "Activity Statistics Aggregator Creator" activities (created above) to the "Scan" state which checks for aggregator measuring components based on each measuring component type for each combination of dimensions. If needed, this process creates additional aggregator measuring components.

Use the following parameters when running this batch process:

- Measuring Component Maintenance Object (maintenanceObject): D1-ACTIVITY
- Restrict by Batch Code (isRestrictedByBatchCode): true
- Restrict to Business Object (restrictToBusinessObject): D1-ActivityStatsAggtorCreator
- Restrict by Status Code (restrictToBOStatus): ACTIVE

Note: Dimension scanning can also be performed manually by clicking **Scan** on the individual activities in the **Activity** portal.

Aggregation

- **D1-ACTAG** (Activity Statistics Aggregation Monitor): Used to aggregate activity data (via aggregator measuring components) to be displayed in the Service Order Management dashboards.

Use the following parameters when running this batch process:

- Restrict by Batch Code (isRestrictedByBatchCode): true
- Restrict to Business Object (restrictToBusinessObject): Aggregator Measuring Component business object, based on the measuring component types configured earlier:
 - D1-ActivityAgingSnapAggtor (Activity Aging Snapshot Aggregator)
 - D1-ActivityProcsAggregator (Activity Processing Accumulation Aggregator)
 - D1-ActivityProcDerivedSnapAgg (Activity Derived Snapshot Aggregator)
 - D1-ActivityProcSnapAggtor (Activity Processing Snapshot Aggregator)
- Restrict by Status Code (restrictToBOStatus): ACTIVE
- Override Maximum Errors (maxErrors): 1000

Note: Aggregation can also be performed manually by clicking **Update Statistics** on the **Activity Statistics** dashboard zone.

Configuring the Product Use Metrics Dashboard

This section describes the process for configuring the **Product Use Metrics** dashboard used with Oracle Utilities Meter Data Management and Oracle Utilities Meter Solution Cloud Service.

The Product Use Metrics displays customer counts such as device counts, channels of an active meters, number of billable services, head end device counts, and other similar data. The data presented on each dashboard is tailored to provide summary information for management. Refer to [Product / Metrics](#) for more information about this dashboard.

This dashboard leverages a method of pre-staging data known as Statistics Snapshots. See [Understanding Statistics](#) for more information on Statistics Snapshots.

Configuring the **Product Use Metrics** dashboard includes the following:

Configure Statistic Control and Statistic Snapshots

Statistic Controls are the source for capturing the numbers of active devices, channels on active meters, billable services, and device counts per head end system.

Statistic Snapshots capture the numbers for each metric. Statistic Controls are configuration records that define the specific types of metrics to capture.

Statistic Snapshots are captured periodically via the F1-STATS (Statistics Control Monitor) batch program.

Configure the following Statistics Control records:

Statistics Control	Description	Category	Status	Snapshot Frequency Hours	Retention Mode	Snapshot Business Object
CHANNEL-COUNT	Channel Count	Product Use Metrics	Active	1.00	Only Retain Most Recent Snapshot	Channel Count Snapshot
DEVICE-COUNT	Device Count	Product Use Metrics	Active	1.00	Only Retain Most Recent Snapshot	Device Count Snapshot
HEAD-END-DEVICE-COUNT	Head End Device Count	Product Use Metrics	Active	1.00	Only Retain Most Recent Snapshot	Head End Device Count Snapshot

Statistics Control	Description	Category	Status	Snapshot Frequency Hours	Retention Mode	Snapshot Business Object
US-CUSTOMER-COUNT	Usage Subscription Customer Count	Product Use Metrics	Active	1.00	Only Retain Most Recent Snapshot	Usage Subscription Customer Count Snapshot
BILLABLE-SERVICES	Billable Services by Service Type, SA Type, and CIS Division	Product Use Metrics	Active	1.00	Only Retain Most Recent Snapshot	Billable Services Statistics Snapshot

See [Capturing Statistics](#) for more information about statistics.

Configure Device Count and Channel Count Snapshot Business Objects and Algorithms (Optional)

By default, the Device Count Snapshot and Channel Count Snapshot business objects check for active usage subscriptions when deriving the total count of active devices and measuring components. However, in some implementations this is not required or appropriate.

The usage subscription check can be disabled if needed by setting the "Exclude US Check (Y or N)" parameter on the "Create XXXXX Count Snapshot" Enter algorithms on the Complete state of the Snapshot business objects to "Y" (this parameter is set to "N" by default).

The table below lists the snapshot business objects and their respective algorithms.

Snapshot Business Object	Count Snapshot Algorithm
Channel Count Snapshot (D1-ChannelCountSnapshot)	Create Channel Count Snapshot (D1-CHLCNTSNP)
Device Count Snapshot (D1-DeviceCountSnapshot)	Create Device Count Snapshot (D1DVCCNTSNP)

Configure Statistics Control Business Object

The Statistics Control (F1-Statistics) business object should be configured to specify the "Statistics Control Monitor" batch control in the **Monitor Process** drop-down list on the "Active" state.

To configure this business object, do the following:

1. Open the Statistics Control (F1-Statistics) business object in the **Business Object** portal.
2. Navigate to the **Lifecycle** tab, and expand the "Active" state.
3. Select "Statistics Control Monitor" from the **Monitor Process** drop-down list.
4. Click **Save**.

Batch Processing

The **Product Use Metrics** dashboard is configured to be refreshed periodically. To refresh the data used in the dashboard, the following batch processes should be processed in sequence after other regularly schedule batch processing is complete.

- **F1-STATS** (Statistics Control Monitor): Used to generate Statistic Snapshots based on Statistic Controls.

Use the following parameters when running this batch process:

- Maintenance Object (maintenanceObject): F1-STATS
- Restrict by Business Object (restrictToBusinessObject): F1-Statistics
- Restrict by Status Code (restrictToBOSstatus): ACTIVE

Data Extracts

This section describes functionality that support extract and export of data for use in external applications and systems.

Configurable Consumption Extracts

Configurable Consumption Extracts are measurement data extracts for a set of usage subscriptions optionally related to a specific market participant.

Configuration options for these extracts include:

- Type of Market Participant, based on Service Point Market Participant or Usage Subscription Market Participant tables and market relationship
- Usage Subscriptions Types associated with the market participant (typically a customer information system receiving bill determinants)
- Unique combinations of unit of measure (UOM), time of use (TOU), and service quantity identifier (SQI) associated with the usage subscriptions
- Specific identifiers used to identify the usage subscriptions, service points, and devices associated with extracted measurement data
- Date and time parameters and frequency of extract
- Extract file naming and compression options

Consumption extracts are exported to a file in a specified file location, either on an application server (in an on-premises implementation) or an Oracle Cloud Infrastructure Object Storage location.

Consumption extracts are created via Consumption Extract Requests. See [Consumption Extract Requests](#) in the *Business User Guide*.

This section describes the configuration needed for these types of consumption extracts.

Consumption Extract Types

Configuration for consumption extracts are defined via a Consumption Extract Type. See [Consumption Extract Type](#) in the *Administrative User Guide* for more information about creating these records.

Configurable consumption extract types should be created using the Extract US Consumption to File (D1-ExtractUSConsumptionToFile) business object. Refer to the embedded help on this business object for more details about the parameters defined for consumption extract types.

Extract US Consumption to File consumption extract types define the following parameters:

- The market participants for which measurement data will be extracted. You define market participants based on their type (Service Point Market Participant or Usage Subscription Market Participant) and market relationship type (retailer, distributor, supplier, and so on), and a specific market participant. Note: If Market Participant Specific is set to "No", the market participant used is based on the Usage Recipient on the Usage Subscription or its Usage Subscription Type.
- The consumption type (interval or scalar)
- One or more Usage Subscription Types and a related unique UOM/TOU/SQI combination
- The specific ID types to include in the extract file for the Usage Subscription, Service Point, child Service Point (if applicable), and Device
- Execution parameters, including:
 - The date and time through which data has been extracted for this consumption extract type

- A Request Type. Request types used with consumption requests should be created using the Consumption Extract Request Type (D2-IntervalDataExtRepoType) business object, and should reference the Consumption Extract (D2-IntervalDataExtRepository) business object in the **Request Business Object** field. (see [The Big Picture of Requests](#) in the *Application Framework Administrative User Guide*)
- The frequency of extracts for this type (ad hoc or daily)
- Batch controls used for the extract process (see **Batch Controls** below)
- File parameters, including:
 - The file location where extract files will be saved (see [External File Storage](#) in the *Application Framework Administrative User Guide*)
 - An optional child folder in the file location
 - File naming options (including an optional prefix and date/time stamp)
 - Whether or not to compress the extract file (file compression is performed using gzip)

Batch Controls

The data extract process and creation of export files is performed by the following batch controls:

- **Extract Current US Intervals to File (D1-ECUSI)**: Used for daily extracts of interval consumption. This process requires that Interval Snapshot Mapping data be generated for any of the interval sizes being extracted. This aids in the efficiency of transposing the interval data into daily interval columns. (see [Interval Snapshot Mapping](#) for more information).
- **Extract Replacement US Intervals to File (D1-ERUSI)**: Used for extracts of replacement historical interval consumption. This process runs against Change Data Capture records in the General Process table (see **Initial Measurement Subsequent Correction Change Data Capture** below).
- **Extract Current US Scalar Reads to File (D1-ECUSS)**: Used for daily extracts of scalar consumption.
- **Extract Replacement US Scalar Reads to File (D1-ERUSI)**: Used for extracts of replacement scalar interval consumption. This process runs against Change Data Capture records in the General Process table (see **Initial Measurement Subsequent Correction Change Data Capture** below).

These batch controls are run for a specific Consumption Extract Type and date range. Batch processing is threaded by on Usage Subscription ID.

Refer to [Batch Controls](#) under **Consumption Extract** in the **Oracle Utilities DataConnect** section of the **Integrations** chapter for general information about consumption extract batch processing,

Initial Measurement Subsequent Correction Change Data Capture

The following algorithms maintain measuring component date/times based on the latest measurement date time for the measuring component. These algorithms also check for a Consumption Extract Type that applies to the current initial measurement's measuring component and identifies whether the initial measurement is for a date/time that has already been extracted.

Algorithm	Description	Consumption Type
D1-UPD-DTMC	Update Latest Measurement Date/Time on MC with Consumption Sync	Interval
D1-UDTSCMCRE	Update Latest Measurement Date/Time on Scalar MC with Consumption Sync	Scalar
D1-UPD-DTMCF	Update Latest Date/Time on MC from a Future Measurement	Interval
D1-UPDDTSCMC	Update Latest Date/Time on Scalar Measuring Component	Scalar

If an initial measurement is for a date/time that has already been extracted, these algorithms create Change Data Capture records in the General Process table that capture the batch code, batch run number, and the initial measurement's ID. The "Replacement" batch processes run off of these records.

Note that the following parameter must be set to "true" on the above algorithms to enable historical change data capture:

- Capture CET Historical Measurement Changes: true

Data Extract File Format - Interval

The interval extract process produces JavaScript Object Notation (JSON) files with the extract data described in the following table.

Note that interval extract files can store up to a maximum of 300 intervals. This means that export files can store approximately:

- 12.5 days worth of hourly data
- 3 days worth of 15 minute data
- 1 day worth of 5 minute data

Field	Sample Value	Comments
usId	995647003500	Usage Subscription ID defined by the Consumption Extract Type
usType	E-RES	Usage Subscription type
pSpId	458081	Parent Service Point ID, Null when there is no parent service point.
spId	458081_001	Child Service Point ID This is the Service Point ID defined by the Consumption Extract Type
dvId	SN823287793219	Device ID defined by the Consumption Extract Type
uomTouSqi	KWH//	UOM / TOU / SQI, separated by forward slashes ("/")
tz	US/Eastern	Time zone of the service point. This is the time zone name from the CI_TIME_ZONE table not the time zone code.
intPerDay	288	Number of Intervals for the day, will be 1 hour less or 1 hour more of intervals for DST transitions
intSize	300	Length of each interval in seconds
mktPart	DIRECT_ENERGY	Market Participant ID of the market participant (if applicable)
stDttm	2020-01-01T00:00:00-05:00	Start of the day, similar to initial measurement, this represents the start of the first interval.

Field	Sample Value	Comments
q1	1.325	Measurement Value for the first interval, the measurement date/time for this interval would be the stDttm plus the intSize
c1	301000	Measurement Condition for the first interval. Null when "Regular" (501000)
q2	1.230	
c2	301000	
...	q/c 3 through 299 here	
q300	.9134	
c300	30100	

Example:

```
{ "usId": "995647003500", "usType": "E-RES", "pSpId": "458081", "spId": "458081_001", "dvcId": "SN823287793219", "uomTouSqi": "KWH", "tz": "US/Eastern", "intPerDay": "288", "intSize": "300", "mktPart": "DIRECT_ENERGY", "stDttm": "2020-01-01T00:00:00-05:00", "q1": "1.325", "c1": "301000", "q2": "1.325", "c2": "301000", "q3": "1.325", "c3": "301000", <intervening intervals>, "q300": "1.325", "c300": "301000" }
```

Data Extract File Format - Scalar

The scalar extract process produces JavaScript Object Notation (JSON) files with the extract data described in the following table.

Name	Sample Value	Comments
c	301000	Measurement Condition for the scalar reading Null when "Regular" (501000)
dvcId	SN823287793219	Device ID defined by the Consumption Extract Type
enDttm	2020-01-02T00:00:00-05:00	End date/time of the reading
mktPart	DIRECT_ENERGY	Market Participant ID of the market participant (if applicable)
pSpId	458081	
q	1.325	Measurement Value for scalar reading
r	678645	Dial reading of the meter

Name	Sample Value	Comments
spId	458081_001	Service Point ID defined by the Consumption Extract Type
stDttm	2020-01-01T00:00:00-05:00	Start date/time of the reading (the End Date/ Time of the previous reading)
tz	US/Eastern	Time zone of the service point. This is the time zone name from the CI_TIME_ZONE table not the time zone code.
uomTouSqi	KWH//	UOM / TOU / SQI, separated by forward slashes ("/")
usId	995647003500	Usage Subscription ID defined by the Consumption Extract Type
usType	E-RES	Usage subscription type

Example (3 records):

```
{ "usId": "995647003500", "usType": "E-RES", "pSpId": "458081", "spId": "458081_001", "dvcId": "SN823287793219", "uomTouSqi": "KWH//", "tz": "US/Eastern", "mktPart": "DIRECT_ENERGY", "stDttm": "2020-01-01T00:00:00-05:00", "enDttm": "2020-01-02T00:00:00-05:00", "q": "1.325", "c": "301000", "r": "678645" }
{ "usId": "995647003500", "usType": "E-RES", "pSpId": "458081", "spId": "458081_001", "dvcId": "SN823287793219", "uomTouSqi": "KWH//", "tz": "US/Eastern", "mktPart": "DIRECT_ENERGY", "stDttm": "2020-01-01T00:00:00-05:00", "enDttm": "2020-01-02T00:00:00-05:00", "q": "1.325", "c": "301000", "r": "678645" }
{ "usId": "995647003500", "usType": "E-RES", "pSpId": "458081", "spId": "458081_001", "dvcId": "SN823287793219", "uomTouSqi": "KWH//", "tz": "US/Eastern", "mktPart": "DIRECT_ENERGY", "stDttm": "2020-01-01T00:00:00-05:00", "enDttm": "2020-01-02T00:00:00-05:00", "q": "1.325", "c": "301000", "r": "678645" }
```

Extending the Extract Processing

Some implementations may wish to extend and/or customize the extract process based on specific requirements.

Extending List of IDs To Use

Consumption Extract Types define specific types of IDs to use for Usage Subscriptions, Service Points, child Service Points (if applicable), and Devices. If an implementation wishes to extend the types of IDs available, they need to add appropriate values to the lookup flags used by each of ID type. The table below lists the lookup codes used by the "IDs to Use" fields.

ID Type	Lookup Flag
Usage Subscription ID	Usage Subscription Identifier Type (US_ID_TYPE_FLG)

ID Type	Lookup Flag
Service Point ID (used for both parent and child service points)	Service Point Identifier Type (SP_ID_TYPE_FLG)
Device ID	Device Identifier Type (DVC_ID_TYPE_FLG)

Processing Records and Creating Output Files

The extract process leverages the generic [Plug-in Driven Background Processes](#) functionality but works in a slightly different manner. Instead of using the Select Records algorithm to retrieve the IDs of the individual records to be processed, that algorithm returns a range of Usage Subscription IDs to be extracted and the Process Records algorithm performs the detailed query to extract the range of Usage Subscription IDs.

This provides two benefits:

1. There is no limitation on the length of the query in the Process Records algorithm.
2. Retrieving data for many Usage Subscriptions at a single time is significantly more efficient.

This means that any required customization can be achieved by creating a new custom (CM) batch control and duplicating the Process Records Groovy script. Changes can be made within the custom Groovy script to the extraction SQL to retrieve additional information or provide additional selection criteria. If any changes are needed to the file format that can be done within the record processing logic that populates the file.

Note: The Process Records scripts include a number of steps each containing specific processing logic and SQL based on the configuration of the Market Participants on the Consumption Extract Type as well as whether or not the specified UOMs measure peak quantities or not. Be sure to edit each of these steps as appropriate when creating customized versions of these scripts.

Maintenance Object Data Export

This section describes the process by which data can be exported from maintenance objects used with Oracle Utilities Customer Cloud Service and Oracle Utilities Meter Solution Cloud Service for use in external applications and systems.

This section provides details regarding how the data export process is used with specific maintenance objects. See [Data Export](#) in the *Application Framework Administrative User Guide* for a general description of the data export process.

Enabling Maintenance Objects for Generalized Data Export

Export of data from most maintenance objects is supported via "Generalized" export. See [Generalized Data Export](#) in the *Application Framework Administrative User Guide* for more information about generalized data export.

Data Export Control Records for Maintenance Objects

Data export from a maintenance object requires a Data Export Control record configured for that maintenance object. See [Enabling Data Export](#) in [Generalized Data Export](#) in the *Application Framework Administrative User Guide* for more information.

Change Data Capture for Measuring Components and Usage Subscriptions

For most maintenance objects, changes are tracked via the Capture Change for Ongoing Export audit algorithm (F1-MO-REGCHN).

Measuring Components and Usage Subscriptions use a "Most Recent" date field to track related transactions (Initial Measurements and Measurements in the case of Measuring Components and Usage Transactions in the case of Usage Subscriptions). These "Most Recent" fields are updated with each new initial measurement or usage transaction created by the system.

In order to prevent the Change Data Capture process from capturing changes based on these frequent transactions (daily for measurements and monthly for usage transactions), the Capture Change for Ongoing Export audit algorithm has been disabled on the Measuring Component and Usage Subscription maintenance objects.

Enabling change data capture and generalized data export for these maintenance objects requires adding the “Generalized Data Export BO Change Data Capture” (D1-BO-REGCHN) Audit algorithm to the appropriate Measuring Component and Usage Subscription business objects. This algorithm creates records in the Data Export Update table used by the generalized export process.

Measurement Data Export

Export of data from the Measurement maintenance object is supported via "Specialized" export. See [Specialized Data Export](#) in the *Application Framework Administrative User Guide* for more information about specialized data export.

The Measurement maintenance object is configured to support data export via the following options:

Option Type	Option Value
Data Export Class	F1SE (Specialized)
Export Batch Control	D1-SMDEC (Specialized Measurement Data Extract Current)

Initial vs. Current vs. Historical Extract

There are three types of extracts used with the Measurement maintenance object:

- **Initial Extracts** gather an initial extract of measurement data, controlled by providing a start and end date time of the measurements that should be extracted. This process should be used to perform the initial extract of the measurement data prior to using the daily current and daily historical extracts.
- **Daily Current Extracts** gather measurement data for measurements within the last 30 days that have been either added or changed. This extract is based on the **Measurement Date/Time** and **Last Update Timestamp** fields on the Measurement table, as well as the **Export Through Date/Time** field on the Data Export Control record (see below) to include only changes since the last extract.
- **Daily Historical Extracts** gather measurement data for measurements older than the last 30 days that have either been added or changed. To avoid having to scan the entire Measurement table, this extract is based on Change Data Capture. During initial measurement data processing if an initial measurement has measurements that are older than 30 days, then a Change Data Capture record is created in the General Process table.

Enabling historical change data capture requires configuration of the following algorithm parameters:

- Capture Historical Measurement Changes: true
- Historical Measurement Data Extract Batch Control: D1-SMDEH (Specialized Measurement Data Extract Historical)

These parameters should be configured as described on the following algorithms:

- Update Latest Measurement Date/Time on MC with Consumption Sync (D1-UPD-DTMC)
- Update Latest Measurement Date/Time on Scalar MC with Consumption Sync (D1-UDTSCMCRE)
- Update Latest Date/Time on MC from a Future Measurement (D1-UPD-DTMCF)
- Update Latest Date/Time on Scalar Measuring Component (D1-UPDDTSCMC)
- Re-derive other values (D1-REDEROVAL)

Note: This use of Change Data Capture is an exception to the general rule described in the [Specialized Data Export](#) section of the *Application Framework Administrative User Guide*.

Data Export Control Records

Data export from the Measurement maintenance object requires a Data Export Control record. This record designates that the Measurement maintenance object should be exported, and tracks the date and time through which data has been exported so far, allowing subsequent export processes to only export incremental changes.

See [Defining Data Export Control](#) in the *Application Framework Administrative User Guide* for more information about creating Data Export Control records.

Batch Controls

Export of data and creation of export files is performed by the following batch controls:

- **Specialized Measurement Initial Extract (D1-SMDIE):** Used for initial extract of measurement data. Unlike the current extract this batch is controlled directly by providing a start and end date time of the measurements that should be extracted. This process should be used to perform the initial extract of the measurement data prior to using the current extract (D1-SMDEC) and the historical extract (D1-SMDEH). For best performance it is recommended to break up the initial extract period into multiple smaller periods and to use multiple threads for each period. The extract will retrieve all measurements with a measurement date/time that is greater than the input start date/time and less than or equal to the input end date/time.
- **Specialized Measurement Data Extract Current (D1-SMDEC):** Used for daily extracts of current (new) measurement data. This process extracts data that has changed since the last extract process has run (based on the **Export Through Date/Time** field on the Data Export Control record. This process updates the **Export Through Date/Time** field at the start of batch processing to eliminate the possibility of not setting an initial measurement as historical by Change Data Capture during the processing window.
- **Specialized Measurement Data Extract Historical (D1-SMDEH):** Used for daily extracts of historical measurement data. This process runs against Change Data Capture records in the General Process table.

Batch processing is threaded by on Measuring Component ID, and creates one or more files based on the number of threads processed and batch control parameters.

File Creation and Naming

The extract process uses two controls to determine the number of files to be created:

1. Each thread will create at least 1 file (more threads result in smaller files).
2. The **File Size Limit** parameter can be used to specify set the number of measurement rows to include in any given file. This can result in a single thread producing multiple files.

The data in each file is not ordered, each thread will retrieve measurement data for a set of Measuring Component IDs, but beyond that there will be no control for how the data is loaded into the file.

File Naming

Since each thread can produce multiple files and the number of files per thread cannot be predicted the file names will also include an indicator for the first file in a thread and the last file in a thread.

- `MSRMT_EXPORT_<file prefix batch parameter>_<batch number>_<batch thread number>_<total thread count>_<thread file indicator>_<process date time>.csv.gz`

where:

- `<file prefix batch parameter>` is an optional file prefix defined using the **File Name Prefix** batch control parameter
- `<batch number>` is the batch number for the process
- `<batch thread number>` is the thread number that created the file
- `<total thread count>` is the total number of threads
- `<thread file indicator>`: is an identified for the first and last files created by a thread, S for first file E for last file
- `<process date time>` is the date and time at which the file was created, in YYYYMMDDhhmmss format (YYYY = year, MM = month, DD = day, hh = hour, mm = minute, ss = second)

Examples: For batch number 135, comprising 10 threads:

- First file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_S_20191104173233.csv.gz
- All files before the last file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_20191104173233.csv.gz
- Last file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_E_20191104173233.csv.gz

File Format

The extract process produces comma separated values (CSV) files with the data described in the following table. The field names in the **Field** column are included in the output file as a header row if the **Include Header** parameter on the batch controls is set to "Y".

Note: All date/times will be converted from OUAF format to the appropriate ISO format in UTC with the time zone provided (as "Z").

Field	Data Type	Sample Content	Description	Applicability		
				Interval	Scalar	Subtractive Interval
MEASR_COMP_ID	CHAR(12)	000004769213	Primary Key of Channel from Meter (aka Device)	X	X	X
MSRMT_DTTM	DATE	2019-01-01T00:00:00Z	Start of the time period the measurement covers. For example, if this were an hourly interval it would cover 2018-12-31T23:00:00Z to 2019-01-01T00:00:00Z.	X	X	X
PREV_MSRMT_DTTM	DATE	2018-12-31T00:00:00Z	Start scalar measurements this identifies the start of the period being measured. Note: there should be another measurement for the same MC with this date as the MSRMT_DTTM.		X	

Field	Data Type	Sample Content	Description	Applicability		
				Interval	Scalar	Subtractive Interval
MSRMT_ COND_FLG	CHAR(6)	501000	Defines the quality of the measurement (e.g. estimated, regular, super). Valid values defined on F1_EXTENDABLE_LOOKUP_VAL for the BUS_OBJ_CD D1-MeasurementConditionLookup.	X	X	X
MSRMT_USE_ FLG	CHAR(4)	D101	Indicates whether the measurement is usable. Valid values defined on CI_LOOKUP.		X	
USER_EDITED_ FLG	CHAR(4)	D1UE	Indicates whether the user has edited the measurement. Valid values defined on CI_LOOKUP.	X	X	X
READING_VAL	NUMBER(16,6)	750000000	This is the Dial Reading which is used to calculate the consumed amount.		X	X
READING_ COND_FLG	CHAR(6)	501000	Defines the quality of the Daily Reading (e.g. estimated, regular, super). Valid values defined on F1_EXTENDABLE_LOOKUP_VAL for the BUS_OBJ_CD D1-MeasurementConditionLookup.			X

Field	Data Type	Sample Content	Description	Applicability		
				Interval	Scalar	Subtractive Interval
COMBINED_MU MULTIPLIER	NUMBER(18,6)	1	Contains the product of the Measuring Component Multiplier and the Installation Constant. The MSRMT_VAL will have been multiplied by this number.	X	X	X
MSRMT_VAL	NUMBER(16,6)	1.23	This is the consumption reported from the meter after going through VEE (aka billing ready).	X	X	X
MSRMT_VAL1	NUMBER(16,6)		This and the subsequent measurement values (MSRMT_VAL 1 through 10) are derived values that are computed from the core MSRMT_VAL. Examples of this are UOM conversion (CCF to THERM) or loss adjustment.	X	X	X
MSRMT_VAL2	NUMBER(16,6)			X	X	X
MSRMT_VAL3	NUMBER(16,6)			X	X	X
MSRMT_VAL4	NUMBER(16,6)			X	X	X
MSRMT_VAL5	NUMBER(16,6)			X	X	X
MSRMT_VAL6	NUMBER(16,6)			X	X	X
MSRMT_VAL7	NUMBER(16,6)			X	X	X
MSRMT_VAL8	NUMBER(16,6)			X	X	X

Field	Data Type	Sample Content	Description	Applicability		
				Interval	Scalar	Subtractive Interval
MSRMT_VAL9	NUMBER(16,6)			X	X	X
MSRMT_VAL10	NUMBER(16,6)			X	X	X
CRE_DTTM	DATE	2019-10-31T11:09:30Z	When the record was created.	X	X	X
LAST_UPDATE_DTTM	DATE	2019-11-09T16:35:00Z	When the record was last updated.	X	X	X

Sample Export File

The following is a sample export file for interval data spanning a six hour window. Note that this does not include labels or column headers, but the data is in the same order as the column descriptions above in the **File Format** section above.

```

Initial Measurement Data Header Export

Export of header data from the Initial Measurement Data maintenance object is supported via "Specialized" export. See [Specialized Data Export](#) in the *Application Framework Administrative User Guide* for more information about specialized data export.

The Initial Measurement Data maintenance object is configured to support data export via the following options:

Option Type	Option Value
Data Export Class	F1SE (Specialized)
Export Batch Control	D1-SIMDC (Specialized IMD Header Extract Current)

Initial vs. Current vs. Historical Extract

There are three types of extracts used with the Initial Measurement Data maintenance object:

- **Initial Extracts** gather an initial extract of initial measurement data headers, controlled by providing a start and end date time of the initial measurement data headers that should be extracted. This process should be used to perform the initial extract of the data prior to using the daily current and daily historical extracts.
- **Daily Current Extracts** gather measurement data for measurements within the last 30 days that have been either added or changed. This extract is based on the **Last Update Timestamp** field on the Initial Measurement Data table, as well as the **Export Through Date/Time** field on the Data Export Control record (see below) to include only changes since the last extract.
- **Daily Historical Extracts** gather data for initial measurements older than the last 30 days that have either been added or changed. To avoid having to scan the entire Initial Measurement Data table, this extract is based on Change Data Capture. During initial measurement data processing if an initial measurement has measurements that are older than 30 days, then a Change Data Capture record is created in the General Process table.

Enabling historical change data capture requires configuration of the following algorithm parameters:

- Capture Historical Measurement Changes: true
- Historical IMD Extract Batch Control: D1-SMDEH (Specialized IMD Header Extract - Historical)

These parameters should be configured as described on the following algorithms:

- Update Latest Measurement Date/Time on MC with Consumption Sync (D1-UPD-DTMC)
- Update Latest Measurement Date/Time on Scalar MC with Consumption Sync (D1-UDTSCMCRE)
- Update Latest Date/Time on MC from a Future Measurement (D1-UPD-DTMCF)
- Update Latest Date/Time on Scalar Measuring Component (D1-UPDDTSCMC)

Note: This use of Change Data Capture is an exception to the general rule described in the [Specialized Data Export](#) section of the *Application Framework Administrative User Guide*.

Data Export Control Records for Maintenance Objects

Data export from the Initial Measurement Data maintenance object requires a Data Export Control record. This record designates that the Initial Measurement Data maintenance object should be exported, and tracks the date and time through which data has been exported so far, allowing subsequent export processes to only export incremental changes.

See [Defining Data Export Control](#) in the *Application Framework Administrative User Guide* for more information about creating Data Export Control records.

Batch Controls

Export of data and creation of export files is performed by the following batch controls:

- **Specialized IMD Header Initial Extract (D1-SIMDI):** Used for initial extract of initial measurement data. Unlike the current extract this batch is controlled directly by providing a start and end date time of the IMD headers that should be extracted. This process should be used to perform the initial extract of the IMD header data prior to using the current extract (D1-SIMDC) and the historical extract (D1-SIMDH). For best performance it is recommended to break up the initial extract period into multiple smaller periods and to use multiple threads for each period. The extract will retrieve all IMD headers with a IMD to date/time that is greater than the input start date/time and less than or equal to the input end date/time.
- **Specialized IMD Header Data Extract - Current (D1-SIMDC):** Used for daily extracts of current (new) initial measurement data. This process extracts data that has changed since the last extract process has run (based on the **Export Through Date/Time** field on the Data Export Control record). This process updates the **Export Through Date/Time** field at the start of batch processing to eliminate the possibility of not setting an initial measurement as historical by Change Data Capture during the processing window.
- **Specialized IMD Header Extract - Historical (D1-SIMDH):** Used for daily extracts of historical initial measurement data. This process runs against Change Data Capture records in the General Process table.

Batch processing is threaded by on Initial Measurement Data ID, and creates one or more files based on the number of threads processed and batch control parameters.

File Creation and Naming

The extract process uses two controls to determine the number of files to be created:

1. Each thread will create at least 1 file (more threads result in smaller files)
2. The **File Size Limit** parameter can be used to specify set the number of initial measurement data rows to include in any given file. This can result in a single thread producing multiple files.

The data in each file is not ordered, each thread will retrieve initial measurement data for a set of Initial Measurement Data IDs, but beyond that there will be no control for how the data is loaded into the file.

File Naming

Since each thread can produce multiple files and the number of files per thread cannot be predicted the file names will also include an indicator for the first file in a thread and the last file in a thread.

- `IMD_EXPORT_<file prefix batch parameter>_<batch number>_<batch thread number>_<total thread count>_<file number>_<last file indicator>_<process date>.csv.gz`

where:

- `<file prefix batch parameter>` is an optional file prefix defined using the **File Name Prefix** batch control parameter
- `<batch number>` is the batch number for the process
- `<batch thread number>` is the thread number that created the file
- `<total thread count>` is the total number of threads
- `<file number>` is the number of the file
- `<last file indicator>`: identifies the last files created by a thread (E)
- `<process date time>` is the date and time at which the file was created, in YYYYMMDDhhmmss format (YYYY = year, MM = month, DD = day, hh = hour, mm = minute, ss = second)

Examples: For batch number 135, comprising 10 threads:

- First file of 3rd out of 10 threads: `IMD_EXPORT_SOME_PREFIX_135_3_10_1_20191104173233.csv.gz`
- All files before the last file of 3rd out of 10 threads: `IMD_EXPORT_SOME_PREFIX_135_3_10_2_20191104173233.csv.gz`
- Last file of 3rd out of 10 threads: `IMD_EXPORT_SOME_PREFIX_135_3_10_E_20191104173233.csv.gz`

File Format

The extract process produces comma separated values (CSV) files with the data described in the following table. The field names in the **Field** column are included in the output file as a header row if the **Include Header** parameter on the batch controls is set to “Y”.

Note: All date/times will be converted from OUAF format to the appropriate ISO format in UTC with the time zone provided (as "Z").

Field	Data Type	Sample Content	Description	Applicability		
				Interval	Scalar	Subtractive Interval
INIT_MSRMT_DATA_ID	CHAR(12)	52482245116604	Primary Key of the initial measurement	X	X	X
MEASR_COMP_ID	CHAR(12)	000004769213	Primary Key of the measuring component for the initial measurement	X	X	X

Field	Data Type	Sample Content	Description	Applicability		
				Interval	Scalar	Subtractive Interval
IMD_EXT_ID	CHAR(12)	external_file	External ID for the initial measurement. Usually the name of the file that the initial measurement data was received in.	X	X	X
BUS_OBJ_CD	CHAR(12)	D1- ManualIMDInterval	The business object that governs the initial measurement	X	X	X
BO_STATUS_CD	VARCHAR(30)	COMPLETED	The status of the initial measurement	X	X	X
BO_STATUS_REASON_CD	VARCHAR(30)	FORCE COMPLETE	A reason code for the status. Generally populated when there was a VEE exception that was overridden and the initial measurement was completed without fixing the error.	X	X	X

				Applicability		
Field	Data Type	Sample Content	Description	Interval	Scalar	Subtractive Interval
D1_FROM_DTTM	DATE/TIME	2019-01-01T00:00:00Z	<p>Start of the time period the initial measurement covers.</p> <p>For subtractive scalar data this represents the prior measurement that will be used as the start reading when calculating consumption.</p> <p>For interval data this represents the start of the first interval for the initial measurement.</p> <p>Note: no measurements will be created for this date/time as MDM represents intervals as the end of the interval. So the first interval of the initial measurement will be this date/time plus the interval size (e.g. if the interval size is 15 minutes then the first interval would be 15 minutes after this date/time).</p>	X	X	X

Field	Data Type	Sample Content	Description	Applicability		
				Interval	Scalar	Subtractive Interval
D1_TO_DTTM	DATE/TIME	2019-01-02T00:00:00Z	<p>Start of the time period the initial measurement covers.</p> <p>For scalar data this date/time will match the measurement.</p> <p>For interval data this will match the date/time of the last interval measurement.</p>	X	X	X
CRE_DTTM	DATE/TIME	2019-01-03T00:00:00Z	Date and time when the initial measurement was initially created	X	X	X
STATUS_UPD_DTTM	DATE/TIME	2019-01-03T00:00:00Z	Date and time when the initial measurement's status was last updated	X	X	X
LAST_UPDATE_DTTM	DATE/TIME	2019-01-03T00:00:00Z	<p>Date and time when the initial measurement was last updated.</p> <p>Note: updates can happen outside of a status change so this can be more recent than the STATUS_UPD_DTTM.</p>	X	X	X

Sample Export File

The following is a sample export file containing initial measurement header records. Note that this does not include labels or column headers, but the data is in the same order as the column descriptions above in the **File Format** section above.

```

Aggregated Measurement Data Export

Export of data from the Aggregated Measurement maintenance object (D1-AGGMSRMT) is supported via "Specialized" export. See [Specialized Data Export](#) in the *Application Framework Administrative User Guide* for more information about specialized data export. The Aggregated Measurement maintenance object is configured to support data export via the following options:

Option Type	Option Value
Data Export Class	FISE (Specialized)
Export Batch Control	D1-SAMDC (Specialized Agg. Measurement Extract Cur.)

Initial vs. Current vs. Historical Extract

There are three types of extracts used with the Aggregated Measurement maintenance object:

- **Initial Extracts** gather an initial extract of aggregated measurement data, controlled by providing a start and end date time of the measurements that should be extracted. This process should be used to perform the initial extract of the aggregated measurement data prior to using the daily current and daily historical extracts.
- **Daily Current Extracts** gather aggregated measurement data for measurements within the last 30 days that have been either added or changed. This extract is based on the Measurement Date/Time and Last Update Timestamp fields on the Aggregated Measurement table, as well as the Export Through Date/Time field on the Data Export Control record (see below) to include only changes since the last extract.
- **Daily Historical Extracts** gather aggregated measurement data for measurements older than the last 30 days that have either been added or changed. To avoid having to scan the entire Aggregated Measurement table, this extract is based on Change Data Capture. During initial measurement data processing if an aggregated measurement has measurements that are older than 30 days, then a Change Data Capture record is created in the General Process table.

Enabling historical change data capture for aggregated measurement data requires configuration of the following algorithm parameters:

- Capture Historical Aggregation Changes: true
- Aggregation Historical Batch Control: D1-SAMDH (Specialized Aggregated Measurement Data Extract Historical)

These parameters should be configured as described on the following algorithms:

- Create General Process Record for Historical Dynamic Aggregation (D1CGPHISAGG)
- Create General Process Record for Historical Static Aggregation (D1CGPHISA)

Note: This use of Change Data Capture is an exception to the general rule described in the [Specialized Data Export](#) section of the *Application Framework Administrative User Guide*.

Data Export Control Records

Data export from the Aggregated Measurement maintenance object requires a Data Export Control record. This record designates that the Aggregated Measurement maintenance object should be exported, and tracks the date and time through which data has been exported so far, allowing subsequent export processes to only export incremental changes.

See [Defining Data Export Control](#) in the *Application Framework Administrative User Guide* for more information about creating Data Export Control records.

Batch Controls

Export of data and creation of export files is performed by the following batch controls:

- **Specialized Aggregate Msrmt. Initial (D1-SAMDI):** Used for initial extract of aggregated measurement data. Unlike the current extract this batch is controlled directly by providing a start and end date time of the measurements that should be extracted. This process should be used to perform the initial extract of aggregated measurement data prior to using the current extract (D1-SAMDC) and the historical extract (D1-SAMDH). For best performance it is recommended to break up the initial extract period into multiple smaller periods and to use multiple threads for each period. The extract will retrieve all aggregated measurements with a measurement date/time that is greater than the input start date/time and less than or equal to the input end date/time.
- **Specialized Agg. Measurement Extract Cur. (D1-SAMDC):** Used for daily extracts of current (new) aggregated measurement data. This process extracts data that has changed since the last extract process has run (based on the **Export Through Date/Time** field on the Data Export Control record. This process updates the **Export Through Date/Time** field at the start of batch processing to eliminate the possibility of not setting an initial measurement as historical by Change Data Capture during the processing window.
- **Specialized Aggregated Measurement Data Extract Historical (D1-SAMDH):** Used for daily extracts of historical aggregated measurement data. This process runs against Change Data Capture records in the General Process table

Batch processing is threaded by on Measuring Component ID, and creates one or more files based on the number of threads processed and batch control parameters.

File Creation and Naming

The extract process uses two controls to determine the number of files to be created:

1. Each thread will create at least 1 file (more threads result in smaller files).
2. The **File Size Limit** parameter can be used to specify set the number of aggregated measurement rows to include in any given file. This can result in a single thread producing multiple files.

The data in each file is not ordered, each thread will retrieve aggregated measurement data for a set of Measuring Component IDs, but beyond that there will be no control for how the data is loaded into the file.

File Naming

Since each thread can produce multiple files and the number of files per thread cannot be predicted the file names will also include an indicator for the first file in a thread and the last file in a thread.

- MSRMT_EXPORT_<file prefix batch parameter>_<batch number>_<batch thread number>_<total thread count>_<thread file indicator>_<process date time>.csv.gz

where:

- <file prefix batch parameter> is an optional file prefix defined using the **File Name Prefix** batch control parameter
- <batch number> is the batch number for the process
- <batch thread number> is the thread number that created the file
- <total thread count> is the total number of threads
- <thread file indicator>: is an identified for the first and last files created by a thread, S for first file E for last file
- <process date time>is the date and time at which the file was created, in YYYYMMDDhhmmss format (YYYY = year, MM = month, DD = day, hh = hour, mm = minute, ss = second)

Examples: For batch number 135, comprising 10 threads:

- First file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_S_20191104173233.csv.gz
- All files before the last file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_20191104173233.csv.gz
- Last file of 3rd out of 10 threads: MSRMT_EXPORT_PREFIX_135_3_10_E_20191104173233.csv.gz

File Format

The extract process produces comma separated values (CSV) files with the data described in the following table. The field names in the **Field** column are included in the output file as a header row if the **Include Header** parameter on the batch controls is set to “Y”.

Note: All date/times will be converted from OUAF format to the appropriate ISO format in UTC with the time zone provided (as "Z").

Field	Data Type	Sample Content	Description
MEASR_COMP_ID	CHAR(12)	000004769213	Primary Key of Channel from Meter (aka Device)
MSRMT_DTTM	DATE	2019-01-01T00:00:00Z	End of the time period the measurement covers. For example, if this were an hourly interval it would cover 2018-12-31T23:00:00Z to 2019-01-01T00:00:00Z.
PREV_MSRMT_DTTM	DATE	2018-12-31T00:00:00Z	For scalar measurements this identifies the start of the period being measured. Note: there should be another measurement for the same MC with this date as the MSRMT_DTTM.
MSRMT_COND_FLG	CHAR(6)	501000	Defines the quality of the measurement (e.g. estimated, regular, super). Valid values defined on F1_EXTENDABLE_LOOKUP_VAL for the BUS_OBJ_CD D1-MeasurementConditionLookup.
MSRMT_USE_FLG	CHAR(4)	D101	Indicates whether the measurement is usable. Valid values defined on CI_LOOKUP.
USER_EDITED_FLG	CHAR(4)	D1UE	Indicates whether the user has edited the measurement. Valid values defined on CI_LOOKUP.
READING_VAL			Values for this field are not included in the aggregated measurement export.
READING_COND_FLG			Values for this field are not included in the aggregated measurement export.
COMBINED_MULTIPLIER			Values for this field are not included in the aggregated measurement export.

Field	Data Type	Sample Content	Description
MSRMT_VAL	NUMBER(16,6)	1.23	This is the consumption reported from the meter after going through VEE (aka billing ready).
MSRMT_VAL1	NUMBER(16,6)		This and the subsequent measurement values (MSRMT_VAL 1 through 10) are derived values that are computed from the core MSRMT_VAL. Examples of this are UOM conversion (CCF to THERM) or loss adjustment.
MSRMT_VAL2	NUMBER(16,6)		
MSRMT_VAL3	NUMBER(16,6)		
MSRMT_VAL4	NUMBER(16,6)		
MSRMT_VAL5	NUMBER(16,6)		
MSRMT_VAL6	NUMBER(16,6)		
MSRMT_VAL7	NUMBER(16,6)		
MSRMT_VAL8	NUMBER(16,6)		
MSRMT_VAL9	NUMBER(16,6)		
MSRMT_VAL10	NUMBER(16,6)		
CRE_DTTM	DATE	2019-10-31T11:09:31Z	When the record was created.
LAST_UPDATE_DTTM	DATE	2019-11-09T16:35:02Z	When the record was last updated.

Sample File

The following is a sample export file for interval data spanning a six hour window. Note that this does not include labels or column headers, but the data is in the same order as the column descriptions above in the **File Format** section above.

Consumption Extract Type

Understanding Consumption Extract Type

The Consumption Extract Type controls which service point's measurements are extracted for Oracle Utilities DataConnect, what type of measurement is extracted, and how the measurements are grouped into TOU periods (if preferred).

The Consumption Extract Type also controls the request type used for creating Consumption Extract Requests of this type, how frequent automated requests are created for incremental extract, the batch jobs that are triggered for extracting data and the algorithms that extract, format, and write the data that is extracted.

Refer to the [Oracle Utilities DataConnect](#) integration section for more details on how this object is specifically put into use.

Configuring Consumption Extract Type

This portal is used to display and maintain a Consumption Extract Type.

Refer to [Understanding Consumption Extract Types](#) for more information.

You can access the portal by selecting **Admin**, then **Integration**, then **Consumption Extract Type**.

The following zones may appear as part of the portal's **Main** tab page:

- **Consumption Extract Type List:** displays all of the Consumption Extract Types so you can choose the one you want to display in more detail
- **Consumption Extract Type:** shows the specific configuration for the selected Consumption Extract Type

Analytics Configuration

This portal provides a bird's eye view of the configuration information for Oracle Utilities Analytics. It provides links and guidelines for the areas that need configuration to successfully run the extract transfer and load processes from Oracle Utilities Analytics.

Refer to the *Oracle Utilities Analytics Administration Guide* for more information.

You can access the portal from the **Admin > Analytics Configuration > Analytics Configuration**.

The following zones may appear as part of the portal's **Main** tab page

- **Bucket Configuration List.** This zone lists bucket configurations to set up.
- **BI-Related Business Objects Information.** This zone lists additional control entities to set up.

The following zones may appear as part of the portal's **OWB-Based ETL** tab page

- **Outbound Sync BOs and Algorithm List.** This zone lists business objects and algorithms involved in the extract process.
- **BI-Oriented Extendable Lookup.** This zone lists extendable lookups to set.
- **External Data Source Indicators List.** This zone lists the external identifiers of the various sources for your analytics data.

Note: Service Point business objects can make use of the following System Events:

- **Service Point Snapshot:** This system event defines the algorithm used to create a snapshot of the Service Point for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - Snapshot."
- **Usage Snapshot:** This system event defines the algorithm used to create a usage snapshot of the Service Point for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - Usage Snapshot."
- **Unreported Usage Analysis Snapshot:** This system event defines the algorithm used to create a snapshot of the Service Point's consumption since the last usage transaction for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - Unreported Usage Analysis Snapshot."
- **SP VEE Exception Snapshot:** This system event defines the algorithm used to create a snapshot of VEE exceptions for the Service Point for use with Oracle Utilities Analytics. The Algorithm Entity for available algorithms is "SP (BO) - VEE Exception Snapshot."

Information Lifecycle Management (ILM)

Understanding Information Lifecycle Management (ILM)

Information Lifecycle Management (ILM) is a separately licensable component of Oracle Utilities Meter Data Management that works in tandem with Oracle database feature of the same name.

For further background on the overall ILM process see the [Information Lifecycle Management](#) chapter of the Oracle Utilities Application Framework *Administrative User Guide*.

This section provides an overview of the components used by the Information Lifecycle Management functionality, including:

- ILM-Enabled Maintenance Objects: Single Retention Period
- ILM-Enabled Maintenance Objects: Multiple Retention Periods
- Adjusting Eligibility of Non-Final Transactions
- Archive Eligibility Hierarchy
- Multiple Retention Period Eligibility Crawling Strategies

Refer to the [Information Lifecycle Management](#) chapter of the Oracle Utilities Application Framework *Administrative User Guide* for general information about how ILM works with OUAF applications.

ILM-Enabled Maintenance Objects: Single Retention Periods

The majority of Maintenance Objects support a single retention period. They can either inherit the system wide retention days that are configured on the ILM Configuration master configuration or they can have a retention period specified via the Maintenance Object option ILM Retention Period in Days.

For these objects either the Maintenance Object specific retention period or the system wide retention period will apply to all transactions.

ILM-Enabled Maintenance Objects: Multiple Retention Periods

For several Maintenance Objects the retention period may vary based on the type of transaction. For example, initial measurement data for non-billed units of measure such as voltage might be archived much more rapidly than measurements that feed into the production of billing determinants.

These maintenance objects are differentiated from the single retention period maintenance objects in a few ways:

- The primary table for the entity has an additional column Retention Period (RETENTION_PERIOD) that captures the retention period in days for each transaction. This value is populated based on the ILM Configuration - MDM master configuration.
- There is additional configuration available on the ILM Configuration -MDM master configuration to define multiple retention periods by maintenance object specific criteria

- Initial Measurement Data: retention periods can be specified by type of IMD (Interval vs Scalar), and primary UOM of the measuring component
- Device Events: retention periods can be specified by device event type category
- Activities: retention periods can be specified by activity type category
- There is a special ILM Crawler batch that supports crawling transactions by their specific retention periods
- A combination of each transactions ILM Date and Retention Period are considered when identifying records to evaluate for eligibility. Refer to batch controls ILM Crawler - Device Event (D1-DECRL), ILM Crawler - IMD (D1-IMDCL), or ILM Crawler - Activity (D1-ACTCR) for more details.
- There is an additional maintenance object option ILM Date Partition Months which feeds into the ILM Crawler batch to delay processing until all records on a partition would be eligible. This is explained later in this section under the header Multiple Retention Period Eligibility Crawling Strategies.

Adjusting Eligibility of Non-Final Transactions

As delivered Oracle Utilities Meter Data Management and Customer to Meter maintenance objects allow non-final transactions to be eligible for archive. This is a logical approach when transactional data has a very long retention period (e.g. 3 year old non-final Initial Measurement Data is unlikely to have relevance and in many circumstances shouldn't be finalized).

If non-final transactions should not be eligible for archive this can be controlled at either the Maintenance Object (MO) or Business Object (BO) level:

- **MO - ILM Restrict By Status (Y/N):** Setting this to "Y" opts into the ability to restrict archiving by status, this is required to be set for either of the MO or BO level restrictions to be considered. To enforce the status it requires that either the **ILM Restrict By BO Final Status (Y/N)** or **ILM Final Status Field Value** options be configured as well.
- **MO - ILM Restrict By BO Final Status (Y/N):** Setting this to "Y" indicates the transactions for the MO must be in a final status to be eligible for ILM. A status is considered to be final based on the BO lifecycle configuration. This can be overridden by the BO option **Final Status Required for Archive (Y/N)**. This is only applicable for an MO that is maintained by business objects.
- **BO - Final Status Required for Archive (Y/N):** Setting this to "Y" indicates the transactions for this particular BO must be in a final status. This setting overrides the MO level **ILM Restrict By BO Final Status (Y/N)**.

The following table helps to illustrate how these three settings impact whether a given transaction must be in a final status:

• MO: ILM Restrict By Status	• MO: ILM Restrict By BO Final Status	• BO: Final Status Required for Archive	• Final Status Required for Eligibility?
• N	• Y	• Y	• N
• N	• Y	• N	• N
• N	• N	• Y	• N
• Y	• N	• N	• N
• Y	• Y	• N	• N
• Y	• Y	• Y	• Y
• Y	• N	• Y	• Y
• Y	• Y	• Not Provided	• Y
• Y	• N	• Not Provided	• N

Note: There are a few MOs that do not support the BO level setting. To best understand how these fields are interpreted for an MO refer to the detailed description of the algorithm plugged into the ILM Eligibility system event for the MO. For example, the generic ILM Eligibility Based on Status (F1-ILMELIG) algorithm does not support the BO level override option.

Archive Eligibility Hierarchy

The table below summarizes details of the eligibility algorithms for each maintenance object supported by ILM. Information on this table includes:

- **Cascaded By:** Indicates how archiving for transactions for the maintenance object is initiated. For example, device events can be archived by themselves or as part of a related activity.
- **ILM Date Computation:** Indicates the type(s) of transactions that impact the calculation of the ILM Date for transactions for the maintenance object. "Itself" indicates that the ILM date is not impacted by other transactions.
- **Specific Eligibility Considerations:** Indicates specific considerations used by the eligibility algorithm.
- **Cascaded Transactions:** Indicates other transactions that are archived when transactions for the maintenance object are archived. For example, VEE exceptions are archived with initial measurements.

Maintenance Object	Cascaded By	ILM Date Computation	Specific Eligibility Considerations	Cascaded Transactions
Initial Measurement		Create date	VEE Exceptions must be eligible Associated Related MC Synchronization activity must be complete	VEE Exceptions
VEE Exception	Initial Measurement	Earlier of related Initial Measurement or VEE Exception Create Date	Related Service Issue Monitor must be complete	
Usage Transaction		The latest create date for all related usage transactions	All related usage transactions must be eligible for archiving	Related Usage Transactions
Device Event	Activity	Create date Superseded by paired event create date if earlier (where applicable)	Related paired events must be eligible Related service issue monitor must be complete Related activity must be complete	

Maintenance Object	Cascaded By	ILM Date Computation	Specific Eligibility Considerations	Cascaded Transactions
Activity	Parent activity	Create date Superseded Device event, child activity, or completion event create date supersede (where applicable)	Cascaded transactions must be eligible Command requests must not be associated to a non-final service issue monitor Command requests must not be associated to an install event on off history entry	Child activities Device events Outbound communications Inbound communications Completion events
Outbound Communication	Activity	Create Date Superseded by initiating activity's create date (where applicable)		Inbound communication
Inbound Communication	Outbound Communication	Create date Superseded by initiating outbound communication create date (where applicable)		Device events

Proactive Archive Eligibility for Transactional Data

Some types of transaction data, including Device Events, Initial Measurement Data, and Usage Transactions can be analyzed for archive eligibility as they are received rather than waiting until their retention period has expired. This means that these records are judged ready to be archived as they are created and do not need to be read, analyzed, and updated during the ILM crawling process. This greatly reduces the number of records to be crawled at the end of the retention period and shortens the window of time required for ILM crawling. This section outlines how the ILM Archive switch (ILM_ARCH_SW) is set to “Y” (Yes) for records of these types as part of their initial processing.

- **Device Events:**

- The ILM Archive switch is set to “Y” for device events that meet the following criteria:
 - No service issue monitors were created for the device event
 - The device event is not a paired device event
- The ILM Archive switch is set to “Y” for device events via the following algorithms:
 - Create Service Issue Monitor from Device Event (D1-DVCEVTSIM)
 - Create Service Issue Monitor from Device Event for Paired Event (D1-PRDVEVSIM)

- **Initial Measurement Data:**

- The ILM Archive switch is set to “Y” by default for initial measurements (this is a different approach than the other record types).
- The ILM Archive switch is set to “N” for initial measurements that meet the following criteria:
 - A consumption synchronization activity has been created for the initial measurement

- A service issue monitor initiated from a VEE exception related to the initial measurement
- The ILM Archive switch is set to “N” for initial measurements that meet the above criteria via the following algorithms:
 - Update Latest Measurement Date/Time on Scalar MC with Consumption Sync (D1-UDTSCMCRE)
 - Update Latest Measurement Date/Time on MC with Consumption Sync (D1-UPD-DTMC)
 - Create Service Issue Monitor from VEE Exception (D2-VEEEXCSIM)
- **Usage Transactions:**
 - The ILM Archive switch is set to “Y” when a usage transaction enters the “Sent” or “Discarded” state (or the “Calculated” or “Discarded” states for a sub-usage transaction) via the following algorithms:
 - Send Usage (D2-SEND-USG)
 - Set ILM Switch to ‘Y’ (D1-SETILMSWY)

Multiple Retention Period Eligibility Crawling Strategies

When multiple retention periods are defined for a maintenance object each record will have its retention period written to the database at the time of record creation. This retention period is then used to identify when the record will be ready for eligibility evaluation (aka crawling).

Note: As specified in the Oracle Utilities Meter Data Management Database Administrator's Guide each unique retention period for the maintenance object will be a sub-partition within a given ILM date partition.

The system supports two methodologies for doing so:

- Evaluate Individual Records:
 - This is our default approach
 - This is the standard approach to evaluating ILM retention for all maintenance objects with a single retention period
 - The ILM date for each record will be compared against the current date less the retention period for that type of record. Simply stated, any records older than the retention period will be evaluated for eligibility.
 - In this option we will process a portion of a partition each day and only once we had processed the entire partition would the DBA be able to take an archiving action on the partition
 - This results in many visits to the partition to determine eligibility
 - The image below illustrates how the evaluate individual records method will crawl one day of records on a partition and sub-partition each day until the retention period for the last day of the partition had expired. All records would then be archived together when the last day of the partition was marked as eligible. This results in daily processing of small amounts of records but frequent visits to the partition.

- Evaluate the Entire Partition
 - This option will be enabled by configuring the ILM Date Partition Months in the maintenance object options
 - In this option all records on a ILM date partition retention period sub-partition will be evaluated at the same time.

- For example, for a monthly partitioning strategy in the month of January we would not evaluate any records in the January partition until January 31st had reached the end of its retention period.
- This means that we would evaluate the 1st through the 31st all at one time
- This option should typically result in a single visit to the partition to determine eligibility
-
- The image below illustrates how the evaluate entire partition method will only crawl records from a given partition and sub-partition when all records on that partition are eligible to be evaluated. Therefore, when the last day of the partition is ready to be evaluated the entire partition will be evaluated. This results in periodic processing with, and in many cases, a single visit to the partition for ILM purposes.

Configuring Information Lifecycle Management (ILM)

For additional information on configuring ILM, see [Enabling ILM for Supported Maintenance Objects](#) in the Oracle Utilities Application Framework *Administrative User Guide*.

The tasks described in the OUAF guide must be applied in conjunction with the task of configuring the Oracle Utilities Meter Data Management specific master configuration.

You can access the portal from the **Admin > General > Master Configuration**.

Once the Master Configuration screen returns, locate the following record:

- **ILM Configuration - MDM:** this enables multiple retention periods to be configured for Initial Measurements, Device Events, and Activities.

Related Eligibility Algorithms

There are a several Oracle Utilities Meter Data Management specific algorithms involved with ILM refer to the detailed description of the algorithm type of each algorithm for more information about the functionality each provides:

1. **ILM Eligibility - Activity (D1-ILMELGACT):** determines eligibility of Activities and cascades child Activities, Communication Out, Communication In, Device Events, and Completion Events.
2. **ILM Eligibility - Communication In (D1-ILMELGCI):** determines eligibility of Communication In.
3. **ILM Eligibility - Communication Out (D1-ILMELGCO):** determines eligibility of Communication Out and cascades Communication In.
4. **ILM Eligibility - IMD (D1-ILMELGIMD):** determines eligibility of Initial Measurement data and cascades VEE Exceptions.

Note: If an Initial Measurement Data record is marked as ready for archive and a corresponding control table record still exists this algorithm will delete the control table record.

5. **ILM Eligibility - Device Event (D1-ILMELGDE):** determines eligibility of Device Event data and cascades VEE Exceptions.
6. **ILM Eligibility - Usage Transaction (D1-ILMELIGUT):** determines eligibility of Usage Transactions.

Note: If a Usage Transaction record is marked as ready for archive and a corresponding control table record still exists this algorithm will delete the control table record.

7. **ILM Eligibility - Usage Transaction Exception (D1-ILMELGUEX):** determines eligibility of Usage Transaction Exceptions.
8. **ILM Eligibility - VEE Exception (D1-ILMELGVEX):** determines eligibility of VEE Exceptions.

The following provides additional information beyond that provided in the ILM Eligibility - Activity (D1-ILMELGACT) algorithms' detailed descriptions on how specific activity types are handled:

- Request Orchestration Activities: Request orchestrations also archive any child activities that were created, and those child activities archive any child activities or data (completion events, device events, etc.).
- Field Activities / Command Activities: Field activities and command request activities are archived either as part of a request orchestration or by themselves. When a field activity/command request is archived it also archives any of the following child transactions:
 - Update/Cancel Orchestrators
 - Communication Out
 - Communication In
 - Completion Event
- Non-Dispatchable Activities: Non-Dispatchable activities archived either as part of a request orchestration or by themselves. When a non-dispatchable activity is archived it also archives child completion events.
- Orchestration Maintenance Activities: Orchestration Maintenance activities are only archived by themselves if they do not have a related activity. When an orchestration maintenance activity is archived it also archives any of the following child transactions:
 - Communication Out
 - Communication In
- Device Event Activities: Presently device event activities are limited to outages which have an initiating and an ending device event. These types of activities cannot be archived until their related device events are either archived or ready to archive. However, the device events do not have to wait for the activity to archive so the device events are not updated with the activity's ILM date.
- Bulk Activities: Bulk Activities are comprised of the Bulk Header and the Bulk Request/Response, and depending on how the header was created there will be one header to many bulk requests/responses. The Bulk Header will only be eligible for archive if all related Bulk Request activities are also eligible for archiving. All related bulk activities are archived together. Bulk activities also generate one-to-many command request activities. Those individual command activities are archived separately.
- Extract Request Activities: These activities are used to request data from the head-end system on a periodic basis. Extract request activities should be in a final state prior to being archived.
- Other Activities: Other types of activities can be archived provided they do not require any special logic for handling for archiving purposes, such as checking for related data. These activity types can archive without checking related transactions:
 - Consumption Sync
 - Dimension Scanner
 - Error Activity
 - Measurement Quantity (deprecated)
 - Meter Read Download Activity
 - Suppression
 - Usage Transaction Correction Processor

In the event that your implementation uses custom activity types that require special handling, a custom algorithm should be created and added prior to the base package algorithm to preemptively handle the activity type category.

Related Batch Controls

There are a several Oracle Utilities Meter Data Management specific batch controls involved with ILM:

1. **ILM Crawler - Activity** (D1-ACTCR): identifies and executes eligibility evaluation for Activities. This batch control supports multiple retention periods.
2. **ILM Crawler - Communication In** (D1-CICRL): identifies and executes eligibility evaluation for Communication In.
3. **ILM Crawler - Communication Out** (D1-COCRL): identifies and executes eligibility evaluation for Communication Out.
4. **ILM Crawler - Device Event** (D1-DECRL): identifies and executes eligibility evaluation for Device Events.
5. **ILM Crawler - IMD** (D1-IMDCL): identifies and executes eligibility evaluation for Initial Measurement Data. This batch control supports multiple retention periods.
6. **ILM Crawler - Usage Transaction Exception** (D1-UEXCL): identifies and executes eligibility evaluation for Usage Transaction Exceptions.
7. **ILM Crawler - Usage Transaction** (D1-UTCRL): identifies and executes eligibility evaluation for Usage Transactions.
8. **ILM Crawler - VEE Exception** (D1-VEXCL): identifies and executes eligibility evaluation for VEE Exceptions.

For additional details see the [Batch Processes](#) section the Oracle Utilities Application Framework *Administrative User Guide*.

Measurement Reprocessing

Configuring Measurement Reprocessing

This section describes the process for configuring Measurement Reprocessing.

Refer to the [About Measurement Reprocessing](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Activity Type Configuration

Configuration for Measurement Reprocessing is performed by adding or changing an Activity Type. You can access the portal by selecting **Admin, Communication, Activity Type**.

Once the Activity Type search screen returns, locate the following records:

- **Measurement Reprocess Activity - Interval:** this Activity Type handles measurement reprocessing for interval Measuring Components.
- **Measurement Reprocess Activity - Scalar:** this Activity Type handles measurement reprocessing for scalar Measuring Components.

Use the **Add** button beside the record to configure for the first time. If a record has already been added, then click the **Edit** button instead. Use the embedded help to guide you through the meaning of each configuration field. By adding these Activity Types you are activating the process within Oracle Utilities Meter Data Management that will monitor changes to either the Measuring Component multiplier (the **Register Multiplier** for register measuring components or **Channel Multiplier** for interval and auto-read register measuring components) or the Install Event's **Installation Constant** or **Installation Date/Time**. If any of these attributes change for a device, then a new Activity will be created that attempts to reprocess the measurements for the affected period.

Algorithm Configuration

The Detect Installation Constant Change for Install Event (D1-DETIECHG) algorithm detects changes to install events, including changes to the **Installation Constant**, changes to the **Installation Date/Time**, and creation of new install events whose date range includes preexisting measurements and which include a change to the **Installation Constant**. When the algorithm detects a change to any of these, it initiates measurement reprocessing.

The "Ignore Install Event Date Changes" parameter can disable automatic initiation of measurement reprocessing in the event of changes to the **Installation Date/Time**.

The "Ignore New Install Events" parameter can disable automatic initiation of measurement reprocessing in the event of a new install event being created with a date range that includes preexisting measurements with a different **Installation Constant**.

Related Batch Controls

There are a few batches involved with Measurement Reprocessing:

- **Measurement Reprocessing Monitor (D1-MRAC)**: this processes any new Measurement Reprocessing activities that are created.
- **Measurement Reprocessing - Retry Monitor (D1-MRER)**: this process retries any Measurement Reprocessing activities that fail to the Issue Detected state.

Outage Storm Mode

Configuring Outage Storm Mode

This section describes the process for configuring Outage Storm Mode.

Note: Refer to the [About Outage Storm Mode](#) section of the *Oracle Utilities Meter Solution Business User Guide* for more functional information.

Master Configuration settings

Configuration for Outage Storm Mode is performed by adding or changing a Master Configuration. You can access the portal from the **Admin > General > Master Configuration**.

Once the Master Configuration search screen returns, locate the **MDM Master Configuration**. Use the Add button beside the record to configure for the first time. If a record has already been added, then click the Edit button instead. The **Estimation Eligibility For Widespread Outages** section is the primary section that needs to be configured for Outage Storm Mode to be enabled. Use the embedded help to guide you through the meaning of each configuration field.

Setup Meter Communication Tracking Aggregation

As part of Outage Storm Mode, aggregations are performed to determine the percentage of meter communication that has occurred for an area. The following configuration supports this:

1. Access the portal for Measuring Component Type through **Admin > Device > Measuring Component Type**. Add a new Measuring Component Type using the **Meter Communication Tracking Aggregator Type (D2-MtrCommTrckngAggregatorType)** business object. Follow the embedded help provided for each section. Two areas listed below are crucial to preparing for this specific aggregation:
 - a. When selecting a Measuring Component Business Object for this record, choose the **Meter Communication Tracking Aggregator** Business Object.
 - b. For the Value Identifiers, there are a few metrics that are can be defined as listed on the D2-AGG-MCTM Algorithm Type:
 1. Read Percentage
 2. Count of Received Measuring Components
 3. Count of Total Measuring Components
2. Access the portal for Activity Type through **Admin > Communication > Activity Type**. Add a new record for the Meter Communication Tracking Dimension Scanner Activity Type.
3. Access the portal for Activity through **Main > Communication > Activity**. Add a new record for the Activity Type you defined in the prior step.

Standard Event Name Configuration

If there is a desire to indicate that a widespread outage has ended for a device when it receives certain device events, the **Standard Event Name** Extendable Lookup can be used for this. You can access the portal from the **Admin > General > Extendable Lookup**.

Any Device Event that should close out Estimation Suppression Activities must be configured with the "End Estimation Suppression" algorithm (D2-EN-ESTSUP) in the Additional Processing Algorithms section. This is often configured for "Power Up" events to indicate that normal power flow has resumed for the meter.

Related Batch Controls

There are a few batches directly involved with Outage Storm Mode:

- **Dimension Scanner** (D1-ADS): monitors the "Meter Communication Tracking Dimension Scanner" business object. New Aggregator Measuring Components will be created for every applicable Service Type, Postal Code, and Head End in the system.
- **Aggregation Monitor** (D2-AGG): runs to execute the logic for the "Meter Communication Tracking Aggregator" Measuring Component. This logic will aggregate all meters for the defined Service Type, Postal Code, and Head End. Once the read percentage is found for that day then a measurement will be created for the Aggregator Measuring Component.
- **Estimation Suppression Monitor** (D1-ESTSU): This batch monitors the Estimation Suppression activities for processing. This batch should be scheduled to run regularly so it can clean up Suppression Activities if they have ended.
- **Widespread Outage** (D2-WSO): This batch queries the Meter Communication Tracking Aggregators to determine if any have experienced a widespread outage. For any actively in outage mode, then the batch will find all related Service Points and execute the logic on the algorithm plugged into the BO system event of "Estimation Suppression". It's recommended that D2-WSO be scheduled shortly after aggregation D2-AGG.

Detailed Examples of Outage Storm Mode

Scenario 1: Meter is marked estimation ineligible, then metered data is received with outage events

The following configuration settings should be assumed for this example:

Master Config option	Value
Check Widespread Outages	Yes
Read Percentage Days to Examine	7
Percent Drop From Norm - Estimation Ineligible	30.0%
Minimum Device Count For Ineligibility	100
Days Before Becoming Ineligible	0
Fill Missing Data With Zero	No
Days Before Filling Zero	
Maximum Estimation Ineligibility Days	3
Percent Within Norm - Resume Estimation	5.0%

Diagram:

Explanation for diagram:

1. The meter was communicating consistently but then a widespread outage occurs in the same postal code so the meter has an estimation suppression created.
2. Two events are received...a Power Down event and a Power Up event. Also, Regular usage data is received from the meter. The reception of non-estimated data marks the meter as eligible for estimation again.
3. Oracle Utilities Meter Data Management estimates data and takes the two events into account. Intervals marked as outage and filled with zeros are created during the outage period by the D1-SMMTR batch.

Scenario 2: Meter is marked estimation ineligible, is filled with zeros, then receives actual data

The following configuration settings should be assumed for this example:

Master Config option	Value
Check Widespread Outages	Yes
Read Percentage Days to Examine	7
Percent Drop From Norm - Estimation Ineligible	30.0%
Minimum Device Count For Ineligibility	100
Days Before Becoming Ineligible	0
Fill Missing Data With Zero	Yes
Days Before Filling Zero	0
Maximum Estimation Ineligibility Days	3

Percent Within Norm - Resume Estimation	5.0%
---	------

Diagram:

Explanation for diagram:

1. The meter loses communication and periodic estimation fills in outage intervals.
2. The meter reestablishes communication and sends in the latest readings and interval data.
3. Oracle Utilities Meter Data Management creates new data that's synchronized to fall in line with the new data from the meter by the Consumption Sync batch. This data replaces the outage measurements as it balances out to the scalar and interval data.

Running Initial Periodic Estimation

This section provides guidelines for running an initial periodic estimation process.

Overview

Prior to running the first execution of periodic estimation an assessment should be made regarding the current state of measurement data on your measuring components. Without proper preparation the first execution can take an extremely long time due to large gaps on measuring components. Since the D1-SMMTR job is threaded by device, all of the initial measurements for a device's interval and scalar channels will be created within a single work unit. This will lead to an abnormally large number of transactions being created within a single commit which can degrade performance.

There are several options available for establishing a consistent starting point for estimation across all measuring component types:

1. Configure the **Maximum Days to Estimate** on each periodic estimation eligible measuring component type. This limits the number of days periodic estimation will look backwards to create estimations. For example, if set to

60 the no estimations over 60 days old would be created and all measuring components would have their **Last Contiguous Measurement Date Time** set to 60 days ago or more recent.

2. Configure the **No of Hours in the Past to Retrieve Last Usable Measurement** option on the Measurement Data Options feature configuration. This configuration works in two specific ways:
 - When the measuring component's **Last Contiguous Measurement Date/Time** has not been initialized then this setting is used to search for usable measurements starting from the **Process Date/Time** less the number of hours configured.
 - If a measurement is found, the most recent measurement within that window will be used.
 - If no measurements are found, estimates will be generated starting from the calculated start date/time.
-  **Note:** Note: if the calculated start date/time is very recent and not yet eligible for estimation then the measuring component's **Latest Contiguous Measurement Date/Time** will be updated with that value.
- When the **Last Contiguous Measurement Date/Time** has already been set for a measuring component this setting will be used similar to the **Maximum Days To Estimate** and will limit how far back estimation will occur.
3. Use the **Initialize Measuring Component Dates (D1-IMCDT)** batch control just prior to the first run of periodic estimation to explicitly set the **Latest Contiguous Measurement Date/Time** across all measuring components to the date you would like to estimate from.

It is important to take into consideration that the periodic estimation process is tuned with the expectation that it will create estimations for a small percentage of the meter population (generally around 2%) for one day. If on the initial run all devices have measuring components that require estimations to be created, it is increasing the typical work load exponentially: 100% of the meter population for many days.

Lastly, it is very important, regardless of the method used, to test a small population of meters before running Periodic Estimation (D1-SMMTR) on your entire meter population. Isolated testing will alert you to potential performance issues without having to cancel a multi-day D1-SMMTR execution.

Avoiding Long Execution Time

In general the single most important thing to avoid long execution times on your first run of the Periodic Estimation batch process (D1-SMMTR) is to ensure that your measurement data is as current as it possibly can be. You should not run the Periodic Estimation process (D1-SMMTR) until you have completed conversion and you have loaded your initial set of initial measurements. If you run the Period Estimation process (D1-SMMTR) any time prior to that you risk generating estimates for data that you have but just haven't loaded yet.

If you must run the Periodic Estimation process (D1-SMMTR) prior to having all of your measurement data current, you should use the **Batch Business Date** on the batch control to limit the horizon of time you will estimating. The **Batch Business Date** won't impact the start of your horizon but it will limit the end.

The following sections provide input on several ways you can control the start of the horizon.

Overview of Options and Start of Estimation Horizon

The table below summaries various options and their impact on the Start of the Estimation horizon.

Note: Always ensure the **Most Recent Measurement Date/Time** is set to the measurement date/time furthest into the future. The **Initialize Measuring Component Dates (D1-IMCDT)** batch control has functionality for initializing the Most Recent Measurement Date/Time as well (if it was not set during conversion).

Measuring Component Type Maximum Days to Estimate	Feature Configuration	Measuring Component Dates	Measurement Data	Start of Estimation Horizon
Not Configured	Not Configured	Not Set	None	Horizon will begin based on the installation date/time: <ul style="list-style-type: none"> • Interval uses the installation date/time • Scalar uses the On event
Not Configured	Not Configured	Not Set	Yes, with some gaps	Horizon will begin based on the installation date/time: <ul style="list-style-type: none"> • Interval uses the installation date/time • Scalar uses the On event
Configured	Any	Not Set	Any	Horizon will begin based on the process date/time less the Maximum Days to Estimate
Configured	Any	Set	Yes - prior to Maximum Days to Estimate	Horizon will begin based on the process date/time less the Maximum Days to Estimate
Configured	Any	Set	Yes - after Maximum Days to Estimate	Horizon will begin based on the Latest Contiguous Measurement Date/Time

Measuring Component Type Maximum Days to Estimate	Feature Configuration	Measuring Component Dates	Measurement Data	Start of Estimation Horizon
Not Configured	Configured	Not Set	None	<p>Horizon will begin based on the process date/time less the hours configured on the feature configuration.</p> <p>If it is not yet time to estimate based on the calculated start of the estimation horizon, then:</p> <ul style="list-style-type: none"> • Interval: Last Contiguous Measurement Date/Time is initialized to the calculated horizon start • Scalar: Last Contiguous Measurement Date/Time is initialized to the calculated horizon start and Adjusted Last Contiguous Measurement Date/Time is set to the appropriate value based on the periodic estimation configuration. <p>Note: this would happen when the Hours Before Estimation (for example 72) is a larger number of hours than the No of Hours in the Past to Retrieve Last Usable Measurement (for example 24)</p>

Measuring Component Type Maximum Days to Estimate	Feature Configuration	Measuring Component Dates	Measurement Data	Start of Estimation Horizon
Not Configured	Configured	Not Set	Yes - outside feature configuration window	<p>Horizon will begin based on the process date/time less the hours configured on the feature configuration.</p> <p>If it is not yet time to estimate based on the calculated start of the estimation horizon, then:</p> <ul style="list-style-type: none"> • Interval: Last Contiguous Measurement Date/Time is initialized to the calculated horizon start • Scalar: Last Contiguous Measurement Date/Time is initialized to the calculated horizon start and Adjusted Last Contiguous Measurement Date/Time is set to the appropriate value based on the periodic estimation configuration. <p>Note: this would happen when the Hours Before Estimation (for example 72) is a larger number of hours than the No of Hours in the Past to Retrieve Last Usable Measurement (for example 24)</p>
Not Configured	Configured	Not Set	Yes - inside feature configuration window	Horizon will begin as of the most recent measurement date/time that was found for the measuring component.
Not Configured	Configured	Set	Any	<p>Horizon will begin based on the most recent of the following:</p> <ul style="list-style-type: none"> • Process date/time less the hours configured on the feature configuration • Last Contiguous Measurement Date/Time

Testing Periodic Estimation on Small Data Sets

This topic provides guidelines for testing periodic estimation on small data sets.

How to Override the System Date

The system or process date is a key driver in the periodic estimation process. It will determine the end date/time of the estimation horizon (along with the periodic estimation configuration). When testing a single device this override can ensure that estimations never go further in time than you would like if you are working with an older set of test data.

There are two methods to override the system date (both use the format YYYY-MM-DD) that will work for the methods being described in this section.

- The **System Override Date** option on the **General System Configuration** feature configuration: this impacts all users and batches
- The **System Override Date** characteristic for a specific user: this impacts only processes executed by a particular user

Testing a Single Device

To test a single device you can emulate the D1-SMMTR batch by using the F1-AutoTransitionBO business service. This service executes the monitor algorithms on the current state of a business object much in the same way as the D1-SMMTR batch control. This business service can be called in one of two ways:

1. Create a BPA script to call the business service for a particular device ID (see sample below).
2. Create an Inbound Web Service and use SoapUI or an analogous product to call that Inbound Web Service (see sample below).
3. Be sure that the credentials used for the Inbound Web Service submission are the ones for which the date was overridden (if you are overriding the system date for a single user).

Sample BPA edit step:

```
move '724182144552' to "F1-AutoTransitionBO/primeKeyValues/pkValue1";
move 'D1-DEVICE' to "F1-AutoTransitionBO/mo";
move 'D1-SMMTR' to "F1-AutoTransitionBO/batchControl";
invokeBS 'F1-AutoTransitionBO' using "F1-AutoTransitionBO";
```

Sample SOAP Inbound Web Service Payload:

```
<soapenv:Envelope
xmlns:soapenv="http://schemas.xmlsoap.org/soap/envelope/"
xmlns:zz="http://ouaf.oracle.com/webservices/d1/ZZ-AutoTransitionBO">
  <soapenv:Header/>
  <<soapenv:Body>
    <zz:autoTran>
      <zz:mo>D1-DEVICE</zz:mo>
      <zz:primeKeyValues>
        <zz:pkValue1>344235660160</zz:pkValue1>
      </zz:primeKeyValues>
      <zz:batchControl>D1-SMMTR</zz:batchControl>
    </zz:autoTran>
  </soapenv:Body>
</soapenv:Envelope>
```

Testing a Subset of Devices

To test a subset of devices you can create a plug-in driven batch:

- Select algorithm: write the select statement that gathers the device IDs that you wish to test, this can be a hard coded list if need be (just select them from dual).

- Process Records algorithm: Use the F1-AutoTransitionBO business service, but call it for the device in the current work unit (this is essentially what D1-SMMTR does)

Testing Periodic Estimation on Large Data Sets

This topic provides guidelines for testing periodic estimation on large data sets.

Before running periodic estimation on a large data set it is important to have an idea of roughly how many devices and for how long you expect to estimate. This can be gauged fairly quickly by looking at the **Latest Measurement Date/Time** on the measuring component. Here is a sample query that will provide a count of measuring components by the number of months from a supplied process date the last contiguous measurement date/time is:

```
select count(*)
, round((to_date(:processDateTime, 'YYYY-MM-DD-
HH24.MI.SS') - latest_msrmt_dttm)/31,0) MONTHS
from dl_measr_comp mc
group by round((to_date(:processDateTime, 'YYYY-MM-DD-
HH24.MI.SS') - latest_msrmt_dttm)/31,0)
order by 2
;
```

Below is a more complex query that will show you by thread how many measuring components for a given **Latest Measurement Date/Time** you will process, it does a bit more work to look at only installed devices and measuring components that are configured for periodic estimation and the measuring component is actually ready to estimate based on that configuration.

The parameters for this are:

- threads: enter 1 to avoid splitting the results into threads
- processDateTime: leave blank to use the system date, otherwise provide a date/time in the format: YYYY-MM-DD-HH24.MI.SS

```
with threads as (
  select rownum thread_nbr
  , lpad(round((rownum - 1) * (rpad('9',12,'9')+1)/:threads,0),12,'0') low_id
  , lpad(round(rownum * ((rpad('9',12,'9')+1)/:threads),0)-1,12,'0') high_id
  from dual
  connect by rownum <= :threads
)
select /*+ parallel */ threads.thread_nbr
, threads.low_id
, threads.high_id
, nvl(mc.adj_latest_msrmt_dttm,mc.latest_msrmt_dttm) LATEST_MSRMT_DTTM
, count(*) MC_COUNT
from threads
inner join dl_dvc dvc
  on dvc.dl_device_id between threads.low_id and threads.high_id
inner join dl_dvc_cfg dc
  on dc.dl_device_id = dvc.dl_device_id
inner join dl_install_evt ie
  on ie.device_config_id = dc.device_config_id
  and ie.dl_install_dttm < sysdate
  and (ie.dl_removal_dttm is null or ie.dl_removal_dttm >= sysdate)
inner join dl_measr_comp mc
  on mc.device_config_id = dc.device_config_id
inner join dl_measr_comp_type mct
  on mct.measr_comp_type_cd = mc.measr_comp_type_cd
  and hrs_wait_before_est > 0
where (to_date(nvl(:processDateTime,sysdate), 'YYYY-MM-DD-
HH24.MI.SS') - latest_msrmt_dttm) * 24 > mct.hrs_wait_before_est
group by threads.thread_nbr
, threads.low_id
```

```
, threads.high_id
, nvl(mc.adj_latest_msrmt_dttm,mc.latest_msrmt_dttm)
order by 1, 4
;
```

Integrations

External Applications

Understanding External Applications

External applications are applications and systems that are external to the Oracle Utilities meter data products, and can include customer information systems such as Oracle Utilities Customer Care and Billing, outage management systems such as Oracle Utilities Network Management System, or other types of applications.

External system service providers utilize processing methods to specify how the system sends and creates data used by the two applications. For example, when Oracle Utilities Meter Data Management is integrated with Oracle Utilities Customer Care and Billing, an external system representing Oracle Utilities Customer Care and Billing would specify how usage requests are received and processed by Oracle Utilities Meter Data Management.

Refer to [Understanding Process Methods](#) for more information about processing methods.

External Applications Impact Data Import and Export

External Applications are configured to identify how a particular external system communicates data with Oracle Utilities Meter Data Management. This includes:

- The identifier type used to locate devices and measuring components. These are used both on import and export of data.
- The date/time format used in various data imports (i.e. whether or not the date/time format includes time zone information).

Please refer to the embedded help for more information about these fields.

Each external application can be associated to an [external system](#) which is used to define the messages that can be sent to that service provider and how each message is sent.

Configuring External Applications

This portal is used to display and maintain External Applications.

Refer to [Understanding External Applications](#) for more information.

You can access the portal from the **Admin**, then **Integration**, then **External Application**.

The following zones may appear as part of the portal's **Main** tab page:

- **External Applications List:** This zone lists all External Application records. Broadcast a record to display the details of the selected record.
- **External Application:** This zone provides information about the selected External Application.
- **Processing Method List:** This zone provides the list of processing methods defined for the External Application.
- **Translation Method List:** This zone provides the list of translation methods defined for the External Application.
- **Inbound BOs Send By Service Provider:** This zone lists inbound Business Objects that are sent by this External Application. The identification is driven by the Business Object having a Business Object Option of type "Sent By Service Provider" that references the current External Application.

Initiating Smart Meter Commands from an External Application

Though often initiated as part of an orchestration activity (such as Enable Service or Exchange Meter) or from the Oracle Utilities Meter Data Management application, smart meter commands can also be initiated from external applications such as a customer information system such as Oracle Utilities Customer Care and Billing, a self-service application such as Oracle Utilities Digital Self-Service Transactions, or an outage management system such as Oracle Utilities Network Management System.

External applications initiate commands through the use of inbound web services, and outbound messages are used to send the results back to the initiating application. This section describes how smart meter commands can be initiated from external applications.

Command Processing Overview

This section provides a high level overview of how the system processes commands initiated from external applications.

For each step in the process, the table below provides a brief description of the processing that takes place, and lists the specific base package objects used. Note that the process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process. This example uses an "On-Demand Read - Interval" command.

Table listing the steps of command initiation and processing

Step	Process	Sample Object
1	External application initiates a command request via inbound web service	Inbound Web Service: D1-OnDemandReadInterval
2	Command activity is created in the Pending state.	Activity Business Object: D1-OnDemandReadInterval
3	The command activity goes through it's lifecycle, creating outbound communications as defined by the head end system, receiving the response.	
4	When the command enters the Completed state, an Enter algorithm sends the result to the initiating application.	Algorithm: Send On Demand Read to Edge Application (D1-SNDRDTEA)
5	The algorithm uses a "Response - Success" processing method (based on the the Response - Success (DISR) processing role) defined for the external application to create an outbound message (based on the outbound message type defined for the processing method).	Processing Method Business Object: How to Send Activity Related O\B Messages (D1-HowToSendActivityResponse) Outbound Message Business Object: Outbound Message for Communication BOs (D1-OutboundMessage)
6	The external system and message sender sends the outbound message to the external application.	

Inbound Web Services

This section provides information about the inbound web services available for initiating smart meter commands from an external application. The table below lists the smart meter commands available, and the specific inbound web services provided for each.

Table listing supported commands and corresponding inbound web services

Command	Inbound Web Service
Device Status Check	Device Status Check (D1-DeviceStatusCheck)
On-Demand Read (Interval)	On Demand Read Interval (D1-OnDemandReadInterval)
On-Demand Read (Scalar)	On Demand Read Scalar (D1-OnDemandReadScalar)
Remote Connect	Remote Connect (D1-RemoteConnect)
Remote Disconnect	Remote Disconnect (D1-RemoteDisconnect)

See [Inbound Web Services](#) for more information about using inbound web services.

Required Data Elements

The inbound web service calls used to initiate commands must include some specific data elements in order to be successfully processed.

The table below lists the specific data elements required when initiating commands via inbound web service calls. Use the [WSDL](#) link to view the full web service description language definition for each command.

Table listing required data elements

Data Element	Description	Used by
requester	The system or person submitting the command request. This should be the name of the external application.	Device Status Check On-Demand Read (Interval) On-Demand Read (Scalar) Remote Connect Remote Disconnect
utilityDeviceIdentifierNumber	The ID of the device in the external system. This should be based on the Utility Device ID Type defined for the external application. For example, if the external application uses Serial Numbers for their device IDs, this would be the device's serial number.	Device Status Check On-Demand Read (Interval) On-Demand Read (Scalar) Remote Connect Remote Disconnect
measurementDestination	The destination for measurements returned by On-Demand read commands, from the Measurement Destination (MSRMT_DEST_FLG) lookup. Valid values include: <ul style="list-style-type: none"> • Calling Edge Application (D1EA) • Calling & Subscribing Edge Application (D1ES) • Measurement Subscribing Edge Application (D1SE) 	On-Demand Read (Interval) On-Demand Read (Scalar)

Send to Edge Application Algorithms

As noted above, when the command enters the Completed state, an Enter algorithm sends the result to the initiating application. The table below lists the specific algorithms used with each command.

Table listing activity business objects and corresponding algorithms

Activity Business Object	Send to Edge Application Algorithm
Device Status Check (D1-DeviceStatusCheck)	Send Device Status Check Notification to Edge Application (D1-SNDDVSTCK)
On Demand Read Interval (D1-OnDemandReadInterval)	Send On Demand Read to Edge Application (D1-SNDRDTEA)
On Demand Read Scalar (D1-OnDemandReadScalar)	Send On Demand Read to Edge Application (D1-SNDRDTEA)
Remote Connect (D1-RemoteConnect)	Send Remote Connect Notification to Edge Application (D1-SRCNTEA)
Remote Disconnect (D1-RemoteDisconnect)	Send Remote Disconnect Notification to Edge Application (D1-SRDNTEA)

Sending Messages Back to the External Application

Sending outbound communications to an external application involves configuring a number of entities. This section provides an overview of the objects required to send outbound communications to external applications.

Outbound Message Types

Outbound message types define the details of outbound messages sent to the external application. You should create an outbound message type for each different type of message to be sent to the external application.

See [Outbound Messages](#) and [Defining Outbound Message Types](#) for more information about creating outbound message types.

Message Senders

Message senders define details for sending messages to external applications. You must create a message sender for each type of message to be sent to the external application.

Note: The Message Class MUST be set to **SOAPSNDR** (Sender for real-time HTTP / SOAP messages).

See [Message Senders](#) for more information about creating message senders.

External Systems

You must create an external system that represents the external application and defines the outbound message types that can be sent to the external application. The external system will be referenced on the external application.

You must configure an outbound message type on the external system for each type of message you will send to the external application. An external system's outbound message types are defined by the following:

- **Outbound Message Type:** The outbound message type (see above) created for the message
- **Processing Method:** The method by which the message will be sent. This should be set to "Real-time".
- **Message Sender:** The message sender (see above) created for the message.
- **Message XSL / Response XSL:** XSL files used to transform your message and the response to the message into the appropriate format used by the external application (Message XSL) and Smart Grid Gateway (Response XSL).

See [External Systems](#) for more information about creating external systems.

External Applications

The external applications that can initiate smart meter commands must be defined as External Applications. Examples can include:

- A customer information system (such as Oracle Utilities Customer Care and Billing)
- A self-service application (such as Oracle Utilities Digital Self-Service Transactions)

Information defined for external applications include:

- **External System:** The external system (see above) that defines the types of outbound messages to be sent to the external application.
- **Our Name/ID in Their System:** The value that the external application uses to identify our system.
- **Utility Device ID Type:** The Device ID Type that will be used when communicating with the external application and it will be the assumed Device ID Type for any device identifiers sent from the external application.
- **Utility Service Point ID Type:** The Service Point ID Type that will be used when communicating with the external application and it will be the assumed Service Point ID Type for any service point identifiers sent from the external application.
- **Processing Methods:** The external application's processing methods define how data relevant to the application is sent and/or created. At least one processing method should reference the outbound message type used to send responses to the external application. External applications that initiate smart meter commands should use the following processing roles:

- **Response- Success:** Used to send an acknowledgement that the command was successfully executed and the results of the command, if applicable.

Refer to [Understanding External Applications](#) and [Configuring External Applications](#) for more information about external applications.

Business Flags

Understanding Business Flags

This product has implemented business flags that represent situations that exist at a customer's service point that are shared across external applications; such as, Oracle DataRaker and Oracle Utilities Customer Care and Billing. The situations that a business flag can represent ranges from critical knowledge that requires manual analysis for resolution to purely informational notifications.

This sharing of information allows users of each system to quickly understand the status of a service point as it relates to situations that users of the system would benefit from. For example, the analytics system (Oracle DataRaker) may identify potential theft situations that should be investigated prior to sending any usage transactions.

The subsequent sections describe business flag functionality that is specific to the service point business flag as implemented by this product.

When creating a new device type there are the following options:

Name	Details	Business Object
Service Point Business Flag Type	Provides configuration for business flags associated to a service point. This type offers an ability to hold a business flag for manual analysis.	D1-SPBusinessFlagType
Service Point Monitor Business Flag Type	Provides configuration for business flags that should initiate service issue monitors and convey results of a field activity to the intended subscribers.	D1-SPMonitorBusinessFlagType

Refer to [About Business Flags](#) in the *Oracle Utilities Framework Administration User Guide* for detailed information about the components of business flags.

Important Business Flag Business Object Options

Below are a list of business object options that are defined on the business flag business object associated to a given business flag type:

- **Valid Action:** identifies a BPA script that can be used to guide the user though an action that can be taken on a business flag. Note: this option should be paired with a business object lifecycle option of "Execution of Valid Actions Permitted" with a value of "true" for any lifecycle status that should support the execution of valid actions.

More detail about these options can be found by visiting a measuring component business object and inspecting the business object options.

Field Activities can Determine Business Flag Confidence

When a business flag results in a field activity being issued and a field team is sent to investigate the service point the result of that field activity investigation will determine the confidence of the business flag. This is done through the field remarks left by the field team. The field activity remarks can either be defined as confirming the business flag

or rejecting it. By selecting the appropriate field activity remark the field team will conclude the investigation into the business flag and the final confidence will be updated as appropriate.

For those field activity remarks that should either confirm or reject the business flag the Business Flag Confidence Update algorithm type should be provided for the field activity remark - activation plug-in spot.

Refer to algorithm type **Assign Business Flag Final Confidence** (D1-ABFFC) for additional details.

Configuring Business Flags

For information on configuring business flags, see [Setting Up Business Flag Configuration](#) in the Oracle Utilities Application Framework *Administrative User Guide*.

Oracle Utilities Customer Care and Billing

Overview

This section provides an overview of how Oracle Utilities Meter Data Management supports integrations with a customer information system. In an integration between Oracle Utilities Meter Data Management (MDM) and a customer information system such as Oracle Utilities Customer Care and Billing (CC&B):

- Oracle Utilities Meter Data Management is typically the "system of record" for meter-related data, including meter records, meter configurations, validation, editing, and estimation (VEE) rules, bill determinant calculation rules, usage data, and calculated bill determinants.
- Oracle Utilities Customer Care and Billing (the customer information system) is typically the "system of record" for account related and service point-related data, including the rates and tariffs used to calculate bills for each account and customer.

Given this breakdown of data between the two systems, any integration between them must account for the passage of data between the two to ensure that each system can accurately perform its business functions.

Configuring Master Data Synchronization

In most integrations with Oracle Utilities Customer Care and Billing (or other CIS), Oracle Utilities Meter Data Management is not used as the system of record for account, customer, or service point-related data. Synchronizing this data between the two systems ensures that all account, customer, and service point-related data in Oracle Utilities Meter Data Management is correct and up to date before usage transaction calculations are performed. This synchronization process is supported through a set of business objects, master configurations, batch controls, and pre-configured Inbound Web Services.

- **Initial Synchronization Requests:** Initial synchronization requests are used when initially setting up Oracle Utilities Meter Data Management. They facilitate import of data that creates devices, device configurations, measuring components, service points, install events, contacts, and usage subscriptions in Oracle Utilities Meter Data Management based on corresponding data in Oracle Utilities Customer Care and Billing.
- **Ongoing Synchronization Requests:** Ongoing synchronization requests are used when updating existing data in Oracle Utilities Meter Data Management based on changes in corresponding data in Oracle Utilities Customer Care and Billing. Ongoing synchronization requests can be used to update contacts, devices, device configurations, measuring components, install events, service points, and usage subscriptions.
- **Composite Synchronization Requests:** Composite synchronization requests are requests that contain synchronization requests for multiple types of data within a single request. For example, a composite request could contain requests to update device, device configuration, measuring component, and install event data. This supports situations where multiple types of data must be updated based on a single change in Oracle Utilities Customer Care and Billing.

Master Configuration

The following master configurations are used in Oracle Utilities Meter Data Management to configure the sync process between CIS and MDM:

Master Configuration	Name / Description
Master Data Synchronization Configuration	Lists all foreign key references that need resolution. Each one should reference the view that contains the external key / production key cross-reference. For entities that undergo both the initial and the ongoing sync, two views are specified. For entities that undergo the ongoing sync, an external system / ID type mapping is specified to cater for entities that might be synchronizing from more than one external system.
Seeder Sync Request Master Configuration	Lists the maintenance objects (device, device configuration, etc.) that require synchronization. Each references the synchronization business object that needs to be instantiated when processing a synchronization request for that maintenance object. For maintenance objects that undergo both initial and the ongoing synchronization, two business objects are specified.

Inbound Data Synchronization Business Objects

The integration between Oracle Utilities Meter Data Management and Oracle Utilities Customer Care and Billing uses the following inbound (to Oracle Utilities Meter Data Management) synchronization business objects:

Object Name	Business Object	Description
Device Config Composite Sync Request	D1-CompositeSyncRequestDC	A composite synchronization request that handles syncing in Device Configuration and creating related Measuring Component. This business object a child of the D1-CompositeSyncRequest business object.
Contact Initial Sync Request	D1-InitialSyncRequestContact	Instances of this business object represent individual initial contact synchronization requests.
Device Configuration Initial Sync Request	D1-InitialSyncRequestDC	Instances of this business object represent individual initial device configuration synchronization requests.
Device Initial Sync Request	D1-InitialSyncRequestDevice	Instances of this business object represent individual initial device synchronization requests.
Install Event Initial Sync Request	D1-InitialSyncRequestIE	Instances of this business object represent individual initial install event synchronization requests.

Measuring Component Initial Sync Request	D1-InitialSyncRequestMC	Instances of this business object represent individual initial measuring components synchronization requests.
Service Point Initial Sync Request	D1-InitialSyncRequestSP	Instances of this business object represent individual initial service point synchronization requests.
Dynamic Option Initial Sync Request	D2-InitialSyncRequestDynOpt	Instances of this business object represent individual initial dynamic option synchronization requests.
Dynamic Option Event Initial Sync Request	D2-InitialSyncRequestDynOptEvt	Instances of this business object represent individual initial dynamic option event synchronization requests.
Usage Subscription Initial Sync Request	D2-InitialSyncRequestUS	Instances of this business object represent individual initial usage subscription synchronization requests.
Ongoing Sync Request Acknowledgement	D1-OngoingSyncReqAckMsg	Used to send a message to the sending system to acknowledge receipt of an ongoing synchronization request.
Scalar Meter Read Ongoing Sync Request	D1-OngoingSyncReqScalarMtrRead	Instances of this business object represent individual ongoing scalar meter read synchronization requests.
Contact Ongoing Sync Request	D1-OngoingSyncRequestContact	Instances of this business object represent individual ongoing contact synchronization requests.
Device Configuration Ongoing Sync Request	D1-OngoingSyncRequestDC	Instances of this business object represent individual ongoing device configuration synchronization requests.
Device Ongoing Sync Request	D1-OngoingSyncRequestDevice	Instances of this business object represent individual ongoing device synchronization requests.
Install Event Ongoing Sync Request	D1-OngoingSyncRequestIE	Instances of this business object represent individual ongoing install event synchronization requests.
Measuring Component Ongoing Sync Request	D1-OngoingSyncRequestMC	Instances of this business object represent individual ongoing measuring component synchronization requests.

Service Point Ongoing Sync Request	D1-OngoingSyncRequestSP	Instances of this business object represent individual ongoing service point synchronization requests.
Dynamic Option Ongoing Sync Request	D2- OngoingSyncRequestDynOpt	Instances of this business object represent individual ongoing dynamic option synchronization requests.
Dynamic Option Event Ongoing Sync Request	D2- OngoingSyncRequestDynOptEvt	Instances of this business object represent individual ongoing dynamic option event synchronization requests.
Usage Subscription Ongoing Sync Request	D2-OngoingSyncRequestUS	Instances of this business object represent individual ongoing usage subscription synchronization requests.
Sync Request Seeder	D1-SyncRequestSeeder	Used to identify the appropriate synchronization business object to create when processing synchronization requests.
Contact Synchronization Add	D1-SynchronizationAddContact	Used when adding a new contact as a result of a synchronization request.
Device Configuration Synchronization Add	D1-SynchronizationAddDC	Used when adding a new device configuration as a result of a synchronization request.
Device Synchronization Add	D1-SynchronizationAddDevice	Used when adding a new device as a result of a synchronization request.
Install Event Synchronization Add	D1-SynchronizationAddIE	Used when adding a new install event as a result of a synchronization request.
Measuring Component Synchronization Add	D1-SynchronizationAddMC	Used when adding a new measuring component as a result of a synchronization request.
Service Point Synchronization Add	D1-SynchronizationAddSP	Used when adding a new service point as a result of a synchronization request.
Usage Subscription Synchronization Add	D2-SynchronizationAddUS	Used when adding a new usage subscription as a result of a synchronization request.

Batch Controls

Batch controls perform processing for initial synchronization requests such as allocating keys to data, resolving foreign keys, and loading data (instantiating business objects representing entities such as devices, measuring components, etc.).

"Initial Sync Request - Resolve Keys XXX" batch controls invoke a generic maintenance object transition process to invoke the "Resolve Keys - Initial Sync" algorithm for synchronization requests of the appropriate type. Parameters used by "resolve keys" batch controls include:

- **Maintenance Object:** (Required) the maintenance object (device, device configuration, etc.) to be processed. This must be set to the Sync Request maintenance object for the batch control (device for device synchronization requests, service point for service point synchronization requests, etc.)
- **Restrict By Batch Code:** Restricts processing to synchronization requests whose current state is linked to this batch code.
- **Restrict By Business Object:** Restricts processing to synchronization requests linked to this business object.
- **Restrict By Status Code:** Restricts processing to synchronization requests of this status (default: KEY_ALLOCATD).
- **Max Errors:** Specifies the maximum number of errors allowed before the process exits.

"Initial Sync Request - Load Data XXX" batch controls load data (created new instances of business objects) for requests of the appropriate type (device, measuring component, etc.). Parameters used by "load data" batch controls include:

- **Maintenance Object:** (Required) the maintenance object (device, device configuration, etc.) to be processed. This must be set to the Sync Request maintenance object for the batch control (device for device synchronization requests, service point for service point synchronization requests, etc.)
- **Restrict By Batch Code:** Restricts processing to synchronization requests whose current state is linked to this batch code.
- **Restrict By Business Object:** Restricts processing to synchronization requests linked to this business object.
- **Max Errors:** Specifies the maximum number of errors allowed before the process exits.

The table below lists the batch controls used by initial synchronization requests:

Batch Code	Name / Description
D1-CMSYN	Composite Sync Request
D1-SIIER	Initial Sync Request - Error
D1-SILCN	Initial Sync Request - Load Data Contact
D1-SILDC	Initial Sync Request - Load Data DC
D1-SILDV	Initial Sync Request - Load Data Device
D1-SILIE	Initial Sync Request - Load Data IE
D1-SILMC	Initial Sync Request - Load Data MC
D1-SILSP	Initial Sync Request - Load Data SP
D1-SILUS	Initial Sync Request - Load Data US
D1-SIKCN	Initial Sync Request - Resolve Keys Contact
D1-SIKDC	Initial Sync Request - Resolve Keys DC
D1-SIKDV	Initial Sync Request - Resolve Keys Device
D1-SIKIE	Initial Sync Request - Resolve Keys IE
D1-SIKMC	Initial Sync Request - Resolve Keys MC

	Contact	Usage Subscription	Service Point	Install Event	Device Configuration	Device	Measuring Component	Dynamic Option	Dynamic Option Event
Foreign Key Resolution / BO Validation Job (dependent on ALL Key Allocation Jobs finishing)	3	8	3	6	3	3	6	3	5
Load Job	4	9	5	7	5	4	7	4	6

Note that before the Key Resolution job is run, all the Key Allocation Jobs need to finish. This ensures that all foreign key references can be subsequently resolved.

Some business object-level validation is dependent on other entities being completely loaded first. The sequence numbers above allow for this. For example, usage subscriptions business object validation is dependent on service points existing; Install Event business object validation is dependent on both service points and devices existing.

Inbound Web Services

Inbound web services are used to facilitate invoking the Sync Request Seeder business object by the middleware components upon receipt of a synchronization request.

The table below lists the pre-configured Inbound Web Services used to process synchronization requests sent from Oracle Utilities Customer Care and Billing.

Inbound Web Service	Description	Schema Name
D1-SyncRequestInbound	Sync Request Inbound	D1-SyncRequestSeeder (BO)
D1-SyncRequestInboundComposite	Sync Request Inbound Composite	D1-CompositeSyncRequestDC (BO)

Example Sync Process Steps

This section provides an overview of the processing that takes place when a synchronization request is sent. For each step in the process, the table below provides a brief description of the processing that takes place, and lists the specific objects involved.

Step	Process	Objects
------	---------	---------

1	<p>Oracle Utilities Customer Care and Billing sends a synchronization request to the middleware integration layer.</p> <p>For example, consider a request to update information about a service point.</p>	
2	<p>The middleware components transforms the request from the Customer Care and Billing format, to the format used by Oracle Utilities Meter Data Management (this format is based on the business object schemas of the synchronization request business objects).</p>	
3	<p>The middleware component invoke the appropriate Inbound Web Service, and sends the transformed request.</p>	<p>Inbound Web Service: D1- SyncRequestInbound (mapped to the D1- SynrRequestSeeder business object)</p>
4	<p>The Inbound Web Service invokes the Sync Request Seeder business object, which in turn, determines which synchronization request business object to create (based on the type of data in the synchronization request and the Seeder Sync Master Configuration).</p>	<p>Synchronization Request BO: D1- OngoingSyncRequestSP</p>
5	<p>For initial synchronization requests, background processing creates master data for each synchronization request, including the following steps:</p> <ul style="list-style-type: none"> • Data Transformation / Schema Validation • Allocate Keys • Resolve Foreign Keys / Validate Business Object • Load Data 	

6	<p>For ongoing synchronization requests, the following steps are performed by Enter algorithms on the synchronization request business object lifecycle states:</p> <ul style="list-style-type: none"> • Data Transformed/Basic Schema Validated: • Determine Sync Request BO • Setup Transformed Data • Pre-Added: • Sync Request Pre-Add Data • FKs Resolved: • Resolve Keys - Ongoing Sync • Updating: • Sync Request Update Data 	<p>Setup Transformed Data Algorithm:</p> <p>D1- SETTRANDT</p> <p>Sync Request Pre-Add Data Algorithm:</p> <p>D1-SR-PREADD</p> <p>Resolve Keys - Ongoing Sync Algorithm:</p> <p>D1-RESKEYFAL</p> <p>Sync Request Update Data Algorithm:</p> <p>D1- SR-UPDDAT</p>
---	---	---

Configuring the Bill Determinant Interface

Oracle Utilities Customer Care and Billing uses bill determinant data (usage transactions based on meter readings) calculated and stored in Oracle Utilities Meter Data Management when calculating bills for customers. This process allows Oracle Utilities Customer Care and Billing to send requests for usage transaction calculations to Oracle Utilities Meter Data Management, which in turn performs the requested calculations, and publishes the results back to Oracle Utilities Customer Care and Billing. Processing usage transaction requests is supported through a set business objects, pre-configured Inbound web services, and processing methods.

Business Objects

The table below lists the business objects used when processing usage transaction requests.

Business Object	Description
D2-UsgTranSeeder	Used to determine the usage transaction business object to use when creating new usage transactions.

Inbound Web Services

Inbound web services are used to facilitate invoking the Usage Transaction Seeder business object by the middleware components upon receipt of a usage transaction request, and to update the usage transaction upon completion of the bill.

The table below lists the pre-configured Inbound Web Services used to process usage transaction requests sent from Oracle Utilities Customer Care and Billing.

Inbound Web Service	Description	Schema Name
D2-UsageTransactionRequestInbound	Usage Transaction Request Inbound	D2-UsgTranSeeder (BO)
D2-UsageTransactionUpdateInbound	Update Usage Transaction Bill Flags	D2-UpdUTMul (Service Script)

Service Provider Processing Methods

Processing methods are used to determine the usage transaction business object to use when creating usage transactions based on the requests, and for determining the method by which usage transactions are sent back to Oracle Utilities Customer Care and Billing.

Processing Method	Business Object	Description
How To Send US Information - Online	D2-HowToSendUSInfoOnline	Used to specify the method (batch control, business object, or outbound message) by which usage transactions are sent to subscribing systems in real time.
How To Send US Related Information	D2-HowToSendUSInformation	How To Send US Related Information Used to specify the method (batch control, business object, or outbound message) by which usage transactions are sent to subscribing systems.
How To Create US Related Information	D2-HowToCreateUSInformation	Used to determine the type of usage transaction business object to create.
How To Send US Related Information Batch	D2-HowToSendUSInfoBatch	Used to specify the method (batch control, business object, or outbound message) by which usage transactions are sent to subscribing systems via batch processing.

Example Bill Determinant Process Steps

This section provides an overview of the processing that takes place when a usage transaction request is sent. For each step in the process, the table below provides a brief description of the processing that takes place, and lists the specific objects involved.

Step	Process	Objects
1	Oracle Utilities Customer Care and Billing sends a usage transaction request to the middleware integration layer.	
2	The middleware components transforms the request from the Customer Care and Billing format, to the format used by Oracle Utilities Meter Data Management (this format is based on the business object schemas of the synchronization request business objects).	

3	<p>The middleware component invoke the appropriate Inbound Web Service, and sends the transformed request.</p>	<p>Inbound Web Service: D2- UsageTransactionRequestInbound (mapped to the D2-UsgTranSeeder business object)</p>
4	<p>The Inbound Web Service invokes the Usage Transaction Seeder business object. This business object:</p> <ul style="list-style-type: none"> • Determines the usage subscription ID based on an external usage subscription ID • Determines the appropriate usage transaction business object to create 	<p>Processing Method: D2- HowToCreateUSInformation (How To Create Usage Subscription Related Information)</p>
5	<p>The usage transaction determines the usage calculation group(s) to use when calculating usage. These are retrieved from the usage subscription (with a fallback to the usage subscription type).</p> <p>This base package logic can be overridden by specifying an algorithm in the Usage Calculation Group Determination Override Algorithm field on the usage subscription type. If an algorithm is specified in this field, its logic overrides the existing method of determining the usage calculation group.</p> <p>A base package algorithm (D2-DRVUSGGRP) is provided that can be used here. This algorithm uses the CCB Rate Schedule extendable lookup used to map the rate schedules in Oracle Utilities Customer Care and Billing to usage calculation groups. The algorithm's logic looks for a combination of rate history list entries on the usage subscription and the type of device configuration installed during the bill period to determine the usage calculation group(s) to use for bill determinants calculation.</p>	
6	<p>The usage transaction business object calculates usage based on the date range provided in the request.</p>	

7	If the usage transaction has a sub usage transactions, it checks the status of each.	
8	If the usage transaction is configured to require an approval, a To Do Entry is created.	
9	The usage transaction then sends the usage transaction to any subscribing systems.	Processing Method: D2- HowToSendUSInformation (How To Send US Related Information)
10	Upon completion of the bill, Oracle Utilities Customer Care and Billing invokes an inbound web service to update the "Used on Bill" and/or "Linked to Frozen Bill Segment" fields as appropriate to indicate if the usage transaction was used on a bill.	Inbound Web Service: D2-UsageTransactionUpdateInbound (Update Usage Transaction Bill Flags)

Oracle Utilities Operational Device Management

Overview

This section provides an overview of how Oracle Utilities Meter Data Management supports integrations with Oracle Utilities Operational Device Management. In an integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management:

- Oracle Utilities Meter Data Management is typically considered the "system of record" for service points (asset locations), contacts, and device installation information (install events)
- Oracle Utilities Operational Device Management is typically considered the "system of record" for assets (devices) and asset specification configuration (device configurations)

Given this breakdown of data between the two systems, any integration between them must account for the passage of data between the two to ensure that each system can accurately perform its business functions. The integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management is based on data synchronization between the two systems.

Configuring Master Data Synchronization

The specific data synchronization flows supported between Oracle Utilities Meter Data Management (MDM) and Oracle Utilities Operational Device Management (ODM) include the following:

- **Asset-Device Synchronization:** As new assets and asset specification configurations are created or changed in ODM, corresponding devices and device configurations must be created or changed in MDM
- **Service Point/Contact - Asset Location/Contact:** As Service Points and/or Contacts are created or changed in MDM, corresponding Asset Locations and Contacts must be created or changed in ODM
- **Install Events- Asset Location/Disposition:** As devices are installed/removed in MDM, corresponding changes to an asset's Disposition (location and status) must be made in ODM

This synchronization process is supported through a set of business objects, master configurations, batch controls, and pre-configured Inbound Web Services. Refer to the *Oracle Utilities Integration for Device Operations Implementation Guide* for more information about this integration and the data synchronization processes used by this integration.

Master Configuration

The following master configurations are used to configure the sync process between MDM and ODM:

Master Configuration	Name / Description
Master Data Synchronization Configuration	Lists all foreign key references that need resolution. Each one should reference the view that contains the external key / production key cross-reference. For entities that undergo both the initial and the ongoing sync, two views are specified. For entities that undergo the ongoing sync, an external system / ID type mapping is specified to cater for entities that might be synchronizing from more than one external system.
Seeder Sync Request Master Configuration	Lists the maintenance objects (device, device configuration, etc.) that require synchronization. Each references the synchronization business object that needs to be instantiated when processing a synchronization request for that maintenance object. For maintenance objects that undergo both initial and the ongoing synchronization, two business objects are specified.
ODM Integration Master Configuration	Specifies the external system used to represent Oracle Utilities Operational Management, and the URL for the Oracle Utilities Operational Management application. Also specifies the outbound message types used to send synchronization requests to Oracle Utilities Operational Management.

Inbound Data Synchronization Business Objects

The integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management uses the following inbound (to Oracle Utilities Mater Data Management) synchronization business objects:

Object Name	Business Object	Description
Device Ongoing Sync Request	D1-OngoingSyncRequestDevice	Used to synchronize devices and device configurations in Oracle Utilities Mater Data Management based on assets and asset specification configurations created/updates in Oracle Utilities Operational Device Management.

Outbound Data Synchronization Business Objects

The integration between Oracle Utilities Meter Data Management and Oracle Utilities Operational Device Management uses the following outbound (from Oracle Utilities Mater Data Management) synchronization business objects (based on the F1-SYNC REQ maintenance object)

Object Name	Business Object	Description
-------------	-----------------	-------------

ODM Sync Request	D1-ODMContactSyncRequest	Used to synchronize contacts in Oracle Utilities Operational Device Management based on contacts created/updated in Oracle Utilities Meter Data Management
ODM Install Event Sync Request	D1-ODMInstallEventSyncRequest	Used to synchronize asset location/disposition in Oracle Utilities Operational Device Management based on install events created/updated in Oracle Utilities Meter Data Management
ODM SP Sync Request	D1-ODMSPSyncRequest	Used to synchronize asset locations in Oracle Utilities Operational Device Management based on service points created/updated in Oracle Utilities Meter Data Management. This includes updating asset locations when equipment is attached to or remove from a service point.

Oracle Utilities Analytics

Overview

Oracle Utilities Meter Data Management can also be integrated with Oracle Utilities Analytics (OUA) to allow users to view analytic data based on usage, events, and other data tracked in Oracle Utilities Meter Data Management.

Oracle Utilities Meter Data Management Analytics comprises the following products:

- **Oracle Utilities Meter Data Analytics:** dashboards, dashboard pages, and analytics used to view usage, event, and other data from Oracle Utilities Meter Data Management
- **Oracle Utilities Meter Data Management Extractors and Schema:** the star schema and extract programs used by Oracle Utilities Meter Data Analytics.

Configuring Extracts

Oracle Utilities Meter Data Management includes the following components used when integrating with Oracle Utilities Analytics:

Master Configuration

The following master configurations are used to configure the sync process between MDM and OUA:

Master Configuration	Description
Analytics Master Configuration - ODI-Based	This master configuration is primarily used to configure the information that will be used in the extraction of data for business intelligence when using the Oracle Data Integrator extract, transform, and load (ETL) process.

Batch Controls

Batch Code	Name / Description
D1-SPSDL	Service Point Snapshot Download
D2-DUGDL	Usage Subscription Usage Calculation Group Download
D2-USGDL	Service Point Usage Snapshot Download
D2-UUSDL	SP Unreported Usage Snapshot Download
D2-VEEDL	SP VEE Exception Snapshot Download

Refer to the following documentation for more information about Oracle Utilities Analytics:

Oracle Utilities Extractors and Schema for Oracle Utilities Meter Data Management Data Mapping Guide

Oracle Utilities Analytics Dashboards for Meter Data Analytics Metric Reference Guide

Oracle Utilities Analytics Admin Guide

Oracle Utilities Analytics Insights

This section describes integrations with Oracle Utilities Analytics Insights (previously known as Oracle DataRaker).

Business Flag Integration

With the business flag integration with Oracle Utilities Analytics Insights:

- Either Oracle Utilities Meter Data Management or Oracle Utilities Analytics Insights can initiate a business flag
- Oracle Utilities Meter Data Management can notify Oracle Utilities Analytics Insights of a change in status of a business flag:
 - if a business flag in error has been discarded
 - if a business flag's confidence has been updated
 - with the results of field work initiated by a business flag

For additional details see [About Business Flags](#) in the Oracle Utilities Application Framework *Administrative User Guide*.

Configuring Business Flag Integration

Oracle Utilities Meter Data Management includes the following components used when integrating with Oracle Utilities Analytics Insights:

Master Configuration

The following master configurations are used to configure the sync process between MDM and Oracle Utilities Analytics Insights:

Master Configuration	Description
----------------------	-------------

Oracle Utilities DataRaker Integration Master Configuration	This master configuration is used to enable deep linking into Oracle Utilities Analytics Insights. Multiple URL patterns are supported with an ability to provide substitution variables to satisfy the URL parameters (e.g. "&searchTech="). This also provides a mapping between Oracle Utilities Meter Data Management service types and the Oracle Utilities Analytics Insights point types.
---	--

Service Provider Processing Methods

The following processing methods should be associated to the service provider configured for Oracle DataRaker:

Processing Role	Description
Business Flag Confidence Change	This role will identify the appropriate message to send when a business flag confidence has been changed (e.g. from Suspected to Confirmed). When not configured no message will be sent.
Business Flag Discarded Notification	This role will identify the appropriate message to send when a business flag has been discarded. When not configured no message will be sent.
Business Flag Field Work Details	This role will identify the appropriate message to send when a business flag has completed that initiated field work. When not configured no message will be sent.
Business Flag Added Notification	This role will identify the appropriate message to send when a business flag has been created from within Oracle Utilities Meter Data Management. When not configured no message will be sent.

Extendable Lookups

The following extendable lookups should be reviewed for Oracle DataRaker:

Extendable Lookup	Description
Business Flag Standard Name	If Oracle DataRaker will be communicating business flags using a non-standard name provide an entry in the Valid External Name with the non-standard name for each standard name communicated by Oracle DataRaker.

Meter Insights and Investigations

The Meter Insights and Investigations functionality leverages the Oracle Utilities Analytics Insights business flag integration to support receipt of revenue protection events (referred to as "insights") from Oracle Utilities Analytics Insights for research and investigation using Oracle Utilities Meter Data Management (or Oracle Utilities Meter Solution Cloud Service). Revenue protection insights sent from Oracle Utilities Analytics Insights for investigation are events that suggest potential theft or loss of revenue such as unexpected consumption from an inactive meter, evidence of meter tampering, discovery of an improperly installed meter (such as a meter installed upside down or in reverse), and so on. Insights received from Oracle Utilities Analytics Insights create business flags, which in turn create related Meter Insight Investigation service tasks (referred to as "investigations"), which can then be researched and investigated using a dedicated **Meter Insights Investigations Viewer** portal.

See [Business Flags](#) in the *Administrative User Guide* for general information about the business flag functionality provided by the Oracle Utilities Application Framework.

See [Business Flag Integration](#) in the *Administrative User Guide* for more information about the Business Flag integration with Oracle Utilities Analytics Insights.

See [Service Issue Monitors](#) in the *Business User Guide* and [Service Task Types](#) in the *Administrative User Guide* for general information about service issue monitors.

See [Using the Meter Insights Investigations Viewer Portal](#) in the *Business User Guide* for more information about viewing meter insight service issue monitors.

Meter Insights and Investigation Business Objects

Business flags and service issue monitors used by Meter Insights and Investigations functionality are based on specific business objects:

Type of Object	Business Object
Business Flag	Revenue Protection Insight (D1-RevenueProtectionInsight)
Service Issue Monitor (Service Task)	Meter Insight Investigation (D1-MeterInsightInvestigation)
Investigation Type (Service Task Type)	Meter Insight Investigation Type (D1-MtrInsightInvestigationType)

Meter Insights and Investigation Processing

The table below provides a brief description of the process by which insights are received and processed, and lists example objects used by the Oracle Utilities Meter Data Management (and Oracle Utilities Meter Solution Cloud Service). Note that the process outlined below has been simplified for illustrative purposes, and does not reference every step performed in this process.

Step	Process	Example Data
1.	Oracle Utilities Analytics Insights sends events ("insights") to Meter Data Management, via the Business Flag integration, creating business flags based on the business flag type configuration.	Business Flag Business Object: Revenue Protection Insight (D1-RevenueProtectionInsight)
2.	An Enter algorithm on the "Create Service Issue Monitor" state creates a Service Issue Monitor based on the Service Task type defined on the business flag's type. The investigation is created in "Pending" status.	Enter Algorithm: Business Flag - Create Service Issue Monitor (D1-CREATESIM) Note: This algorithm is on the parent business object (D1-SPMonitorBusinessFlag). Service Issue Monitor (Service Task) Business Object: Meter Insight Investigation (D1-MeterInsightInvestigation)

Step	Process	Example Data
3.	<p>The investigation evaluates the service point (based on configuration of the service task type).</p> <ul style="list-style-type: none"> • If there are no issues, the investigation moves into the Discarded (No Investigation Needed) state. • Otherwise, the investigation continues to the Open state. 	<p>Evaluate Algorithm: Meter Insight Investigation - Analyze Service Point For Service Issues (D1-MII-ANZ)</p>
4.	<p>An Enter algorithm on the Open state creates a To Do entry.</p>	<p>Open Enter Algorithm: Meter Insight Investigation - Create To Do Entry (D1-MIICRTODO)</p>
5.	<p>Once the investigation is in the Open state, a business user can use the Meter Insights Investigation Viewer portal to examine the issue. See "Using the Meter Insights Investigation Portal" in the <i>Business User Guide</i> for more information about using this portal.</p> <p>The user can add comments and update the investigation to one of the following states:</p> <ul style="list-style-type: none"> • Waiting for Field Work • Issue Resolved • No Issue • Discarded <p>When the investigation moves into the Issue Resolved, No Issue, or Discarded states, it transitions the business flag the Completed state with a Final Confidence based on the investigation's state (see below).</p>	

Step	Process	Example Data
6.	<p>If the service issue monitors enters the Waiting for Field Work state, a Monitor algorithm evaluates the Completion Criteria on the Service Task Type and transitions the investigation to one of the following states:</p> <ul style="list-style-type: none"> • Fieldwork Error • Open • Issue Resolved • No Issue • Inconclusive <p>When the investigation moves into the Issue Resolved, No Issue, or Inconclusive states, it transitions the business flag the Completed state with a Final Confidence based on the investigation's state (see below).</p>	<p>Waiting For Field Work Monitor Algorithm: Evaluate Completion Criteria (D1-MIIEVCMCR)</p>
7.	<p>If the service issue monitors enters the Issue Resolved state:</p> <ul style="list-style-type: none"> • An Enter algorithm completes the To Do entry • An Enter algorithm transitions the Business Flag to the Completed state (Final Confidence: Confirmed) 	<p>Enter Algorithm: Generic To Do Completion on Enter (D1-TODOCMPL) Enter Algorithm: Transition Business Flags - Completed (D1-TRBUSFLGC)</p>
8.	<p>If the service issue monitors enters the No Issue state,</p> <ul style="list-style-type: none"> • An Enter algorithm completes the To Do entry • Transitions the Business Flag to Completed (Final Confidence: Rejected) 	<p>Enter Algorithm: Generic To Do Completion on Enter (D1-TODOCMPL) Enter Algorithm: Transition Business Flags - Rejected (D1-TRBUSFLGR)</p>
9.	<p>If the service issue monitors enters the Inconclusive state,</p> <ul style="list-style-type: none"> • An Enter algorithm completes the To Do entry • Transitions the Business Flag to Completed (Final Confidence: Suspected) 	<p>Enter Algorithm: Generic To Do Completion on Enter (D1-TODOCMPL) Enter Algorithm: Transition Business Flags - Suspected (D1-TRBUSFLGI)</p>

Step	Process	Example Data
10.	<p>If the service issue monitors enters the Discarded state</p> <ul style="list-style-type: none"> An Enter algorithm completes the To Do entry Transitions the Business Flag to Completed (Final Confidence: Rejected) 	<p>Enter Algorithm: Generic To Do Completion on Enter (D1-TODOCMPL)</p> <p>Enter Algorithm: Transition Business Flags - Rejected (D1-TRBUSFLGR)</p>

Configuring Meter Insights and Investigations

Configuring the Meter Insights and Investigations functionality involves creation and configuration of the following:

- [Business Flag Types](#)
- [Extendable Lookup Values](#)
- [To Do Types](#)
- [Service Tasks Types](#)
- [Master Configuration](#)

Business Flag Types

Create a business flag type for each type of revenue protection insight that will be received from Oracle Utilities Analytics Insights, including the following:

- **Business Object:** Service Point Monitor Business Flag Type (D1-SPMonitorBusinessFlagType)
- **Related Transaction BO:** Revenue Protection Insight (D1-RevenueProtectionInsight)
- **Service Issue Monitor Type:** The service task type for investigations created from business flags of this type.

Note: Because the **Service Issue Monitor Type** field is required, when initially creating business flag types, select a placeholder Service Issue Monitor Type to enable you to save the business flag type. After you have created the appropriate service task types, return to each business flag type and select the correct Service Issue Monitor Type.

Define other fields based on your business requirements.

Extendable Lookups

The **Meter Insights Investigation Viewer** portal uses the following profile extendable lookups when displaying consumption and insights (events):

- **360 View Event Bar Profile:** Defines events to highlight that are pertinent to investigations, including your new business flag types
- **Final Values Overlay Profile:** Defines values to graph that are pertinent to investigations

Use the **Extendable Lookup** portal to create new extendable lookup values:

1. Create a new 360 View Event Bar Profile extendable lookup value that includes your business flag types as well as other events pertinent to your investigations.
2. Create a new Final Values Overlay Profile extendable lookup value that includes the values to graph that are pertinent to your investigations.

These extendable lookup values will be referenced by your service task types.

To Do Types

Use the **To Do Type** portal to create a To Do Type (or update an existing To Do Type) with the Set Investigation Priority (D1-STINVS GPR) algorithm defined for the **Calculate Priority** system event.

These To Do Types will be referenced by your service task types.

Service Task Types

Create a service task type for each type of revenue protection insight (each type of investigation) that will be received from Oracle Utilities Analytics Insights, including the following:

- **Business Object:** Meter Insight Investigation Type (D1-MtrInsightInvestigationType)
- **Related Transaction BO:** Meter Insight Investigation (D1-MeterInsightInvestigation)
- **Evaluation Criteria:** The criteria used to evaluate the service point, including the existence of business flags of specified types (the business flag types you created earlier). See the embedded help for more details.
- **Service Investigation Order:** The field activity type and Field Task Type for field activities created by the investigation.
- **Completion Criteria:** The criteria used to determine if the service investigation order (field activity) should be completed and the result to be returned to the investigation. See the embedded help for more details.
- **Consumption Data Source:** Details that specify the types of consumption data will be displayed and how it is displayed in the [Meter Insights Investigation Viewer](#) portal, including the 360 Event Bar Profile and Final Values Overlay Profile extendable lookup values created earlier.
- **To Do Information:** The To Do Type and To Do Role used for To Do Entries created by the investigation. This should reference the To Do Type configured earlier.

Note: After you have created the appropriate service task types, return to the corresponding business flag type and select the correct service task type from the **Service Issue Monitor Type** drop-down list.

Master Configuration

Create a Meter Insights Configuration master configuration to capture key details used by Oracle Utilities Analytics Insights when creating insights including:

- Tolerances details related to specific types of insights (Flipped Meter, Unauthorized Consumption, and Leak Detection)
- Core sources of consumption for electric, gas, and water service types (including service point types, and unit of measure/time of use/service quantity identified combinations for each)

The master configuration is synchronized with Oracle Utilities Analytics Insights, and is used by Oracle Utilities Analytics Insights when generating insights for potential investigation.

Usage and Event Integration

Oracle Utilities Smart Grid Gateway adapters can be configured to publish initial measurement and device event data for use in Oracle Utilities Analytics Insights or other external systems. Published data is posted to a user-defined directory that Oracle Utilities Analytics Insights can monitor for import.

Initial measurement and device event data is published in the “native” data format (the format of the initial measurement and device event seeder business objects). This format includes normalized unit of measure, condition, and device event codes. See the *Oracle Utilities Smart Grid Gateway Adapter Development Kit Administrative User Guide* for more details about this format.

Note: Initial measurement data published via this feature is published prior to VEE processing. In addition, filtering can NOT be applied to initial measurement or device event data published via this feature.

Configuring DataRaker Usage and Event Integration

Oracle Utilities Smart Grid Gateway adapters use OSB and BPEL components when publishing initial measurement and device event data for integration with Oracle Utilities Analytics Insights.

OSB Projects

The following “CM” Oracle Service Bus projects are used to configure the integration between SGG and Oracle Utilities Analytics Insights:

Adapter	OSB Projects
Landis+Gyr	SGG-D3-USAGE-CM (used to publish usage) SGG-D3-EVENT-CM (used to publish device events)
NES	SGG-D4-USAGE-CM (used to publish usage) SGG-D4-EVENT-CM (used to publish device events)
MV90	SGG-D5-USAGE-CM (used to publish usage)
Sensus	SGG-D6-USAGE-CM (used to publish usage) SGG-D6-EVENT-CM (used to publish device events)
Silver Spring Networks	SGG-D7-SSNXML-CM (used to publish usage) SGG-D7-CSV-CM (used to publish device events)
Itron OpenWay	SGG-D8-ITRONXML-CM (used to publish usage) SGG-D8-EXCEPTION-CM (used to publish device events)
Adapter Development Kit	SGG-DG-SEEDER-CM (used to publish usage and device events)

The following components provided with these projects are used in publishing measurement data and device events to Oracle Utilities Analytics Insights:

- The **DataRakerBusinessService** business service is used to send data to a pre-configured JMS queue (defined as an Endpoint URI), from which the data will be published. This business service is specified in the `EnvironmentSettings.xq` file (see below).
- The **DataRakerServiceAccount** service account is used to define and maintain the user name and password needed to access the JMS queue defined in the **DataRakerBusinessService** business service.

Enabling Data Publishing

Publishing initial measurement and device event data is enabled by referencing a publisher business service (`DataRakerBusinessService`) in the `publishServices/service` element in the `EnvironmentSettings.xq` files provided with the OSB projects listed above as follows:

```
<publishServices>
  <service>[publisherBusinessService]</service>
</publishServices>
```

BPEL Composites

The `SGGDRIntegration` BPEL composite handles publishing the data to Oracle Utilities Analytics Insights or other systems.

Configuring Publishing Output

The following parameters can be used to configure details of how the data is provided to Oracle Utilities Analytics Insights, including the directory where files are posted for Oracle Utilities Analytics Insights to consume, number of records per file, polling frequency, etc. These parameters are defined during installation. See the *Oracle Utilities Smart Grid Gateway Installation Guide* for more details about defining values for these parameters.

Parameter	Description	Default Value
SGG_DR_INT_QUEUE	JNDI name of queue to publish SGG payloads. This is the JMS queue defined in the DataRakerBusinessService business service. This should NOT be changed.	DataRakerQueue
SOA_DR_PUBLISH_SIZE	The number of records (SGG payloads) to accumulate in a published file.	100
SOA_DR_FILE_SIZE	The maximum file size for the accumulated (SGG payloads) file in kilobytes.	524288
SOA_DR_ELAPSED_TIME	The period of time in second which, when exceeded, causes a new outgoing file to be created.	600
SOA_DR_POLLING_FREQ	The polling frequency in seconds of the staging directory for new files.	60
SOA_DR_STAGING_DIR	Mount point/directory for the staging directory for accumulated SGG payload files. This is used internally and should NOT be changed.	/spl/sploutput/staging
SOA_DR_INTEGRATION_DIR	Mount point/directory from which Oracle DataRaker will consume the converted XML files.	/spl/sploutput/int

Oracle Utilities Analytics Visualization

Timeliness and Quality Aggregations Overview

Oracle Utilities Meter Solution Cloud Service and Oracle Utilities Customer Cloud Service can be integrated with Oracle Utilities Analytics Visualization (OUAV) to allow users to view analytics data based on the quality and timeliness of measurement data.

This section describes integration of Oracle Utilities Meter Solution Cloud Service and Oracle Utilities Customer Cloud Service with Oracle Utilities Analytics Visualization (OUAV).

See [Operational Analytics](#) in the *Administrative User Guide* for general information about integrating with Oracle Utilities Analytics Visualization.

Base Package Timeliness and Quality Aggregation Measuring Components and Measurement Business Objects

Oracle Utilities Meter Data Management and Oracle Utilities Customer To Meter include a number of standard timeliness and quality aggregation processes delivered as part of the base product that can be used with Oracle Utilities Analytics Visualization (OUAV). These aggregate measurement data (including quantities and counts) for

constituent measuring components based on the following dimensions: Postal, City, Head-End, Device Type, Usage Calculation Group, Market and Service Provider, and Service Type.

The table below lists the names (and business object codes) for these aggregators, along with the corresponding Oracle Utilities Analytics Visualization subject area.

Aggregator	Description
Measurement Timeliness Quantity Aggregator Business Object: D2-MsrmtTimelinessQuantityAggr OUAV Subject Area: Meter - Aggregated Timeliness Quantity	Aggregates measurement quantities that arrived on time or are late.
Measurement Timeliness Count Aggregator Business Object: D2-MsrmtTimelinessCountAggr OUAV Subject Area: Meter - Aggregated Timeliness Count	Aggregates measurement counts that arrived on time or are late.
Measurement Quality Count Aggregator Business Object: D2-MsrmtQualityCountAggregator OUAV Subject Area: Meter - Aggregated Measurement Count	Aggregates measurement counts and distributes the constituents' counts across Value Identifiers based on condition codes.
Measurement Measured Quantity Aggregator Business Object: D2-MeasuredQuantityAggregator OUAV Subject Area: Meter - Aggregated Measurement Quantity	Aggregates measurement quantities and distributes the constituents' measurements across Value Identifiers based on condition codes.

Refer to the [Oracle Utilities Analytics Visualization User Guide](#) for more information about Oracle Utilities Analytics Visualization subject areas.

In addition, the base package also includes measurement business objects used to store aggregated measurement data. These include:

- Measured Quantity Measurement (D2-MeasuredQuantityMsrmt)
- Quality Count Measurement (D2-QualityCountMsrmt)
- Timeliness Count Measurement (D2-TimelinessCountMsrmt)
- Timeliness Quantity Measurement (D2-TimelinessQuantityMsrmt)

Configuring Timeliness and Quality Aggregation for Use with Oracle Utilities Analytics Visualization

This topic outlines the configuration needed for timeliness and quality aggregations used with Oracle Utilities Analytics Visualization.

Master Configuration

Create a Timeliness Master Configuration, defining the following:

- **Heating Degree Days Factor:** A number-based factor that contains heating degree days. These are aggregated and stored on the Measurement Measured Quantity Aggregator.
- **Cooling Degree Days Factor:** A number-based factor that contains cooling degree days. These are aggregated and stored on the Measurement Measured Quantity Aggregator.

- **Number of Hours to Consider IMD as Late:** The number of hours after which an initial measurement is considered late.
- **Buckets:** Value Identifiers that specify the late buckets used by the Measurement Timeliness Count and Measurement Timeliness Quantity aggregators.

Extendable Lookup: BI Aggregation — Usage Group Mapping

If your implementation makes use of dynamic usage calculation group determination on usage subscriptions (via the **Calculation Group Determination Override Algorithm** on the usage subscription type, the **Rate History** collection on the usage subscription, and the Customer Rate Schedule extendable lookup (D2-CCBRateScheduleLookup)), you will need to configure the BI Aggregation Usage Group Mapping extendable lookup (D2-UsageCalculationGroupLookup) with the usage calculation groups you wish to aggregate. If in the future you add new usage calculation groups, you will also need to add those usage calculation groups to this extendable lookup if you want them to be aggregated.

Note that an aggregation measuring component will be created for all dimension combinations and each usage calculation group in the extendable lookup (this is done to alleviate the need to execute the usage group determination algorithm for all usage subscriptions during the dimension scanning process).

Note: Configuring this extendable lookup is required **ONLY** if using dynamic usage calculation group determination.

Measuring Component Types

Create a master aggregator measuring component type and sub aggregator measuring component types for the four types of aggregators outlined above. Details for each aggregator measuring component type are listed below.

Note: When creating the master aggregator measuring component type, we recommend setting the **Aggregation Horizon** at 7 days or less. See [Aggregation Recommendations](#) on page 590 for more information.

Measurement Measured Quantity Aggregator

- **Measuring Component Type Business Object:** Master Measurement Aggregator Type (D2-MasterMsrmtAggregatorType)
- **Measuring Component Business Object:** Measurement Measured Quantity Aggregator (D2-MeasuredQuantityAggregator)
- **Measurement Business Object:** Measured Quantity Measurement (D2-MeasuredQuantityMsrmt)
- **Value Identifiers** (recommended):

Value Identifier Type	Description	Unit of Measure
Measurement	kWh	Kilowatt-Hours
Value 01	Regular kWh	Kilowatt-Hours
Value 02	Estimated kWh	Kilowatt-Hours
Value 03	User-Edited kWh	Kilowatt-Hours
Value 06	Count	Count
Value 07	Heating Degree	Fahrenheit
Value 08	Cooling Degree	Fahrenheit
Value 09	Ave kWh	Kilowatt-Hours

- **Sub Aggregator MC Types** (see below):
 - Measurement Quality Count Aggregator Type
 - Measurement Timeliness Count Aggregator Type
 - Measurement Timeliness Quantity Aggregator Type

Measurement Quality Count Aggregator

- **Measuring Component Type Business Object:** Sub Measurement Aggregator Type (D2-SubMeasurementAggType)
- **Measuring Component Business Object:** Measurement Quality Count Aggregator (D2-MsrmtQualityCountAggregator)
- **Measurement Business Object:** Quality Count Measurement (D2-QualityCountMsrmt)
- **Value Identifiers** (recommended):

Value Identifier Type	Description	Unit of Measure
Measurement	kWh	Kilowatt-Hours
Value 01	Regular Count	Count
Value 02	Estimated Count	Count
Value 03	User-Edited Count	Count
Value 04	N Meas/No IMD Count	Count
Value 05	No Meas/IMD Exists Count	Count
Value 06	Read Outage Count	Count
Value 07	Read Other Count	Count
Value 08	Missing Count	Count

Measurement Timeliness Count Aggregator

- **Measuring Component Type Business Object:** Sub Measurement Aggregator Type (D2-SubMeasurementAggType)
- **Measuring Component Business Object:** Measurement Timeliness Count Aggregator (D2-MsrmtTimelinessCountAggr)
- **Measurement Business Object:** Timeliness Count Measurement (D2-TimelinessCountMsrmt)
- **Value Identifiers** (recommended):

Value Identifier Type	Description	Unit of Measure
Measurement	kWh	Kilowatt-Hours
Value 01	On Time Count	Count
Value 02	Late Count	Count
Value 03	Very Late Count	Count
Value 04	Very, Very Late Count	Count

Value Identifier Type	Description	Unit of Measure
Value 05	Missing Count	Count

Measurement Timeliness Quantity Aggregator

- **Measuring Component Type Business Object:** Sub Measurement Aggregator Type(D2-SubMeasurementAggType)
- **Measuring Component Business Object:** Measurement Timeliness Quantity Aggregator (D2-MsrmtTimelinessQuantityAggr)
- **Measurement Business Object:** Timeliness Quantity Measurement (D2-TimelinessQuantityMsrmt)
- **Value Identifiers** (recommended):

Value Identifier Type	Description	Unit of Measure
Measurement	kWh	Kilowatt-Hours
Value 01	On Time kWh	Kilowatt-Hours
Value 02	Late kWh	Kilowatt-Hours
Value 03	Very Late kWh	Kilowatt-Hours
Value 04	Very, Very Late kWh	Kilowatt-Hours

Activity Type

Create a Measurement Quantity Scanner activity type, based on the following business objects:

- **Business Object:** Measurement Quantity Scanner Type
- **Related Transaction Business Object:** Measurement Quantity Scanner

Timeliness and Quality Aggregation Processing for Use with Oracle Utilities Analytics Visualization

This topic describes the processes involved in running timeliness and quality aggregation processing for use with Oracle Utilities Analytics Visualization.

Execute Measurement Quantity Scan

Create an activity of the Measurement Quantity Scanner activity type, and process the activity (by clicking **Scan** in the **Record Action** section in the **Activity** zone).

This process uses the Measurement Quality and Timeliness Dimension Scanner batch control (D1-MQTDS) which creates measuring component aggregators that will also serve as the measuring component dimensions. This process will create a measuring component aggregator for each unique combination of Postal Code, City, Device Type, Head-End System, Usage Group, Market, Service Type, Geographic Code, Manufacturer/Model, Service Provider (where Market Relationship Type is specified on the dimension scanner activity).

Note: The Measurement Quality and Timeliness Dimension Scanner batch control (D1-MQTDS) supports multi-threading.

This step will create aggregator measuring components for all **Valid MC Types to Aggregate** defined on the master aggregator type (Measurement Measured Quantity Aggregator).

The created aggregator measuring component's characteristics will contain the Postal Code, City, Device Type, Head-End System, Usage Group, Market, Service Type, Geographic Code, Manufacturer/Model, Service Provider information.

Execute Aggregation

Once the measuring component aggregators have been created, run the Aggregation Monitor (D2-AGG) batch process. This will process ALL active master aggregators (together with the linked sub aggregators) that satisfy the batch filter parameters. Aggregated measurements will be created for the span of the aggregator horizon which is the current date less the horizon days in intervals defined on the master aggregation measuring component type (Measurement Measured Quantity Aggregator).

Condition Top Range and Condition Bottom Range parameters on the Aggregate Measurement Counts and Quantity (D2-AGG-MCQ) algorithm (an Enter algorithm on the Aggregate state of the Measurement Measured Quantity Aggregator (D2-MeasuredQuantityAggregator) business object) define condition ranges for quantity and count aggregation buckets.

This batch process should be run on a scheduled reoccurring basis.

Aggregated Data

Aggregated measurements are created in the Measurement (D1_MSRMT) and Aggregation Measurement (D1_AGG_MSRMT) tables, using the following base package measurement business objects:

- Measured Quantity Measurement (D2-MeasuredQuantityMsrmt)
- Quality Count Measurement (D2-QualityCountMsrmt)
- Timeliness Count Measurement (D2-TimelinessCountMsrmt)
- Timeliness Quantity Measurement (D2-TimelinessQuantityMsrmt)

Oracle Utilities Analytics Visualization Fact views access the Aggregation Measurement table.

Oracle Utilities Analytics Visualization Dimension views access the Measuring Component and Measuring Component Characteristics tables.

Consumption Analytics Aggregations Overview

This section outlines the configuration needed to support integration with Oracle Utilities Analytics Visualization for the following consumption-based analytics:

- Usage by Network Location
- Usage by Region
- Usage by Customer Classification
- Unaccounted for Losses

These analytics are accessed in Oracle Utilities Analytics Visualization (OUAV) via the following subject areas:

Analytics	OUAV Subject Areas
Usage by Network Location	Meter - Distribution Nodes
Usage by Region	
Usage by Customer Classification	Meter - Customer Classification
Unaccounted for Losses	Meter - Downstream Usage
	Meter - Downstream Service Points
	Meter - Facility Usage
	Meter - Facilities

Configuring Dynamic Aggregation for Consumption Analytics

This section outlines the configuration needed for consumption analytics aggregations used with Oracle Utilities Analytics Visualization.

Consumption analytics leverage data generated through dynamic aggregation, and requires configuration of the following objects:

- Data Sources
- Aggregator Measuring Component Types
- Aggregation Groups
- Measuring Component Sets

Refer to [Dynamic Aggregation](#) for more information about configuring dynamic aggregation.

Note: The configuration outlined below is based on data in the demonstration database. This sample configuration uses Electric service for Usage by Network Location, Region, and Customer Classification, and Gas service for Unaccounted for Losses.

Data Sources

Create the following data sources, based on the Measurements from US Service Points (D1-DataSourceMeasurements) business object:

For Usage by Network Location, Usage by Region, and Usage by Customer Classification (Electric)

Field / Section	Value				
Data Source	CM-E-KWH-60-TRANS				
Description	Electric kWh 60min Transformer Interval Measurements				
Status	Active				
Data Source Class	Measurements from US Service Points				
Interval / Scalar	Interval				
Sourced Measuring Component Type	<table border="1"> <thead> <tr> <th>Measuring Component Type</th> <th>Value Identifier Type</th> </tr> </thead> <tbody> <tr> <td>Measuring Component Types for measuring components to be aggregated</td> <td>Measurement</td> </tr> </tbody> </table>	Measuring Component Type	Value Identifier Type	Measuring Component Types for measuring components to be aggregated	Measurement
Measuring Component Type	Value Identifier Type				
Measuring Component Types for measuring components to be aggregated	Measurement				

For Unaccounted for Losses (Gas)

Field / Section	Value
Data Source	CM-G-CCF-60-FACIL
Description	Gas CCF 60min Facility Interval Measurements
Status	Active
Data Source Class	Measurements from US Service Points
Interval / Scalar	Interval

Field / Section	Value				
Sourced Measuring Component Type	<table border="1"> <thead> <tr> <th>Measuring Component Type</th> <th>Value Identifier Type</th> </tr> </thead> <tbody> <tr> <td>Measuring Component Types for measuring components to be aggregated</td> <td>Measurement</td> </tr> </tbody> </table>	Measuring Component Type	Value Identifier Type	Measuring Component Types for measuring components to be aggregated	Measurement
Measuring Component Type	Value Identifier Type				
Measuring Component Types for measuring components to be aggregated	Measurement				

Aggregator Measuring Component Types

Create the following aggregator measuring component types, based on the Dynamic Aggregator - Type (D1-AggregationIntervalType) business object:

For Usage by Network Location, Usage by Region, and Usage by Customer Classification (Electric)

Field / Section	Value						
Measuring Component Type	CM-E-I-AGG-KWH-60-TRANS						
Description	Electric - Interval - Aggregation - kWh 60min Transformer Load						
Measuring Component Business Object	Dynamic Aggregator - Interval (D1-AggregatorInterval)						
Measurement Business Object	Aggregation Measurement (D1-AggregationMeasurement)						
Measuring Component Class	Aggregator						
Service Type	Electric						
Allow Negative Consumption	Allowed						
Consumptive/Subtractive	Consumptive						
Interval Size	01:00:00						
Data Source	Electric kWh 60min Transformer Interval Measurements						
Value Identifiers	<table border="1"> <thead> <tr> <th>Value Identifier Type</th> <th>Short Hand Description</th> <th>Unit of Measure</th> </tr> </thead> <tbody> <tr> <td>Measurement</td> <td>kWh</td> <td>Kilowatt-Hours</td> </tr> </tbody> </table>	Value Identifier Type	Short Hand Description	Unit of Measure	Measurement	kWh	Kilowatt-Hours
Value Identifier Type	Short Hand Description	Unit of Measure					
Measurement	kWh	Kilowatt-Hours					

For Unaccounted for Losses (Gas)

Field / Section	Value
Measuring Component Type	CM-G-I-AGG-CCF-60-FACIL
Description	Gas - Interval - Aggregation - CCF 60min Downstream
Measuring Component Business Object	Dynamic Aggregator - Interval (D1-AggregatorInterval)

Field / Section	Value																														
Measurement Business Object	Aggregation Measurement (D1-AggregationMeasurement)																														
Measuring Component Class	Aggregator																														
Service Type	Gas																														
Allow Negative Consumption	Allowed																														
Consumptive/Subtractive	Consumptive																														
Interval Size	01:00:00																														
Data Source	Gas CCF 60min Facility Interval Measurements																														
Value Identifiers	<table border="1"> <thead> <tr> <th>Value Identifier Type</th> <th>Short Hand Description</th> <th>Unit of Measure</th> <th>SQI</th> <th>Value Calculation Method</th> </tr> </thead> <tbody> <tr> <td>Measurement</td> <td>CCF</td> <td>100 Cubic Feet (Gas)</td> <td></td> <td>Sum</td> </tr> <tr> <td>Value 01</td> <td>Count</td> <td>Count</td> <td></td> <td>Count</td> </tr> <tr> <td>Value 02</td> <td>Average</td> <td>100 Cubic Feet (Gas)</td> <td>Average</td> <td>Average</td> </tr> <tr> <td>Value 03</td> <td>Min</td> <td>100 Cubic Feet (Gas)</td> <td>Minimum</td> <td>Min</td> </tr> <tr> <td>Value 04</td> <td>Max</td> <td>100 Cubic Feet (Gas)</td> <td>Maximum</td> <td>Max</td> </tr> </tbody> </table>	Value Identifier Type	Short Hand Description	Unit of Measure	SQI	Value Calculation Method	Measurement	CCF	100 Cubic Feet (Gas)		Sum	Value 01	Count	Count		Count	Value 02	Average	100 Cubic Feet (Gas)	Average	Average	Value 03	Min	100 Cubic Feet (Gas)	Minimum	Min	Value 04	Max	100 Cubic Feet (Gas)	Maximum	Max
Value Identifier Type	Short Hand Description	Unit of Measure	SQI	Value Calculation Method																											
Measurement	CCF	100 Cubic Feet (Gas)		Sum																											
Value 01	Count	Count		Count																											
Value 02	Average	100 Cubic Feet (Gas)	Average	Average																											
Value 03	Min	100 Cubic Feet (Gas)	Minimum	Min																											
Value 04	Max	100 Cubic Feet (Gas)	Maximum	Max																											

Aggregation Groups

Create the following aggregation groups based on the Aggregation Group (D1-AggregationGroup) business object:

For Usage by Network Location and Usage by Region (Electric)

Field / Section	Value
Aggregation Group	CM-E-CONS-TRANS
Description	Electric Dynamic Consumption
Status	Finalized
Aggregation Category	Analytics
Time Zone	US Pacific Time

Field / Section	Value								
Aggregation Schedule	<ul style="list-style-type: none"> • Aggregation Schedule Type: Defined Lag • Aggregation Cut-Off Time: 0:00:00 • Aggregation Horizon: 24:00:00 • Aggregation Lag: 48:00:00 								
Aggregation Measuring Component Sets	<table border="1"> <thead> <tr> <th>Sequence</th> <th>Measuring Component Set</th> <th>Initiation Method</th> <th>Measuring Component Set Class</th> </tr> </thead> <tbody> <tr> <td>10</td> <td>Electric - Consumption - Transformer - Interval</td> <td>Manual</td> <td>Aggregation Foundation</td> </tr> </tbody> </table>	Sequence	Measuring Component Set	Initiation Method	Measuring Component Set Class	10	Electric - Consumption - Transformer - Interval	Manual	Aggregation Foundation
Sequence	Measuring Component Set	Initiation Method	Measuring Component Set Class						
10	Electric - Consumption - Transformer - Interval	Manual	Aggregation Foundation						

For Usage by Customer Classification (Electric)

Field / Section	Value								
Aggregation Group	CM-E-CONS-PROF								
Description	Consumption - Profile Class								
Status	Finalized								
Aggregation Category	Analytics								
Time Zone									
Aggregation Schedule	<ul style="list-style-type: none"> • Aggregation Schedule Type: Defined Lag • Aggregation Cut-Off Time: 0:00:00 • Aggregation Horizon: 24:00:00 • Aggregation Lag: 48:00:00 								
Aggregation Measuring Component Sets	<table border="1"> <thead> <tr> <th>Sequence</th> <th>Measuring Component Set</th> <th>Initiation Method</th> <th>Measuring Component Set Class</th> </tr> </thead> <tbody> <tr> <td>10</td> <td>Consumption - Profile Class - Interval</td> <td>Manual</td> <td>Aggregation Foundation</td> </tr> </tbody> </table>	Sequence	Measuring Component Set	Initiation Method	Measuring Component Set Class	10	Consumption - Profile Class - Interval	Manual	Aggregation Foundation
Sequence	Measuring Component Set	Initiation Method	Measuring Component Set Class						
10	Consumption - Profile Class - Interval	Manual	Aggregation Foundation						

For Unaccounted for Losses (Gas)

Field / Section	Value
Aggregation Group	CM-G-LOSS
Description	Gas Dynamic Consumption

Field / Section	Value								
Status	Finalized								
Aggregation Category	Analytics								
Time Zone	US Pacific Time								
Aggregation Schedule	<ul style="list-style-type: none"> • Aggregation Schedule Type: Defined Lag • Aggregation Cut-Off Time: 0:00:00 • Aggregation Horizon: 24:00:00 • Aggregation Lag: 48:00:00

Dynamic Aggregation Processing for Consumption Analytics

Processing of dynamic aggregation for consumption analytics uses the standard approach to dynamic aggregation execution. Refer to [Dynamic Aggregation](#) in the *Business User Guide* for more information about dynamic aggregation execution and processing.

Oracle Utilities Network Management System

Overview

This section provides an overview of how Oracle Utilities Meter Data Management supports integrations with Oracle Utilities Network Management System. In an integration between Oracle Utilities Meter Data Management and Oracle Utilities Network Management System:

- Oracle Utilities Smart Grid Gateway can notify Oracle Utilities Network Management Systems of device events that have been received (e.g. last gasp and power up).
- Oracle Utilities Network Management Systems can request:
 - Oracle Utilities Smart Grid Gateway to perform various smart meter commands for a device or list of devices (e.g. device status check)
 - Oracle Utilities Smart Grid Gateway to suppress device event notifications for a certain set of device event types.

Configuring Device Event Notification Suppression

Oracle Utilities Meter Data Management includes the following components used when integrating with Oracle Utilities Network Management Systems:

Service Provider Processing Methods

The following processing methods should be associated to the service provider configured for Oracle Utilities Network Management System:

Processing Role	Description
Bulk Response	This role will identify the appropriate message to send with the results of a bulk command execution. For example, this would be used if a large list of devices had been supplied to execute device status check in order to verify outage status.
Response - Success	This role will identify the appropriate message to send for a successful smart meter command
Send Device Event	This role sets up the subscription for device events that Oracle Utilities Network Management System has interest in.
Suppression Notification	This role identifies the appropriate message to send when a notification has been set or removed.

Activity Types

The following processing activity types should be configured:

Activity Type	Description
Bulk Request Header	Configuration for the bulk request header activity type which is used in making smart meter command requests for a list of meters.
Bulk Response	Configuration for the bulk response activity type which organizes the response for bulk requests.
Device Event Notification Suppression	Identifies the device event categories and types that are subject to suppression.

Oracle Utilities Customer Self Service

Overview

Oracle Utilities Meter Data Management can be integrated with Oracle Utilities Customer Self Service (OUCSS) to allow utility customers to:

- View their usage data
- Create self-service meter readings (i.e. submit their own meter readings)
- Perform rate comparisons (via integration between CC&B and MDM)

Master Configuration

The following master configurations are used to configure the sync process between MDM and OUCSS:

Master Configuration	Description
Self Service Master Configuration	This master configuration is used for general configuration related to the MDM to OUCSS interface. This includes a variety of configuration including: temperature source, rate comparison, supported usage calculation groups, etc.

Supporting Oracle Utilities Meter Data Management Services

Oracle Utilities Meter Data Management provides the following services used by Oracle Utilities Customer Self Service:

Service Name	Description	Logic	Inbound Web Service
Create Self-Service Meter Read	Allows users to submit their own meter reads via the Customer Self Service application.	Service Script: WX-CrSSMRead	WX-CreateSelfServiceMeterRead
Get Scalar Consumption Summary	Retrieves consumption data for display in the Customer Self Service application.	Service Script: WX-GetSCsum	WX-GetScalarConsumptionSummary
Get Usage Overview	Retrieves an overview of a customer's usage for a user-specified duration for display in the Customer Self Service application	Service Script: WX-GetUsgOVw	WX-GetUsageOverview
Multiple Account TOU Usages by Service Request Type	Uses the Get Usage Details service to retrieve usage for a list of accounts for display in the Customer Self Service application. Each account's usage is summarized by service type, UOM and SQL.	Service Script: WX-MulAccTOU	WX-MultipleAccountTOUUsagesByServiceType
Multiple Account Usages by Service Request Type	Uses the Get Usage Details service to retrieve usage for a list of accounts for display in the Customer Self Service application. Each account's usage is summarized by service type, UOM and SQL.	Service Script: WX-MulAccCmp	WX-MultipleAccountUsagesByServiceType
Multiple Account Usage Download Request	Uses the Get Usage Details service to retrieve usage for a list of accounts (by usage subscription) for display in the Customer Self Service application.	Service Script: WX-MulAccUsg	WX-MultipleAccountUsagesDownload

Get Usage Details	Retrieves usage details for a customer for a user-specific time period (year, month, day) for display in the Customer Self Service application	Business Service: WX- RETWSSTOUMapping	WX- RETWSSTOUMappingService
Usage Adjustment Retrieval	Retrieves usage adjustment types based on a user-specified rate schedule. Used by the Rate Compare feature of the Customer Self Service application.	Service Script: WX-RetUsgAdj	WX-RetUsgAdj OR WX- UsageAdjustmentRetrieval

These services are based on the service scripts and business services noted above, and are invoked via the corresponding Inbound Web Services.

Refer to the *Oracle Utilities Customer Self Service Implementation Guide* for more information about integrating Oracle Utilities Meter Data Management with Oracle Utilities Customer Self Service.

Configuring Rate Compare Usage Adjustment Profiles

This section describes the steps involved in setting up usage adjustment profiles in Oracle Utilities Meter Data Management for use with the Rate Compare feature in Oracle Utilities Customer Self-Service.

This section provides an overview of the steps involved in setting up usage adjustment profiles. The sections that follow provide additional details and examples for each type of data that must be configured.

1. Create a characteristic type and values for each type of usage adjustment to be made available for rate comparison purposes. For example, if you wanted to allow adjustments for installation of solar panels, use of an energy-efficient appliance, or use of an electric vehicle, you would create three characteristic types (one for each type of adjustment), and values for each option within each type (each type of appliance or electric vehicle supported).
2. Create profile (stand-alone) measuring components that correspond to each characteristic type value.
3. Create profile data for each measuring component. This is interval data that represents the impact of the usage adjustment on a customer's consumption.
4. Create a profile factor for each usage adjustment type.
5. Create factor values for each factor. These values correspond to the characteristic type value, and link characteristic type values to profile measuring components.
6. Create one (or more) [Profile Accumulation](#) usage calculation rules that will apply the usage adjustment profile to the customer's interval consumption when calculating usage for the rate comparison request.
7. Create entries in the Customer Rate Schedule extendable lookup to associate the usage calculation group that contains the "Profile Accumulation" usage calculation rule to a rate schedule in Oracle Utilities Customer Care and Billing.
8. Create entries in the Usage Adjustment Types extendable lookup for each usage adjustment type.
9. Set up the Rate Compare Configuration section of the Self-Service Master Configuration to link usage adjustment factors and usage adjustment types to rate schedules Oracle Utilities Customer Care and Billing (defined in the Customer Rate Schedule extendable lookup).

Characteristic Types

Create a characteristic type and values for each type of usage adjustment you wish to make available to customer self-service users. For example, to create a usage adjustment profile for use of an electric vehicle, you would create an "electric vehicle" characteristic type and define values for each type of electric vehicle users can select.

Example Characteristic Type:

- Characteristic Type: ELEC_VEH

- Description: Electric Vehicles
- Type of Char Value: Predefined Value
- Characteristic Values:

Characteristic Value	Description
LEAF	Nissan Leaf
TESLA	Tesla Model S
VOLT	Chevrolet Volt

Profile Measuring Components

Create profile measuring components for each characteristic type value. These measuring components will be used to store profile data for each type of usage adjustment.

Note: The base package does not include stand-alone measuring component/measuring component type business objects, but the demonstration database contains "Standalone Interval" and "Standalone Interval Measuring Component Type" business objects that can be used to create profile measuring components and types.

Example Profile Measuring Component Type:

- Measuring Component Type: KWH-PROFILE
- Description: KWH Profile
- Measuring Component Business Object: Standalone Interval (demo)
- Measurement Business Object: Measurement
- Service Type: Electric
- Allow Negative Consumption: Allowed
- Consumptive / Subtractive: Consumptive
- Seconds Per Interval: 01:00:00
- Value Identifiers:
- Value Identifier Type: Measurement
- Short-Hand Description: kWh
- UOM: Kilowatt-Hours

Example "Nissan Leaf" Profile Measuring Component:

- Measuring Component Type: KWH Profile
- Number of Digits Left: 5
- Number of Digits Right: 5
- Time Zone: US Pacific Time
- Status: Active
- How To Use: Additive
- External ID: Nissan Leaf

Example "Tesla Model S" Profile Measuring Component:

- Measuring Component Type: KWH Profile
- Number of Digits Left: 5

- Number of Digits Right: 5
- Time Zone: US Pacific Time
- Status: Active
- How To Use: Additive
- External ID: Tesla Model S

Example "Chevrolet Volt" Profile Measuring Component:

- Measuring Component Type: KWH Profile
- Number of Digits Left: 5
- Number of Digits Right: 5
- Time Zone: US Pacific Time
- Status: Active
- How To Use: Additive
- External ID: Chevrolet Volt

Profile Data

Create profile data for each profile measuring component. This data represents the impact of the usage adjustment on a customer's consumption.

Note that this profile data can (and often will) include negative interval values to represent the difference in consumption applicable for the usage adjustment type. For example, if an energy-efficient electric clothes dryer uses an average of 30 kilowatt hours less per month than an average electric clothes dryer, profile data for that appliance might be a "straight line" hourly profile (a profile in which all intervals are of the same value) in which each value equals "0.042" (30 kWh per month divided by an average of 720 hours per month).

Factors / Factor Values

Create a profile factor for each usage adjustment type. This factor should use the "Factor Characteristic Source N/A Algorithm" to derive the appropriate characteristic type value based on the factor value, and should reference the characteristic type created earlier.

Example Electric Vehicle Factor:

- **Factor:** ELECTRIC_VEHICLE
- **Description:** Electric Vehicle
- **Factor Class:** Profile
- **Characteristic Source Algorithm:** Factor Characteristic Source N/A Algorithm
- **Factor Characteristic Type:** Electric Vehicle

Example "Nissan Leaf" Factor Value

- **Factor:** Electric Vehicle
- **Factor Characteristic Type:** Electric Vehicle
- **Factor Characteristic Value:** LEAF
- **Effective Date/Time:** 01-01-2014 12:00:00AM
- **Profile:** Nissan Leaf, KWH Profile

Example "Tesla Model S" Factor Value

- **Factor:** Electric Vehicle

- **Factor Characteristic Type:** Electric Vehicle
- **Factor Characteristic Value:** LEAF
- **Effective Date/Time:** 01-01-2014 12:00:00AM
- **Profile:** Tesla Model S, KWH - 60 Minutes

Example "Chevrolet Volt" Factor Value

- **Factor:** Electric Vehicle
- **Factor Characteristic Type:** Electric Vehicle
- **Factor Characteristic Value:** LEAF
- **Effective Date/Time:** 01-01-2014 12:00:00AM
- **Profile:** Chevrolet Volt / KWH - 60 Minutes

Profile Accumulation Usage Calculation Group and Rule

Create a usage calculation group that contains a "Profile Accumulation" usage calculation rule. This rule will calculate usage by accumulating historical usage with profile data, based on a selected profile factor value.

Note: Profile Accumulation rules should use eligibility criteria to ensure they are only executed when the "Calculation Mode" on the usage transaction is set to "Hypothetical Calculation" (D2HC).

Example: Profile Accumulation Usage Calculation Rule

- **Usage Calculation Group:** Electric Residential Interval KWH
- **Usage Calculation Rule:** KWH_PROFILE_ACCUMULATION
- **Sequence:** 10
- **Description:** KWH Profile Accumulation
- **Category:** Usage Calculation
- **Vector Source Configuration:**
- **Vector Type:** Channels Linked to Usage Subscription
- **Unit of Measure:** Kilowatt-Hours
- **Time of Use:**
- **Service Quantity Identifier:**
- **Target SPI:** 01:00:00
- **Result Processing Configuration:**
- **Apply TOU Map to Derived Vector:** Yes
- **TOU Map:** Summer / Winter, 15 minute interval
- **Result Storage Configuration:**
- **Insert Primary SQ Entry:** Yes
- **Save Derived Vector:** No
- **Service Quantity Identifier:**
- **Extract Interval Data:** No

Customer Rate Schedule Extendable Lookup

Create an entry in the "Customer Rate Schedule" extendable lookup to associate the usage calculation group that contains the "Profile Accumulation" usage calculation rule to an applicable rate schedule in Oracle Utilities Customer Care and Billing.

Example Customer Rate Schedule extendable lookup:

- **Rate:** E-INT-RES
- **Description:** Electric Residential Interval Rate
- **Default Usage Calculation Group:** Electric Residential Interval KWH (E-INT-RES)

Usage Adjustment Types Extendable Lookup

Create an entry in the "Usage Adjustment Type" extendable lookup for each type of usage adjustment that will be available to customer self-service users. These entries are used in the Rate Compare Configuration section of the Self-Service Master Configuration (see below).

Example Electric Vehicle entry:

- **Usage Adjustment Type:** ELEC_VEHICLE
- **Description:** Purchase of Electric Vehicle
- **Override Description:** Purchase of Electric Vehicle
- **External Reference ID:** Purchase of Electric Vehicle

Self-Service Master Configuration - Rate Compare Configuration

Configure the "Rate Compare Configuration" section of the Self-Service Master Configuration to associate usage adjustment factors and usage adjustment types with an applicable rate schedule in Oracle Utilities Customer Care and Billing (defined in the Customer Rate Schedule extendable lookup).

Example Self-Service Master Configuration:

- **Factor Characteristic Type Indicating No Value Variation:** N/A
- **External Reference Factor Value Characteristic Type:** External Reference ID
- **Minimum Days of Usage Adjustment Data:** 2
- **Rate / Usage Adjustments:**
 - **Rate:** Electric Residential - Interval KWH
 - **Usage Adjustments:**
 - Usage Adjustment Factor: Electric Vehicle
 - Usage Adjustment Type: Purchase of Electric Vehicle

Oracle Utilities Dataconnect / Opower

Overview

Oracle Utilities DataConnect facilitates extraction of data from Oracle Utilities Meter Data Management for use in external applications such as analytics applications and energy management systems. This section describes how Oracle Utilities DataConnect works and how to implement and configure the system to support data extract processing.

Oracle Utilities DataConnect can be used to extract two types of data:

- Measurement data for service points based on the Service Point Types defined for a Consumption Extract Type. When extracting usage measurement data, Oracle Utilities DataConnect extracts both interval measurement data as well as frequently read scalar usage data (which is converted into interval measurements during the extraction process).
- Individual service points and install events (based on Service Point Types defined in an extract algorithm).

The extraction processes used for each type of data are separate, but extracted data can be correlated in external systems through service point data included in each type of extract. All data extracts contain the following data elements that can be used for this correlation:

- Service Point ID: The service point ID in Oracle Utilities Meter Data Management
- CIS Service Point ID: The ID used for the service in a customer information system (CIS) such as Oracle Utilities Customer Care and Billing

External systems receiving data extracted from Oracle Utilities DataConnect can use either (or both) of these IDs to associate extract measurement data to extracted master data.

Note: There are two versions of DataConnect. The initial version is referred to as “Legacy DataConnect”. The current and recommended version is simply referred to as “DataConnect” or “Current DataConnect”. Implementations are recommended to use the current version. “Legacy DataConnect” remains available for implementations that used the initial version, but is not recommended for new implementations.

Consumption Extract

When sending interval measurement usage data to an external system, both historical and current data needs to be extracted. Historical data can be extracted as part of an initial load process, and only needs to be provided during initial setup of the integration. Historical data should include data history for all active service points for a specified historical period. Current data should be extracted on a regular ongoing (or incremental) basis. However, in addition to sending current data, any historical corrections received by the system should be extracted as well.

Extract Requests

There are several types of consumption extract requests:

- **Initial Load:** Initial load extract requests are created and submitted manually via the [Consumption Extract Request](#) portal. Consumption extract requests are based on a specified [Consumption Extract Type](#) (see below) and extraction date range. An initial load request must be created and submitted for each consumption extract type defined in the system.
- **Incremental / Ongoing (Current Data):** Incremental / ongoing extract requests can be manually created, but more often will be created via a batch process. The "Create Daily Consumption Extract Requests" batch control scans active consumption extract types and creates a request for each one that has Frequency of "Automated Daily." Ad-hoc incremental requests can be created and submitted manually if needed.
- **Historical Correction:** Historical correction extracts are created via batch process. Algorithms on the Finalized state of the initial measurement and measurement business objects determine if a finalized initial measurement or rederived values are historical corrections. These algorithms create records which are evaluated by a batch process which extracts the measurements for the related initial measurements.

Consumption Extract Type

[Consumption Extract Types](#) define the specific parameters used when processing a consumption extract request. Consumption Extract Types control the service point type, type of measurement, and how the measurements are grouped into TOU periods if applicable. Consumption extract types also define the algorithm and batch processes to use when extracting data for different types of requests (initial load, incremental, and historical).

There are two consumption extract type business objects provided with the base package:

- **Energy Management Extract** (D2-ConsumptionExtractType): This business object retrieves interval data and converts it to a specified Target UOM and Interval Size. This business object does not support TOU mapping.

- **Energy Management Extract with TOU Mapping** (D2-ConsumptionExtractTypeTOU): This business object retrieves interval data, converts it to a specified Target UOM and Interval Size, and maps it to a specific TOU map prior to extraction.

Historical Versus Current Data

The "Extract Through Date/Time" field on the Consumption Extract Type is used to differentiate between current data (the most recently extracted data) and historical corrections, and is set to the last date on which data was extracted for that extract type. For example, if data is extracted on June 1, 2015, the "Extract Through Date/Time" would be set to "June 1, 2015 12:00AM." If/when data is extracted the next day, "Extract Through Date/Time" would be updated to "June 2, 2015 12:00AM."

When evaluating data for extract:

- Interval data is considered current if its measurement date time is after the "Extract Through Date/Time".
- Interval data is considered a historical correction if its measurement date time is on or before the "Extract Through Date/Time".

Historical data changes to an initial measurement can be detected when it enters the Finalized state. If the initial measurement is determined to be for a historical period by comparing its end date/time against the "Extracted Through Date/Time" on the Consumption Extract Type, a general process record will be written for the initial measurement so that measurements for it can be extracted. In addition, re-derived values on final measurements can also trigger the creation of a general process record for related initial measurements.

The following algorithms are used in this process:

- The "Create General Process Record if IMD is Historical Correction" algorithm is used to determine if a finalized initial measurement data is a historical correction. If it is, the algorithm creates a general process record for the initial measurement. This algorithm is provided in the base package, but not specified on initial measurement business objects by default. This algorithm should be defined as an Enter algorithm on the Finalized state of the initial measurement business objects.
- The "Create General Process Record for Re-derived Values" algorithm creates general process records for initial measurements associated with re-derived values. Processing will proceed as if a historical correction came in through an initial measurement. This algorithm is provided in the base package, but not specified on measurement business object by default. This algorithm should be defined as an Enter algorithm on the Re-derive state of the final measurement business object.

Consumption Extract Requests

Initial load and ongoing consumption extracts are created via [Consumption Extract Requests](#). While extracts of these types can be created via adhoc submission of a batch job, requests are the preferred method for these types of consumption extracts.

The consumption extract request business object lifecycle includes logic that maintains and updates the "Extraction Through Date/Time" field on Consumption Extract Types, which is used to determine if daily requests should be created by the "Create Daily Consumption Extract Requests" batch control, and detect historical corrections.

A single business object is provided in the base package for consumption extract requests:

- **Consumption Request** (D2-IntervalDataExtRepository): This business object contains the information and lifecycle responsible for submitting the extract job, monitoring the run until it's finished, and then updating the Consumption Extract Type's "Extract Through Date/Time" on the Consumption Extract Type. This business object is based on the Request (F1-REQ) maintenance object.

The consumption extract process uses a set of base package algorithms to extract and format the interval data for export. These algorithms are specified in the "Algorithms" section on the Consumption Extract Type as appropriate. These algorithms can be configured to allow for extraction of data for frequently-read scalar measuring components as well as interval measuring components. Frequently-read scalar measuring components are defined as scalar measuring components whose Read Method is set to "Automatic Read." When extracting measurements for frequently-read scalar measuring components, scalar measurements are converted to interval measurements as part of

the extraction process. This conversion uses the profile associated with the measuring component type. If no profile can be found, the interval data uses a flat line profile.

Initial Load / Incremental / Ongoing Requests: the following algorithms are used to extract and format interval data for initial load and incremental / ongoing requests:

- **Extract Initial Load/Ongoing Consumption for DataConnect (D2-IDEXTPRD):** This algorithm retrieves a service point's consumption for a given period and writes the results to a flat file.
- **Extract Tab-Delimited Initial Load/Ongoing Consumption (with UTC Offset) (D2-IDEXTPRDU):** This algorithm retrieves a service point's consumption for a given period and writes the results to a tab-delimited flat file. This algorithm also supports adjusting the consumption based on Daylight Saving Time.
- **Extract Initial/Ongoing Consumption and Apply TOU Map for DataConnect (D2-IDEXTPTOU):** This algorithm retrieves a service point's consumption for a given period, applies a TOU Map to the consumption, and writes the results to a flat file.
- **Extract Tab-Delimited Initial/Ongoing Consumption and Apply TOU Map (with UTC Offset) (D2-IDEXTPTUU):** This algorithm retrieves a service point's consumption for a given period, applies a TOU Map to the consumption, and writes the results to a tab-delimited flat file. This algorithm also supports adjusting the consumption based on Daylight Saving Time.

Historical Corrections: the following algorithms are used to extract and format interval data for historical correction requests:

- **Extract Historical Correction Consumption for DataConnect (D2-IDEXTIMD):** This algorithm retrieves historical correction consumption for a service point and writes the results to a flat file.
- **Extract Tab-Delimited Historical Correction Consumption (with UTC Offset) (D2-IDEXTIMDU):** This algorithm retrieves historical correction consumption for a service point and writes the results to a tab-delimited flat file. This algorithm also supports adjusting the consumption based on Daylight Saving Time.
- **Extract Historical Corrections and Apply TOU Map for DataConnect (D2-IDEXTITOU):** This algorithm retrieves historical correction consumption for a service point, applies a TOU map to the consumption, and writes the results to a flat file.
- **Extract Tab-Delimited Historical Corrections and Apply TOU Map (with UTC Offset) (D2-IDEXTITUU):** This algorithm retrieves historical correction consumption for a service point, applies a TOU map to the consumption, and writes the results to a tab-delimited flat file. This algorithm also supports adjusting the consumption based on Daylight Saving Time.

Batch Controls

The consumption extraction process uses a set of base package batch controls to extract and format the interval data for export.

- **Create Daily Consumption Extract Requests (D2-CRERQ):** This batch process scans for active Consumption Extract Types, and for each one that has Frequency of Automated Daily creates a pending request. This process should be scheduled to run daily (or at another regular interval).

The following sample batch controls are provided to extract and format interval data. Unique batch controls of each of these is required for each consumption extract type. You should create custom versions of the above batch controls for each consumption extract type in your implementation. Extract type-specific versions of these batch controls should be specified in the "Batch Control" section on the Consumption Extract Type as appropriate.

- **Initial Load/Ongoing Consumption Extract (D2-IDEPD):** This batch process extracts interval data for a specified period. This batch control uses the "Initial Load/Ongoing Extract Algorithm" defined on the Consumption Extract Type.
- **Historical Corrections Consumption Extract (D2-IDEHC):** This batch process extracts interval data for historical corrections. This batch control uses the "Historical Corrections Extract Algorithm" defined on the Consumption Extract Type.

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path or object storage location and file name for this file.)

for a delimited flat file containing extracted data. Refer to [External File Storage](#) for more information about setting up object storage locations.

Example Setup Steps

Setting up consumption extracts involves the following steps:

1. Create Consumption Request Types: you should create a consumption request type for each unique type of request required by your implementation.
2. Create [Consumption Extract Types](#): you should create a consumption extract type for each unique combination of output details (target UOM, target interval size, TOU map/template) and measurement selection criteria.
3. Add the "Create General Process Record if IMD is Historical Correction" historical correction algorithm as an Enter algorithm on the Finalized state of the initial measurement business objects.
4. Add the "Create General Process Record for Re-derived Values" historical correction algorithm as an Enter algorithm on the Finalized state on the measurement business object.
5. Create and submit initial load consumption extract requests for each consumption extract type you created earlier.
6. Set up batch processes for daily extract requests and historical corrections. Batch processing for consumption extracts should include the following:
 - a. The **Create Daily Consumption Extract Requests** (D2-CRERQ) batch control should be configured to run on a regular (i.e. daily) schedule to create ongoing consumption extract requests.
 - b. The **Request Monitor (Deferred)** (F1-SUBRQ) batch control should be used to monitor for pending requests and transition them to the "Submit Job" state.
 - c. Historical corrections consumption extract batch controls (based on D2-IDEH, one for each consumption extract type), should be configured to run on a regular basis to check for and create historical correction extracts.

Master Data Extract

Extraction of service point, device, and install event master data is performed through use of data synchronization, audit algorithms, business objects and related batch processes.

Batch processes are used to create initial load extracts for service point, device, and install event master data. Following the initial load, data synchronization requests are created when master data is changed.

Maintenance Object Audit Algorithms

Detecting changes in service point, device, and install event master data can be detected via audit algorithms on the Service Point (D1-SP), Device Configuration (D1-DVCCONFIG), Device (D1-DEVICE), and Install Event (D1-INSTLEVT) maintenance objects. The Generic Change Data Capture (F1-GCHG-CDCP) algorithm type provided in the base package can be used to create audit algorithms for the Service Point and Install Event maintenance objects.

In addition, the "Device Change Data Capture (Install Event-Based)" (D1-IEDV-CDCP) algorithm type provided in the base package can be used to create an audit algorithm on the Device maintenance object to determine if an install event sync request record is to be created. A change in a related device's details will instantiate an Install Event Extract Sync Request (of the type defined for the "Install Event Sync Request BO" algorithm parameter) if one does not already exist in the initial state for the Install Event.

Business Objects and Algorithms

The maintenance object audit algorithms create data synchronization requests based on the "Sync Request BO" maintenance object options. Extraction of service points and install events are supported by the following data synchronization business objects.

- Current DataConnect
 - **SP/Meter Sync for DataConnect**(D1-ExternalRepositorySPMtrSync): used to extract service point and meter information. This business object should be defined as a value for the "Sync Request BO" options on the Service Point, Device Configuration, and Device maintenance objects.

- Legacy DataConnect
 - **SP Sync for Legacy DataConnect** (D1-ExternalRepositorySPSync): used to extract service point information. This business object should be defined as a value for the "Sync Request BO" options on the Service Point maintenance object.
 - **Install Event Sync for Legacy DataConnect** (D1-ExternalRepositoryIESync): used to extract install event information. This business object should be defined as a value for the "Sync Request BO" options on the Install Event maintenance object.

These business objects use the following Pre-Processing algorithms to take initial data snapshots, and define the batch control used to extract data and export to a flat file:

- Legacy DataConnect
 - **Capture SP Initial Snapshot for Legacy DataConnect** (D1-SPEINISNP)
 - **Capture SP/Meter Initial Snapshot for Legacy DataConnect** (D1-SPMINISNP)
 - **Capture Install Event Initial Snapshot for Legacy DataConnect** (D1-IEEINISNP)

The Sync Request Monitor batch control (F1-SYNRQ) monitors synchronization requests in the Pending state and executes Monitor algorithms that check for related synchronization requests, and transitions them to the "Determine if Sync Needed" state. Enter algorithms on the "Determine If Sync Needed" states extract a final snapshot of the data to extract and export.

- Current DataConnect
 - **Capture SP/Meter Final Snapshot for DataConnect** (D1-SPMFINSNP)
- Legacy DataConnect
 - **Construct SP Final Snapshot for Legacy DataConnect** (D1-SPEFINSNP)
 - **Capture Install Event Final Snapshot for Legacy DataConnect** (D1-IEEINISNP)

The "Prepare Delimited Extract Data" Enter algorithm (D1-PRPEXTDTA) on the "Send Request" state prepares the data for extraction, and creates a general process record for the synchronization request (based on the batch control defined by the pre-processing algorithm). Note that this algorithm is defined on the "Send Request" state of the Generic Sync for DataConnect (D1-ParentExternalRepositorySyn) parent business object.

Batch Controls

The master data extraction process uses a set of batch processes to create data synchronization requests and extract files. The following batch processes are used to create initial synchronization requests:

- Current DataConnect
 - **SP/Meter Initial Load for DataConnect** (D1-SPMIL): This batch control creates initial synchronization requests for service points, device configurations, and devices.
- Legacy DataConnect
 - **SP Initial Load for Legacy DataConnect** (D1-SPEIL): This batch control creates initial synchronization requests for service points.
 - **Install Event Initial Load for Legacy DataConnect** (D1-IEEIL): This batch control creates initial synchronization requests for install events.

These batch processes should be run to create initial load data synchronization requests based on the "Sync for DataConnect" business objects. The following batch processes are used to create extract files from synchronization requests.

- Current DataConnect
 - **SP/Meter Extract for DataConnect** (D1-SPMSR): This batch control creates extract file(s) that contain service point, device configuration, and device information.
- Legacy DataConnect

- **SP Extract for Legacy DataConnect (D1-SPESR):** This batch control creates extract file(s) that contain service point information.
- **Install Event Extract for Legacy DataConnect (D1-IEESR):** This batch control creates extract file(s) that contain install event information.

These batch controls are defined as values for the "Batch Control for Extract" algorithm parameters on the Pre-Processing algorithms on the "Sync for DataConnect" business objects (see above).

Use the Batch Control portal for more information about these batch controls. The extract batch controls contain parameters that can be used to specify details (including path and file name) for a delimited flat file containing extracted data.

Example Setup Steps

Setting up master data extracts involves the following steps:

1. Add audit algorithms on the Service Point and Install Event maintenance objects.
2. Add the DataConnect synchronization request business objects as "Sync Request BO" options on the Service Point and Install Event maintenance objects.
3. Add the "Install Event's Device Change Data Capture" algorithm as an audit algorithm on the Device maintenance object.
4. Execute initial load batch processes for service points and install events.
5. Once the initial load synchronization has been executed, changes to service points, install events, or related devices will trigger the creation of new synchronization requests and resulting extraction files.

Extract Flat File Formats

The data included in each file is based on a specific Data Area. For each Data Area, this section provides a table that lists the name and corresponding schema element and metadata field for each data element extracted by the Data Area. Reference the [Data Areas](#) below to see the details for the fields included in each output.

Process	Description	Data Area
Install Event Snapshot for Legacy DataConnect	The Install Event Snapshot for DataConnect data area is used for install event master data extract.	D1-ExternalRepositoryIESnapsht
SP Meter Snapshot for DataConnect	The Service Point and Meter Snapshot for DataConnect v1+ data area is used for service point and meter master data extract.	D1-ExternalRepositorySPMtrSnap
Service Point Snapshot for Legacy DataConnect	The Service Point Snapshot for DataConnect data area is used for service point master data extract.	D1-ExternalRepositorySPSnapsht
Extract Snapshot for DataConnect (Condition)	The Consumption Extract Snapshot data area is used for interval consumption extract, with measurement conditions.	D2-IntDataExtSnapshotMsrmtCond
Extract Snapshot for Legacy DataConnect	The Consumption Extract Snapshot data area is used for interval consumption extract.	D2-IntervalDataExtRepoSnapshot

Process	Description	Data Area
Extract Snapshot for Legacy DataConnect (TOU Mapping)	The Consumption Extract Snapshot (TOU Mapping) data area is used for interval consumption extract mapped to TOU periods.	D2-IntervalDataExtRepoTOUSnap
Extract Snapshot for DataConnect	The Consumption Extract Snapshot data area is used for interval consumption extract, with UTC offset.	D2-IntervalDataExtRepoSnpstUTC
Extract Snapshot for DataConnect (TOU Mapping)	The Consumption Extract Snapshot (TOU Mapping) data area is used for interval consumption extract mapped to TOU periods, with UTC offset.	D2-IntervalDataExtRepoTOUSnUTC

Specifics for how the flat files are created are defined on batch controls and algorithms used by the extract process.

- **File Name and Path:** Parameters on batch controls define the file name, path, and other details about the output file.
- **File Size and Contents:** Batch controls for initial load/ongoing consumption requests include a parameter to specify the number of service points to be included in each file.
- **Character Encoding and File Delimiter:** Parameters on the Prepare Delimited Extract Data (D1-PRPEXTDTA) algorithm are used to specify the character encoding and delimiter used in the flat files for master data extracts.

Example Extract File

The following example illustrates comma-separated interval data extracts based on the Consumption Extract Snapshot data area:

```
19502793-60E-KMUS,714532246966,19502793-60E-KMSP,KWH, ,3,600,1.366,2015-01-01,07.00.00,No

```

Message Formats

Oracle Utilities Meter Data Management supports three core transactional data imports: Initial Measurement Data, Device Event Data, and Usage Transactions. To see the appropriate format for each of these imports please see the following:

- **Initial Measurement Data:** Please see the IMD Seeder (D1-IMDSeeder) business object for the appropriate format
- **Device Events:** Please see the Device Event Seeder (D1-DeviceEventSeeder) business object for the appropriate format
- **Usage Transactions:** Please see the Usage Transaction Seeder (D2-UsgTranSeeder) business object for the appropriate format*

Data Import - Message Driven Bean Configuration

Overview

This section describes the steps for configuring the Message Driven Bean (MDB) feature of Oracle Utilities Meter Data Management and Oracle Utilities Smart Grid Gateway to listen to inbound JMS messages. This feature is used when importing IMDs and device events from head-end systems or when receiving Usage Transactions from CIS.

JMS Configuration

JMS configuration involves setting up JMS queues which will receive inbound usage readings and device events. The JMS queues need to be created first on the application server where the OSB component is deployed. This server is referred to as remote server in the sections below. In the following section the JMS queue on the remote server is assumed to be created with the name **DestinationQueueWatch-CM**.

Note: The JMS changes described in the following sections are not persistent during patches or upgrades. They will need to be re-created after applying any patches or upgrades to Oracle Utilities Smart Grid Gateway. It is recommended to keep a backup of the `$SPLBASE/splapp/config.xml` file.

Create a new JMS Module

Log in to the Oracle Utilities Smart Grid Gateway Weblogic console and create a JMS Module with an appropriate name. Specify the following values for this JMS module:

- **Name:** the name of JMS module. For example, JMSModule-CM
- **Target:** the name of the target server where the Oracle Utilities Smart Grid Gateway application is running. This should be specified as myserver.

Create a Foreign JMS Server

Create a Foreign JMS server under the JMS module created in the above step. Specify the following values for this foreign JMS server:

- **Name:** Name of the foreign server. For example, JMSFAServer-CM
- **Target:** This should be specified as myserver
- **JNDI Initial Context Factory:** This should be specified as `weblogic.jndi.WLInitialContextFactory`
- **JNDI Connection URL:** The URL of the server where OSB is deployed. For example: `t3://osbserver:7001`
- **JNDI Properties Credential:** Password for the OSB server user
- **JNDI Properties:** The `java.naming.security.principal` additional property should be specified and set to the OSB server user. For example, `java.naming.security.principal=weblogic`

Create a Foreign Destination

Create a Foreign destination for each remote queue. Specify the following values for this foreign destination:

- **Name:** Name of foreign destination. For instance, `DestinationQueue-CM`
- **Local JNDI Name:** Local JNDI name for the foreign JMS queue. For example, `ForeignDestinationQueue-CM`
- **Remote JNDI Name:** JNDI name of the queue on the remote server. For example, `DestinationQueueWatch-CM`

Create a Remote Connection Factory

Create a remote connection factory for the foreign JMS server. Specify the following values for this remote connection factory:

- **Name:** Name of remote connection factory. For example, `DestinationQueueConnectionFactory-CM`
- **Local JNDI Name:** Local JNDI name for the Remote Connection Factory. For example, `ForeignDestinationQueueConnectionFactory-CM`

- **Remote JNDI Name:** JNDI name of the JMS Connection Factory on the remote server. For example, `weblogic.jms.XAConnectionFactory`

Message Driven Bean Configuration

Configuration of message driven beans (MDB) involved modifying the `ejb-jar.xml` and `weblogic-ejb-jar.xml` configuration files delivered with Oracle Utilities Smart Grid Gateway. It is recommended that instead of modifying these files directly you create "Customer Modification" (CM) versions of these files to make changes to these configuration files. This ensures that your modifications are not overwritten by future application patches.

The following section describes the changes required in the CM files for configuring the MDBs to read from the foreign JMS queues set up in the steps above. This requires creating the following files under `$$PLEBASE/templates`:

- `cm_ejb-jar.xml.wls.jms_1.include`
- `cm_ejb-jar.xml.wls.jms_2.include`
- `cm_weblogic-ejb-jar.xml.jms.include`.

Note: After making these changes the `initialSetup` script needs to be run and Oracle Utilities Smart Grid Gateway application needs to be redeployed. However the `initialSetup` script will overwrite the JMS configuration changes made in the steps above. So it is recommended to keep a backup of the `$$PLEBASE/splapp/config.xml` file before running this script.

Changes to `cm_ejb-jar.xml.wls.jms_1.include`

The following is an example of the `cm_ejb-jar.xml.wls.jms_1.include` file:

```
<message-driven>
  <description>MDB for DestinationQueue-CM</description>
  <display-name>DestinationQueueWatcher-CM</display-name>

  <ejb-name>DestinationQueueWatch-CM</ejb-name>

  <ejb-class>com.splwg.ejb.mdb.MessageProcessor</ejb-class>
  <messaging-type>javax.jms.MessageListener</messaging-type>
  <transaction-type>Bean</transaction-type>
  <message-destination-type>javax.jms.Queue</message-destination-type>
</message-driven>
```

The values specified in the above file include the following:

- **ejb-name:** This is the name of the MDB.

Changes to `cm_ejb-jar.xml.wls.jms_2.include`

The following is an example of the `cm_ejb-jar.xml.wls.jms_2.include` file:

```
<assembly-descriptor>
<security-role>
<role-name>cisusers</role-name>
</security-role>
<container-transaction>
<method>

  <ejb-name>DestinationQueueWatch-CM</ejb-name>

  <method-name>onMessage</method-name>
</method>
<trans-attribute>NotSupported</trans-attribute>
</container-transaction>
```

```
</assembly-descriptor>
```

The values specified in the above file include the following:

- **ejb-name:** This is the name of the MDB

Changes to `cm_ejb-jar.xml.wls.jms_2.include`

The following is an example of the `cm_weblogic-ejb-jar.xml.jms.include` file:

```
<weblogic-enterprise-bean>
<ejb-name>DestinationQueueWatch-CM</ejb-name>
  <message-driven-descriptor>
    <pool>
      <max-beans-in-free-pool>5</max-beans-in-free-pool>
      <initial-beans-in-free-pool>1</initial-beans-in-free-pool>
    </pool>
  <destination-jndi-name>ForeignDestinationQueue-CM</destination-jndi-name>
  <connection-factory-jndi-name>ForeignConnectionFactory-CM</
connection- factory-jndi-name>
  </message-driven-descriptor>
</weblogic-enterprise-bean>
```

The values specified in the above file include the following:

- **ejb-name:** This should be the name of the MDB as specified in `ejb-jar.xml`
- **destination-jndi-name:** This should be the JNDI name of the foreign destination as provided in JMS module ' Foreign server ' Foreign destination ' Local JNDI name.
- **connection-factory-jndi-name:** This should be the JNDI name of the connection factory as provided in JMS module ' Foreign server ' Remote Connection Factory ' Local JNDI name.

Notification Queue Configuration

Payload statistics and payload summary records must be submitted sequentially in order for them to be processed correctly. To prevent them from being processed at the same time, you should set the number of notification queue polling threads to 1. Follow these steps to configure the number of notification queue threads:

1. Log in to the WebLogic Server Administration Console.
2. Under Helpful Tools, click **Configure Applications**.
3. Click on **Webservices**.
4. Click on the NotificationQueue link. for the EJB that you want to configure.
5. Go to the Configuration tab.
6. In the Change Center, click **Lock & Edit**.
7. Specify the new value of polling threads in **Max Beans in Free Pool**.
8. Click **Save**.
9. Click **Release Configuration**.
10. Restart the OUAF WebLogic instance.

Creating Application Links in External Applications

When integrating Oracle Utilities applications with other external applications, you can create links from external applications to specific portals and pages within the Oracle Utilities applications (also known as "deep linking"). These links typically leverage Business Process Assistant (BPA) scripts that direct the user to the appropriate target portal or page for a specific entity such as an account or service point. Refer to [Creating Application Links in External Applications](#) in the *Application Framework Administrative User Guide* for more information about creating links.

Note: When creating application links, the use of the following parameters will help speed up launching the target page

- **initNav=false:** skips launching the default home page for the user
- **minSidebar=true:** minimizes the Sidebar for the user

Go To Portal Script

The Framework provides a generic script (F1-GoToPrtl) that can be used to navigate to the maintenance portal for a specified maintenance object and entity. Refer to [Navigating to a Given Record's Maintenance Portal](#) in the *Application Framework Administrative User Guide* for more information about using this script.

Go To MDM Script

Oracle Utilities Meter Data Management includes the Go To MDM script (D1-GoToMDM) that can be used to navigate directly to a specific 360 Degree View tab. This script uses the following syntax:

```
script=D1-GoToMDM&FLAG=<FLAG_VALUE>&PKVALUE1=<ID>
```

where:

- **<FLAG_VALUE>:** A value from the DRILL_ENTITY_FLG lookup that specifies which 360 Degree View page to open.
- **<ID>:** The primary key value for the entity (such as a Device, Measuring Component, or Service Point) you wish to view.

Examples:

Script	Flag Value	ID	Example
D1-GotoMDM	FLAG=D1DV (360 View for Device)	Device ID	script=D1-GotoMDM&FLAG=D1DV&PKVALUE1=Device ID}
D1-GotoMDM	FLAG=D1MC (360 View for Measuring Component)	Measuring Component ID	script=D1-GotoMDM&FLAG=D1MC&PKVALUE1=Measuring Component ID}
D1-GotoMDM	FLAG=D1SP (360 View for Service Point)	Service Point ID	script=D1-GotoMDM&FLAG=D1SP&PKVALUE1=Service Point ID}

Full URL Example:

```
https://<ENV_BASE_URL>/ouaf/cis.jsp?  
minSidebar=true&initNav=false&script=D1-  
GotoMDM&FLAG=D1DV&PKVALUE1={your Device ID}
```
